ACKNOWLEDGEMENT

This research was sponsored by the U.S. Department of Energy, Office of Nuclear Energy, Light Water Reactor Sustainability Program, Materials Research Pathway, under contract DE-AC05-00OR22725 with UT-Battelle, LLC/Oak Ridge National Laboratory. The authors extend their appreciation to Dr. Keith Leonard for his programmatic support. We would like to thank Dr. Mikhail Sokolov and Dr. Randy Nanstad for their technical review of this manual. We also appreciate help from Dr. Jungwon Kim in setting up the GitLab webpage for hosting the source codes, executable files, etc. for the analysis program.

1. OVERVIEW

The J-integral vs. crack growth resistance curve (J-R curve) is a useful tool for evaluating materials fracture toughness in the ductile region. The widely applied standard for conducting such tests is American Society for Testing Materials (ASTM) Standard E1820-18 [1], in which the normalization analysis method is described in Annex 15. The normalization method requires only load-displacement data and crack size measurements before and after testing, which greatly simplifies the fracture toughness testing and alleviates many issues that arise when testing in extreme conditions. Despite these advantages, the normalization method requires complicated analysis procedures and there is currently no publicly available open-source software to perform such analysis. To facilitate the application of this method, an automated program is seen as the best option to yield valid and replicable results. A program was developed using MATLAB® to perform the complex data analysis procedures of the normalization method. The program was then compiled using the MATLAB Application Compiler tool for general use. The compiled software, in the form of a standalone executable program, has a user-friendly graphical interface and is readily compatible with modern Windows operating systems. The program is applicable for the four most commonly used fracture toughness specimen geometries:

1. C(T): compact tension
2. DC(T): disk compact tension (crack mouth opening displacement on the load line)
3. SEB(LLD): single edge bend with load line displacement measurement
4. SEB(CMOD): single edge bend with crack mouth opening displacement measurement

From the load-displacement data, crack length measurements, and material parameters, the program generates analysis parameters, adjusted crack lengths, J-R curve data, fracture toughness values, and the derived J-R curve figure. The general flow of the program can be viewed in Appendix 1.

2. PROGRAM REQUIREMENTS

2.1. System Requirements

Operating System:	Windows® 10 (Recommended), Windows 8.1 or Windows 7
Processor:	Intel® or AMD® x86-64 processor; 1Ghz or faster
Disk Space:	2GB of free HDD space
RAM:	4GB (Minimum), 8GB (Recommended)
Graphics:	Processor Integrated Graphics (Minimum)

2.2. Installation

Users should run Normalization_installer.exe for the installation of the analysis program package. Once complete, users should save the program shortcut link in the same folder containing all input data files to be used. The program must then be run from this shortcut. On completion of running the program, the output data files will also be saved in this same folder. It is recommended to copy the program shortcut link into individual folders where each dataset is separately stored. This ensures that the correct files are being analyzed and there is no risk of overwriting previous data files.

3. USER GUIDE

3.1. Starting Instructions

Upon startup of the normalization program, a pop-up window with instructions (Fig. 1) will appear giving a general guide to the user through the first few steps of the analysis, including the selection of specimen geometry, load-displacement data, and initial material and testing parameters. The user should click the “OK” button to proceed to the next step.

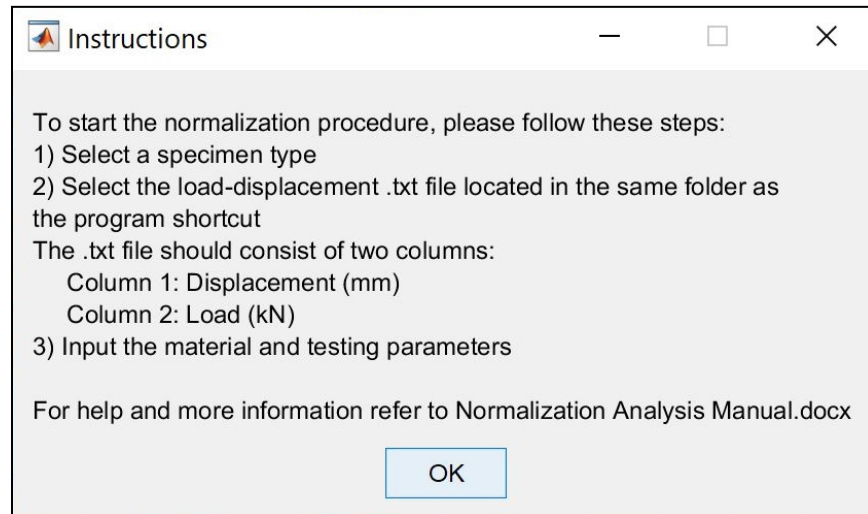

Fig. 1 Program startup pop-up window.

3.2. Specimen Geometry and Load-Displacement Data Selection

Following the initial instructions panel, another pop-up window (Fig. 2) will appear in which the user has to select the specimen geometry that will be analyzed. The four options for specimen geometries are C(T), DC(T), SEB(LLD), and SEB(CMOD).

Fig. 2 Pop-up window for specimen geometry.

Afterwards, a file selection pop-up window (Fig. 3) will open the folder where the program shortcut is located and prompt the user to choose a text file for the load-displacement data to be analyzed. The file must have two columns with the first column being the displacement in units of mm and the second column being the load in units of kN.

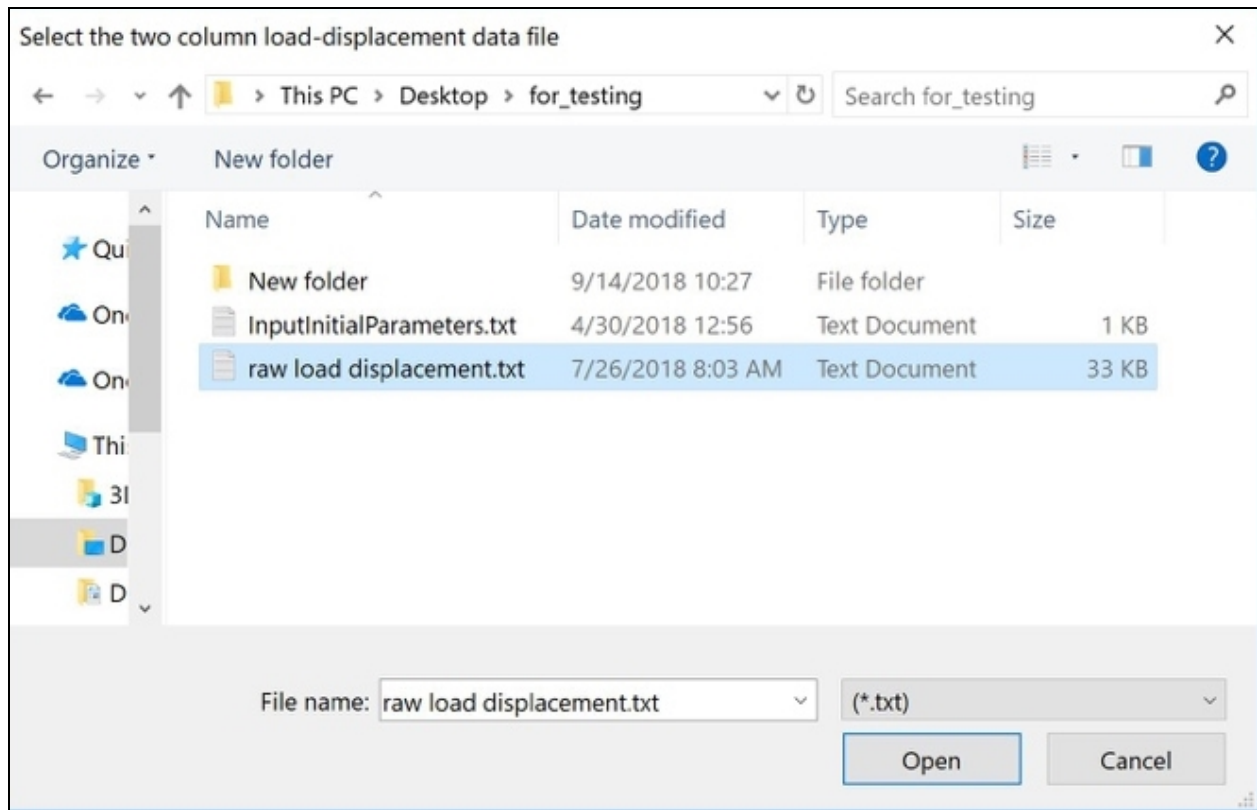

Fig. 3 Pop-up window for selecting the load-displacement data file.

3.3. Specimen Identification

After selecting the text file with the load-displacement data, the user is required to input the specimen ID (Fig. 4). The specimen ID will be in the file name extension of each output file. After inputting the specimen ID, the user should click the “OK” button to proceed to the next step.

Fig. 4 Pop-up window for inputting specimen ID.

3.4. Initial Test Parameters

Once the specimen ID is inputted, the user will be prompted (Fig. 5) to input the initial test parameters by either manual input or selecting a text file containing the parameters. If the user chooses a text file, the file should have one column and nine rows with each row containing the numerical values of the parameters in the following order:

XXX.XXX
XXX.XXX
XXX.XXX
XXX.XXX
XXX.XXX
XXX.XXX
XXX.XXX
XXX.XXX
XXX.XXX

Young Modulus (GPa)
Poisson's Ratio
Ultimate Tensile Stress (MPa)
Yield Stress (MPa)
Thickness (mm)
Net Thickness excluding side grooves (mm)
Width (mm)
Avg. Initial Crack Length (mm)
Avg. Final Crack Length (mm)

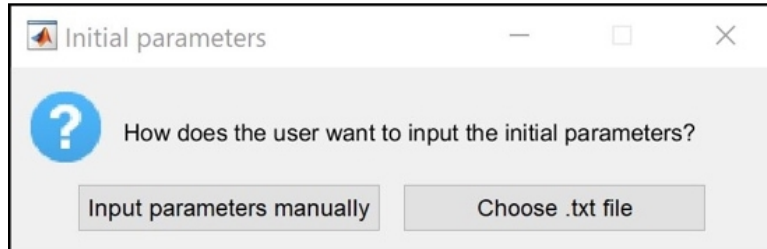

Fig. 5 Pop-up window for inputting the initial parameters.

Whether the user inputs parameters manually or chooses a text file to populate the parameters, a pop-up window (Fig. 6) for the test parameters will appear and the user can view and edit the parameters if needed. The user should click the “OK” button to proceed to the next step.

A screenshot of a software window titled "Test parameters". It contains several input fields with labels and values: "Young's modulus (GPa):" with value "280", "Poisson's ratio:" with value "0.3", "Ultimate tensile strength(MPa):" with value "1200", "Yield strength (MPa):" with value "900", "Thickness (mm):" with value "17", "Net thickness (mm):" with value "10", "Width (mm)" with value "20", "Avg. initial crack length (mm):" with value "8", and "Avg. final crack length (mm):" with value "12". At the bottom right are "OK" and "Cancel" buttons.

Fig. 6 Test parameter pop-up window.

3.5. Displacement Measurement Conversation (only for C(T) specimens)

In the case of analyzing a C(T) specimen, an additional dialogue box (Fig. 7) will appear prompting the user to specify whether the displacement was measured along the load line (LL) or not. If the user chooses No, another dialogue box (Fig. 8) will appear prompting the user to enter the distance between the clip gauge (CG) and the load line in unit of mm. The program will then automatically convert the CG displacement measurement to the load line displacement based on the following equation [2]:

$$V_{LL} = V_c \left(\frac{a_0 + rb_0}{a_0 + rb_0 + c} \right)$$

where

V_{LL} = load line displacement,

V_c = clip gauge displacement measured at a distance c from the load line,

a_0 = initial crack length,

r = constant equal to 0.33,

b_0 = initial uncracked ligament length,

c = distance from the load line to the clip gauge location.

Fig. 7 Displacement gauge location window.

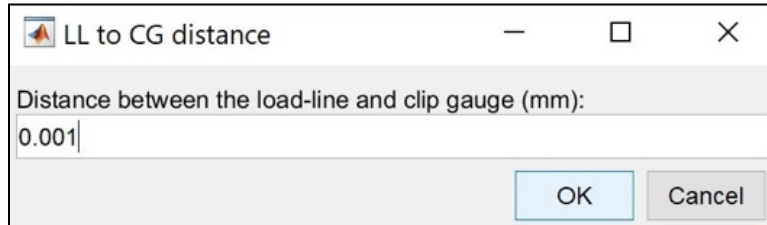

Fig. 8 Load line (LL) to clip gauge (CG) distance dialogue box.

3.6. Normalization Curve Fitting

In this step, the normalization program will fit the normalized load and displacement data (Fig. 9a) based on the procedures in section A15.2.7 of ASTM E1820. The program will start with the first normalized plastic displacement ($\text{first-}v_{pli}$) of 0.001 and make an initial fitting up to, but not including the normalized maximum load. The obtained fitting parameters become the initial values for the fitting coefficients in Eq. A15.5 of ASTM E1820. Then, starting with $\text{first-}v_{pli} = 0.001$, the program will automatically search for the suitable normalized load-displacement data for the fitting such that the difference between the fitted curve and the final normalized load is less than 0.5% of the final formalized load. Once the user clicks the “OK” button of the residual analysis window, another window (Fig. 9b) will appear asking whether the fitted curve is acceptable. If both the residual value and fitted curve are accepted by the user, the program will continue to the J-R curve calculation in section 3.8. Otherwise, the program will try to reperform the normalization curve fitting detailed in the next section 3.7.

Fig. 9 Normalization curve fitting.

3.7. Refit the Normalization Curve

If the user clicks the “No” button in Fig. 9b, the program will perform additional fitting to find a satisfactory solution. In detail, the program will begin by incrementing the starting- v_{pli} by +0.002 each time the user clicks the “No” button in Fig. 9b. This incremented starting- v_{pli} is then iterated down with a step size of -0.001 until the starting- v_{pli} equals first- v_{pli} , and the curve fitting parameters are also revised with each successive iteration. If no acceptable curve is found and starting- v_{pli} exceeds 0.006, the program will then permanently increment the first- v_{pli} by +0.001 and resume the loop of incrementing on the starting- v_{pli} until a satisfactory curve and residual value is found. Once first- v_{pli} exceeds 0.006, the program will display an error box stating that normalization cannot be performed with the data set. If the curve is accepted at any point, the program will continue to calculate the adjusted crack length values and J-R curve. For more information, users are referred to the Appendix 2: Normalization Function Program Flow Chart and the source codes for the normalization analysis program

3.8. J-R Curve Calculation

Once the fitted normalized load displacement curve is accepted, the program will calculate the J-R curve. First, the adjusted crack length values are calculated and then the J-R curve is derived as in Fig. 10. The same plot also includes the construction line, the exclusion lines, the offset line, and the power regression line fitting J-R curve data points between two exclusion line. In addition, a pop-up window will ask if the J-R curve is acceptable. If the user clicks on “Yes,” the program will continue to section 3.9 for data qualification. If the user selects “No,” the program will restart the normalization analysis with the first- $v_{pli} = \text{first-}v_{pli} + 0.001$. This loop will stop working when first- $v_{pli} > 0.006$ without an acceptable J-R curve. In that case, a pop-up window will let the user know that the normalization analysis cannot be performed to yield the J-R curve. For more information, users are referred to the Appendix 2: Normalization Function Program Flow Chart and the source codes for the normalization analysis program.

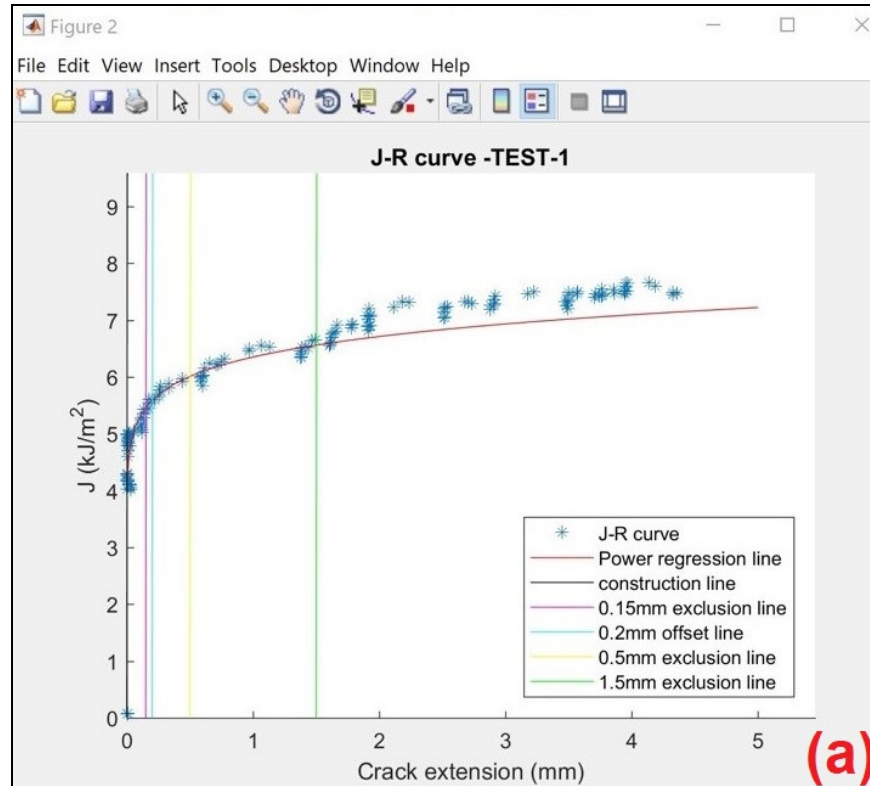

Fig. 10 J-R curve analysis.

3.9. Qualification of Data

Once the J-R curve is accepted, a window box (Fig. 11) will appear showing if the power coefficient C_2 defined in section A9.6.5 of ASTM E1820 meets the qualification requirement by comparing C_2 value with 1.0. If $C_2 \geq 1.0$, no fracture toughness values can be determined and the program will close. If $C_2 < 1.0$, after clicking the “OK” button, another window box (Fig. 12) will appear showing what additional qualifications in ASTM E1820 need to be met to qualify J_Q as J_{IC} . This window box also shows the values of the J_Q , K_{JQ} , and tearing modulus defined in [3].

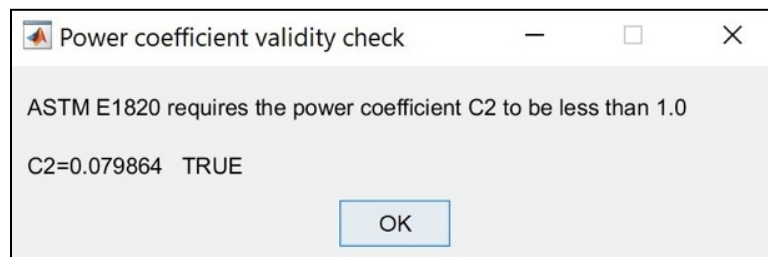

Fig. 11 Qualification of the fitting coefficient C_2 .

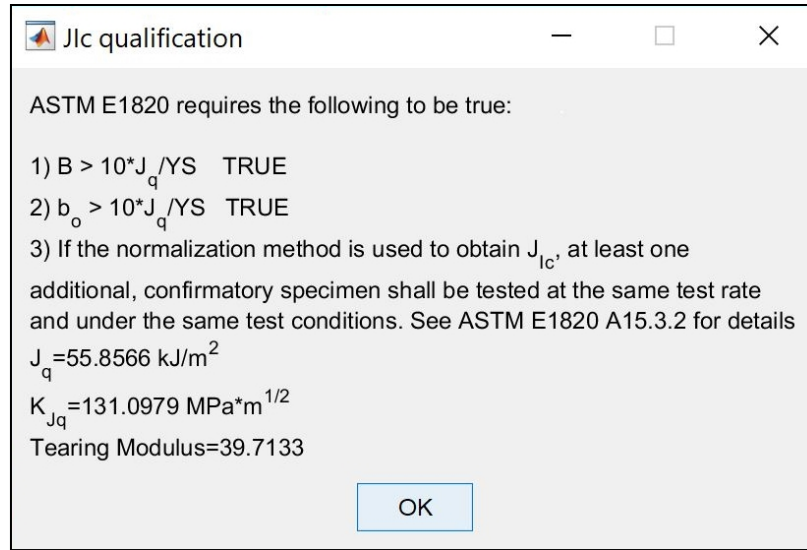

Fig. 12 J_{lc} qualification.

3.10. Results Output

Lastly, if the normalization analysis is successfully completed by the program, a final pop-up window (Fig. 12) will appear to let the user know that results have been saved in four text files and one png picture file. All output files have the specimen ID defined in section 3.3 as part of the file name extension, namely:

Output file name	Output data type
AdjustedCrackLength-SpecimenID.txt	Adjusted crack length values per ASTM E1820 section A15.2.8
JRresults-SpecimenID.txt	J-R curve data, J _q , K _{Jq} , and tearing modulus results
FittingParameters-SpecimenID.txt	Fitting parameters in the normalization analysis (see Eq. A15.5 in ASTM E1820)
InputInitialParameters-SpecimenID.txt	Material/test parameters defined in section 3.4
JRcurve-SpecimenID.png	The J-R curve picture

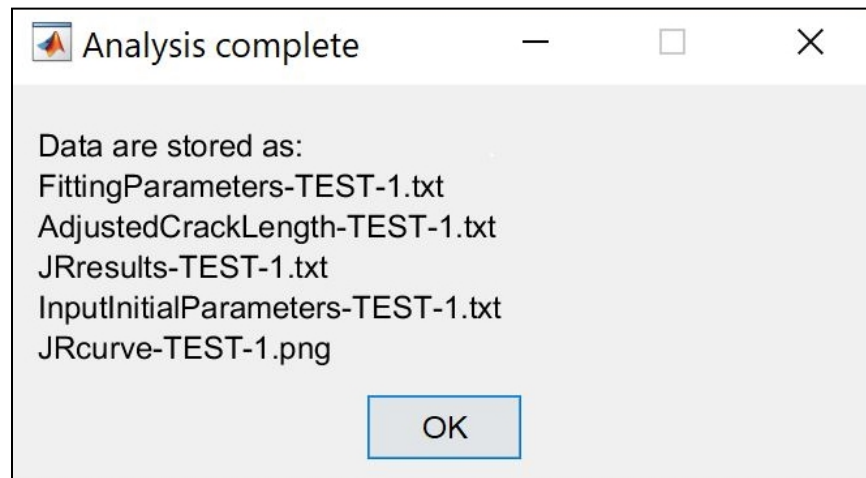

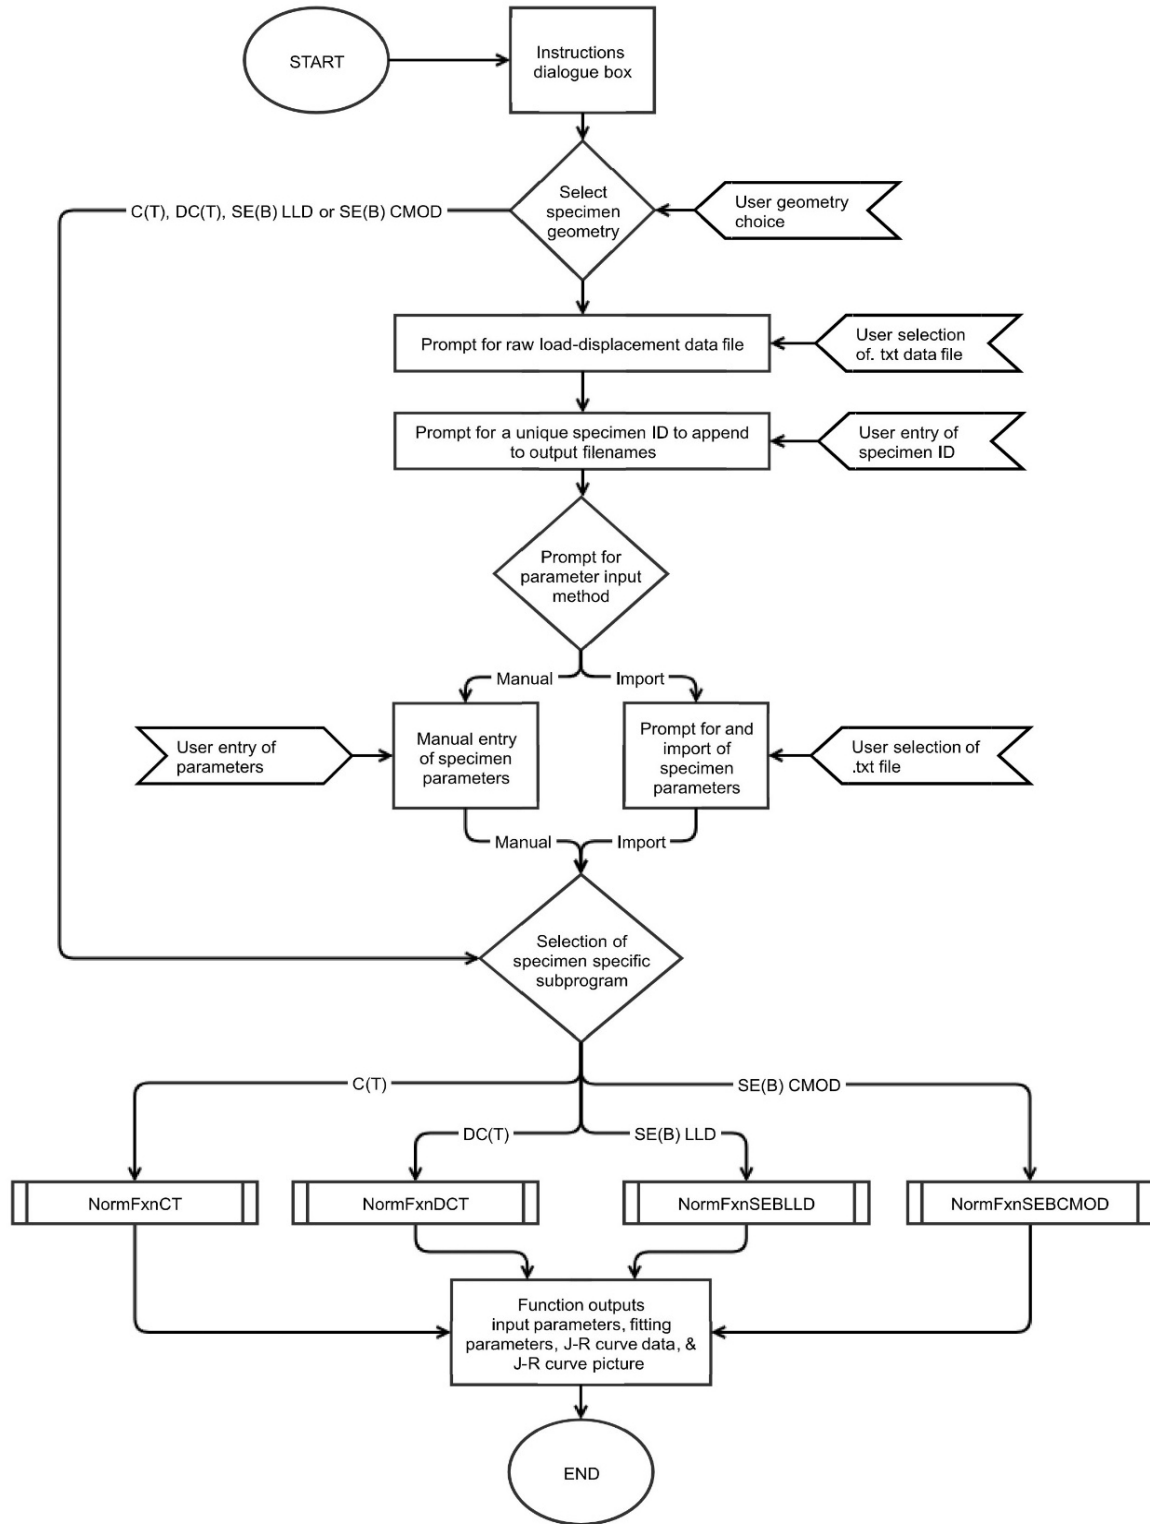

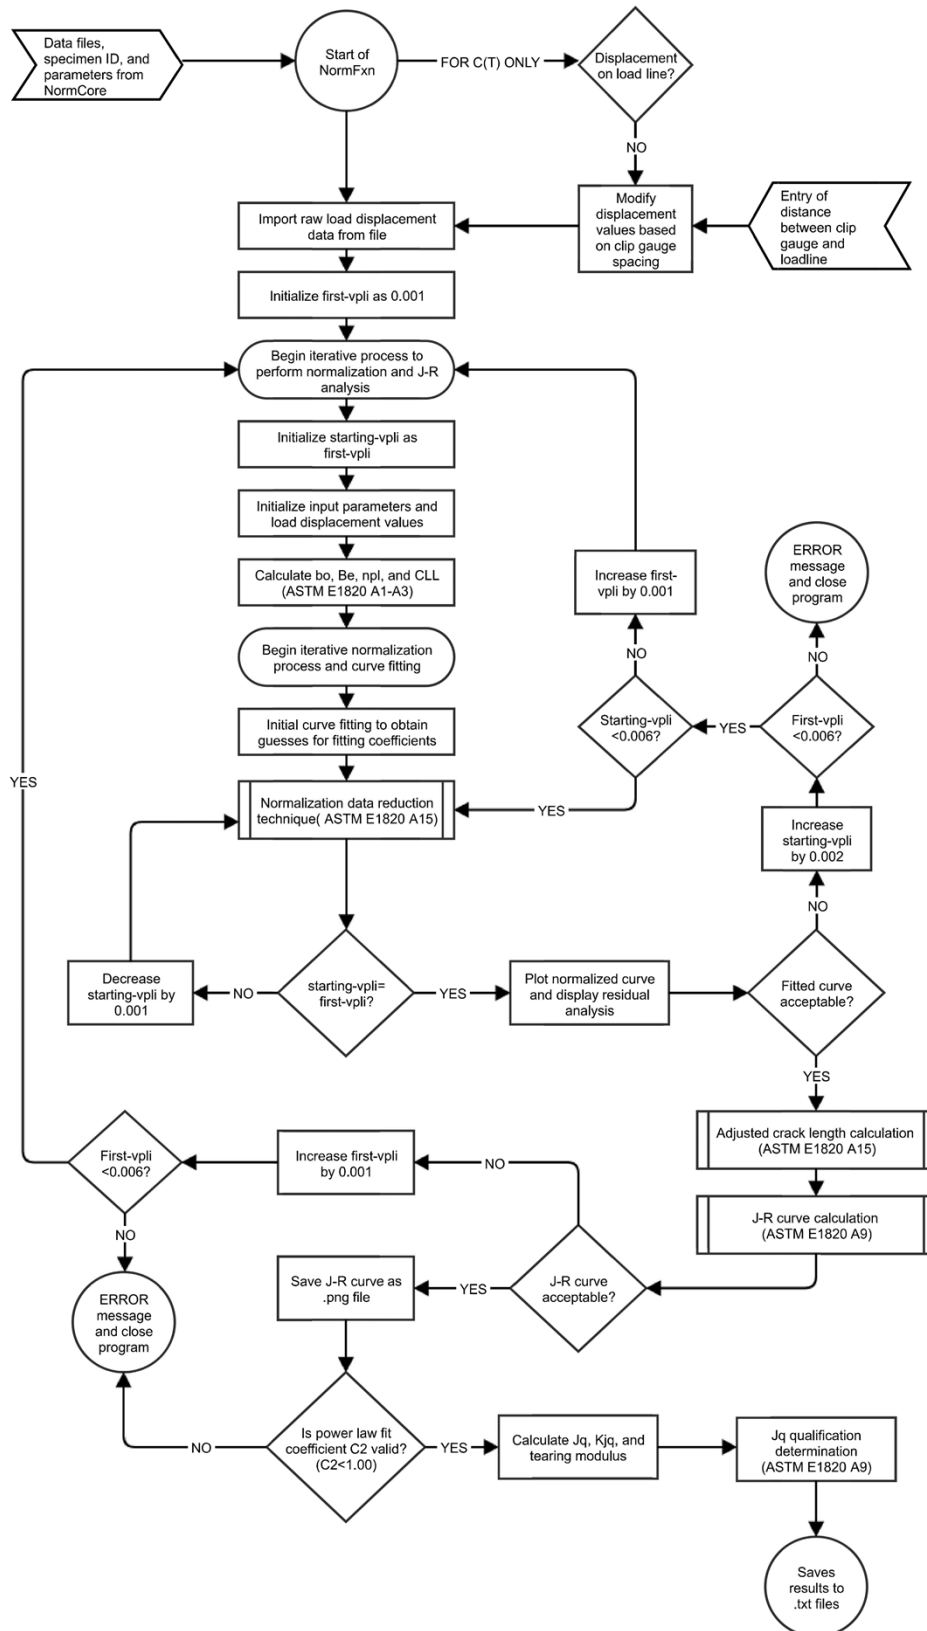

Fig. 13 Pop-up window for output files.
