Compilation of Data from ORNL Characterization of German Reference Fuel Composite EUO 2358-2365

J. D. Hunn
Oak Ridge National Laboratory

This document was prepared to document the distribution of additional data summarized in a previous report entitled "Results from ORNL Characterization of German Reference Fuel from the EUO 2358-2365 Composite," ORNL/TM-2005/546 (also known as ORNL/CF-04/06), April 2004. This previous report was a compilation of the characterization data obtained on a sample of TRISO-coated 500 μm diameter UO_2 produced in Germany and obtained by the AGR program for use as a historical reference material. This sample came from the EUO 2358-2365 composite studied by General Atomics (GA) and referenced in GA document #910852 "Acceptance Test report for German Fuel Particles." The ORNL designation for the material characterized was AGR-06.

This update includes the individual particle data from measurements of kernel diameter, particle diameter, and coating thickness. This individual particle data was not included in the previous report, which only contained the summary data from the image analysis.

Table of Contents

| | | |
|----------|---|-----------|
| 1 | <i>Kernel Size and Shape</i> | 4 |
| 2 | <i>Particle Size and Shape</i> | 7 |
| 3 | <i>Particle Size and Shape After Removing OPyC</i> | 10 |
| 4 | <i>Coating Thickness</i> | 13 |
| 4.1 | Kernel diameter | 14 |
| 4.2 | Buffer thickness | 16 |
| 4.3 | IPyC thickness | 19 |
| 4.4 | SiC thickness | 21 |
| 4.5 | OPyC thickness | 23 |
| 4.6 | Total particle radius | 26 |

1 Kernel Size and Shape

Shadow images for a random orientation of 6704 kernels (about 4.7 g) extracted from AGR-06 were obtained. Image analysis software was used to find the center of each kernel projection, identify 360 points around the perimeter, and measure the distance from center to each perimeter point (defined as the kernel radius). The uncertainty for this measurement was $\pm 1 \mu\text{m}$. This data was then compiled to report sphericity (maximum radius/minimum radius), mean diameter, standard deviation in diameter, maximum diameter, and minimum diameter for each kernel measured. Note that image analysis actually measured the radius of the kernel. The radius was multiplied by two in order to report the data in terms of diameter. This was done because these values are usually specified and reported in terms of diameter. The error introduced by making this conversion was small because the kernel cross sections were fairly symmetrical. The summary data from each kernel in the sample was then compiled to obtain the average, standard deviation, maximum, and minimum of the individual kernel quantities (sphericity, mean diameter, standard deviation in diameter, maximum diameter, and minimum diameter). Figure 1-1 contains the summary data and shows the distributions of the kernel sphericity and mean kernel diameter.

The measured kernels had an average mean diameter of $506 \mu\text{m}$ with a standard deviation in the distribution of $8 \mu\text{m}$. The distribution was close to Gaussian. Based on variable sampling statistics, the average mean diameter of the German kernels is predicted to be $504 - 508 \mu\text{m}$ with 95% confidence. Less than 1% of the kernels measured had mean diameters outside the range $485 - 525 \mu\text{m}$. The largest kernel measured had a mean diameter of $565 \mu\text{m}$. The smallest kernel had a mean diameter of $472 \mu\text{m}$.

Table 1-1 shows the output obtained from the image analysis software for the first 55 kernels analyzed. This table is an embedded Excel file. Double click the table to access the full data set for all 6704 kernels.

2 Particle Size and Shape

Shadow images were obtained for a random orientation of 1118 coated particles (about 1.5 g) riffled from AGR-06. Image analysis as described above was used to measure the size and shape of the particles. Figure 2-1 contains the compiled data and shows the distributions of the particle sphericity and mean particle radius. In reporting the data for the particle size and shape, data was left in terms of the measured radius rather than multiplying by two to estimate the diameter, because the faceting of the coated particles was such that it was more appropriate to report the data in terms of radius.

The measured particles had an average mean radius of 461 μm with a standard deviation in the distribution of 12 μm . The distribution was close to Gaussian. Based on variable sampling statistics, the average mean radius of the German particles is predicted to be 460 - 462 μm with 95% confidence. Less than 1% of the particles measured had mean radii outside the range 445 - 485 μm . The largest particle measured had a mean radius of 501 μm . The smallest particle had a mean radius of 425 μm . The minimum mean radius of 425 μm suggested that no particles measured are missing more than 80% of their 100 μm thick buffer layer uniformly around the particle. However, the more aspherical particles exhibited local radii of as low as 391 μm , which could indicate that more than 80% of the buffer is missing at that location.

Table 2-1 shows the output obtained from the image analysis software for the first 51 particles analyzed. This table is an embedded Excel file. Double click the table to access the full data set for all 1118 particles.

3 Particle Size and Shape After Removing OPyC

The same sample of particles described in section 2 was remeasured after removing the outer pyrocarbon (OPyC) layer by heating in air at 800°C for 4 hours. Figure 3-1 shows the data summary for 1283 particles measured. The measured particles had an average mean radius of 426 μm with a standard deviation in the distribution of 12 μm . The distribution was close to Gaussian. The difference in the average mean radius before and after OPyC removal was 35 μm . Direct measurement of the OPyC thickness as described in section 4.5 yielded an average mean thickness of 36 μm . The sample of particles before and after removal of the OPyC exhibited the same standard deviation in mean radius. This was expected for an OPyC layer with a standard deviation in thickness of a few microns. Note that the number of particles measured in Figure 2-1 was 1118. These numbers were different because the technique used did not measure every particle in the sample. Some particle projections were cutoff at the edges of the images and not analyzed.

Table 3-1 shows the output obtained from the image analysis software for the first 54 particles analyzed. This table is an embedded Excel file. Double click the table to access the full data set for all 1283 particles.

4 Coating Thickness

Coating thicknesses were measured on 186 particles by mounting particles in a clear epoxy and grinding and polishing the particles to close to, but not beyond, the midpoint. The polished cross sections were imaged with bright field reflected mode with a computer-automated optical microscope and the images were computer analyzed to extract the thickness info for each layer. The deviation of the measured layer thickness from the actual layer thickness due to the polished cross section not being exactly at a midplane was corrected by measuring the outer diameter of the particle and applying a geometric correction.

4.1 Kernel diameter

The cross section measurement provides a secondary measurement of the kernel diameter. This measurement introduces more uncertainty than the shadow image technique in section 1 because of some uncertainty in the kernel buffer interface created during grinding and greater effect from error introduced by correction to midplane. Figure 4-1 shows the data summary for the kernel radius. The average mean radius was 257 μm . The mean kernel size measured by this technique was slightly higher than what was measured by shadow imaging (253 μm). This error could also be related to a real gap between the kernel and buffer that may be included in the cross sectioned kernel radius.

Table 4-1 shows the output obtained from the image analysis software for the first 50 particles analyzed. This table is an embedded Excel file. Double click the table to access the full data set for all 186 particles.

4.2 Buffer thickness

Figure 4-2 shows the data summary for the measurements made on the buffer. The average mean buffer thickness was 94 μm with a standard deviation in the distribution of 11 μm . The thickness distribution was close to Gaussian. Based on variable sampling statistics, the average mean buffer thickness of the German kernels is predicted to be 92-96 μm with 95% confidence. The thickest point measured in a buffer layer was 131 μm . The thinnest point measured in a buffer layer was 63 μm . Figure 4-3 shows an example of a buffer with a high standard deviation in thickness. This resulted in a faceted particle. The non-uniform buffer layer also resulted in more thickness deviation in the outer layers. Where the buffer layer was thinner, the other layers also tended to be thinner. The strong dependence on particle shape and coating uniformity on the buffer uniformity suggest that some optimization of the buffer coating step would be valuable. It would be interesting to study the correlation between irregularity in the buffer thickness and coating bed fluidization conditions.

Table 4-2 shows the output obtained from the image analysis software for the first 50 particles analyzed. This table is an embedded Excel file. Double click the table to access the full data set for all 186 particles.

4.3 IPyC thickness

Figure 4-4 shows the data summary for the measurements made on the inner pyrocarbon (IPyC). The average mean IPyC thickness was 39 μm with a standard deviation in the distribution of 3 μm . The thickness distribution was close to Gaussian. Based on variable sampling statistics, the average mean IPyC thickness of the German kernels is predicted to be 38-40 μm with 95% confidence. The thickest point measured in an IPyC layer was 56 μm . The thinnest point measured in an IPyC layer was 21 μm .

Table 4-3 shows the output obtained from the image analysis software for the first 50 particles analyzed. This table is an embedded Excel file. Double click the table to access the full data set for all 186 particles.

4.4 SiC thickness

Figure 4-5 shows the data summary for the measurements made on the SiC. The average mean SiC thickness was 33.9 μm with a standard deviation in the distribution of 1.4 μm . The thickness distribution was close to Gaussian. Based on variable sampling statistics, the average mean SiC thickness of the German kernels is predicted to be 33-35 μm with 95% confidence. The thickest point measured in a SiC layer was 43 μm . The thinnest point measured in a SiC layer was 24 μm . The maximum standard deviation in thickness around a SiC layer was only 2.5 μm . This indicated that the SiC layers were very uniform in thickness on each particle. The largest local deviations in SiC thickness that were observed were associated with large deviations in the buffer thickness.

Table 4-4 shows the output obtained from the image analysis software for the first 50 particles analyzed. This table is an embedded Excel file. Double click the table to access the full data set for all 186 particles.

4.5 OPyC thickness

Figure 4-6 shows the data summary for the measurements made on the OPyC. The average mean OPyC thickness was 36 μm with a standard deviation in the distribution of 2 μm . The thickness distribution was close to Gaussian. Based on variable sampling statistics, the average mean OPyC thickness of the German kernels is predicted to be 35-37 μm with 95% confidence. The thickest point measured in an OPyC layer was 51 μm . The thinnest point measured in an OPyC layer was 26 μm . Figure 4-7 and Figure 4-8 show that the thickest and thinnest regions observed in the OPyC layers were associated with faceted regions in the particle.

Table 4-5 shows the output obtained from the image analysis software for the first 50 particles analyzed. This table is an embedded Excel file. Double click the table to access the full data set for all 186 particles.

4.6 Total particle radius

The mean kernel radius and mean layer thickness data were summed for each particle as a comparison check against the data obtained from the whole particle measurements made in section 2. The average mean radius obtained by summing the data from the cross section measurements was 461 μm with a standard deviation in the distribution of 10 μm (Figure 4-9). This agreed well with the data obtained by shadow imaging the whole particles summarized in Figure 2-1 (461 μm with a standard deviation in the distribution of 12 μm).

| | Mean Radius |
