CONTENTS

ABSTRACT

SCALE is a comprehensive modeling and simulation suite for nuclear safety analysis and design developed and maintained by Oak Ridge National Laboratory under contract with the U.S. Nuclear Regulatory Commission, U.S. Department of Energy, and the National Nuclear Security Administration to perform reactor physics, criticality safety, radiation shielding, and spent fuel characterization for nuclear facilities and transportation/storage package designs.

Visit the SCALE website for additional information.

1. INTRODUCTION

W. A. Wieselquist

The SCALE code system includes verified and validated tools for criticality safety, reactor physics, radiation shielding, radioactive source characterization, and sensitivity and uncertainty analysis. SCALE is developed, maintained, tested, and managed by Oak Ridge National Laboratory (ORNL) and may be obtained through the Radiation Safety Information Computational Center (RSICC).

This manual documents version 6.3 of the SCALE code system, with initial release of 6.3.0 in 2022. The previous 6.2 series had its last maintenance release, 6.2.4, in 2020. This section describes the key features in 6.3 relative to 6.2 and details on how to run SCALE.

Maintenance releases of SCALE 6.3 (6.3.1, 6.3.2, etc.) will be made as needed to fix any issues discovered. Historically, there has been approximately one maintenance release per year. Note that once users have been granted a license from RSICC, any subsequent maintenance releases may be obtained free of charge directly from the SCALE team by sending an email to scalehelp@ornl.gov.

The next major release of SCALE with additional features will be SCALE 7.0 in ~2025.

The SCALE manual is included with installation; however, an online version is also available. The online version is new as of SCALE 6.3 and is in a convenient format for users, containing detailed lists of changes as well as any issues discovered in a particular version, starting with SCALE 6.3.0.

Instructions on installing or building SCALE, testing the configuration with the sample problems are available in Sect. 12.

1.1 ORGANIZATION

SCALE's top-level applications have been historically called "sequences" because of their original design, which called specific modules in sequence to solve specific problems. With the development of SCALE 6.3, we have found it more useful to think of SCALE as a set of products. A product is potentially more than one sequence and attempts to logically group capabilities around a particular application area. This is useful both from the standpoint of helping a user identify which sequences they should use and from a development point of view, as domain experts are assigned to each product. See Table 1.1.1 for the relationships between end user applications, SCALE products, and sequences.

Table 1.1.1: Relationship between end-user applications, SCALE products, and sequences

End user Application Area	Product	Example Sequences
Reactor Physics	Polaris	`polaris`

	TRITON	`t-depl`

Table 1.1.1 – continued from previous page

End user Application Area	Product	Example Sequences
Spent Fuel Inventory	ORIGAMI	`origami`
	ORIGEN	`arp` `origen`
Activation and Decay	ORIGEN	`couple` `origen`
Radiation Shielding	MAVRIC	`mavric`

Sensitivity and Uncertainty	TSUNAMI	`tsunami-3d-k5`
		`tsunami-3d-k6`
		`tsunami-ip`
		`tsar`
		`tsurfer`
		`tsunami-1d`
		`tsunami-2d`

	Sampler	`sampler`

The reconceptualization of sequences as products also facilitates management and discussion of certain key SCALE components, such as nuclear data. Table 1.1.2 briefly describes each product and contains links to the relevant section(s) in the manual.

Table 1.1.2: SCALE Products

Product	Purpose	Reference
Fulcrum	SCALE Graphical User Interface	Sect. 12.3.1
CSAS	Solve Monte-Carlo (and deterministic) criticality problems	Sect. 2.1
MAVRIC	Solve Monte-Carlo fixed source radiation transport with automatic variance reduction for difficult shielding tallies	Sect. 4.1
ORIGAMI	Generate fast LWR spent fuel inventory predictions	Sect. 5.4
ORIGEN	General depletion	Sect. 5.1.5
Polaris	Easy-to-use lattice physics	Sect. 3.2
Sampler	General Uncertainty Propagation	Sect. 6.4
TSUNAMI	Sensitivity and experiment selection analysis	Sect. 6.1, Sect. 6.2
VADER	Trending analysis	Sect. 6.5
TRITON	Solve coupled neutron transport and depletion problems for nuclear reactor systems	Sect. 3.1
XSProc	Accurate multi-group cross section self-shielding methods	Sect. 7.1
DATA	Verified and validated SCALE fundamental nuclear data	Sect. 10.1
AMPX	Transform ENDF-formatted data into SCALE libraries	external
OMNIBUS	Flexible user interface for HPC Applications	external

1.2 SCALE 6.3 UPDATES BY PRODUCT

The new features relative to SCALE 6.2 are described below, organized in terms of products as shown in Table 1.1.2.

1.2.1 FULCRUM

The major new feature in Fulcrum is the 3D visualization of geometry, including results overlay capability.

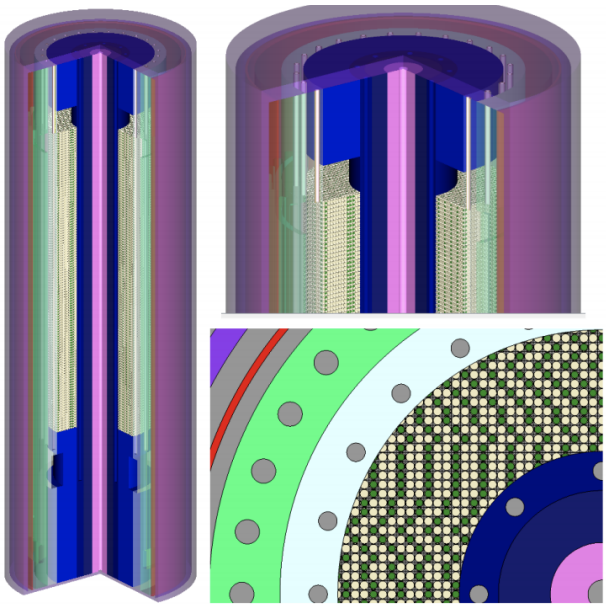

Fig. 1.2.1: Fulcrum visualization of geometry including new 3D.

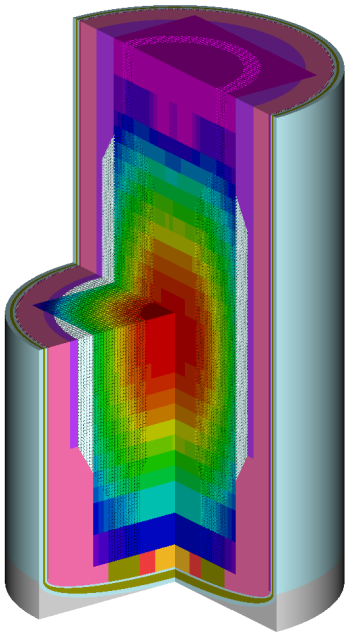

Fig. 1.2.2: Fulcrum visualization of 3D reactor geometry with flux overlay.

1.2.2 CSAS

The key new CSAS feature in 6.3 is the ability to call Shift for neutron transport. The same CSAS user interface is available for both CSAS-KENO and CSAS-Shift, and the majority of KENO features are supported by Shift. See Sect. 2.2 for details.

- CSAS-KENO now allows specification of the upper thermal scattering cutoff energy. A value above the default 10 eV may be necessary for high-temperature graphite–moderated systems. See Sect. 8.1.7.2.17 for details.
- CSAS now supports reusable energy and spatial grid definitions in the `definitions` block, especially useful for producing *.3dmap files for visualization in Fulcrum. See Sect. 2.1.4.2.1 for details.
- Shift can randomly place spheres within volumes, also useful for tristructural isotropic (TRISO) packing in pebbles. See Sect. 2.2.4.1.3 for details.

1.2.3 VADER

VADER is the modernization of the trending analysis code USLStats previously externally distributed with SCALE. VADER uses the SON input format introduced in SCALE 6.2. See Sect. 6.5 for details.

1.2.4 MAVRIC

The key new MAVRIC feature in 6.3 is the ability to call Shift for neutron and gamma transport. Append `-shift` to the sequence name to use Shift as in the example below.

Note: Some features in MAVRIC using the default Monaco transport engine are not yet available in Shift.

1.2.5 TRITON

TRITON was updated with a host of new capabilities in SCALE 6.3.

- TRITON can now call the new Shift Monte Carlo code instead of KENO. Shift was designed with parallelism and robustness as the highest priorities. With Shift enabled, few-group macroscopic cross sections on 3D hex and Cartesian meshes can be generated, similar to but more general than existing capabilities in TRITON-NEWT and Polaris. See Sect. 3.1.3.3.15 for details.
- Shift can randomly place spheres within volumes, which is available in both CSAS-Shift and TRITON-Shift. See Sect. 2.2.4.1.3 for details.

- A new flow block has been added to the TRITON timetable, intended for simulating molten salt reactors. See Sect. 3.1.3.3.11 for details.

1.2.6 POLARIS

The main Polaris improvement for 6.3 is a noticeable decrease in runtime, by a factor of 3 to 5 for almost all use cases. This was enabled through numerous performance-related refactors of the geometry, transport, and self-shielding components.

In addition, the following updates were made.

- Additional accident-tolerant fuel compositions (see Sect. 3.2.5.9) and new dopant properties (see Sect. 3.2.5.11).
- Polaris can now generate ORIGEN library files (*.f33) (see Sect. 3.2.7.4).
- Gamma detector modeling was added.
- Output file was improved.

See Sect. 3.2.2 for details on the updates.

1.2.7 ORIGEN

Extensive improvements to ORIGEN were made for SCALE 6.3, including the following.

- Modernized library construction integrated into the ORIGEN sequence instead of external the COUPLE sequence (see Sect. 5.1.5.2.21 for details).
- Sensitivity analysis capability (see Sect. 5.1.5.2.28 for details).
- OBIWAN command line utility (see Sect. 5.2 for details).

1.2.8 ORIGAMI

There were minimal changes to ORIGAMI for SCALE 6.3; however, the ORIGEN reactor library data has been refreshed and includes higher burnups and enrichments (see Sect. 5.3 for details).

1.2.9 XSPROC

The main changes to XSProc for SCALE 6.3 comprise adjustments to the default self-shielding parameters to reduce biases at high temperature and high burnup, as well as to improve the Bondarenko method accuracy for fuel models with multiple radial temperature zones. The input below demonstrates a lattice cell with multiple temperature rings using the fast Bondarenko-based self-shielding method (Bonami).

1.2.10 DATA

One of the main data updates for SCALE 6.3 is the inclusion of additional ENDF/B-VIII.0 data resources and the removal of ENDF/B-VII.0 data. New data resources include the following:

- New ice and other compounds such as reactor-grade graphite present in ENDF/B-VIII.0.
- Continuous-energy (CE) cross section data based on ENDF/B-VII.1 and ENDF/B-VIII.0.
- New multigroup (MG) libraries for fast-spectrum and thermal-spectrum systems (reactivity and depletion results closer to higher fidelity CE results).

See Sect. 10.1 for details.

Note that all 3D Monte Carlo codes in SCALE (TRITON, CSAS, MAVRIC) support both CE and MG methods. MG data and methods are faster but more approximate solutions.

1.2.11 SAMPLER

Sampler includes considerable updates to help users understand the causes of uncertainty in their simulations. Updates include the following:

- New sensitivity metrics for understanding nuclear data responsible for the majority of uncertainty (see Sect. 6.4.2.5 for details).
- Ability to analyze uncertainty due to delayed neutron data using the new `perturb_kinetics` option.
- A new analysis block which includes ability to calculate correlation coefficients between arbitrary outputs (see Sect. 6.4.3.7 for details).

1.2.12 TSUNAMI

For SCALE 6.3, the following enhancements were made to TSUNAMI.

- New Shift-based iterated fission probability (IFP) method with better performance than previous KENO-based IFP and Clutch methods.
- Improved performance of TSUNAMI-IP similarity and uncertainty calculations.
- New general HDF5 format for the sensitivity coefficients (see Sect. 6.3.4.1.3 for details).

1.2.13 AMPX

AMPX continues to be included in SCALE 6.3 and has been used exclusively to generate all libraries described in Sect. 10.1. The major enhancements were modernization related—to increase robustness of generated CE and MG libraries and to enable reading the new international GNDS data format. AMPX is now an open-source code system; the newest features are available by contacting the AMPX team.

1.2.14 OMNIBUS

Omnibus is the new frontend for the high-performance Shift Monte Carlo and Denovo deterministic transport codes that enables cutting-edge execution of Shift on GPU and Hybrid GPU/CPU platforms. As this capability evolves rapidly, please contact the authors of [IntroPJE+16] for details on getting the latest version of this frontend and manual [IntroJED+20].

1.3 USING SCALE

SCALE sequences have been incrementally developed over several decades, with the primary goals of robustness, accuracy, and ease-of-use. One side effect of this evolution can be seen in our user interfaces: the text-based input that drives a calculation. There is no standard SCALE input. For example, TRITON, CSAS, and MAVRIC are similar in their style, which predates SCALE 6.2, when numerous new user interfaces were introduced.

For example:

- The Polaris sequence for lattice physics was modeled after the brevity and conciseness of CASMO and has a distinct syntax and output.
- The ORIGEN code for general depletion and decay uses the SON syntax introduced in SCALE 6.2 as a significant upgrade from FIDO, but it keeps the same basic input structure and has a more general feel compared to Polaris.
- The Sampler code for uncertainty propagation was created with a syntax originally intended to be the upgrade to the TRITON, CSAS, and MAVRIC style, but it was superseded by SON.
- The shell sequence, which can perform a limited set of common file system operations across platforms.

The SCALE input file is quite flexible in that it can contain numerous sequence inputs executed sequentially. For example, in the input below, we irradiate a milligram of iron in a beginning-of-life pressurized water reactor spectrum for one day and then decay for nine days.

```
=shell
cp ${DATA}/arplibs/w17_e50.f33 f33
end

=origen
case{
  lib{ file=f33 pos=1 }
  mat{ iso=[Fe=0.001] units=GRAMS }
  flux=[1e14  0] %neutrons/cm^2-s
  time=[   1 10] %days
}
end
```

The first *=shell* sequence copies a specific ORIGEN library from the SCALE data directory to the temporary working directory. ORIGEN can then find this file to load one-group cross sections for this test irradiation.

1.3.1 RUNNING SCALE FROM FULCRUM

The most convenient way to run SCALE from a desktop is by launching Fulcrum. The Fulcrum executable is provided in the *bin* directory where SCALE was installed (e.g., `C:\SCALE-6.3.0\bin\Fulcrum.exe`). Fulcrum includes an online help document to assist users with its many features, and it includes links to the user manual and primers.

1.3.2 RUNNING SCALE FROM THE COMMAND LINE

Using the command line, SCALE can be executed using the *scalerte* command from the *bin* directory inside the SCALE installation (e.g., `C:\SCALE-6.3.0\bin\scalerte`). Your directory may differ based on the installation. Assuming the location of *scalerte* is known, a SCALE input can be run simply as

```
scalerte -m my.inp
```

with the *-m* option requesting SCALE to output status updates to the terminal. See Sect. 12 for details.

1.4 USER GUIDANCE AND TECHNICAL ASSISTANCE

This SCALE manual serves as the primary reference for SCALE users. The fundamental theory and all code options are documented herein. Several SCALE primers are available to serve as step-by-step guides for new users performing common calculations using the GUIs. SCALE training courses are presented several weeks each year, during which users can interact directly with the software developers and expert users from ORNL. Additional technical information on SCALE can be found at http://scale.ornl.gov—including training course schedules, a link to an online user forum, newsletters, benchmark reports, and downloads. Technical assistance is also provided via email at scalehelp@ornl.gov.

1.5 CODE AVAILABILITY

The SCALE code system is packaged and distributed by the RSICC and is also distributed through the Organization for Economic Cooperation and Development (OECD) Nuclear Energy Agency (NEA) Data Bank in France and the Research Organization for Information Science and Technology (RIST) in Japan.

1.6 HISTORY

The SCALE code system dates back to 1969, when ORNL began providing the transportation package certification staff at the US Atomic Energy Commission (AEC) with computational support in the use of the new KENO code. KENO was used to perform criticality safety assessments with the statistical Monte Carlo method. From 1969 to 1976, the AEC certification staff relied on ORNL personnel to assist them in the correct use of codes and data for criticality, shielding, and heat transfer analyses of transportation packages. However, the certification staff learned that occasional users had difficulty becoming proficient in performing the calculations often needed for an independent safety review. Thus, shortly after the certification staff was moved to the US Nuclear Regulatory Commission (NRC), the NRC proposed development of an easy-to-use analysis system that provided the technical capabilities of the individual modules with which they were familiar. With this proposal, the concept of SCALE as a comprehensive modeling and simulation suite for nuclear safety analysis and design was born. The NRC staff provided ORNL with some general development criteria for SCALE: (1) focus on applications related to nuclear fuel facilities and package designs, (2) use well-established computer codes and data libraries, (3) design an input format for the occasional or novice user, (4) prepare standard analysis sequences (control modules) to automate the use of multiple codes (functional modules) and data to perform a system analysis, and (5) provide complete documentation and public availability. With these criteria, the ORNL staff laid out the framework for the SCALE system and began development efforts. The initial version of SCALE (Version 0) was distributed in July 1980. Although the capabilities of the system continue to evolve, the philosophy established with the initial release still serves as the foundation of SCALE 6.3, more than 40 years later. In July 1980, the initial version of SCALE was made available to the Radiation Safety Information Computational Center (RSICC) at ORNL. This system was packaged and released by RSICC as CCC-288/SCALE 0. Subsequent additions and modifications resulted in the following releases: CCC-424/SCALE1 in 1981; CCC-450/SCALE 2 in 1983; CCC-466/SCALE 3 in 1985; CCC-545/SCALE 4.0 in 1990; SCALE 4.1 in 1992; SCALE 4.2 in 1994; SCALE 4.3 in 1995; SCALE 4.4 in 1998; SCALE 4.4a in 2000; CCC-725/SCALE 5 in 2004; CCC-732/SCALE 5.1 in 2006; CCC-750/SCALE 6.0 in 2009; CCC-785/SCALE 6.1 in 2011; CCC-834/SCALE 6.2 in 2016.

1.7 ACKNOWLEDGEMENTS

Most team members are credited for their authorship of the sections in this manual that correspond to their work. A few individuals have been essential to the development and maintenance of SCALE but are not credited by authorship. These individuals include B. Taylor, J. Batson, M. Henley, S. Poarch, B. Bevard, L. Aloisi, D. Bowen, and R. Grove.

We also acknowledge the support of Dr. A. Chambers and the DOE/NCSP and D. Algama, D. Barto, L. Kyriazidis, and H. Esmaili of the NRC.

2. CRITICALITY SAFETY

Introduction by B. T. Rearden [1] and K. B. Bekar

SCALE provides a suite of computational tools for criticality safety analysis primarily based on the Monte Carlo codes KENO and Shift for eigenvalue neutronics calculations. [CritSafetyGPJD+11], [CritSafetyPJE+16].

Two variants of KENO provide identical solution capabilities with different geometry packages. KENO V.a uses a simple and efficient geometry package sufficient for modeling many systems of interest to criticality safety and reactor physics analysts. KENO-VI uses the SCALE Generalized Geometry Package, which provides a quadratic-based geometry system with much greater flexibility in problem modeling but with slower runtimes. Both versions of KENO perform eigenvalue calculations for neutron transport primarily to calculate multiplication factors (*keff*) and flux distributions of fissile systems in both continuous-energy and multigroup modes. KENO's grid geometry capability extends region-based features for accumulating data for source or biasing parameter specifications, as well as for tallying results from a calculation for visualization or communication of data into or out of a calculation.

Shift, an advanced Monte Carlo code specifically designed for efficient parallel and GPU executions for high-performance computers, provides both eigenvalue and fixed-source Monte Carlo transport capabilities as well as hybrid capabilities for variance reduction methods with the Denovo deterministic transport solver. [CritSafetyPJE+16], [CritSafetyESSC10]. Shift supports different geometry engines including the Oak Ridge Adaptable Nested Geometry Engine (ORANGE) designed to provide particle transport capabilities on both KENO V.a and KENO-VI geometries as well as geometry visualization capabilities in the Fulcrum user interface. Shift with both versions of KENO geometries performs eigenvalue calculations in both continuous-energy and multigroup modes. Shift supports most widely used primary capabilities available with KENO codes.

Capabilities with both KENO codes and Shift code are typically accessed through the integrated SCALE sequences described below. Criticality safety analysts may also be interested in the sensitivity and uncertainty analysis techniques that can be applied for code and data validation as described elsewhere in this document.

[1] Formerly with Oak Ridge National Laboratory.

Criticality Safety Analysis Sequences

The Criticality Safety Analysis Sequences (CSAS) with KENO V.a (CSAS5), KENO-VI (CSAS6), and Shift (CSAS5-Shift, CSAS6-Shift) provide a reliable, efficient means of performing *keff* calculations for systems routinely encountered in engineering practice. The CSAS sequences implement XSProc to process material input and provide a temperature and resonance-corrected cross section library based on the physical characteristics of the problem being analyzed. If a continuous energy cross section library is specified, no resonance processing is needed, and the continuous energy cross sections are used directly in KENO, with temperature corrections provided as the cross sections are loaded.

CSAS sequences with 3D Monte Carlo transport capabilities currently available in SCALE 6.3 are listed in Table 2.1. The transport module run by each sequence, and the geometry engine used by each transport module, are also provided in this table. Note that the sequence names CSAS25 and CSAS26—similarly, CSAS25-Shift and CSAS26-Shift—are only the alias names of the CSAS sequences, and they were added to the SCALE repository for backward compatibility purposes.

Table 2.1: Valid CSAS sequences available in SCALE 6.3

Sequence Name	Transport Module	Geometry Engine
CSAS5, CSAS25	KENO V.a	KENO V.a
CSAS6, CSAS26	KENO-VI	SGGP [1]
CSAS5-Shift, CSAS25-Shift	Shift with KENO V.a geometry	ORANGE [2]
CSAS6-Shift, CSAS26-Shift	Shift with KENO-VI geometry	ORANGE

[1] SGGP is SCALE General Geometry Package

[2] ORANGE is a new C++ geometry package, the Oak Ridge Adaptable Nested Geometry Engine, has been designed to provide particle transport capabilities on both KENO V.a and KENO-VI geometries in SCALE sequences as well as geometry visualization capabilities in the Fulcrum user interface.

For continuous energy calculations, reaction rate tallies can be requested within the CSAS input, and for multigroup calculations, reaction rate calculations are performed using the KENO Module for Activity-Reaction Rate Tabulation (KMART) post-processing tools. A conversion tool is provided to up-convert KENO V.a input to KENO-VI either as a direct KENO input (K5toK6) or, more commonly, as a CSAS sequence (C5toC6). Note that these capabilities are only available with CSAS5 and CSAS6 sequences.

The CSAS5 search capability available in previous SCALE versions is no longer supported by the CSAS sequences in SCALE 6.3. Research is being conducted to support the equivalent search capabilities in a more robust modernized code framework for the next SCALE release.

CSAS sequences support parallel execution of KENO V.a, KENO-VI, and Shift transport modules. When running on multiple cores, Shift performance is always better than KENO codes since its design was targeted for high-performance computers.

Criticality Accident Alarm System Analysis with KENO and MAVRIC

Criticality accident alarm systems (CAAS) safety analyses modeling presents challenges because the analysis consists of a criticality problem and a deep-penetration shielding problem [CritSafetyPPJ09]. Modern codes are typically optimized to handle one of these types of problems, but not both. The two problems also differ in size-the criticality problem depends on materials relatively close to the fissionable materials, whereas the shielding problem can cover a much larger range.

CAAS analysis can be performed using the CSAS6 criticality sequence and the MAVRIC shielding sequence. First, the fission distribution (in space and energy) is determined via CSAS6. This information is collected on a grid geometry that overlies the physical geometry model and is saved as a Monaco mesh source file. The mesh source is then used as the source term in MAVRIC. The absolute source strength is set by the user to the total number of fissions (based on the total power released) during the criticality excursion. MAVRIC can be optimized to calculate a specific detector response at one location or to calculate multiple responses/locations with roughly the same relative uncertainty. See Sect. 4.2 for further details.

Note: The Sourcerer sequence is no longer supported in SCALE 6.3 because it depends on several legacy components not supported in SCALE 6.3. The equivalent capability will be designed as another start data type in CSAS sequences for the next SCALE release.

Note: DEVC sequence is a deprecated capability in SCALE 6.3.

2.1 CSAS: CONTROL MODULE FOR ENHANCED CRITICALITY SAFETY ANALYSIS SEQUENCES WITH KENO

K. B. Bekar, *L. M. Petrie* [1], *S. Goluoglu* [1], *D. F. Hollenbach* [1] and *N. F. Landers* [1]

The **C**riticality **S**afety **A**nalysis **S**equences with KENO codes provide reliable and efficient means of performing k_{eff} calculations for systems that are routinely encountered in engineering practice. Two CSAS sequence implementations, CSAS5 and CSAS6, with two variants of KENO codes, KENO V.a and KENO-VI, provide identical solution capabilities with different geometry packages. In the multigroup calculation mode, CSAS uses XSProc to process the cross sections for temperature corrections and problem-dependent resonance self-shielding and calculates the k_{eff} of a three-dimensional (3D) system model. If the continuous-energy calculation mode is selected no resonance processing is needed and the continuous-energy cross sections are used directly in KENO codes, with temperature corrections provided as the cross sections are loaded. The geometric modeling capabilities available in KENO codes coupled with the automated cross-section processing within the control sequences allow complex, 3D systems to be easily analyzed.

The CSAS5 search capability available in previous SCALE versions is no longer supported by the CSAS5 sequence in SCALE 6.3.

In SCALE 6.3, CSAS5 and CSAS6 support two new sequence data blocks, definitions and tallies data, to allow flexible definition and output control of mesh tallies. The mesh responses neutron flux, fission rate, and fission source can now be requested multiple times on different spatial and energy grids in the same calculation.

[1] Formerly with Oak Ridge National Laboratory.

2.1.1 ACKNOWLEDGMENTS

CSAS5 and its related Criticality Safety Analysis sequences are based on the old CSAS2 control module (no longer in SCALE) and the KENO V.a functional module described in Sect. 8.1. Therefore, special acknowledgment is made to J. A. Bucholz, R. M. Westfall, and J. R. Knight who developed CSAS2. G. E. Whitesides is acknowledged for his contributions through early versions of KENO. Appreciation is expressed to C. V. Parks and S. M. Bowman for their guidance in developing CSAS5.

2.1.2 INTRODUCTION

Criticality Safety Analysis Sequence with KENO V.a (CSAS5) and KENO-VI (CSAS6) provide reliable and efficient means of performing k_{eff} calculations for systems that are routinely encountered in engineering practice, especially in the calculation of k_{eff} of three-dimensional (3D) system models. CSAS5 and CSAS6 implement XSProc to process material input and provide a temperature and resonance-corrected cross-section library based on the physical characteristics of the problem being analyzed. If a continuous energy cross-section library is specified, no resonance processing is needed and the continuous energy cross sections are used directly in KENO codes, with temperature corrections provided as the cross sections are loaded.

The search capability available in the CSAS5S in previous SCALE versions is no longer supported by the CSAS5 in SCALE 6.3. This capability was excluded when doing modernization work for CSAS sequences in SCALE 6.2 and permanently disabled in SCALE 6.3 due to the inconsistencies between the legacy code implementation and the modern CSAS framework. Research is being continued to support equivalent search capabilities in a more robust modernized code framework for the next SCALE release.

In SCALE 6.3, CSAS5 and CSAS6 support two new sequence data blocks, definitions and tallies data, to allow flexible definition and output control of mesh tallies. The mesh responses neutron flux, fission rate, and fission source can now be requested multiple times on different spatial and energy grids in the same

calculation. This capability helps users efficiently manage computational resources when collecting detailed information, depending on their requirements. For example, fission density can be tallied in a very fine spatial mesh in a few energy groups while performing calculations in high resolution with SCALE's very fine group multigroup library (1597 energy groups), or fission density can be tallied on multiple spatial fine meshes rather than using a large global fine mesh to keep the runtime and memory footprint of the calculation at reasonable levels.

2.1.3 SEQUENCE CAPABILITIES

In the CSAS sequence framework, SCALE data handling is automated as much as possible. CSAS and many other SCALE sequences apply a standardized procedure to provide appropriate number densities and cross sections for the calculation. XSProc is responsible for reading the standard composition data and other engineering-type specifications, including volume fraction or percent theoretical density, temperature, and isotopic distribution as well as the unit cell data. XSProc then generates number densities and related information, prepares geometry data for resonance self-shielding and flux-weighting cell calculations, if needed, and (if needed) provides problem-dependent multigroup cross-section processing. Sequences that execute KENO codes include a KENO Data Processor to read and check the KENO data. When the data checking has been completed, the control sequence executes XSProc to prepare a resonance-corrected microscopic cross-section library in the AMPX working library format if a multigroup library has been selected.

For each unit cell specified as being cell-weighted, XSProc performs the necessary calculations and produces a cell-weighted microscopic cross-section library. KENO codes may be executed to calculate the k_{eff} or neutron multiplication factor using the cross-section library that was prepared by the control sequence.

Computational capabilities available in KENO codes—including the determination of k-effective, neutron lifetime, generation time, energy-dependent leakages, energy- and region-dependent absorptions, fissions, the system mean-free-path, the region-dependent mean-free-path, average neutron energy, flux densities, fission densities, reaction rate tallies, mesh tallies, source convergence diagnostics, problem-dependent continuous-energy temperature treatments, parallel calculations, restart capabilities, and many more—are also provided by the CSAS5 sequence. Details of each capability, their input methods, and output edits are provided in Sect. 8.1 of this document and will not be repeated here.

2.1.3.1 Multigroup limitations

The CSAS control module was developed to use simple input data and prepare problem-dependent cross sections for use in calculating the effective neutron multiplication factor of a 3D system using KENO codes, KENO V.a and KENO-VI. An attempt was made to make the system as general as possible within the constraints of the standardized methods chosen to be used in SCALE. Standardized methods of data input were adopted to allow easy data entry and for quality assurance purposes. Some of the limitations of the CSAS multigroup sequences are a result of using preprocessed multigroup cross sections. Inherent limitations in multigroup CSAS calculations are as follows:

1. Two-dimensional (2D) effects such as fuel rods in assemblies where some positions are filled with control rod guide tubes, burnable poison rods and/or fuel rods of different enrichments. The cross sections are processed as if the rods are in an infinite lattice of identical rods. If the user inputs a Dancoff factor for the cell (such as one computed by MCDancoff), XSProc can produce an infinite lattice cell, which reproduces that Dancoff. This can mitigate some two dimensional lattice effects

2.1.3.2 Continuous energy limitations

When continuous energy KENO calculations are desired, none of the resonance processing capabilities of XSProc are applicable or needed. The continuous energy cross sections are directly used in KENO. An existing multigroup input file can easily be converted to a continuous energy input file by simply specifying the continuous energy library. In this case, all cell data is ignored. However, the following limitations exist:

1. If CELLMIX is defined in the cell data, the problem will not run in the continuous energy mode. CELLMIX implies new mixture cross sections are generated using XSDRNPM-calculated cell fluxes and therefore is not applicable in the continuous energy mode.
2. Only VACUUM, MIRROR, PERIODIC, and WHITE boundary conditions are allowed. Material-specific albedos, e.g., WATER, CARBON, POLY, etc., are for multigroup only.
3. Problems with DOUBLEHET cell data are not allowed as they inherently utilize CELLMIX feature.

2.1.4 INPUT DATA GUIDE

This section describes the input data required for the CSAS with KENO transport codes. A typical CSAS input, shown in Example 2.1.1, starts with the sequence identifier always preceded by the = sign (=CSAS5 and =CSAS6), and it is followed by the problem title. Then, a cross section library name is specified, and all these entries are followed by several data blocks each starting with READ data_block and ending with END data_block.

Example 2.1.1: A typical CSAS sequence input

```
=sequence_identifier parm=(parm_options)
problem title

' ----- XSProc data
' cross section library name (REQUIRED)
ce_v7.1

' List of material specifications in standard SCALE format (REQUIRED)
read composition
...
end composition

' Specify data for resonance processing (OPTIONAL)
read celldata
...
end celldata

' ---- New CSAS sequence data blocks

' Used to define energy bounds and grid geometries for
' the tallies defined in tallies data block
' (REQUIRED if tallies data block exists)
read definitions
...
end definitions

' Used to define tallies in a more robust way (OPTIONAL)
read tallies
...
end tallies

' ---- KENO transport data
' Specify the problem geometry (REQUIRED)
read geometry
```

(continues on next page)

(continued from previous page)

```
...
end geometry

' Other input data blocks (OPTIONAL)
```

The input data for the CSAS sequence are composed of three broad categories of data, as shown in Example 2.1.1. The first is XSProc data, including Standard Composition Specification Data and Unit Cell Geometry Specification Data. This first category specifies the cross section library and then defines the composition of each mixture and optionally unit cell geometry that may be used to process the cross sections. This data block is necessary for the CSAS sequence.

Note: Sequence implementation determines the calculation (transport) mode automatically, either as multigroup or continuous-energy, by testing the cross section library whose name has been entered.

Warning: Continuous-energy mode does not process data entered in *celldata data* block(s).

The second category of data, the CSAS sequence input data, includes two new data blocks, **definitions data** and **tallies data**, for flexible tally definitions. These new blocks available in all CSAS sequences in SCALE 6.3 currently provide only accumulation of neutron flux, fission rate, and neutrons produced from fission on **different** energy and spatial grids. Although similar to capabilities activated with old-style KENO parameter input methods (with `GFX`, `CDS`, and `FIS` as described in Sect. 8.1.3.3), these input methods do not allow tallying the requested quantities on different energy and spatial grids. This limitation is relaxed with the new CSAS input blocks.

The third category of data, the KENO input data, is used to specify the geometric and boundary conditions that represent the physical 3D configuration of a KENO problem.

CSAS ensures data consistency among these three category of data. For example, it verifies that mixture numbers used in the KENO **geometry data** block must correspond to those defined either in the **composition data** or **celldata data** blocks. Note that in multigroup mode, a unique mixture number can be specified in the **celldata data** block by `CELLMIX=` if the cell is cell-weighted.

Note: As depicted in Example 2.1.1, a successful CSAS calculation requires at least a problem title and cross section library definitions, followed by **composition data** and **geometry data**. Depending on the requirements of the problem, other optional data blocks can be activated. Following CSAS5 input demonstrates this minimal requirement.

```
=csas5
sample problem 14  u metal cylinder in an annulus
ce_v7.1

read comp
   uranium  1 den=18.69 1 300  92235 93.2 92238 5.6 92234 1.0 92236 0.2 end
end comp

read geom
   global unit 1
      cylinder  1 1 8.89 10.109 0.0 orig 5.0799 0.0
```

(continues on next page)

(continued from previous page)

```
      cylinder  0 1 13.97 10.109 0.0
      cylinder  1 1 19.05 10.109 0.0
end geom
end data
end
```

Unlike the CSAS5 and CSAS6 versions in previous SCALE releases, in SCALE 6.3, user can enter all data blocks in any order in both CSAS5 and CSAS6 inputs. Following CSAS5 input illustrates this input flexibility.

```
=csas5
sample problem 14  u metal cylinder in an annulus
ce_v7.1

read geom
   global unit 1
      cylinder  1 1 8.89 10.109 0.0 orig 5.0799 0.0
      cylinder  0 1 13.97 10.109 0.0
      cylinder  1 1 19.05 10.109 0.0
end geom

read comp
   uranium  1 den=18.69 1 300  92235 93.2 92238 5.6 92234 1.0 92236 0.2 end
end comp

end data
end
```

All data are entered in free form, allowing alphanumeric data, floating-point data, and integer data to be entered in an unstructured manner. Up to 252 columns of data entry per line are allowed. Data can usually start or end in any column with a few exceptions. As an example, the word END beginning in column 1 and followed by two blank spaces or a new line will end the problem and any data following will be ignored. Each data entry must be followed by one or more blanks to terminate the data entry. For numeric data, either a comma or a blank can be used to terminate each data entry. Integers may be entered for floating-point values. For example, 10 will be interpreted as 10.0. Imbedded blanks are not allowed within a data entry unless an E precedes a single blank as in an unsigned exponent in a floating-point number. For example, 1.0E 4 would be correctly interpreted as 1.0×10^4.

The word "END" is a special data item. An "END" may have a name or label associated with it (e.g., "END DATA"). The name or label associated with an "END" is separated from the "END" by a single blank and is a maximum of 12 characters long. *At least two blanks or a new line MUST follow every labeled and unlabeled ``END``. It is the user's responsibility to ensure compliance with this restriction. Failure to observe this restriction can result in the use of incorrect or incomplete data without the benefit of warning or error messages.*

Multiple entries of the same data value can be achieved by specifying the number of times the data value is to be entered, followed by either `R`, `\*`, or `$`, followed by the data value to be repeated. Imbedded blanks are not allowed between the number of repeats and the repeat flag. For example, `5R12`, `5*12`, `5$12`, or `5R 12`, etc., will enter five successive 12's in the input data. Multiple zeros can be specified as nZ where n is the number of zeroes to be entered.

The purpose of this section is to define the input data in discrete subsections relating to a particular type of data. Tables of the input data are included in each subsection, and the entries are described in more detail in the appropriate sections.

Resonance-corrected cross sections are generated using the appropriate boundary conditions for the unit cell description (i.e., void for the outer surface of a single unit, white for the outer surface of an infinite array of cylinders). As many unit cells as needed may be specified in a problem. A unit cell is cell-weighted by using the keyword "CELLMIX=" followed by a unique user specified mixture number in the unit cell data.

To check the input data without actually processing the cross sections and without performing transport calculations, the sequence parameter options `PARM=CHECK` or `PARM=CHK` should be entered, as shown below.

```
=CSAS5 PARM=CHK

=CSAS6 PARM=CHK
```

This will cause the input data for CSAS to be checked and appropriate error messages to be printed. If plots are specified in the data, they will be printed. This feature allows the user to debug and verify the input data while using a minimum of computer time.

2.1.4.1 XSProc data

The XSProc reads the standard composition specification data and the unit cell geometry specifications. It then produces the mixing table and unit cell information necessary for processing the cross sections if needed. Sect. 7 of this manual provides a detailed description of the input data and processing options. CSAS sequences are responsible for passing data such that mixing table and problem-dependent cross sections from XSProc calculations are conveyed to the transport calculations. Note that reported elapsed time in each transport calculation does not include the time required to process and prepare multigroup cross section data. When running the transport module concurrently on multiple cores, these data are broadcasted to all instances of the transport module running on each computational node.

In contrast, in continuous-energy mode, only mixing table data generated from XSProc utilities are passed to the transport module. In addition to this, the defined continuous-energy data library is first verified by the utilities that exist in XSProc, and then temperature correction is applied to each nuclide data using the defined temperatures when loading these data from disk by each instance of the transport module. Therefore, elapsed time reported at the end of each transport module calculation also includes the time spent on temperature correction and data loading.

In multigroup mode, the XSProc calculation path for each unit cell is always determined with the following hierarchy to prepare the problem-dependent multigroup cross section data:

- All non-fissionable cells are processed with BONAMI by default, and this cannot be changed.
- All fissionable cells are processed with CENTRM by default, and this can be overridden by defining a cross section processing option with the sequence parameter option (PARM=BONAMI or PARM=2REGION).
- Double-het cells defined in the **celldata data** block are **always** processed with CENTRM, and this cannot be changed.

CSAS sequences always print a cross section processing summary of the cells used/defined in the problem. This can be seen in Sect. 2.1.5.3. See Sect. 7 of this manual for detailed description of these unit cell processing options.

2.1.4.2 CSAS input data

Two new data blocks, **definitions data** and **tallies data**, are currently supported by CSAS sequences to provide flexible tally definitions. These new data blocks are currently available to define the mesh responses flux, fission_density, and fission_source on different spatial and energy grids. This section introduces these two new data blocks and discusses the limitations with some details.

Definitions data

The **definitions data** input block allows (1) multiple spatial grids to be defined using the **gridGeometry data** blocks inside the definitions data block, and (2) multiple energy grids to be defined using the **energyBounds data** inside the **definitions data** block. The syntax for defining a **gridGeometry** inside a definitions block is the same as defining a standalone grid at the root level of input (i.e., KENO's **gridgeometry data** block). The syntax for defining energyBounds is already used for defining energy grids in the MAVRIC sequence. See Sect. 8.2 for further details.

In addition to specifying a list of individual energy group boundaries, equal-width energy bins and equal-width lethargy bins can be requested. Moreover, any available SCALE library structure can be requested (e.g., n56 for the group structure from SCALE's 56-group neutron library). CSAS5 allows using combinations of some of these input methods, as shown in the example given in Example 2.1.2.

Note: As shown in example given Example 2.1.2 `READ` keyword is not required when defining energy boundaries with **energyBounds** data block. This may show differences from one CSAS sequence to another.

Example 2.1.2: Typical spatial and energy grid specifications in the **definitions data** block

```
READ DEFINITIONS

read grid 1
   xlinear 30 -10 70
   ylinear 10 -20 60
   zlinear 50 -30 40
end grid

read grid 2
   numxcells=10 xmin=-18.5 xmax=+68.5
   numycells=25 ymin=-28.5 ymax=+58.5
   numzcells=10 zmin=-38.5 zmax=+48.5
end grid

'user specified energy grid
read energyBounds 1
   bounds 2e7 0.625 1e-5 end
end energyBounds

'user specified energy grid using equal-energy bins'
energyBounds 2
   linear=10 1e-5 2e7
end energyBounds

'user specified energy grid using equal-lethargy bins'
energyBounds 3
   logarithmic=10 1e-5 2e7
end energyBounds

'SCALE 56-group neutron structure with additional energy points'
energyBounds 10
```

(continues on next page)

(continued from previous page)

```
   n56
   bounds 1.1  0.11 0.011 0.0011 end
energyBounds

END DEFINITIONS
```

In continuous-energy mode, a special DEFAULT keyword allows modification of the default energy group structure that was previously defined with the NGP parameter and/or the KENO **energy data** block.

Note: The default energy group structure is currently acquired from the SCALE 252-group neutron library. This may be overridden by defining data with the NGP parameter, data in the KENO **energy data** block, or data in the **definitions data** block entered with DEFAULT keyword.

Caution: CSAS does not allow using **definitions data** block together with KENO NGP parameter and/or KENO **energy data** block.

Caution: CSAS does not allow using **definitions data** block together with KENO FIS, GFX, CDS, and MSH parameters.

In multigroup mode, **DEFAULT** energy boundaries are always obtained from the multigroup library used by KENO codes in the neutron transport calculation, and this cannot be overriden by a **DEFAULT** energy boundaries specification in the definitions data block. In other words, an energyBounds **DEFAULT** is not permitted in multigroup mode.

Warning: In multigroup mode, **DEFAULT** energy boundaries are always acquired from the library used by the KENO V.a transport, and it cannot be changed.

Caution: In multigroup calculations, energy points of the user-defined energy boundaries must be a subset of the energy points of the energy structure obtained from the multigroup library used by KENO transport. Otherwise, execution will be terminated and an appropriate error message is displayed.

The sample definitions data block given in Example 2.1.3 defines an energy grid labeled 1 and an energy grid labeled DEFAULT in the definitions data block.

Example 2.1.3: Definitions data block with DEFAULT energyBounds specification

```
READ DEFINITIONS

'user defined energy grid 1
  read energyBounds 1
     bounds 2e7 0.625 1e-5 end
```

(continues on next page)

(continued from previous page)

```
  end energyBounds

'user defined default energy grid
  energyBounds DEFAULT
     bounds    2e7 8.2e5 2.0e4 1.05e2 5.0 0.65 0.15 0.04 1.e-5 end
  end energyBounds

END DEFINITIONS
```

When using this definitions block in continuous-energy mode, KENO codes read DEFAULT energy boundaries from the definitions data and utilizes these data in all tally calculations (`energyBounds DEFAULT` overrides the current default that is acquired from the SCALE 252-group library) if requested otherwise in the tallies block for the supported mesh responses. The two energy boundaries read from definitions data are printed in KENO's energy boundaries edit in the output as shown in Fig. 2.1.1.

```

energy boundaries marked as DEFAULT will be used in all tally calculations if otherwise not requested.
```

Fig. 2.1.1: Sample energy boundaries output edit when running CSAS with the above definitions data in the continuous-energy mode.

Unlike continuous-energy mode, when the data defined in the sample definition block given above are processed in mutigroup mode, reading the energy boundaries `DEFAULT` from the definitions data is ignored, and the user is notified with a warning message, as shown in Fig. 2.1.2. However, the calculation is terminated because the energy boundaries given with energy identifier 1 does not conform to the default energy boundaries acquired from the library used by KENO transport (in this test case, the SCALE 28-group neutron and 19-group gamma library was used). The corresponding error message is also shown in Fig. 2.1.2 printed to the output just before the code termination.

```
***** warning ***** csas message number cs-400 follows:

calculation.

...

***** error ***** keno message number k5-388 follows:
inconsistent energy intervals. energy boundaries specified in definitions data with the identification number  1
must be a sub set of the DEFAULT energy boundaries acquired from the multi group library used by transport.

***** warning ***** keno message number k5-378 follows:
in multi group mode, DEFAULT energy boundaries used for tallying are always obtained from the multi group library used by
transport.
```

Fig. 2.1.2: CSAS terminates execution with an error message when the definitions data given above are used in multigroup mode.

Tallies data

The new tallies data input allows mesh responses to be requested using any energy grid and/or spatial grid from the definitions block. Three response types shown in Table 2.1.1 were added as mesh tally options for CSAS. Note that the same responses can also be activated by `GFX`, `FIS`, and `CDS`, but only using the default energy boundaries.

Table 2.1.1: Mesh tallies available with **tallies data** block.

Description	Old KENO input method to activate the same tally	New response name in t
Neutron flux averaged over mesh volumes	`GFX`	`flux`
Fission rates per voxel volume	`FIS`	`fission_density`
Neutron production per voxel volume	`CDS`	`fission_source`

Note: Either input method (parameter input or tallies data) can be used to request the mesh tallies described in Table 2.1.1. It is recommended to request mesh tallies using the new response names (`flux`, `fission_density`, `fission_source`) with the tallies data block rather than the old-style parameter inputs (`GFX`, `FIS`, `CDS`) with the limited energy and spatial grid options.

A typical mesh tally input block is given in Example 2.1.4. Each spatial and energy grid used by each mesh tally must be defined in the definitions data block. Note that, as shown in Example 2.1.4, the same mesh response can be defined multiple times using different spatial and energy grids.

Example 2.1.4: Typical mesh tally specifications in tallies data

```
READ TALLIES

   read mesh 1
      response=FLUX
      grid=1
      energy= 1
   end mesh

   read mesh 2
```

(continues on next page)

(continued from previous page)

```
      response=FISSION_DENSITY
      grid=2
      energy=2
   end mesh

   read mesh 3
      response=FISSION_SOURCE
      grid=3
      energy=default
   end mesh

   read mesh 13
      response=FISSION_SOURCE
      grid=3
      energy=2
   end mesh

END TALLIES
```

The KENO codes in SCALE 6.3 support multiple sets of energy group boundaries for tallying purposes. A data container was designed to store all energy boundaries that are either set up by KENO for some internal use or specified by the user. Note that multiple sets of energy boundaries can be defined only by using the new definitions data block available in CSAS and TRITON sequences. In continuous-energy mode, KENO with the NGP parameter or data in energy data block provides only a single set of energy boundaries, and these always override KENO's default energy group boundaries used in all tallies.

After processing data entered in the definitions and tallies data blocks, KENO codes print the summary of all corresponding definitions in energy boundaries, grid definitions, and tally definitions output edits. The following sample input can be used to demonstrate the new output edits in KENO codes with continuous-energy mode:

```
read definitions

 read gridgeometry 11
    numxcells=2 numycells=2 numzcells=2
    xmin=-0.73 xmax=0.73
    ymin=-0.73 ymax=0.73
    zmin=0 zmax=10.0
 end gridgeometry

 read gridgeometry 12
    numxcells=2 numycells=2 numzcells=8
    xmin=-0.73 xmax=0.73
    ymin=-0.73 ymax=0.73
    zmin=0 zmax=10.0
 end gridgeometry

read gridgeometry 13
    numxcells=4 numycells=2 numzcells=4
    xmin=-0.73 xmax=0.73
    ymin=-0.73 ymax=0.73
    zmin=0 zmax=10.0
 end gridgeometry

 read energyBounds 12

```

Fig. 2.1.3: Energy boundaries edit in KENO output

Another edit that was added to KENO's output is the grid definitions edit, which summarizes the mesh grids that were either defined by the user or automatically constructed by KENO for Shannon entropy tallies. The grid definitions output edit corresponds to the above provided sample input and is shown in Fig. 2.1.4. Note that Fig. 2.1.4 shows only a part of the mesh tallies output edit.

Fig. 2.1.5: Tally definitions edit in KENO output

After the calculations have been completed for all the requested tallies, KENO also prints another output table that summarizes the mesh tallies, as shown in Fig. 2.1.6. Other than the mesh tally input specifications, the mesh tallies output edit also summarizes the intervals of the energy and spatial grids used in tally calculations and approximate memory allocation required to compute and write this tally to 3dmap output file. Note that Fig. 2.1.6 shows only a part of the mesh tallies output edit.

Fig. 2.1.6: Mesh tallies edit in KENO output

See the relevant subsections in Sect. 8.1.5 for further details for all these output edits.

Mesh tally output files

Depending on the user input specifications, the naming of the mesh tally 3dmap output files show some variations. Table 2.1.2 lists the 3dmap output filenames for each response type if only a single tally was requested for each response type. And, Table 2.1.3 lists the 3dmap output filenames for each response type if multiple mesh tallies are requested with the same response type. In such a case, the output filenames are updated with the keyword meshtally followed by the mesh id (mesh identifier used to define each mesh in tallies data).

Table 2.1.2: Mesh tally 3dmap file naming when a single response is requested

response	3dmap file name
`flux`	`${BASENAME}.flux.3dmap`
`fission_density`	`${BASENAME}.fission_density.3dmap`
`fission_source`	`${BASENAME}.fission_source.3dmap`

Note: Mesh tallies activated with old-style input method (using the `GFX`, `CDS`, and `FIS` parameters) also use the definitions for 3dmap file naming given in Table 2.1.2.

Table 2.1.3: Mesh tally 3dmap file naming when a response is requested multiple times

response	3dmap file name
`flux`	`${BASENAME}.meshtally_${MESHID}_flux.3dmap`
`fission_density`	`${BASENAME}.meshtally_${MESHID}_fission_density.3dmap`
`fission_source`	`${BASENAME}.meshtally_${MESHID}_fission_source.3dmap`

2.1.4.3 KENO data

Table 2.1.4 contains the outline for the KENO input. A typical KENO input is divided into 13 data blocks. A brief outline of commonly used data blocks is shown in Table 2.1.4. Note that parameter data must precede all other KENO data blocks when running standalone KENO codes; however, this is not applied to the KENO calculations performed as part of each CSAS sequence. As described in above sections, a minimal CSAS input always requires **geometry data**, and KENO data blocks listed in Table 2.1.4 can be defined in any order.

Information on all KENO input is provided in Sect. 8.1 of this document and will not be repeated here.

Table 2.1.4: Outline of KENO data

Type of data	**Starting flag**	**Comments**	**Termination flag**
Parameters	READ PARAMETER	Enter desired parameter data	END PARAMETER
Geometry	READ GEOMETRY [1]	Enter desired geometry data Always required by CSAS	END GEOMETRY
Array data	READ ARRAY [1]	Enter desired array data	END ARRAY

continues on next page

Table 2.1.4 – continued from previous page

Type of data	Starting flag	Comments	Termination flag
Boundary conditions	READ BOUNDS	Enter desired boundary conditions	END BOUNDS
Volume data	READ VOLUME	Enter desired volume data (KENO-VI only)	END VOLUME
Energy group boundaries	READ ENERGY	Enter desired neutron energy group boundaries	END ENERGY
Start data or initial source	READ START	Enter desired start data	END START
Plot data	READ PLOT	Enter desired plot data	END PLOT
Grid geometry data	READ GRID	Enter desired mesh data	END GRID
Reaction	READ REACTION	Enter desire reaction tallies (CE mode only)	END REACTION
KENO data terminus	END DATA	Enter to signal the end of all KENO. data	
[1] Geometry input is different for both KENO V.a and KENO-VI See Sect. 8.1.3.4 for further details.			

Note: Unlike standalone KENO calculations, each KENO data block can be entered in any order when running KENO codes as part of CSAS sequence.

2.1.5 DESCRIPTION OF OUTPUT

This section contains a brief description and explanation of the CSAS sequence. As CSAS was designed as a SCALE control module/sequence its own output is minimal. To avoid duplicate output edits, it suppresses the output from KENO Data processor except a few diagnostic and warning messages while processing the KENO data blocks. Because the KENO Data processor and KENO codes produce the same output edits for some input data, capturing both output sections and keeping printing them may result in duplicate information in the output sections for those input data.

CSAS always captures the XSProc and KENO outputs and prints them in the code output. Because these output sections are described and their details are discussed in Sect. 8.1.5 and Sect. 7.1.1 and relevant XSProc sections, they will not be described in this section.

When CSAS is run with PARM=CHECK, only outputs from KENO Data processor and XSProc input processor are shown in the code output.

The sample output sections presented in this section were from one of the calculations performed by CSAS5. Here, only CSAS5 examples are given to prevent repetition because CSAS6 prints the same tables in the same format with the same content.

2.1.5.1 Program verification information

After the header page, program verification information is printed that lists the name of the program and the revision number. The job name, date, and time of execution are also printed as shown in Fig. 2.1.7. This information may be used for quality assurance purposes.

```
                                        program verification information
                                      code system: SCALE   version: 6.3.0

                     program:  csas6
                     version:  6.3.0
                    username:  5kq
                    hostname:  kbb-mac

           date of execution:  2021-10-11
           time of execution:  11:02:39
```

Fig. 2.1.7: Sample program verification table.

2.1.5.2 Mixture table

The first table printed by CSAS codes lists the compositions read and processed from the data entered in the **composition data** block. Basically, this table echos what user defined in the **composition data** block; data for each mixture are printed. First the mixture number, density, and temperature are printed, followed by a table of the nuclides which make up the mixture. This table contains the following data: mixture ID number, nuclide ZA number, atom density and temperature. A sample mixture table is shown in Fig. 2.1.8.

```
 Mixture table for component comps at line:5, column:1
Mixture = 1 with density(g/cc) = 18.7600 and temperature(K) = 300.00
        Entry      Mixture      Nuclide     Density (atoms/b-cm)     Temperature (K)
            1            1        92234             4.827163e-04              300.00
            2            1        92235             4.479718e-02              300.00
            3            1        92236             9.572338e-05              300.00
            4            1        92238             2.657677e-03              300.00
        Entry      Mixture      Nuclide     Density (atoms/b-cm)     Temperature (K)
 End of mixture table for component comps at line:5, column:1
```

Fig. 2.1.8: An example of a mixture table.

Note: This output table prints only all mixtures read and processed from the composition data block. Any mixture defined with `CELLMIX` in celldata block is not printed here.

Note: The mixing table printed in KENO output may not reflect the mixture properties listed in this output table. Any mixture which is defined in composition data block but not used in KENO transport process will not be printed in KENO mixing table data edits. KENO also prints the mixture data defined with `CELLMIX` or defined in **Double-het** cell treatment in KENO mixing table data edits in the output. See Sect. 8.1.3.10 for further details about the KENO mixing data.

2.1.5.3 Cross section processing summary

In multigroup mode, cross section processing calculation path with XSProc show some differences depending on the type of the unit cells being processed and/or desired calculation methodology defined by user as discussed in Sect. 2.1.4.1. CSAS sequences summarize which of the XSProc calculation path is used when processing the unit cells in XSProc in the output.

A typical cross section processing summary table printed by a CSAS sequence in the code output is shown in Fig. 2.1.9.

The first record printed in this table is the multigroup cross section library which will be used in the calculations. This is followed by the cross section processing summary of the unit cells for this problem. This table includes the total number of unit cells being processed, and the number of unit cells processed with CENTRM and BONAMI calculations path. The last record printed in this table is the total elapsed time to process the XSProc data and build all the unit cells for the subsequent XSProc calculations.

```
Loaded MG Library: /ornldev/code/Scale/S63/INSTALL/G_63_b1500/data/scale.rev05.xn252v7.1

-------------------------------------------------------------------------------------------------
 Cross section processing summary of the cells:
-------------------------------------------------------------------------------------------------

 Total 7 cells are being processed:
      1 *default cells* (non-fissionable) processed with BONAMI.
      6 cells specified in CELLDATA block processed with CENTRM (sequence default option).

 NOTE: *default cells* are the cells not specified in CELLDATA block (They are processed as
       infinite homogeneous cells).

-------------------------------------------------------------------------------------------------

SequenceInputBuilder prepared 7 unit cells in 0.25 seconds.
```

Fig. 2.1.9: Summary of cross section processing.

Caution: CSAS sequence always creates a unit cell for all the mixtures defined in the composition data block and stores them in a cell container. Then, XSProc cross section processing is applied to all the unit cells stored in the cell container regardless of whether they are used in KENO transport calculation. Performing cross section processing for the unused mixtures, especially fissile mixtures, might waste the allocated computational resources for this calculation.

2.1.6 WARNING AND ERROR MESSAGES

CSAS sequence contains two types of warning and error messages. The first type of messages are from XSProc and SCALE sequence implementation which are common to many of the SCALE sequences. The second type of messages are mainly from the KENO Data processor as part of CSAS sequence implementation, and identified by CS- followed by a number. The details of the messages from KENO Data processor can be seen in Sect. 8.1.6.

Warning messages appear when a possible error is encountered. It is the responsibility of the user to verify whether the data are correct when a warning message is encountered. The functional modules, XSProc and KENO, activated by CSAS sequences will be executed if no error messages are generated and a warning message has been generated.

When an error is recognized, an error message is written and an error flag is set so the functional modules will not be activated. the code stops immediately if the error is too severe to allow continuation of input. However, it will continue to read and check the data if it is able. When the data reading is completed, execution is terminated if an error flag was set when the data were being processed. If the error flag has not been set, execution continues. When error messages are present in the output, the user should focus on the first error message, because subsequent messages may have been caused by the error that generated the first message.

The messages listed below complement the messages, which are from KENO Data processor, listed in KENO manual section, Sect. 8.1.6.

> CS-21 A UNIT NUMBER WAS ENTERED FOR THE CROSS-SECTION LIBRARY. (LIB= IN PARAMETER DATA.) THE DEFAULT VALUE SHOULD BE USED IN ORDER TO UTILIZE THE CROSS SECTIONS GENERATED BY CSAS. MAKE CERTAIN THE CORRECT CROSS-SECTION LIBRARY IS BEING USED.

This message is from subroutine CPARAM. It indicates that a value has been entered for the cross-section library in the KENO V.a parameter data. The cross-section library created by the analytical sequence should be used. *MAKE CERTAIN THAT THE CORRECT CROSS SECTIONS ARE BEING USED.*

> CS-55 *** ERRORS WERE ENCOUNTERED IN PROCESSING THE KENO DATA. EXECUTION IS IMPOSSIBLE. ***

This message from subroutine SASSY is printed if errors were found in the KENO input data for CSAS. When the data reading and checking have been completed, the problem will terminate without executing. Check the printout to locate the errors responsible for this message.

> CS-62 *** ERROR *** MIXTURE _____ IN THE GEOMETRY WAS NOT CREATED IN THE STANDARD COMPOSITIONS SPECIFICATION DATA.

This message from subroutine MIXCHK indicates that a mixture specified in the KENO geometry was not created in the standard composition data.

> CS-68 *** ERROR *** AN INPUT DATA ERROR HAS BEEN ENCOUNTERED IN THE _____ DATA ENTERED FOR THIS PROBLEM.

This message from the main program, CSAS, is printed if the subroutine library routine LRDERR returns a value of "TRUE," indicating that a reading error has been encountered in the "KENO PARAMETER" data. The appropriate data type is printed in the message. Locate the unnumbered message stating "ERROR IN INPUT. CARD IMAGE PRINTED ON NEXT LINE". Correct the data and resubmit the problem.

> CS-69 ***ERROR*** MIXTURE _____ IS AN INAPPROPRIATE MIXTURE NUMBER FOR USE IN THE KENO GEOMETRY DATA BECAUSE IT IS A COMPONENT OF THE CELL-WEIGHTED MIXTURE CREATED BY XSDRNPM.

This message from subroutine CMXCHK indicates that a mixture that is a component of a cell-weighted mixture has been used in the KENO geometry data.

> CS-100 *** ERROR *** THIS PROBLEM WILL NOT BE RUN BECAUSE ERRORS WERE ENCOUNTERED IN THE INPUT DATA.

This self-explanatory message indicates that an error occurred in input processing. User should examine the printout to locate the error or errors in the input data. Correct them and resubmit the problem.

2.1.7 SAMPLE PROBLEMS

This section contains example problems to demonstrate some of capabilities available in CSAS with KENO codes. A brief problem description and the associated input data for multigroup mode of calculation are included for each problem. The same sample problems may be executed in the continuous energy mode by changing the library name from `v7.1-252` to `ce_v7.1`. The complete list of libraries distributed with SCALE is provided in the Nuclear Data Libraries chapter.

2.1.7.1 CSAS5 sample problems

This section contains sample problems to demonstrate some of the options available in CSAS5. Note that sample problem 8 does not run in continuous-energy mode because they use CELLMIX or DOUBLEHET cell type.

CSAS5 sample problem 1: k_{eff} calculation

The purpose of this problem is to calculate the k-effective of a system. This problem is the same as the KENO V.a sample problem 12 in Appendix B except the cross-section library and KENO V.a mixing table are prepared by CSAS. The problem represents a critical experiment consisting of a composite array [CSAS5Tho64, CSAS5Tho73] of four highly-enriched (93.2%) uranium metal cylinders having a density of 18.76 g/cc and four 5.0677-L Plexiglas containers filled with uranyl nitrate solution. The uranium metal cylinders have a radius of 5.748 cm and a height of 10.765 cm. The uranyl nitrate solution has a specific gravity of 1.555 and contains 415 g of uranium per liter. The ID of the Plexiglas bottle is 19.05 cm and the inside height is 17.78 cm. The Plexiglas is 0.635 cm thick. The center-to-center spacing between the metal units is 13.18 cm in the Y direction and 13.45 cm in the Z direction. The center-to-center spacing between the solution units is 21.75 cm in the Y direction and 20.48 cm in the Z direction. The spacing between the Y-Z plane that passes through the centers of the metal units and the Y-Z plane that passes through the centers of the solution units is 17.465 cm in the X direction.

The metal units in this experiment are designated in Table II of [CSAS5Tho64] as cylinder index 11 and reflector index 1. A photograph of the experiment, Fig. 9 in [CSAS5Tho73], is given in Fig. 2.1.10.

CSAS5 Sample problem 8: k_∞ for a pebble bed fuel

This problem demonstrates setting up a fuel pebble from a pebble bed reactor, and calculating its k_∞. The pebble consists of a fuel grain of UO_2 0.025 cm in radius, coated with 0.003 cm of pyrolytic carbon, a further coat of 0.0035 cm thick silicon carbide, with a final coat of 0.004 cm thick pyrolytic carbon. 15000 grains are packed with graphite into an internal fuel sphere of 2.5 cm radius clad with a 0.5 cm thick covering of carbon and surrounded by helium. The fuel is 8.2% enriched ^{235}U. The pebbles are stacked into an infinite square pitched array with a pitch of 6 cm.

This problem uses DOUBLEHET cell type, which is applicable only in the multigroup mode of KENO calculations. Therefore, the continuous energy version of this problem will end with an error message.

2.1.7.2 CSAS6 sample problems

This section contains sample problems to demonstrate some of the options available in CSAS6. A brief problem description and the associated input data for multigroup mode of calculation are included for each problem. The same sample problems may be executed in continuous-energy mode by changing the library name to an continuous-energy library. See Appendix A (Sect. 2.3) for additional examples.

CSAS6 Sample problem 1: Aluminum 30 Degree Pipe Angle Intersection

The purpose of this problem is to calculate the k-effective of a system composed of intersecting aluminum pipes, in the shape of a Y, filled with a 5% enriched UO_2F_2 solution. The UO_2F_2 solution at 299 K contains 907.0 gm/l of uranium, no excess acid, and has a specific gravity of 2.0289 gm/cm^3. The assembly is composed of a 212.1 cm long vertical pipe and a second pipe that intersects the vertical pipe 76.7 cm from the outside bottom at an angle of 29.26 degrees with the upper vertical pipe. Both pipes have 13.95 cm inner diameters and 14.11 cm outer diameters. The vertical pipe is open on the top and 1.3 cm thick on the bottom. The Y-leg pipe, in the YZ-plane, is 126.04 cm in length with the sealed end 0.64 cm thick. The assembly is filled with solution to a height 129.5 cm above the outside bottom of the vertical pipe. From the point where

the pipes intersect, the assembly is surrounded by water 37.0 cm in the ±X directions, 100 cm in the +Y direction, -37 cm in the -Y direction, to the top of the assembly in the +Z direction, and -99.6 cm in the -Z direction.

CSAS6 Sample problem 2: Plexiglas Cross

The purpose of this problem is to calculate the k-effective of a system composed of intersecting Plexiglas pipes, in the shape of a cross, filled with a 5% enriched UO_2F_2 solution. The room temperature UO_2F_2 solution contains 896.1 gm/l of uranium, no excess acid, and has a specific gravity of 2.015 gm/cm^3. The pipes have a 13.335 cm inner diameter and 16.19 cm outer diameter. The vertical pipe is open on the top and 3.17 cm thick on the bottom. The horizontal pipe ends are 3.17 thick. The vertical pipe is 210.19 cm in length and filled with solution to a height of 117.2 cm. The two horizontal legs, positioned in the XZ-plane, intersect the vertical pipe 91.44 cm from the outside bottom at an 89 degree angle with the upper section of the pipe. Each horizontal is 91.44 cm in length and filled with the above specified UO_2F_2 solution. A water reflector surrounding the solution filled pipes extends out from the point where the pipes intersect 111.76 cm in the ±X directions, 20.64 cm in the ±Y directions, 29.03 cm in the +Z direction, and -118.428 cm in the -Z direction.

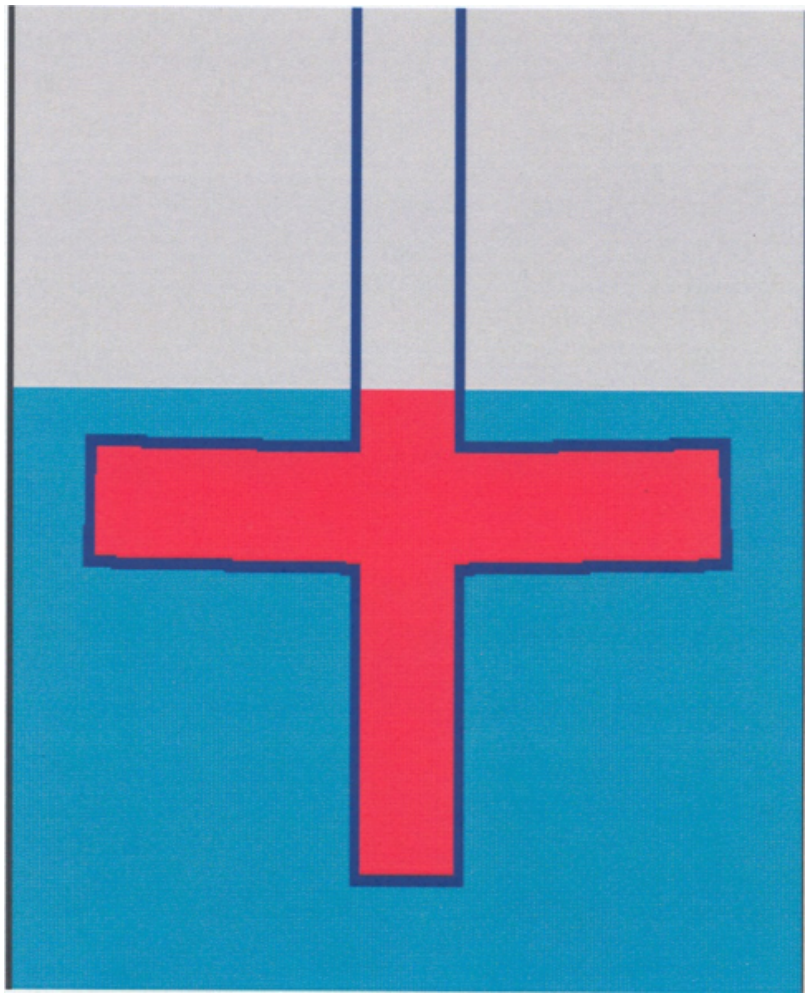

Fig. 2.1.12: Critical assembly of UO_2F_2 solution in a Plexiglas cross.

CSAS6 Sample problem 3: Sphere

This problem models an assembly consisting of a 93.2% enriched bare uranium sphere, 8.741 cm in radius, having a density of 18.76 gm/cm^3. Problem 3 models the assembly as a single bare sphere. The second problem models the assembly as a hemisphere with mirror reflection on the flat surface. The next three problems model the sphere using chords. This set of four problems is designed to illustrate the use of multiple chords in a problem.

CSAS6 Sample problem 7: Grotesque without the Diaphragm

The purpose of this problem is to calculate the k_{eff} of a system composed of eight enriched uranium units placed on a diaphragm, with an irregularly shaped centerpiece positioned in the center hole of the diaphragm [CSAS5Mih99]. The assembly and centerpiece are shown in Fig. 2.1.13, which is Fig. 4 from [CSAS5Mih99]. The eight units consist of an approximate parallelepiped with an irregular top, a parallelepiped, and six cylinders of various sizes. The centerpiece, which penetrates the hole in the diaphragm, consists of a cylinder topped by a parallelepiped topped by a hemisphere. The diaphragm is not modeled in this example.

CSAS6 Sample problem 8 Infinite Array of MOX and UO2 Assemblies

The purpose of this problem is to calculate the k_{eff} of a system composed of an infinite array of MOX assemblies interspersed between UO_2 assemblies. Both assembly types contain 331 pins in a hexagonal lattice with a pin pitch of 1.275 cm and an assembly pitch of 23.60 cm as shown in Fig. 2.1.14. The moderator is borated water at 306°C having a density of 0.71533 gm/cc and composed of 99.94 wt % H_2O and 0.06 wt % natural boron. Each fuel rod is 355 cm in length, has a radius of 0.3860 cm, 0.722-cm-thick Zr cladding with no gap, and is at a temperature of 754°C.

The UO_2 fuel consists of 4.4 wt % ^{235}U and 95.6 wt % ^{238}U at a density of 8.7922 gm/cc. The UO_2 fuel also contains 9.4581E-9 atoms/b-cm of ^{135}Xe and 7.3667E-8 atoms/b-cm of ^{149}Sm.

The MOX fuel consists of 96.38 wt % UO_2 and 3.62 wt % PuO_2 at a density of 8.8182 gm/cc. The UO_2 fuel is composed of 2.0 wt % ^{235}U and 98.0 wt % ^{238}U. The PuO_2 fuel is composed of 93.0 wt % ^{239}Pu, 6.0 wt % ^{240}Pu- and 1.0 wt % ^{241}Pu. The MOX fuel also contains 9.4581E-9 atoms/b-cm of ^{135}Xe and 7.3667E-8 atoms/b-cm of ^{149}Sm.

These two assemblies are placed so they represent an infinite array in the X and Y dimensions as shown in Fig. 2.1.15. There is 20 cm of water above and below fuel assemblies. This problem uses CENTRM/PMC as the resolved resonance processor cross section. Since an infinite array cannot be explicitly modeled, a section of the array is modeled and the X and Y sides have mirror reflection.

2.2 CSAS-SHIFT: CRITICALITY SAFETY ANALYSIS SEQUENCE WITH SHIFT

K. B. Bekar, *G. Davidson*, *B. Langley*, *B.J. Marshall*

The CSAS-Shift sequence integrates the Shift advanced Monte Carlo solver into the CSAS framework as an alternative to the KENO transport solvers to perform reliable and efficient eigenvalue calculations for criticality safety and reactor physics analysis. It supports both KENO V.a and KENO-VI geometries and provides most widely used KENO capabilities available in the CSAS5 and CSAS6 sequences for both multigroup and continuous-energy transport modes. The highly scalable Shift Monte Carlo solver enables faster solutions when running on multiple cores, and it shows better performance to achieve the same level of accuracy compared to the CSAS sequences with the KENO codes.

2.2.1 INTRODUCTION

The CSAS-Shift sequence was designed to provide the modeling and simulation capabilities required for criticality safety and reactor physics analysis through the Shift Monte Carlo solver.

Shift is a massively parallel Monte Carlo radiation transport package in the Exnihilo radiation transport code suite [CSAS-ShiftPJE+16], [CSAS-ShiftESSC10]. Shift was developed including features such as support for both fixed-source and eigenvalue Monte Carlo transport capabilities with multiple geometry and physics engines, hybrid capabilities for variance reduction methods, and advanced parallel decompositions to scale

well from laptops to small computing clusters to advanced supercomputers. Shift supports different geometry engines, including the Oak Ridge Adaptable Nested Geometry Engine (ORANGE) designed to provide particle transport capabilities on both KENO V.a and KENO-VI geometries as well as geometry visualization capabilities in the Fulcrum user interface. Shift with both versions of KENO geometries performs eigenvalue calculations in both continuous-energy and multigroup modes. Shift supports most widely used primary capabilities available with the KENO codes and provides some unique capabilities with ORANGE such as modeling randomly packed media and efficient parallel calculations for volume estimates.

CSAS-Shift provides all capabilities for both multigroup and continuous-energy transport modes. Like the CSAS5 and CSAS6 implementation, in the multigroup calculation mode, CSAS-Shift sequences automate the processing of the cross sections for temperature corrections and problem-dependent resonance self-shielding for utilization in multigroup neutron transport calculations using SCALE's cross section processing module, XSProc. If continuous-energy calculation mode is selected, no resonance processing is needed, and the continuous-energy cross sections are used directly in the Shift code, with temperature corrections provided as the cross sections are loaded.

CSAS-Shift with the highly scalable Shift solver enables some unique capabilities and faster solutions when running on multiple cores, and it shows better performance to achieve the same level of accuracy compared to the CSAS sequences with the KENO codes. CSAS-Shift input requirements, supported and unsupported capabilities, and input and output details are described in the following sections.

2.2.2 CSAS-SHIFT INPUT REQUIREMENTS

CSAS-Shift's design is aimed to make a smooth transition between KENO codes to the Shift transport code. Therefore, the original input data layout available in CSAS sequence with the KENO transport codes was kept the same for the CSAS sequence with Shift transport. CSAS-Shift uses the same CSAS5 and CSAS6 inputs, the only input modification that should be required is changing the sequence name by appending `-shift` to the sequence name, as shown in Example 2.2.1.

Like CSAS sequences with KENO codes, CSAS-Shift sequences are named with the KENO geometry that they support: CSAS5-Shift for the models with KENO V.a geometry, and CSAS6-Shift for the models with KENO-VI geometry.

Example 2.2.1: CSAS sequence inputs with KENO and Shift transport

```

end geometry

end data
end
```

Warning: CSAS-Shift sequence implementation may ask the user for some minor input updates for a successful calculation.

2.2.3 SEQUENCE CAPABILITIES

In the CSAS-Shift sequence framework, SCALE data handling is automated as much as possible. Similar to many other SCALE sequences, CSAS-Shift also applies a standardized procedure to provide appropriate number densities and cross sections for the calculation. XSProc is responsible for reading the standard composition data and other engineering-type specifications—including volume fraction or percent theoretical density, temperature, and isotopic distribution, as well as the unit cell data. XSProc then generates number densities and related information, prepares geometry data for resonance self-shielding and flux-weighting cell calculations, and (if needed) provides problem-dependent multigroup cross section processing.

Sequences that execute Shift transport include a data processor named ExnihiloInputBuilder to read and check the KENO data. This data processor processes the KENO data and creates a ParameterList input used by Shift to construct the problem and perform transport calculations. When the data checking has been completed, the CSAS-Shift sequence executes XSProc to prepare a resonance-corrected macroscopic cross section library in the AMPX working library format for the subsequent Shift transport calculation if a multigroup library has been selected.

Similar to CSAS sequences with KENO transport, the CSAS-Shift sequence supports both CELLMIX and Double-het capabilities. For each unit cell specified as being cell-weighted, XSProc performs the necessary calculations and produces a cell-weighted macroscopic cross-section library. Shift may be executed to calculate the k_{eff} or neutron multiplication factor using the cross section library that was prepared by the control sequence.

Computational capabilities available in CSAS sequences with KENO codes—including the determination of k-effective, flux densities, fission densities, mesh tallies, Shannon entropy tally, problem-dependent continuous-energy temperature treatments, parallel calculations, and many more—are also provided by the CSAS-Shift sequence.

CSAS-Shift also supports two new CSAS sequence data blocks, definitions and tallies data, to allow flexible definition and output control of mesh tallies. The mesh responses neutron flux, fission rate, and fission

source can now be requested multiple times on different spatial and energy grids in the same calculation. This capability helps users efficiently manage computational resources when collecting detailed information, depending on their requirements.

Criticality safety tools in SCALE attain some unique capabilities provided by Shift with the new geometry engine ORANGE, such as parallel volume estimates for KENO-VI geometric regions and modeling randomly packed media, which is enabled by implementing a random-packing algorithm to place spherical particles within simple bounding geometries. This capability allows constructing tristructural isotropic (TRISO) particle models for advanced reactor modeling and simulation activities. See Sect. 2.2.4.1.3 for further details.

Details for some of these capabilities, their input methods, and output edits are provided in the following sections.

2.2.3.1 Multigroup limitations

Some of the limitations of the CSAS-Shift multigroup sequences are a result of using preprocessed multigroup cross sections. Inherent limitations in multigroup CSAS-Shift calculations are as follows:

1. Spatial effects such as fuel rods in assemblies where some positions are filled with control rod guide tubes, burnable poison rods, and/or fuel rods of different enrichments. The cross sections are processed as if the rods are in an infinite lattice of identical rods. If the user inputs a Dancoff factor for the cell (such as one computed by MCDancoff), XSProc can produce an infinite lattice cell which reproduces that Dancoff. This can mitigate some spatial lattice effects.

2.2.3.2 Continuous-energy limitations

The continuous-energy cross sections are directly used in Shift. An existing multigroup input file can easily be converted to a continuous-energy input file by simply specifying the continuous-energy library. In this case, all cell data is ignored. However, the following limitations exist:

1. If CELLMIX is defined in the cell data, the problem will not run in continuous-energy mode. CELLMIX implies new mixture cross sections are generated using XSDRNPM-calculated cell fluxes; therefore it is not applicable in continuous-energy mode.
2. Problems with DOUBLEHET cell data are not allowed, as they inherently utilize the CELLMIX feature.

2.2.3.3 Unsupported Capabilities

Although Shift Monte Carlo code was designed with several advanced capabilities, it does not currently support some of the unique features available in KENO codes. Therefore, CSAS-Shift does not provide some of the capabilities available in CSAS5 and CSAS6 sequences.

The missing capabilities are mostly considered as the outdated features or those seldomly used by CSAS users in their analysis. The equivalent capabilities will be activated in the Shift transport code in the next SCALE release, depending on the need basis.

Table 2.2.1 summarizes the capabilities currently supported by CSAS with KENO codes but not supported by CSAS-Shift sequences.

Table 2.2.1: Unsupported CSAS capabilities

Capability	Input method(s) to activate the capability	Comments
Adjoint transport	parameter data `ADJ`	Adjoint transport capability is not available in Shift
Prompt-only *nu*	parameter `PNU`	Shift does not support using prompt neutron spectrum only in continuous-energy mode
Use unionized mixture cross section	parameter `UUM`	Shift does not support KENO-like mechanism to store cross sections on a material-based unionized energy grid for a faster cross section lookup in continuous-energy mode Although this method benefits for faster runtimes for some KENO models, storing all data may require prohibitively large amount of memory for problem with a large number of materials. Different approaches are being developed in Shift transport, and some experimental implementation is available in CSAS-Shift. See Table 2.2.4 for more details.
Matrix k_{eff}	parameters `MKP`, `CKP`, `FMP MKU`, `CKU`, `FMU MKH`, `CKH`, `FMH MKA`, `CKA`, `FMA HAL`, `HHL`, `FMA`	An alternative k-eff calculation method available in KENO codes are not supported by Shift.
Start data types 2, 3, 4, 5 and 9	`start data` block `NST`= 2, 3, 4, 5, and 9	Start data types 2 - 5 have not been implemented because GLOBAL ARRAY of KENO V.a geometry is not supported by ORANGE geometry engine used by Shift transport. Start type 9 designed to read starting distribution from a mesh source file is not currently supported by CSAS-Shift.
Biasing or weighting data	`bias data` block	KENO-like biasing capability is not currently supported by Shift transport.
Periodic and White Albedo boundary conditions	`bounds data` block	Shift transport does not currently support PERIODIC and WHITE boundary conditions for both KENO V.a and KENO-VI geometries.

continues on next page

Table 2.2.1 – continued from previous page

Capability	Input method(s) to activate the capability	Comments
Differential Albedos	`bounds data` block, `PAX` in `parameter data` block	Material specific albedos available with KENO multigroup transport is not supported by Shift multigroup transport
GLOBAL ARRAY instead of GLOBAL UNIT in KENO V.a geometry	`geometry data` block	Shift with ORANGE geometry engine does not currently support GLOBAL ARRAYs instead of the GLOBAL UNIT in KENO V.a geometry.
LOOP construct in array data	`array data` block	LOOP construct in array data input block is not supported by ORANGE geometry engine as part of Shift code.
Volume calculation (random sampling)	`type=RANDOM` in `volume data` block	Random volume estimates for KENO-VI geometry is not available in ORANGE geometry engine used by Shift transport
Accumulate mesh fluxes	parameter `MFX`	Shift does not support to tally mesh fluxes which are averaged over the region volumes in each mesh voxel.
Compute and print mean free paths	parameter `MFP`	This capability is not currently implemented in Shift.
Region-dependent fissions and absorptions	parameters `FAR` and `GAS`	Although these tallies are available in Shift transport they are not currently implemented in CSAS-Shift.
Mixture-dependent reaction tallies	`reaction data` block	Although these tallies are available in Shift transport they are not currently implemented in CSAS-Shift.
Time controlled termination	parameter `TME`	Shift does not have job termination capability controlled by the user-defined time limit.
Terminate execution on user signal	by creating a file named `stop_keno` in the working directory	CSAS-Shift does not support this capability
Restart capability	parameters `RES`, `BEG`, `APP`, `RST`, `WRS`	Restart capability is not available in Shift

continues on next page

Table 2.2.1 – continued from previous page

Capability	Input method(s) to activate the capability	Comments
Print particle tracks	parameter TRK	Although Shift has its own mechanisms to print information about each particle history, this capability is not fully integrated in CSAS-Shift sequence. It will be available in next releases.
Problem Characterization Output Edit	always ON	This capability is not currently implemented in CSAS-Shift.
Frequency Distributions	always ON	This capability is not currently implemented in CSAS-Shift
Plots of avg. k-eff and Shannon entropy	always ON	CSAS-Shift does not plot the average k-eff by generations run, the k-eff by generations skipped, and Shannon entropy per generation. Instead of the char-plots, CSAS-Shift creates Ptolemy plots and stores them in a dedicated plot directory. Fulcrum may be used to visualize these plots. See Sect. 2.2.6.1.12
Summary of Source Convergence Diagnostics	parameter SCD	CSAS-Shift does not perform the posterior entropy tests available in KENO. Instead, result of a single test performed by Shift is captured and printed in the relevant output section.
Print capabilities for mixed cross section	parameters AMX, XS1, XS2, PKI P1D, XAP, XSL	Currently, no capability is available to print the cross sections used by Shift transport.
Flux moments and angular flux calc.	parameters TFM, PMF, PMM	CSAS-Shift does not support any of these capabilities.
Print starting points	PSP parameter in start data	This capability is not currently implemented in CSAS-Shift
Plot capability	parameter PLT plot data block	Old-style plotting capabilities available in KENO codes are not supported. Fulcrum can be used for geometry visualization.
HTML output	parameter HTM	Old-style HTML-based output method is not supported.

2.2.4 INPUT DATA GUIDE

This section describes the input data required for the CSAS-Shift sequence. A typical CSAS6-Shift input, shown in Example 2.2.2, starts with the sequence identifier always preceded by the = sign, and it is followed by the problem title. Then, a cross section library name is specified, and all these entries are followed by several data blocks each starting with *READ data_block* and ending with *END data_block*.

Example 2.2.2: A typical CSAS-Shift sequence input

```
=CSAS6-Shift parm=(parm_options)
problem title

' ----- XSProc data
' cross section library name (REQUIRED)
ce_v7.1

' List of material specifications in standard SCALE format (REQUIRED)
read composition
   ...
end composition

' Specify data for resonance processing (OPTIONAL)
read celldata
   ...
end celldata

' ---- New CSAS sequence data blocks

' Used to define energy bounds and grid geometries for
' the tallies defined in tallies data block
' (REQUIRED if tallies data block exists)
read definitions
   ...
end definitions

' Used to define tallies in a more robust way (OPTIONAL)
read tallies
   ...
end tallies

' ---- KENO transport data
' Specify the problem geometry (REQUIRED)
read geometry
   ...
end geometry

' Other input data blocks (OPTIONAL)
```

Because CSAS-Shift uses the same input data used by CSAS5 and CSAS6, details of the input data blocks, compositions, celldata, definitions, and tallies will not be repeated here, and they can be seen in Sect. 2.1.4. Data blocks in the KENO transport data category will be discussed in the following section.

2.2.4.1 KENO input data in CSAS-Shift

Table 2.2.2 presents the lists of the KENO input data blocks supported by CSAS-Shift sequence. The input method in some data blocks may show some minor differences between the CSAS-KENO and CSAS-Shift sequences. Similarly, some capabilities provided by each input block also have some differences. All these details are discussed in this section. KENO input data blocks, that are `reaction data`, `bias data`, `mixt data`, and `plot data`, are not currently supported by the CSAS-Shift sequences.

Table 2.2.2: Summary of KENO input data blocks available in CSAS-Shift sequences.

Data block	**Status**	**Comments**
Parameters*	Supported	See Sect. 2.2.4.1.1 for more details.
Geometry	Supported	See Sect. 2.2.4.1.2 for more details.
Array data	Supported	
Boundary conditions	Supported	See Sect. 2.2.4.1.2 for more details.
Volume data	Supported	See Sect. 2.2.4.1.2 for more details.
Energy boundaries	Supported	
Start data	Supported	See Sect. 2.2.4.1.4 for more details.
Grid geometry data	Supported	
Plot data	Not available	The data in this block will be ignored in the calculations
Bias data	Not available	Execution will be terminated.
Reaction data	Not available	The data in this block will be ignored in the calculations
Mixt data	Not available	The data in this block will be ignored in the calculations
* Must precede all other data blocks in this table.		

Similar to CSAS5 and CSAS6, `geometry data` is the only KENO data block required to perform Shift transport calculation as part of the CSAS-Shift sequence. Other data blocks are optional, and the same default values listed in various locations in Sect. 8.1 are also applied to the data in each data block in CSAS-Shift. Note that parameter data must precede all other KENO data blocks if it is entered.

When CSAS-Shift is run with a user input including `bias data` block, the execution will be terminated with the error message given in Example 2.2.3. Note that CSAS-Shift ignores the data entered in the unsupported `plot data`, `mixt data`, and `reaction data` blocks and continues the calculation. User is notified with a warning message as shown in Example 2.2.4.

Example 2.2.3: Error message printed by CSAS-Shift output when `biasing data` is found in user input.

```
***Error: Failed to run ExnihiloModule with assertion:
-----------------------------------------------
 These input cards are unsupported by Shift.
-----------------------------------------------
 They must be removed from the input to run.
-----------------------------------------------
 line: 19   column: 1   biasing
-----------------------------------------------

 ^^^ at /ornldev/code/Scale/S63/Source/packages/Module/Exnihilo/InputProcessorBase.cpp:193
```

Example 2.2.4: A typical warning message printed by CSAS-Shift output when an unsupported data block is found in user input.

```
===========================================================================================
Input Warnings:
===========================================================================================

***Warning: Plot block found. This is not currently supported by Shift and will be ignored for now.
```

Note: CSAS5-Shift and CSAS6-Shift also support PARM=CHECK or PARM=CHK sequence parm options. This will allow checking the input data without performing cross section calculation as well as Shift transport calculations.

=CSAS6-SHIFT PARM=CHK

Parameter data

The KENO parameter data block in both CSAS5 and CSAS6 sequences provides many control parameters to activate the capabilities available in KENO transport for the problem being run. CSAS-Shift supports only a subset of these parameters, as listed in Table 2.2.3. Detailed description of these parameter can be seen in Sect. 8.1.3.3.

Parameters entered in the `parameter data` input block are processed by CSAS-Shift sequence implementation, and then the ParameterList input is updated to accordingly activate/deactivate the equivalent capabilities with Shift transport if the asking feature is currently supported by Shift. CSAS-Shift usually ignores the unsupported parameters by notifying the user with a warning message, and then it continues the calculation. For some specific parameters, code can terminate the execution and ask the user to remove this parameter from the input and rerun the code for a successful calculation.

Caution: CSAS-Shift notifies users of the unsupported parameters with a warning message before **Numeric and Logical Parameters** edit in the output, and then it ignores this parameter. It is the user's responsibility to examine which input parameter is ignored in the current calculation.

Note: CSAS-Shift defaults the value of a parameter, which is currently supported but not defined in the `parameter data` input block, to the KENO default. In other words, both CSAS and CSAS-Shift use the same defaults for the same parameters.

Table 2.2.3: Summary of KENO parameters currently supported by CSAS-Shift

PARAMETERS:		Format: READ PARAM *parameter_data* END PARAM See Sect. 8.1.3.3 for details.			
KEY	**DE-FAULT**	**DEFINITION**	**KEY**	**DE-FAULT**	**DEFINITION**
RND=	given	random number	THC=	10.0	thermal energy cutoff (eV)
SIG=	0.0	deviation limit	DBL=	0.4	DBRC lower energy cutoff (eV)
WTA=	0.5	average weight	DBH=	210	DBRC upper energy cutoff (eV)
WTL=	1/WTH	Russian Roulette weight	MSH=	0.0	mesh size of the cubic mesh
GEN=	203	number of generations	DBR=	0	use DBRC for scattering
NPG=	1000	number per generation	DBX=	2	Doppler Broadening method
NSK=	3	generations skipped	CET=	0	CE TSUNAMI calculation mode
NGP=	252	number of energy groups for tallying	CFP=	-1	number of latent generations for CE- SUNAMI
PTB=	YES	use probability tables	SCD=	YES	fission source convergence diag.
FLX=	NO	collect and print region fluxes	CDS=	NO	accumulate neutron production
FDN=	YES	fission densities	FIS=	NO	fission rate mesh tally
NUB=	YES	neutrons per fission	GFX=	NO	compute grid fluxes
FST=	NO	print F*(r) 3dmap	CGD=	NO	use mesh for CLUTCH F*(r) calc.
RUN=	YES	execute problem	TRK=	NO	NOT FULLY IMPLEMENTED

Table 2.2.4: Summary of parameters only available in CSAS-Shift

PARAMETERS:		
KEY	**DEFAULT | DEFINITION**	
PN_ORDER=	5	Legendre polynomial order
DOUBLE_INDEXING=	0.0	Accelerate xsec calculation using double
THINNING_TOLERANCE=	0.0001	Tolerance to use thinning the unionized x

In CSAS5 and CSAS6, users can control the number of scattering angles in multigroup calculations by entering the SCT parameter in the KENO `mixing data` block. The similar capability in CSAS-Shift was provided by adding a new parameter, PN_ORDER=, to the `parameter data` block because the `mixing data` block is not supported by CSAS-Shift sequences. Its default is set as 5.

Geometry data

CSAS-Shift with ORANGE geometry supports all KENO V.a and KENO-VI geometry capabilities except the following:

- Using `GLOBAL ARRAY` instead of `GLOBAL UNIT`. Further details for this capability are available in KENO V.a, see Sect. 8.1.3.4 and Sect. 8.1.4.6
- `LOOP` construct in `array data` block
- Material-specific albedo boundary conditions
- PERIODIC and WHITE albedo boundary conditions
- Random volume estimates for KENO-VI geometry (`TYPE=random` option in `volume data`)

CSAS-Shift can perform volume calculations with the stochastic ray-tracing method concurrently on the replicated domain on multiple cores.

Random geometry

Another new capability CSAS-Shift provides is the modeling of random packed media. The primary features that require input specification for this capability are the regular array and stochastic placement of spherical geometry without clipping along the region boundary, where the available region boundaries are spheres, cuboids, and cylinders.

To implement these new features, a new data block named `randomgeom` was added to SCALE. The `randomgeom` block is composed of `randommix` specifications, which are then composed of key/value pairs. The basic structure of the `randomgeom` block and then `randommix` specifications is as follows:

Example 2.2.5: New randomgeom data block in CSAS-Shift

```
read randomgeom

    RANDOMMIX = ID
       TYPE=random/cubic/fcc
       UNITS= U1 U2 ... UN end
       PFS= pf1 pf2 ... pfN end
       CLIP= yes/no
       SEED= int
    end RANDOMMIX

end randomgeom
```

with

- randommix keyword with ID number or name
- random/cubic/face-centered cubic array options
- list of existing unit number(s) in geometry
- fraction of volume occupied by units `U1 ... UN`
- boundary clipping on or off
- control random seed for random placement

Similar to the array block, this input block requires that the unit geometry specified as part of a randommix in the units list must exist in the geometry and must have a spherical outer boundary. The PF input, specified with the PFS keyword, must be the same length as the units list, and the sum of the PFS list must be less than 1.0. In practice, the actual limit to the total PF depends on the size and number of the units specified by the user, so the requirement for PFS to be less than 1.0 is just a simple check. The TYPE keyword specifies the placement methodology; TYPE=random will call the stochastic placement algorithm, whereas TYPE=cubic will place the unit geometry in a simple cubic structure (one sphere in a cuboid), and TYPE=fcc will place the unit geometry in a face-centered cubic (FCC) structure. For all type options, the CLIP keyword will control the clipping of geometry along the boundary. The SEED keyword is an integer used to determine the random seed used for placement of the stochastic geometry and for choosing which particle to place in the BCC and FCC lattice structure.

A "fill" material—the interstitial media surrounding the random spherical geometry units—is not present in the randomgeom block. The fill media is handled in the unit specification within the KENO geometry data block in the input file. As in a normal array in KENO geometry, the randommix specified in the randomgeom block is used to fill a region in a unit. However, unlike in the array specification, when using a randommix in a unit, the user must also specify a media filling that region. This feature allows the same randommix to be used in multiple different units with varying fill materials. The basic unit format along with a randommix on the media record itself is as follows:

```
read randomgeom
   randommix=ID
      ...
   end randommix
end randomgeom

read geometry
   ...

   unit U
      surfaces ...
      media ...
      media F biasID surfaces randommix=ID
      boundary S
   ...

end geometry
```

In the sample case shown in Example 2.2.6, a single pebble is filled with a single TRISO particle type. Fig. 2.2.1 shows how TRISO particles are placed in a single pebble with the randomgeom capability. The individual location of particles is written in the Shift Hierarchical Data Format (HDF5) output file, so these locations can be used for verification or other purposes as needed.

Example 2.2.6: One TRISO type in a pebble

```
=csas6-shift
...

read geometry
   unit 1
      com='kernel1'
      sphere 1 2.50e-02
      sphere 2 3.40e-02
      sphere 3 3.80e-02
      sphere 4 4.15e-02
      sphere 5 4.55e-02
```

(continues on next page)

(continued from previous page)

```
      media 100 1 1
      media 101 1 2 -1
      media 102 1 3 -2
      media 103 1 4 -3
      media 104 1 5 -4
      boundary 5
   global unit 10
      com='pebble'
      sphere 1 2.5
      sphere 2 3.0
      cuboid 3 6p5.0
      media 101 1 1 RANDOMMIX='trisos'
      media 106 1 2 -1
      media 0 1 3 -2
      boundary 3
end geometry
read randomgeom
   randommix = 'trisos'
      type= random
      units= 1 end
      pfs= 0.05 end
      clip= no
      seed= 0
    end randommix
end randomgeom

end data
end
```

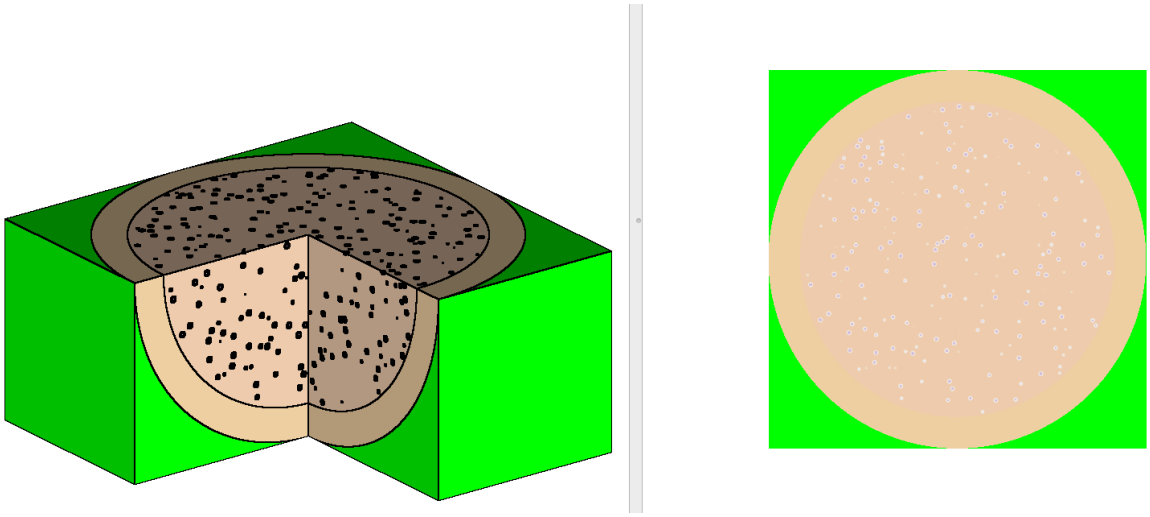

Fig. 2.2.1: Visualization of 3D and 2D cuts of the single TRISO model.

Start data

CSAS-Shift supports only START types 0, 1, 6, 7, and 8. CSAS-Shift start data implementation does not currently support the PSP option, which is used to print source positions sampled by the Shift transport.

Implementations for start types 0, 1, 7, and 8 in CSAS-Shift are are similar to those in CSAS5 and CSAS6. However, there are some minor differences in start type 6.

In KENO start type 6 implementation, the following rules are applied when selecting the starting points (see Sect. 8.1.4.8 and Sect. 8.1.3.3 for more details).

- Start NPG initial fission neutrons at first-NPG starting points defined by start type 6 data if NPG < LNU. Remaining starting points beyond NPG will be discarded.
- Start NPG initial fission neutrons at LNU starting points defined by start type 6 data if NPG = LNU.
- Start LNU initial fission neutrons at the starting points defined by start type 6 data, then randomly select the remaining fission source points (NPG-LNU) from these starting points if NPG > LNU.

where LNU, a start type 6 data parameter, is the total number of starting points specified in the start data block; and NPG, a parameter in the parameter data block, is the number of neutrons per generations.

Unlike KENO, the CSAS-Shift input processor does not follow the above rules when selecting positions for the initial fission neutrons. It calculates the probability of each point being selected and passes all starting points with this information to the Shift module. The Shift module always samples NPG initial fission source points using these data.

For example, the KENO code processes the following input and then samples the initial fission points.

```
=csas6 parm=bonami
Godiva test problem
test-8grp

read composition
   u-234       1 0 0.000491995 300   end
   u-235       1 0 0.0449996 300   end
   u-238       1 0 0.002498 300   end
end composition
read parameter
   htm=no gen=10 npg=15
end parameter

read geometry
   global unit 1
      sphere 1 8.67
      media 1 1 1
      boundary 1
end geometry

read start
   nst=6 ps6=yes psp=yes
   tfx=1.0 tfy=1.0 tfz=1.0 lnu=5
   tfx=2.0 tfy=2.0 tfz=2.0 lnu=20
end start
end data
end
```

The summary of the sampling process is printed in KENO output, as shown in Fig. 2.2.2. KENO first starts 5 neutrons at (1.0, 1.0, 1.0) and the remaining 10 neutrons at (2.0, 2.0, 2.0) since LNU=20 > NPG=15.

```
start type 6 was used.

neutrons started in non-fissile mixtures will use the fission spectrum for mixture     1

neutrons were started at the following positions.

         neutrons    1 to    5 were started at x=    1.00000E+00  y=    1.00000E+00  z=    1.00000E+00
        relative to the global coordinate system.

         neutrons    6 to   15 were started at x=    2.00000E+00  y=    2.00000E+00  z=    2.00000E+00
        relative to the global coordinate system.
```

Fig. 2.2.2: Start type 6 output printed by CSAS6.

However, CSAS-Shift creates a probability distribution from the defined start type 6 points and samples starting positions for NPG=15 particles using this distribution, as shown in Fig. 2.2.3.

```
===============================================================================================
 Starting Source Distribution
===============================================================================================

Starting source type 6 was used for the initial neutron distribution.

Neutrons started in non-fissile mixtures will use the Watt-fission spectrum in start type 6.

***Warning: PSP option is not currently supported in start type 6 on line:24 column:11

Neutrons were started at the following positions relative to the global coordinate system.

- Neutrons were started at ( 1.000000 , 1.000000 , 1.000000 ) with 25% probability.
- Neutrons were started at ( 2.000000 , 2.000000 , 2.000000 ) with 75% probability.
```

Fig. 2.2.3: Start type 6 output printed by CSAS-Shift.

2.2.5 NOTES TO CSAS-SHIFT USERS

In Monte Carlo calculation, the variance of the eigenvalue (k-eff) at each generation is calculated as a sample variance, which is the quantity obtained by assuming no correlation over the generations. However, there is a correlation among the fission sources over generations since the deviation of fission source at a generation from its equilibrium distribution is transferred to the following generations. To resolve this issue, KENO codes use an iterative method to estimate the real variance. [CritSafetyUMN97]

This methodology is not available in Shift transport (i.e., Shift does not estimate the real variances). However, the CSAS-Shift sequence uses this methodology as a post-processing stage to estimate the real variances. Therefore, Shift's reported uncertainty values (which are sample variance) in the message file are different from the CSAS-Shift sequence reported values (real variance) in the output file. It is highly recommended that k-eff uncertainties reported in the output file be used in the analyses where criticality is being assessed.

Caution: k-eff uncertainties printed in message and output files show differences. It is highly recommended that *k-eff uncertainties reported in the output file* be used in the analyses where criticality is being assessed.

2.2.6 CSAS-SHIFT OUTPUT

The CSAS-Shift sequence output is similar to the CSAS5 and CSAS6 outputs, except the output section dedicated to the transport module. See Sect. 2.1.5 for the layout of the output, mixture table edit, and cross section processing summary edits for a typical CSAS sequence.

This section contains a brief description of the output section dedicated to the Shift transport module. This section provides representative samples of the output format. The actual data contained in this section are not necessarily consistent with results computed by the current version of CSAS-Shift.

2.2.6.1 Shift output

The output layout of the Shift transport module is generally similar to the typical KENO output edits printed in the CSAS sequence output. However, some output edits are printed in a very different format, and these are discussed in this section.

Warning and error messages show stylistic differences compared to the traditional CSAS and KENO messages, and their details are not documented in this manual.

Program verification information

Program verification information Fig. 2.2.4 is printed after the header page. It lists the name of the program, the date the load module was created, the library that contains the load module, the computer code name from the configuration control table, and the revision number. The job name, date, and time of execution are also printed. This information may be used for quality assurance purposes.

Fig. 2.2.6: Sample input warnings table.

Tables of parameter data

The CSAS-Shift parameter edits list both numeric and logical parameters in the same table. In each table row, the name of the KENO parameter, its short description, the current value of the parameter, and its input method are printed. If the parameter value has been entered by user in the KENO parameter data block, the input method is printed as *(input *)*. Otherwise, the input method is printed as *(default)*. The user should always verify that the parameter data block was entered as desired. An example of the parameters table is shown in Fig. 2.2.7.

```

```

Fig. 2.2.7: Sample table of numeric and logical parameter data.

Energy boundaries data

The CSAS-Shift implementation supports multiple sets of energy boundaries specifications for some of the tallies. This can be done by using the definitions data block as described in the CSAS manual Sect. 2.1.4. However, it prints only the default energy group bounds in the energy boundaries data edit, as illustrated in Fig. 2.2.8. Energy group boundaries used for each mesh tally will be printed in the mesh tallies output edit.

Fig. 2.2.8: Sample energy boundaries edit.

Mixing table data edits

CSAS-Shift uses the same format and contents as those described for KENO codes in Sect. 8.1.3.10 for the mixing table data edits. In this table, the mixture number, density, and temperature are first printed, followed by a table of the nuclides which make up the mixture. This table contains the following data: nuclide ID number, nuclide mixture ID number, atom density, weight fraction of nuclide in mixture, ZA number, atomic weight, temperature, and nuclide title. Mixture temperature is the same as the nuclides' temperatures for the multigroup calculations, but it may show some differences in continuous-energy calculations. See Sect. 8.1.3.10 for details.

A sample mixing table data edit is shown in Fig. 2.2.9 for a multigroup calculation.

Geometry data edits

CSAS-Shift captures the output edit from ORANGE and prints these data as the overview of the geometry. Its format is completely different from the traditional KENO geometry output format but includes more descriptive sections for each geometry piece, as shown in Fig. 2.2.10.

Volume information

Volume tables for both KENO V.a and KENO-VI geometries are always printed by CSAS-Shift using the KENO-style volume editing format and cannot be suppressed. KENO V.a and KENO-VI volume tables show some differences, and all these details are described in KENO manual. See Sect. 8.1.5.17 for further details.

A sample volume output edit for KENO-VI geometry printed by CSAS-Shift is shown in Fig. 2.2.11.

 The maximum order of error associated with the calculated volumes is    1.1134 percent.
```

Fig. 2.2.11: Sample volume output edit.

Initial source edits

A summary table is always printed for start types 0, 1, 6, 7, and 8. The table format is the same for both KENO V.a and KENO-VI geometries. Fig. 2.2.12 illustrates typical starting data for start type 0. The parameter used in this example was `NST=0`.

```
=================================================================================================================================
 Starting Source Distribution
=================================================================================================================================

Starting source type 0 was used for the initial neutron distribution.

Neutrons were started with a flat distribution in a cuboid defined by:

         xmin = -70.590000 xmax = 70.590000 ymin = -70.590000 ymax = 70.590000 zmin = -68.610000 zmax = 68.610000
```

Fig. 2.2.12: Example of start data.

K-effectives by generation

At the completion of each generation, CSAS-Shift prints the k_{eff} for that generation and associated information obtained from the Shift transport module. An example of this printout is given in Fig. 2.2.13.

k-effectives by Generation

*** Execution terminated due to completion of the specified number of generations.

Fig. 2.2.13: Example of k-effectives and source entropy by generation.

The data printed include (1) the generation number, (2) the k-effective calculated for the generation, (3) the average value of k-effective through the current generation (excluding the `nskip`-1 generations), (4) the deviation associated with the average k-effective, and (5) Shannon entropy for the generation.

After the last generation, a message is printed to indicate why execution was terminated. If matrix k-effectives were calculated, then this is followed by a message stating the method used to determine the matrix k-effective. The user should examine this portion of the printed results to ensure that the two methods of calculating k-effective are in acceptable agreement and to verify that the average value of k-effective has become relatively stable. If the k-effectives appear to be oscillating or drifting significantly, then the user should consider rerunning the problem with a larger number of histories per generation.

Note: k-eff values from Shift calculation are always printed to the standard output (and `.msg` file). There is no user option to suppress this.

Warning: k-eff uncertainties printed in the message file always show differences compared to those printed in this output edit. Users should use the results printed in this output edit in their analysis. See Sect. 2.2.5 for more details.

Final k-effective edit

The final k-effective edit prints the average k-effective, its associated deviation, and the limits of k-effective for the 67, 95, and 99% confidence intervals. The number of histories used in calculating the average k-effective is also printed. This is done by skipping various numbers of generations. The user should carefully examine the final k-effective edit to determine whether the average k-effective is relatively stable. If a noticeable drift is apparent as the number of initial generations skipped increases, then it may indicate a problem in converging the source. If this appears to be the case, the problem should be rerun with a better initial source distribution and should be run for sufficient number of generations so that the average k-effective becomes stable. The final k-effective edit is printed as shown in Fig. 2.2.14.

Fig. 2.2.14: Example of the final k-effective edit.

Plot of average k-effective by generations run and by generations skipped

ASCII character plots of the average k-effective versus the number of generations run, and the average k-effective versus the number of generations skipped, are not printed by CSAS-Shift in the code output. Instead, two Ptolemy plot files are created and copied into the plots directory in `${OUTDIR}`. The name of the plot files and their final destinations are printed in the output, followed by the final k-effective edit as illustrated in Fig. 2.2.15. These plot files can be loaded and visualized by Fulcrum.

```
================================================================================================================================================
 Plot of average k-effective by generations run
================================================================================================================================================

 Plot file, k6smp18_keff_by_generations00000.ptp, copied to k6smp18.plots directory.

================================================================================================================================================
 Plot of average k-effective by generations skipped
================================================================================================================================================

 Plot file, k6smp18_keff_by_generations_skipped00000.ptp, copied to k6smp18.plots directory.

 ***** k-effective satisfies the chi**2 test for normality at the 95 % level
```

Fig. 2.2.15: Information about the average k-eff plot files.

Shannon Entropy Diagnostics

CSAS-Shift does not perform any posterior entropy tests like those available in KENO codes. Instead, it captures diagnostic test results performed by Shift and prints its details in the Shannon entropy diagnostics output edit, as shown in Fig. 2.2.16

```
================================================================================================================================================
 Shannon Entropy Diagnostics
================================================================================================================================================

Inactive cycles 5.84208 +- 0.0566254
Active cycles 5.71327 +- 0.00709912
First half of active cycles 5.69563 +- 0.00867071
Last half of active cycles 5.73091 +- 0.0107595

The difference between the first and and second half of the active cycles (delta / sigma = 2.55283) is just outside the 95% confidence interval

The first cycle to cross over one sigma of the final entropy was cycle 2, which was before the first active cycle 3.

================================================================================================================================================
 Plot of Shannon Entropy by generation
================================================================================================================================================

 Plot file, k6smp18_shannon_entropy00000.ptp, copied to k6smp18.plots directory.
```

Fig. 2.2.16: Sample Shannon Entropy Diagnostics edit.

Fission densities

The fission density edit is optional. CSAS-Shift prints the neutron production density and the fission density for each geometry region if parameters `FDN=YES` and `NUB=YES` are specified in the parameter data (these are the default values). If `NUB=NO` is specified but `FDN=YES`, then only the production density will be given. An example of the fission density edit is shown in Fig. 2.2.17

```
================================================================================================================================================
 Fission densities
================================================================================================================================================

```

Fig. 2.2.17: Example of the fission density edit.

Flux Edit

Printing the fluxes is optional; they are printed only if `FLX=YES` is specified in the parameter data. The fluxes are printed for each unit and each geometry region in the unit for every energy group. A sample of a flux edit is given in Fig. 2.2.18.

```

Final timing report table

The final timing report table summarizes the time elapsed for input processing, cell processing (for multigroup mode), cross section processing (for multigroup mode), the entire transport process (Shift transport), and post-processing performed by the CSAS-Shift sequence after obtaining all results from the Shift transport calculation. A sample timing report obtained for a multigroup calculation is shown in Fig. 2.2.20.

```

2.3 EXAMPLE APPLICATIONS OF CSAS6

Several example uses of CSAS6 are shown in this section for a variety of applications.

2.3.1 RUN KENO-VI USING CSAS6

CSAS6 creates a microscopic working format library and a mixing table that is passed to KENO-VI. The library is created using XSProc to process the cross section data in the resolved resonance regions of the isotopes contained in the library. CSAS6 then executes KENO-VI, which calculates k_{eff} for the problem. The following examples are for using the multigroup mode of calculation for KENO-VI. Using the continuous energy mode can be accomplished by simply changing the library name to one of the continuous energy libraries.

EXAMPLE 1. CSAS6 – Determine the k_{eff} of a system.

Consider a problem consisting of eight uranium metal cylinders that are 93.2% wt enriched, having a density of 18.76 g/cm^3. The cylinders are arranged in a $2 \times 2 \times 2$ array. Each has a radius of 5.748 cm and a height of 10.765 cm. The center-to-center spacing in the horizontal (X-Y) plane is 13.74 cm and the vertical center-to-center spacing is 13.01 cm. Because the cross section processing will be done assuming an infinite homogeneous medium and no cell mixtures are used, there is no unit cell data. The input data for this problem follow.

EXAMPLE 2. CSAS6 – Determine the k_{eff} of an array of fuel pellets in a UO_2F_2 solution.

Consider a 60 cm inside diameter cylindrical tank filled with 5.0%-enriched UO_2 fuel rods and 5.0%-enriched UO_2F_2 solution at 295 gm/liter. A $51 \times 51 \times 1$ array of fuel rods is centered on the bottom of the tank. The fuel rods are 366 cm long, 0.45 cm in radius, clad with 0.01-cm-thick Al, and at a pitch of 1.5 cm. The fuel rods sit on the bottom of the container and the container and solution rise 5.0 cm above the top of the rods. The container is 10 cm thick in the side and bottom and open at the top. Determine the k_{eff} of the system. Input data for this problem follow.

2.3.2 RUN KENO-VI CONTAINING CELL-WEIGHTED MIXTURES

CSAS6 creates a microscopic working format library and a mixing table that is passed to KENO-VI. The microscopic cross sections of the nuclides used in the unit cell geometry description are cell-weighted by specifying CELLMIX= followed by a unique mixture number. This mixture number utilizes the cell-weighted cross sections that represent the heterogeneous system. CSAS6 executes KENO-VI and calculates k_{eff} for the problem.

EXAMPLE 1. CSAS6 – Calculate the k_{eff} of an array of fuel assemblies using cell-weighted cross sections.

Consider the $4 \times 4 \times 1$ array of fuel assemblies in a square aluminum cask described in Sect. 2.3.1, Example 2. Calculate the k_{eff} of the system by using the cell-weighted mixture 200 to represent the fuel pins in the fuel assembly. Note that mixtures 1, 2, and 3, representing UO_2, zirconium, and water, respectively, are used in the unit cell description. Cell-weighting is applied to the microscopic cross sections that are used in the cell, making them incorrect for use elsewhere. Because water is used both inside the cell and between the fuel assemblies, an additional mixture, mixture 6, has been added to represent the water between the fuel assemblies. The input data for this problem follow.

2.3.3 RUN KENO-VI CONTAINING MULTIPLE UNIT CELLS

CSAS6 can create a microscopic working format library and a mixing table that contains more than one unit cell. Each unit cell is explicitly defined in the CELLDATA section of the standard composition data. Materials may appear in only one unit cell. All materials in the standard composition that are not contained in a unit cell are processed assuming infinite homogeneous media. CSAS6 passes the created working library to KENO-VI which calculates k_{eff} for the problem.

EXAMPLE 1. CSAS6 – Calculate the k_{eff} of a system using two unit cell descriptions.

Consider an infinite XY-array composed of two types of fuel assemblies in a checkerboard pattern moderated by water. Each assembly consists of a 17 × 17 × 1 array of zirconium-clad, enriched UO_2 fuel pins in a square pitched array. In one array the uranium is 3.5%-enriched and in the other array the uranium is 2.9%-enriched. The UO_2 has a density of 9.21 g/cm^3. The pin diameter is 0.8 cm and is 366 cm long. The clad is 0.07 cm thick, and the pitch is 1.3 cm. Each fuel bundle is contained in a 0.65-cm-thick Boral sheath. The bundles are separated by an edge-to-edge spacing of 1.0 cm. The water and zirconium is input in the standard composition data once for every unit cell in which it appears because a material may appear in only one unit cell. Determine the k_{eff} of the infinite array. Note that periodic boundary conditions are required to obtain an infinite checkerboard array. Input data for this problem follow.

EXAMPLE 2. CSAS6 – Calculate the k_{eff} of a system using two unit cell descriptions and cell-weighted mixtures.

Consider a problem in which a stainless steel cylinder with an inner diameter of 56 cm and an inside height of 91 cm is filled with pellets of UO_2 in borated water. The steel is 0.125 cm thick. The spherical 2.57%-enriched UO_2 pellets have a diameter of 1.07 cm and are arranged in a triangular pitch array with a pitch of 1.13 cm. The spherical 2.96%-enriched UO_2 pellets have a diameter of 1.07 cm and are arranged in a triangular pitch array with a pitch of 1.12 cm. The cylindrical tank is filled half full of the 2.96% pellets in borated water, and the remainder is filled with the 2.57%-enriched pellets in borated water.

Mixture 100 is the cell-weighted mixture containing the 2.57%-enriched uranium pellets and mixture 200 is the cell-weighted mixture containing the 2.96%-enriched uranium pellets. Determine the k_{eff} of this system. Input data for this problem follow.

2.4 DEVC: DENOVO EIGENVALUE CALCULATION

Douglas E. Peplow and Cihangir Celik

2.4.1 INTRODUCTION

The DEVC (Denovo EigenValue Calculation) sequence is an interface to the Denovo discrete-ordinates package [DEVCESSC10] for calculating criticality eigenvalue problems. This sequence reads an input file very similar to a CSAS6 input file [DEVCGPJD+11] that contains an extra block of input for describing the Denovo mesh grid and calculational parameters. Many of the subroutines are shared from the MAVRIC routines that interface with Denovo for fixed-source calculations.

This manual assumes that the user is familiar with the discrete-ordinates method for radiation transport and the Denovo package. DEVC provides an easy way for users to modify existing CSAS6 inputs and use them to run Denovo. The DEVC sequence also provides a way to create mesh geometry for Denovo from the combinatorial solid geometry description used by KENO-VI.

The steps in the DEVC sequence are listed in Table 2.4.1.

Table 2.4.1: Steps in DEVC for an input file named *input*.inp

Step	Module/Task	Creates file	To stop after
0	Check user input		
1	Self-shielding (celldata/cellm ix) calculations		
2	Produces optional *.png plots		
	Produces optional *.3mdap files (to visualize grid in MeshFileViewer)		`parm=check`
3	Creates AMPX cross sections for the "real" materials	`ft02f001`	`parm=cross`
4	Creates Denovo binary stream input file and the macromaterial table file	`xkba_b.inp` `input.mmt`	`parm=input`
5	Runs Denovo to compute k_{eff} and either the fluxes or the fission source	`input.dff` or `input.dso`	

The DEVC sequence uses KENO-VI geometry. Users can specify what output Denovo will generate: fluxes by space and energy in a binary *.dff (Denovo flux file) file or the space-only fission source distribution in a binary *.dso (Denovo spatial output) file. The eigenvalue is printed in the main output text file.

Some of the more common KENO starting source types are supported. Other starting source types may be added or extended to all of the different array types in the future. Currently, starting sources are not sent to Denovo because the Arnoldi solver does not use it. This may change in the future.

2.4.2 SEQUENCE INPUT

The input file for a DEVC calculation looks similar to a CSAS6 input file, as shown in Table 2.4.2. The major difference is that the parameter block contains information for the Denovo calculation, not the KENO Monte Carlo calculation. A macromaterial block is used to describe how the KENO-VI materials are mapped onto the Denovo mesh grid. Only multi-group cross-section libraries can be used with Denovo.

Table 2.4.2: Input file for a DEVC calculation (and differences with a CSAS6 input file, where black text is the same as CSAS6 and green text is new for DEVC sequence)

`=devc parm=…`
`Title for the problem`
`library`
	Parm: check, cross, input
	Multi-group cross-section library name

`read xxx` `end xxx`	Standard CSAS6 blocks used by DEVC: composition, celldata, geometry, array, plot and gridGeometry.
`read bounds` `end bounds`	Bounds are used if the boundary of the global unit is a cuboid.
`read start` `end start`	Most KENO start types are supported for some array types. Currently, Denovo does not make use of a starting source.
`read xxx` `end xxx`	Not used by DEVC: volume, x1ds, energy, biasing, importance, reactions, and search

`read parameters`
`gridGeometry 7`

2.4.2.1 Parameters block

This block contains the parameters for the Denovo eigenvalue calculation, the grid geometry, and the macromaterials. Boundary conditions listed in the parameters block will override those listed in the bounds block (using CSAS6 syntax). Table 2.4.3 lists the Denovo calculation parameters and their default values, and Table 2.4.4 lists the keywords for the setting the boundary conditions and file saving options. The grid geometry is defined in a sub-block in the parameters block, or the keyword `"gridGeometryID=\ *n*\ "` can be used to point to a grid geometry defined in its own input block.

Table 2.4.3: Denovo parameters in the parameters block

keyword	type	default	restrictions/comments
read parameters			
discretization=	integer	4	0-diamond difference, 1-DD with flux fix-up:lin0, 2-theta-weighted DD, 3-linear discontinuous finite element, 4-step characteristics, 5-trilinear discontinuous finite element

ymin=	integer	0	1 - reflective
ymax=	integer	0	2- periodic
zmin=	integer	0	3 - white
zmax=	integer	0	(these will override the "read bounds" block if specified here.)
fluxes			save space/energy fluxes (default)
fissionSource			save the space-only fission source
end parameters			

2.4.2.2 Grid geometry block

Grid geometries ("`gridGeometry` *id*") require an identification number and then a description of a three-dimensional rectangular mesh by specifying the bounding planes of the cells in each of the *x*, *y*, and *z* dimensions. The keyword "`xPlanes ... end`" can be used to list plane values (in any order). The keyword "`xLinear` *n a b*" can be used to specify *n* cells between *a* and *b*. The keywords "`xPlanes`" and "`xLinear`" can be used together and multiple times — they will simply add planes to any already defined for that dimension. Any duplicate planes will be removed. Similar keywords are used for the *y* and *z* dimensions.

When using multiple instances of the keywords *``Linear`` and *``Planes`` for a given dimension, duplicates should be removed from the final list. In some cases, double precision math will leave two planes that are nearly identical but not removed (e.g., 6.0 and 5.9999999). To prevent this, a default tolerance is set to remove planes that are within 10^{-6} cm of each other. The user is free to change this by using the keyword "`tolerance=`" and specifying something else. Note that the tolerance can be reset to a different value in between each use of *``Linear`` or *``Planes``.

The keyword "`make3dmap`" for a particular grid geometry definition will create a file called "*outputName*.grid*id*.3dmap", which can be visualized using the Java Mesh File Viewer. These files will contain crude geometry information (unit, region, material) that corresponds to the center of each voxel.

Keywords for the grid geometry block are listed in Table 2.4.5.

Table 2.4.5: Grid geometry input keywords

keyword	type	restrictions/comments
read parameters		
gridGeometry *id*		covers a cuboid where all points are in defined regions
title=	character	contained in double quotes (title="yada yada yada")
x planes … end	real array	a list of *x* plane values (order not important)
x Linear *n min max*	int real real	adds *n*+1 *x* planes (*n* cells) evenly from min to max
y planes … end	real array	a list of *y* plane values (order not important)
y Linear *n min max*	int real real	adds *n*+1 *y* planes (*n* cells) evenly from min to max
z planes … end	real array	a list of *z* plane values (order not important)
z Linear *n min max*	int real real	adds *n*+1 *z* planes (*n* cells) evenly from min to max
tolerance=	real	for removing duplicate planes from *planes or *Linear
make3dmap		makes a *.3dmap file showing the grid geometry
xdivide=	integer	once all xplanes are entered, further divide them by this
ydivide=	integer	once all yplanes are entered, further divide them by this
zdivide=	integer	once all zplanes are entered, further divide them by this
end gridGeometry		
gridGeometryID=	integer	Either define a grid geoemtry in a sub block or refer to a grid geometry defined in its own block
end parameters		

2.4.2.3 Macromaterial block

In order to get more accurate solutions from a coarse-mesh discrete-ordinates calculation, Denovo can represent the material in each voxel of the mesh as a volume-weighted mixture of the real materials in the problem. When constructing the Denovo input, DEVC can estimate the volume fraction taken by each real material in each voxel by a sampling method. The user can specify parameters for how to sample the geometry. Note that finer sampling makes more accurate estimates of the material fraction but requires more setup time to create the Denovo input. Users should understand how the macromaterials are sampled and consider that when constructing a mesh grid. This is especially important for geometries that contain arrays. Careful consideration should be given when overlaying a mesh on a geometry that contains arrays of arrays.

Because the list of macromaterials could become large, the user can also specify a tolerance for how close two different macromaterials can be to be considered the same, thereby reducing the total number of macromaterials. The macromaterial tolerance, "`mmTolerance=`", is used for creating a different macromaterial from the ones already created by looking at the infinity norm between two macromaterials.

The number of macromaterials does not appreciably impact Denovo run time or memory requirements.

Keywords for the macromaterial block are listed Table 2.4.6. Two different sampling methods are available — ray tracing [DEVCIPE+09] with the keyword `mmRayTest` and point testing [DEVCJoh13] with the keyword `mmPointTest`.

Table 2.4.6: Macromaterial block input

keyword	type	length	default	restrictions/comments
read macromaterial				
mmSubCell=	integer		1	rays per dimension to throw at each voxel
mmTolerance=	real		0.01	smallest volume fraction for macromaterial
mmSubCells	integer	6		rays per dimension to throw (x:ny,nz; y:nx,nz; z: nx,ny)
mmPointTest				use recursive bisection point testing method
mmRayTest				use ray tracing method
mmRTSpeed				optimize ray-tracing method for speed
mmRTMemory				optimize ray-tracing method for memory conservation
end macromaterial				

Ray tracing

This method estimates the volume of different materials in the Denovo mesh grid elements by throwing rays through the KENO-VI geometry and computing the average track lengths through the each material. Rays are traced in all three dimensions to better estimate the volume fractions of materials within each voxel. The `mmSubCell` parameter controls how many rays to trace in each voxel in each dimension. For example, if `mmSubCell`= n, then when tracing rays in the z dimension, each column of voxels uses a set of $n \times n$ rays starting uniformly spaced in the x and y dimensions. With rays being cast from all three orthogonal directions, then a total of $3n^2$ rays are used to sample each voxel. One can think of subcells as an equally spaced sub-mesh with a single ray positioned at each center. The number of subcells in each direction, and hence the number of rays, can be explicitly given with `mmSubCells ny nz nx nz nx ny end` keyword for rays parallel to the x axis, y axis, and z axis. Fig. 2.4.1 shows different subcell configurations (in two dimensions) for a given voxel.

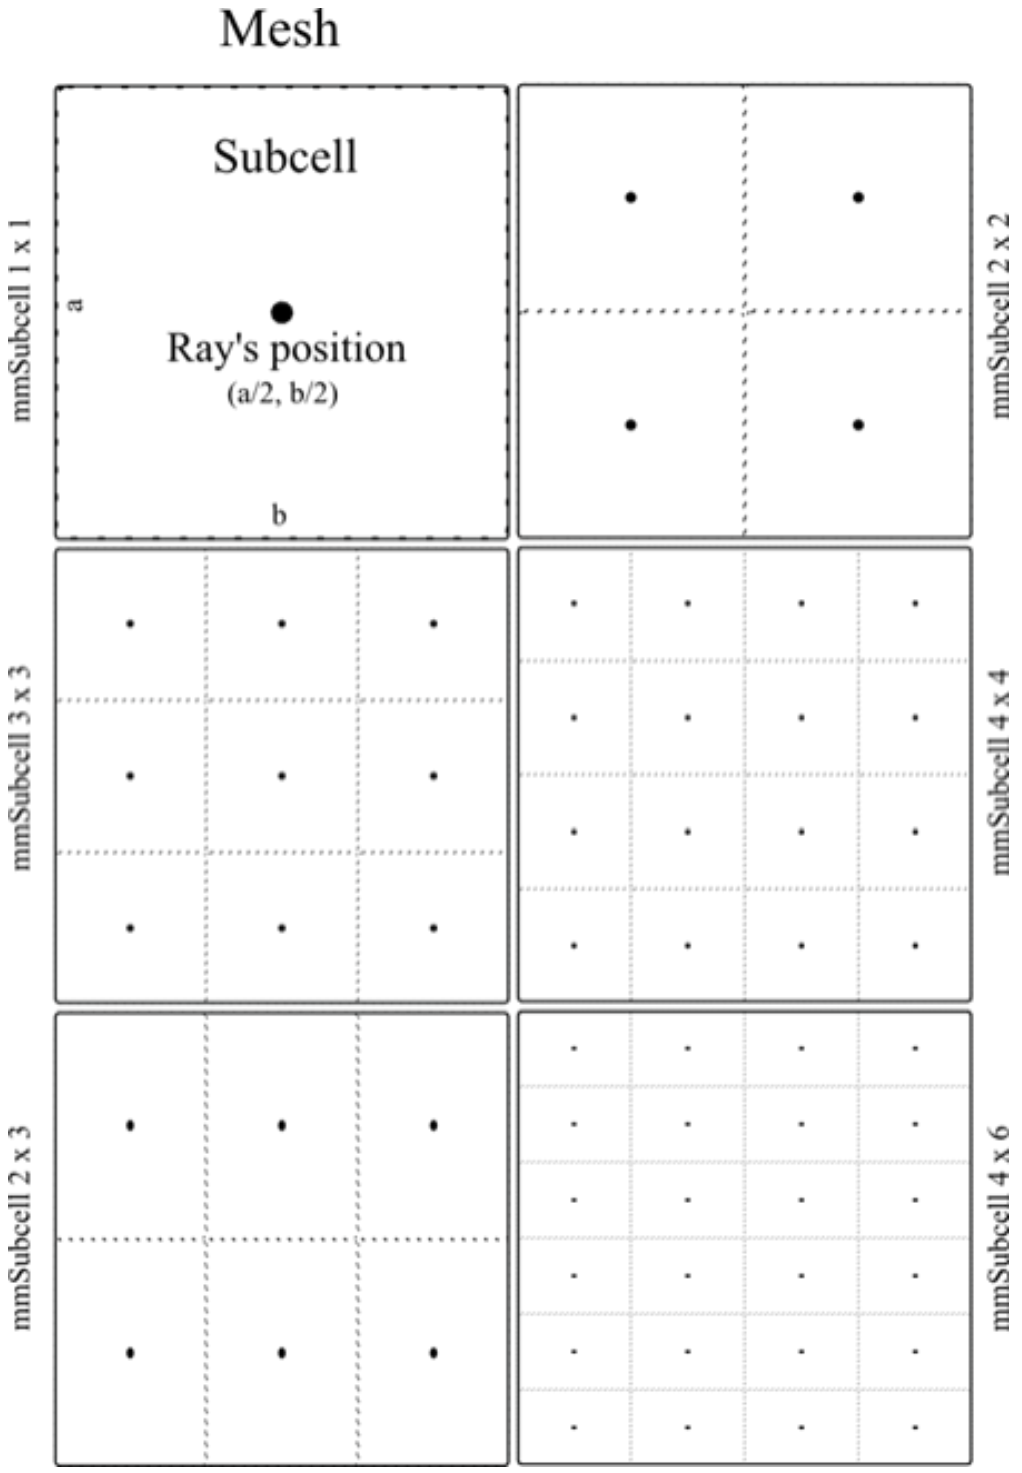

Fig. 2.4.1: Ray positions within a voxel with different mmSubCells parameters.

Ray tracing is a more robust method compared to the simple point testing method used in previous versions of SCALE/MAVRIC; however, it requires more memory than point testing. Ray tracing gives more accurate estimates of volume fractions because track lengths across a voxel give more information than a series of test points. Ray tracing is also much faster than point testing because the particle tracking routines are optimized

for quickly determining lists of materials and distance along a given ray.

Ray tracing operates on the grid geometry supplied by the user and shoots rays in all three directions starting from the lower bounds of the mesh grid. An example of arbitrary assembly geometry is shown in Fig. 2.4.2. A ray consists of a number of steps that corresponds to crossing a different material along the path of the ray. Ratios of each step's length to the voxel length in the ray's direction determine the material volume fraction of that step in that voxel, and summation of the same material volume fractions gives the material volume fraction of that material in that voxel. Ray tracing through a single voxel that contains a fuel pin is illustrated in Fig. 2.4.3.

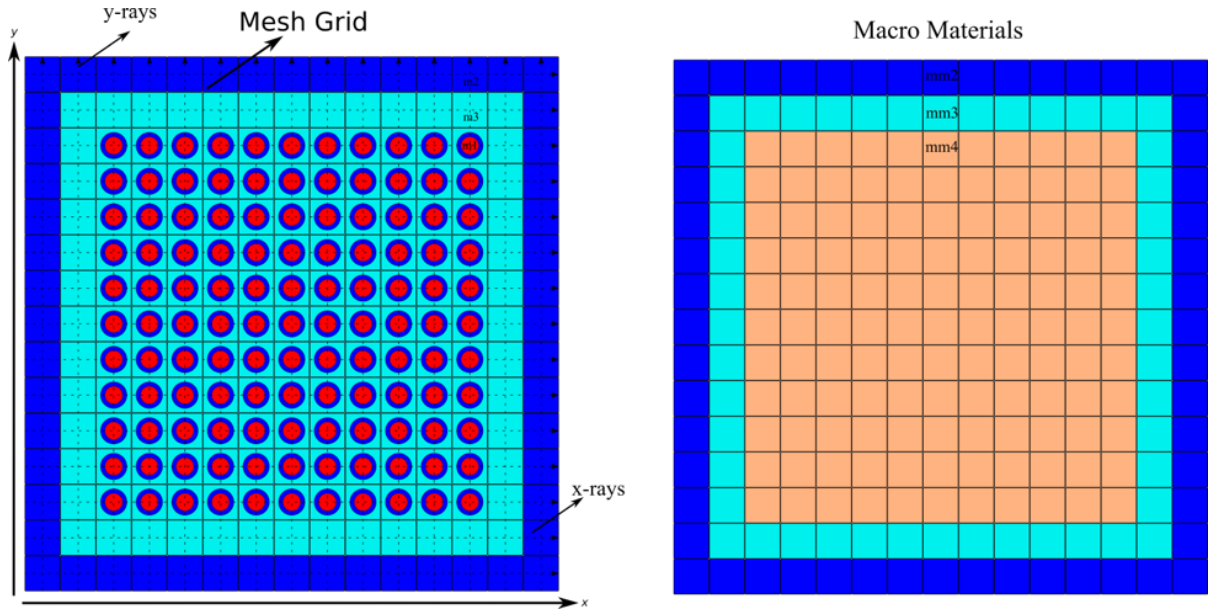

Fig. 2.4.2: Geometry model (left) and the Denovo representation (right) of an assembly using macromaterials determined by ray tracing.

The final constructed macromaterials for this model are also shown in Fig. 2.4.2. Voxels that contain only a single material are assigned that original material number in the constructed macromaterials. For the voxels that contain a fuel pin with three different materials, the result is a new macromaterial consisting of the volume weighted fractions of each original material.

After the rays are shot in all three directions, the material volume fractions are updated and macromaterials are created by using these material volume fractions. Material volume fraction calculations for a single voxel, as shown in Fig. 2.4.3, are given by

$$F_m = \sum_{d=x,y,z} \sum_{r=1}^{N_r} \sum_{s=1}^{N_s} \begin{cases} \frac{L_{d,r,s}}{L_d}, & m_s == m \\ 0, & \text{otherwise} \end{cases} \quad \text{and} \quad V_m = \frac{F_m}{\sum_{n=1}^{N_m} F_n}, \tag{2.4.1}$$

where F_{m} = sampled fraction of material m in the voxel,

d = direction of the rays (x, y, z),

r = ray number,

N_{r} = total number of rays in the voxel for direction of d,

s = step number,

N_s = total number of steps for ray r in the voxel for direction of d,

$L_{d,r,s}$ = length of the steps s for ray r in the voxel for direction of d,

$L_{d,}$ = length of the voxel along direction of d,

m_s = material of step s,

m = material number,

N_m = total number of materials in the voxel, and

V_m = volume fraction of material m in the voxel.

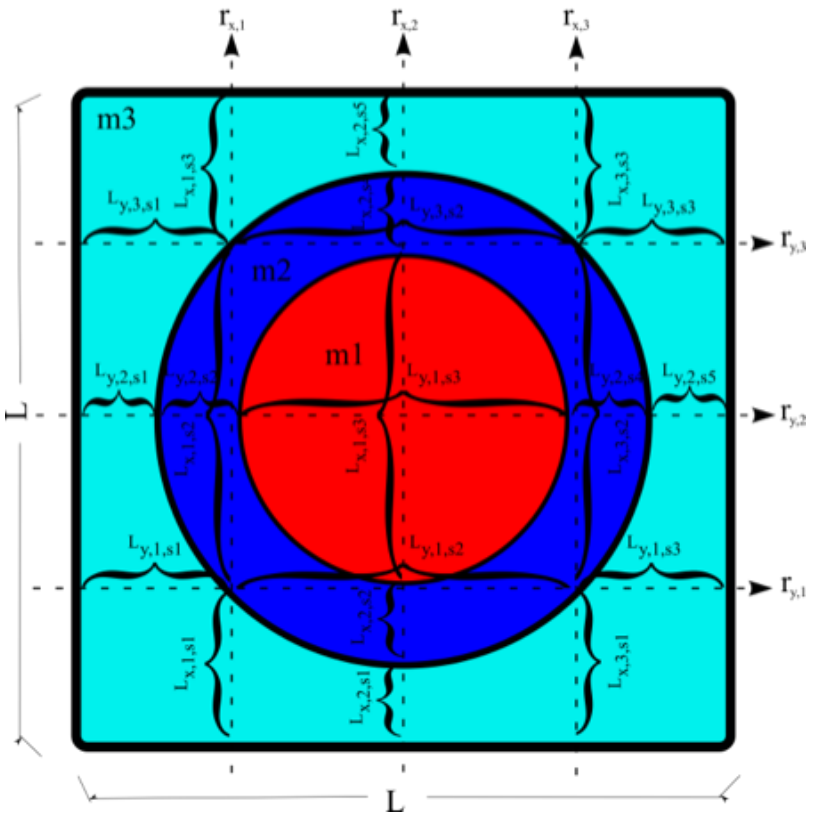

Fig. 2.4.3: Ray tracing (in two dimensions) through a voxel.

Point testing

The recursive bisection method uses a series of point tests to determine the macromaterial fractions. For a given voxel, the material at the center is compared to the material at the eight corners. If they are all the same, the entire volume is considered to be made of that material. If different, the volume is divided into two in each dimension. Each subvolume is tested, and the method is then applied to the subvolumes that are not of a single material. When the ratio of the volume of the tested region to the original voxel becomes less than a user-specified tolerance (in the range of 10^{-1} to 10^{-4}), then further subdivision and testing are stopped. This is illustrated in Fig. 2.4.4.

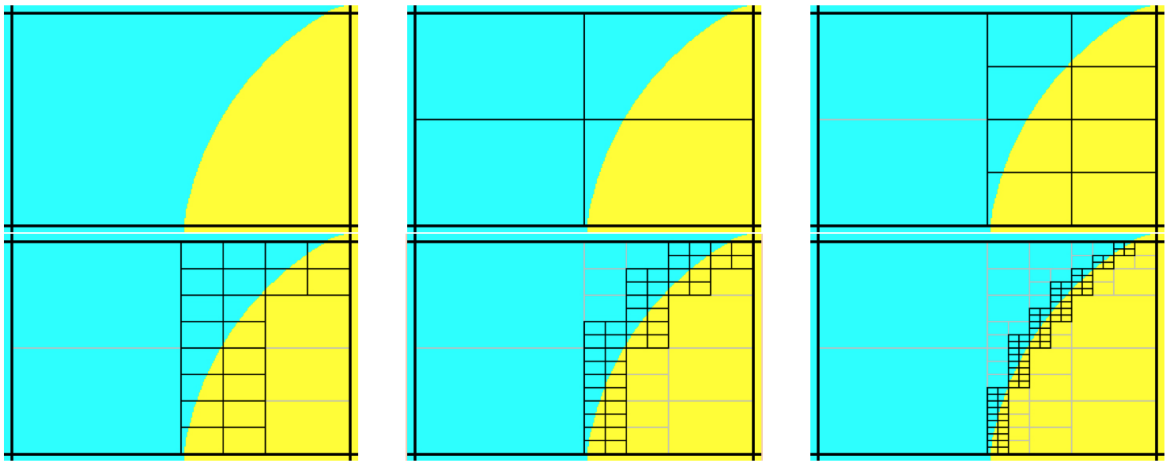

Fig. 2.4.4: Progression of the recursive bisection method (from upper left to lower right).

In point testing, the keyword "`mmTolerance=`*f*" is interpreted to be where *f* is the smallest fraction of the voxel volume to consider. This same tolerance *f* is also used to limit the number of macromaterials. Before a new macromaterial is created, if one already exists where the fraction of each actual material matches to within the given tolerance, then the existing material will be used. If using only a single point at the center of each voxel, use "`mmTolerance=1`". The `mmSubCell` keyword is not used in point testing.

Example

Fig. 2.4.5 shows an example of a cask geometry with two types of spent fuel (yellows), steel (blue), resin (green), and other metals (gray). When the Denovo geometry is set up by testing only the center of each mesh cell, the curved surfaces are not well represented (upper right). By applying the ray-tracing method and defining a new material made of partial fractions of the original materials, an improved Denovo model can be made. In the lower left of the figure, the Denovo model was constructed using one ray (in each dimension) per voxel and a tolerance of 0.1. This gives 20 new materials that are a mixture of the original 13 actual materials and void. With `mmSubCells=3` and an `mmTolerance=0.01`, 139 macromaterials are created.

A macromaterial table listing the fractions of each macromaterial is saved to a file called "*outputName*.mmt", where *outputName* is the name the user chose for his or her output file. This file can be used by the Mesh File Viewer to display the macromaterials as mixtures of the actual materials, as seen in lower row of Fig. 2.4.5. See the Mesh File Viewer help pages for more information on how to use colormap files and macromaterial tables.

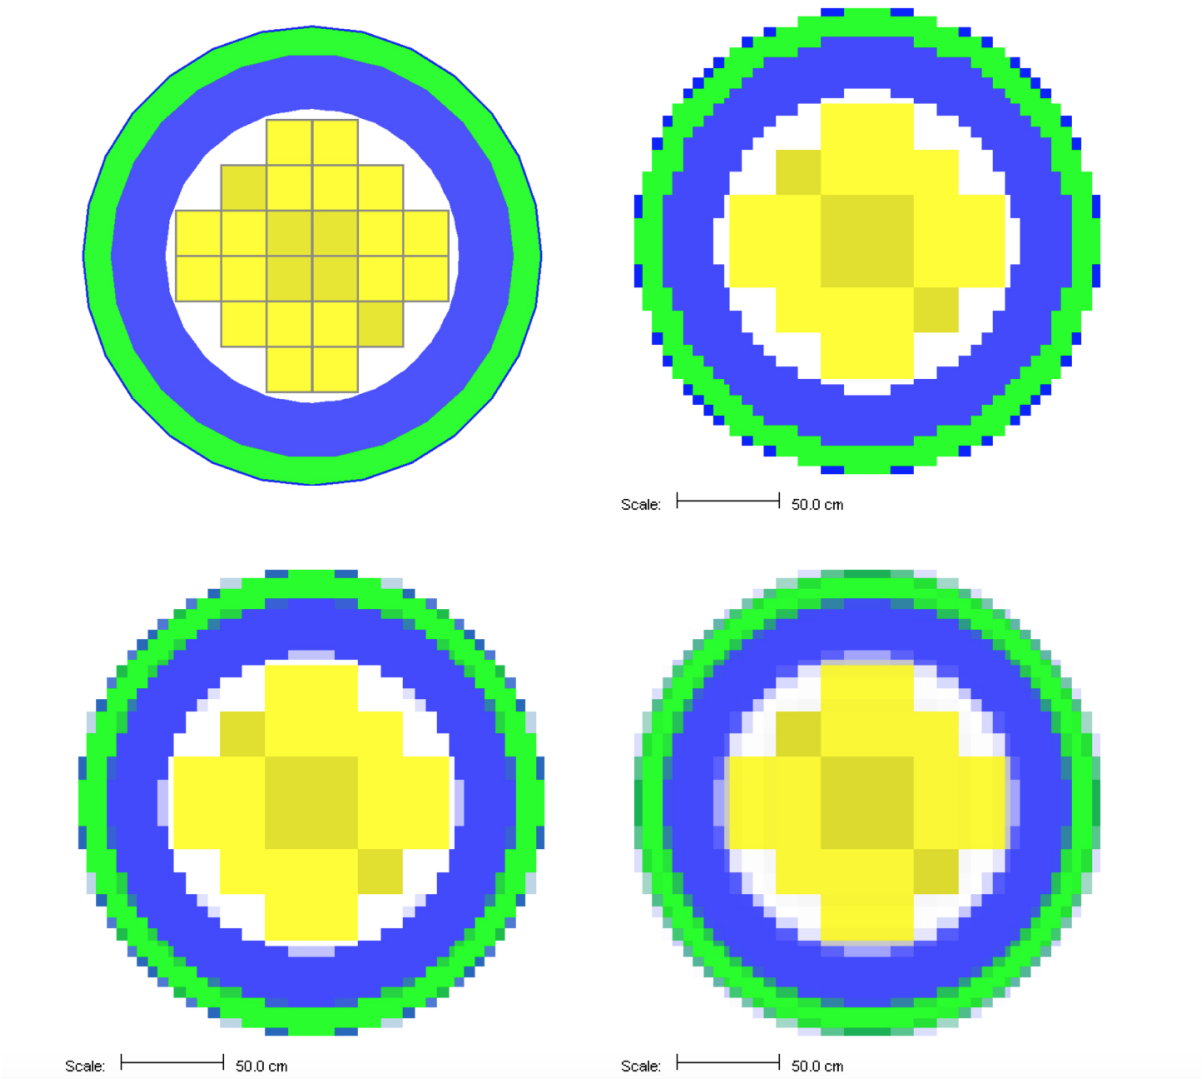

Fig. 2.4.5: Cask geometry model (upper left) and the Denovo representation using (upper right) cell center testing. Representations using macromaterials determined by ray tracing are shown for (lower left) mmSubCell=1/mmTolerance=0.1 and (lower right) mmSubCell=3/mmTolerance=0.01.

2.4.2.4 Starting sources block

The default KENO-VI starting source is "flat over the volume specified by the unrotated, untranslated geometry record specified in the first position of the global unit boundary record in fissile material only". For DEVC, the default starting source strength is uniform in the fissile voxels contained within the bounding box of the global unit (uniform density). If macromaterials are used, the amounts in each voxel are volume averaged between fissile and non-fissile materials. Table 2.4.7 and Table 2.4.8 describe the starting sources available in the DEVC interface to Denovo.

Table 2.4.7: Starting source types (within the fissile areas of the listed shape)

	KENO-VI start type	DEVC
nst=0	the first surface of boundary (default)	The bounding box of global unit
nst=0	Within boundary of global array having a reflector key set to false	Not supported
nst=0	A cuboid defined by XSM, XSP, YSM, YSP, ZSM, and ZSP	Supported
nst=1	A cuboid defined by XSM, XSP, YSM, YSP, ZSM, and ZSP with cosine distributions	Supported
nst=2	Arbitrary fraction (FCT) in element NXS, NYS, NZS of the global array with the remainder in a cuboid defined by XSM, XSP, YSM, YSP, ZSM, and ZSP with cosine distributions	Supported for some array types (see Table 2.4.8)
nst=3	At the location TFX, TFY, TFZ in the element NXS, NYS, NZS of the global array	Supported for some array types (see Table 2.4.8)
nst=4	At the location TFX, TFY, TFZ in units NBX of the global array	Supported
nst=5	Across units NBX in the global array	Not supported
nst=6	List of points TFX, TFY, TFZ in global coordinates	Limited to 1 point
nst=6	List of points TFX, TFY, TFZ in element NXS, NYS, NZS of the global array	Limited to 1 point and only for some array types (see Table 2.4.8)
nst=7	Flat distributions in X and Y with [1-$\cos^2$(z)] in Z for a cuboid defined by XSM, XSP, YSM, YSP, ZSM, and ZSP	Supported
nst=8	Flat distributions in X and Y with a segmented distribution in Z for a cuboid defined by XSM, XSP, YSM, YSP, ZSM, and ZSP	Not supported
nst=9	Use a mesh source lite file	Not supported

Table 2.4.8: Supported array types for starting sources

no arrays	supported
cuboid	supported
hexagonal	supported
shexagonal	no
rhexagonal	no
dodecahedral	no

The starting source initialized in Denovo is always a volumetric source—DEVC does not create point sources (which would activate the first collision option in Denovo).

2.4.3 SEQUENCE OUTPUT

The main text output file consists of the output from the cross-section processing codes and Denovo. The user should examine the output and pay attention to any warnings or errors. Table 2.4.9 lists the files generated during the DEVC sequence.

Table 2.4.9: Files created by DEVC for an input file named *input*.inp

Filename		**Viewer**	**Description**
Output Summary			
	input.out		main text output file, contains k_{eff}
	input.msg		messages file
Denovo			
	xkba_b.inp	V[a]	input file for Denovo - if this file is renamed to have a *.dsi extension (Denovo simple input), it is viewable in the Mesh File Viewer
	ft02f001		AMPX formatted cross sections for Denovo
	input.mmt	V	macromaterial table, use with *.dso or *.dsi file
	input.dff	V	Denovo fission fluxes
	input.dso	V	Denovo fission source distribution
[a]V - can be displayed with the Mesh File Viewer.			

2.4.3.1 Using the mesh file viewer

The Mesh File Viewer is a Java utility shipped with SCALE that is used for viewing mesh tallies from Monaco, as well as importance maps and mesh-based sources in MAVRIC. The Mesh File Viewer can be used with DEVC to view the Denovo input file (*.dsi, showing the starting source), the Denovo output fission source distribution (*.dso) file, or the Denovo output flux (*.dff) file.

With any Denovo file, material information for each voxel can be displayed. Users can use the graphical user interface to select colors for each material in the DEVC input and save them to a colormap text file (*.cmp) for later use. For example, Fig. 2.4.6 shows a cask model that has 13 materials with the default colors assigned by the viewer. A better color map (uranium is yellow, steel is blue, etc.) and an image using that color map are also shown in Fig. 2.4.6.

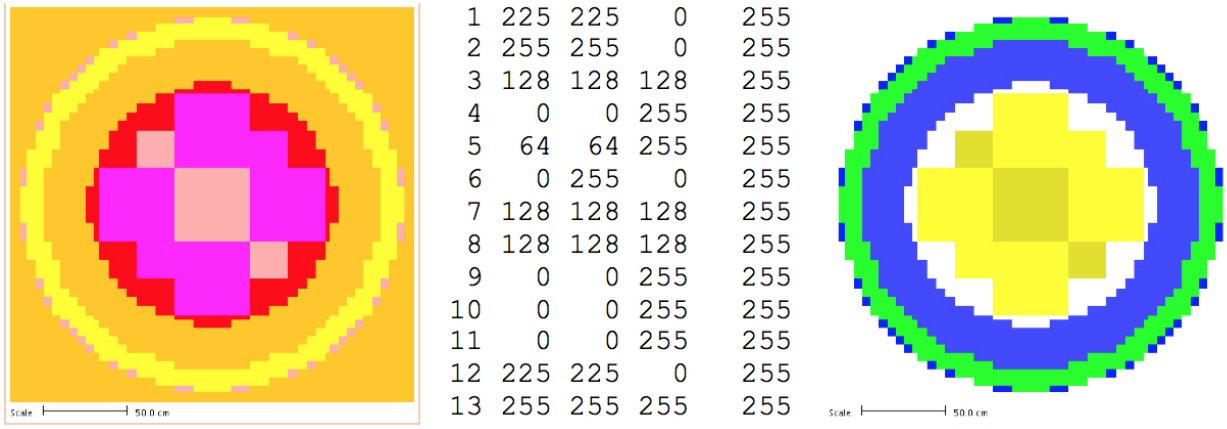

Fig. 2.4.6: Viewing material information with the Mesh File Viewer.

If the Denovo input was made using the mixed macromaterials, that can also be shown with the Mesh File Viewer. When one of the mesh files is loaded and the geometry is displayed (e.g., the materials for a cask model shown in Fig. 2.4.7), there will be many values since each macromaterial is treated by the Java viewer as a separate material. Redefining the color map using the GUI is not realistic.

A colormap needs to be defined for the original materials of the problem. For this example, there are 13 original materials, but when using macromaterials, 73 macromaterials are used in the discrete-ordinates model (as listed in the *.mmt file). The colormap file should only contain values for the 13 original materials. When loading the colormap, a corresponding *.mmt file can also be loaded. This will display mixed colors for the macromaterials, as shown in Fig. 2.4.7.

The final result is an image where the colors for the different values of the geometry attribute (which in the above example is material) are mixed in the ratio of the macromaterial definition.

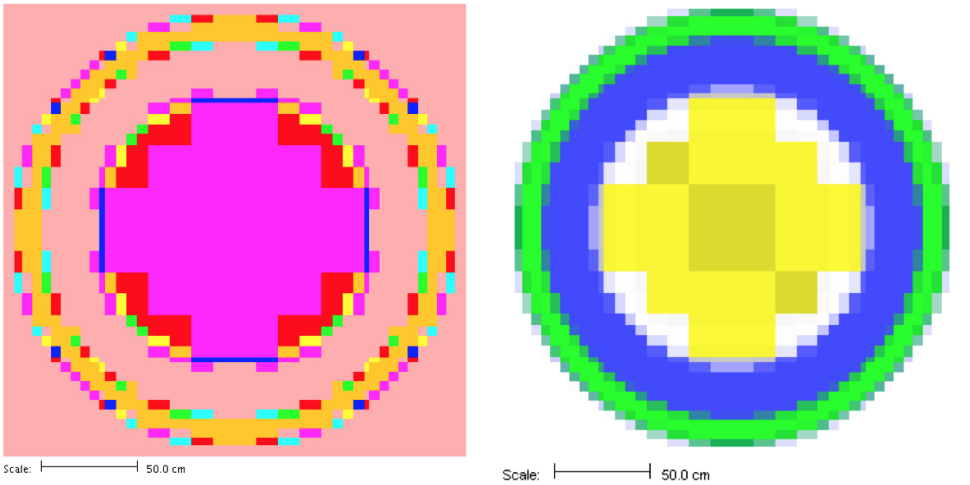

Fig. 2.4.7: Viewing material information from a Denovo input file.

2.4.3.2 Viewing the starting source

The Java MeshFileViewer (scale/cmds/meshview) can be used to visualize the Denovo binary stream input file to show materials and starting source strengths. An example is shown in Fig. 2.4.8.

Material Numbering

The cross sections produced by the SCALE cross-section mixing module ICE typically have a number of materials equal to the maximum material ID specified by the user in the "read composition" block. For a user input that contains materials 1, 3, and 5, the GIP-formatted cross-section file will contain five entries. For each lattice cell calculation that uses a cellmix= parameter, one more entry is contained in the GIP file. Hence, the GIP file does not contain the user's value from the "cellmix=" parameter but instead numbers the cellmix materials sequentially starting from 1+maximum(material ID). The Denovo geometry input and macroMixTable file produced by DEVC are modified to match the GIP cross-section file. When viewing the Denovo binary input file with the Mesh File Viewer, the GIP numbering for materials will be seen.

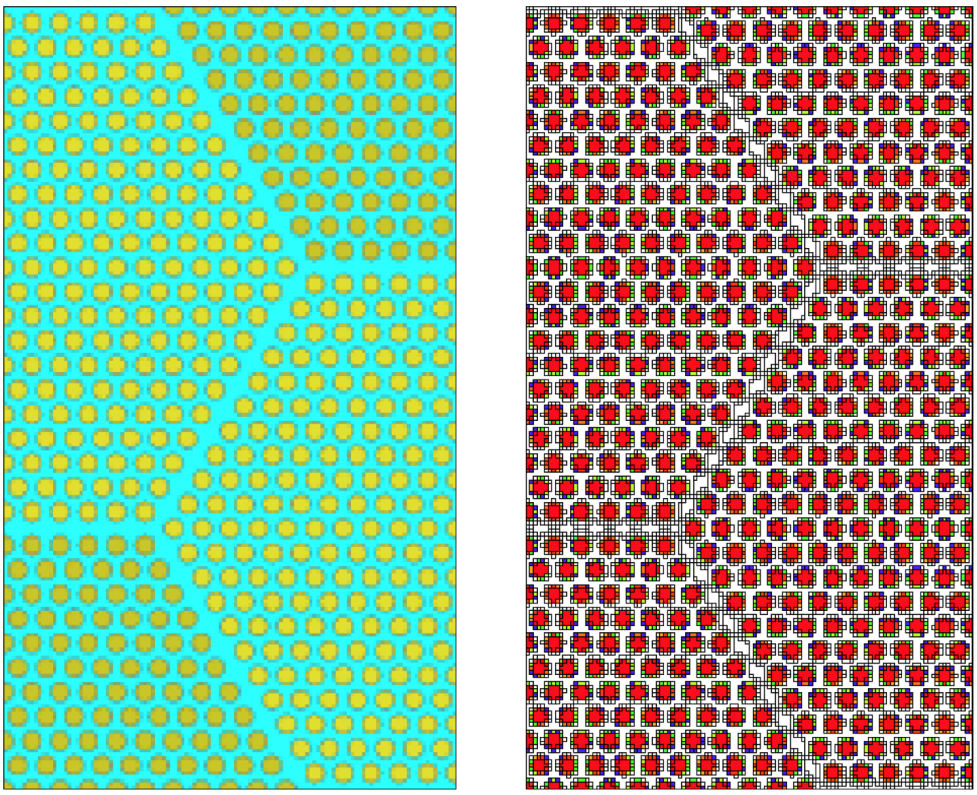

Fig. 2.4.8: Fine-mesh version of sample problem 8, showing the materials using macromaterial blending of UO_2, MOX, clad, and water (left) and the starting source strength limited to cells with fissionable material (right).

2.4.4 SAMPLE PROBLEMS

Sample problems have been made that correspond to the eight CSAS6 sample problems. In each problem, the KENO parameters block was commented out, a parameters block containing Denovo calculation parameters was added, and a grid geometry block was added. These sample problems use a coarse discretization and loose tolerances to obtain a short runtime. Users will typically use much finer discretization (mesh, quadrature) and higher fidelity parameter settings for real eigenvalue calculations. The voxelized geometry and starting source distribution are shown below in Fig. 2.4.9.

Results for the sample problems are displayed in Table 2.4.10. The sample problems used QR 1/1, a P_0 scattering expansion, a k tolerance of 0.001 and coarse meshes for speed. The higher fidelity runs used finer spatial meshes, default parameters of QR 2/2, P_0 scattering expansion, and the default *k* tolerance (10:sup:-*5*). Results for the longer-time CSAS6 and higher fidelity Denovo calculations are shown in Fig. 2.4.10.

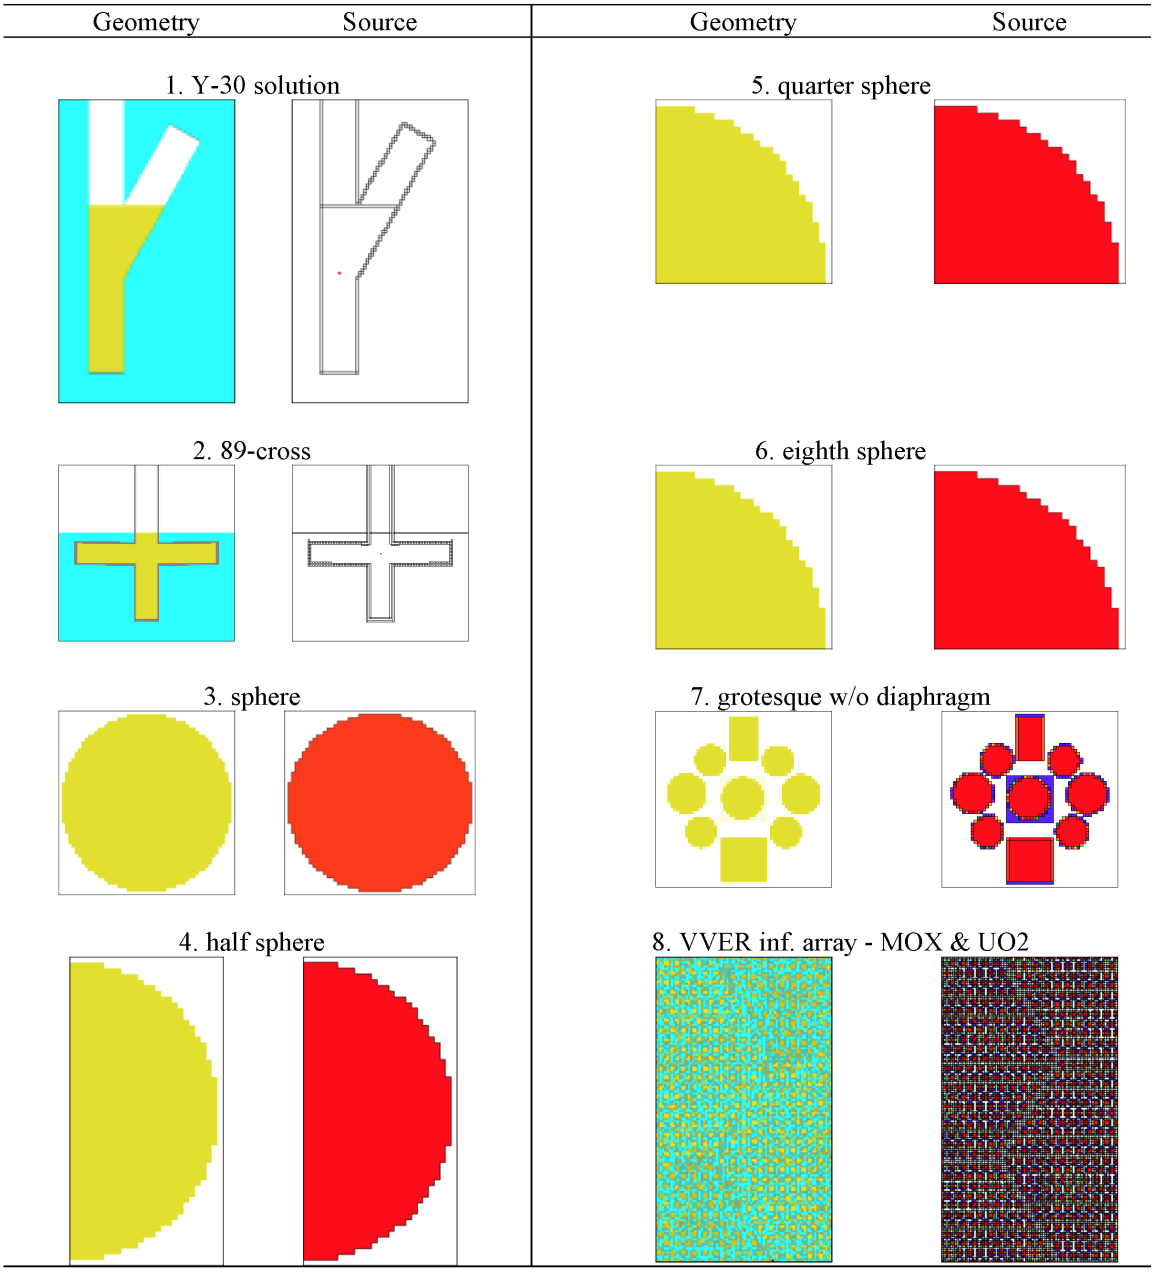

Fig. 2.4.9: Denovo geometry (left) and starting source distribution (right) for the sample problems.

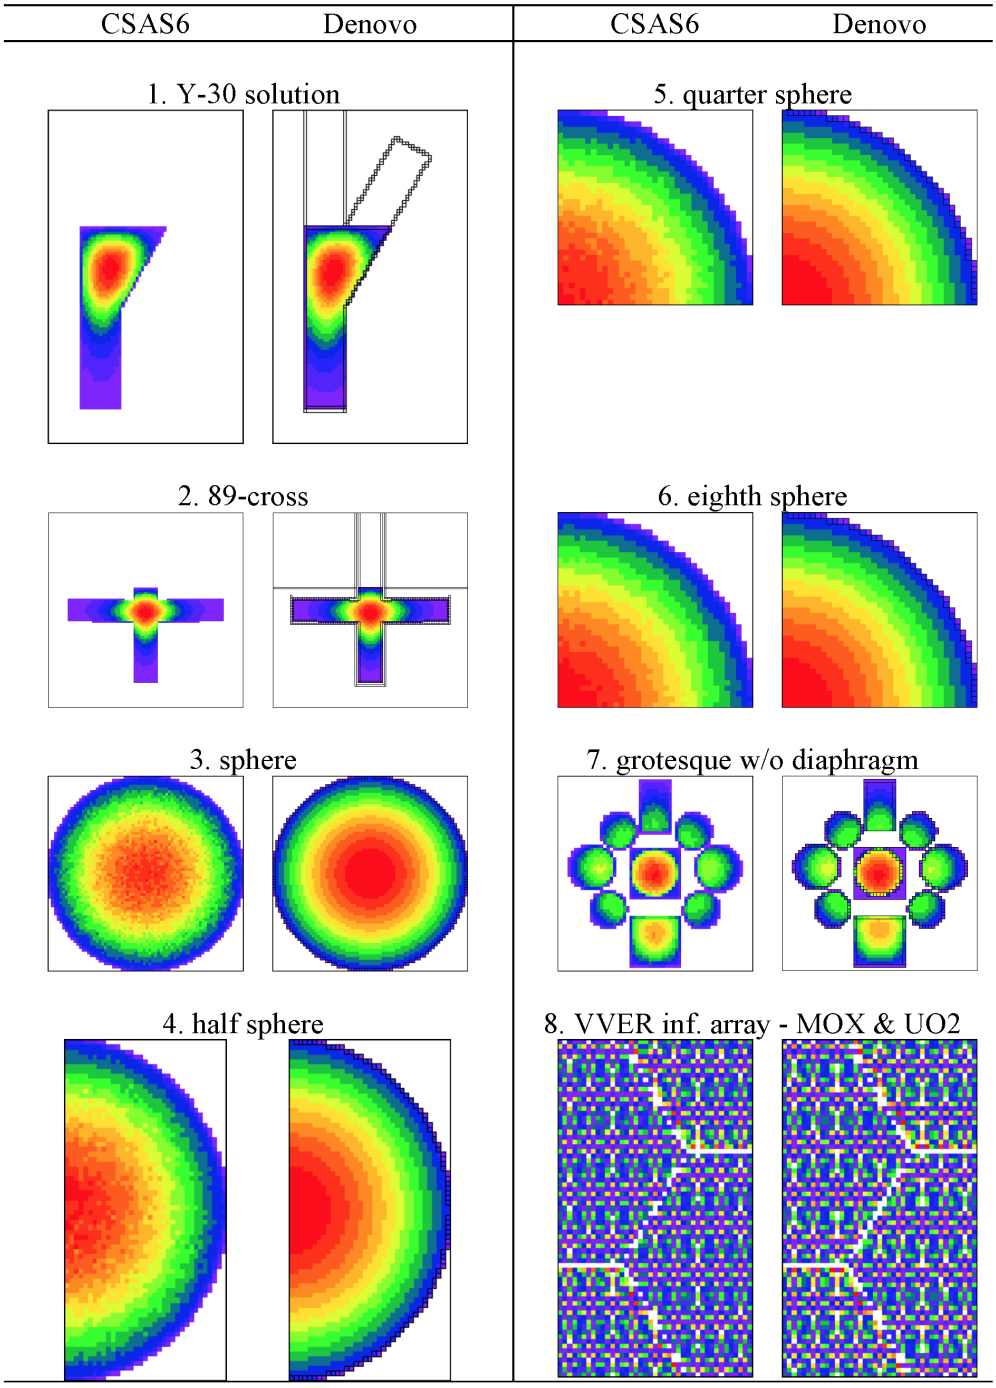

Fig. 2.4.10: Fission source distributions computed by CSAS6 (left) and Denovo (right).

Table 2.4.10: Sample problem results

	CSAS6						Denovo using DEVC

2.5 KMART5 AND KMART6: POSTPROCESSORS FOR KENO V.A AND KENO-VI

K. B. Bekar and *L. M. Petrie* [1]

KMART5 and KMART6 (**K**eno **M**odule for **A**ctivity-**R**eaction Rate **T**abulation) are modules whose primary purpose is to postprocess a KENO V.a or KENO-VI restart file with the corresponding working cross-section library to generate nuclide activity tables. It also allows collapsing and printing fluxes calculated by KENO. The KENO problem must have a mixing table, must calculate the fluxes, and must write a restart file containing the calculated data. KMART calculations are generally imbedded within a CSAS5 or CSAS6 input file immediately following the CSAS input as a stacked input case.

[1] Formerly with Oak Ridge National Laboratory

2.5.1 INTRODUCTION

KMART5 and KMART6 (**K**eno **M**odule for **A**ctivity-**R**eaction Rate **T**abulation) are modules whose primary purpose is to postprocess a KENO V.a or KENO-VI restart file with the corresponding working cross-section library to generate nuclide activity tables. It also allows collapsing and printing fluxes calculated by KENO. The KENO problem must have a mixing table, must calculate the fluxes, and must write a restart file containing the calculated data.

2.5.2 KMART INPUT DATA

Input data for KMART is read into the program using free form blocked input similar to KENO. The data blocks are started with a READ *BLOCK NAME* and ended with an END *BLOCK NAME*. There are three data blocks that KMART can read. The first data block is named INITIAL, and the input starts with the keywords READ INITIAL. There are ten possible keyworded entries in this block that may be entered in any order.

Keyword	Variable	Description
PRTVOLS	PRINT_VOLUMES	A flag to cause the volumes calculated by KENO to be printed by KMART. Off by default, turn on by entering.
KUNIT=	KUNIT	The logical unit number of the KENO restart file. The default is 35
FNI=	RESTART	*Mode_in* extra field in the input restart file name [restart_*mode_in*.keno_input] and [restart_*mode_in*.keno_calculated]. The default is an empty field.
XUNIT=	XUNIT	The logical unit number of the cross-section library. The default is 4
ACTBY-GRP	ACTIVITIES_BY_GROUP	A flag which turns on printing activities by group. If the fluxes are collapsed, the activities will be by broad group, otherwise they will be by fine group. Off by default, turn on by entering
RRPVOL	REACTION_RATES_PER_UNIT_VOLUME	A flag causing the activities to be printed per unit volume rather than integrated over the volume of the region. Off by default, turn on by entering
KENO3D	NK3D K3DFILE	Unit number on which to write data for plotting with KENO3D. File name of the KENO input file (minus the trailing extension). The plot data file will be named K3DFILE.kmt.
NOPRINT	PRINT_RESULTS	A flag allowing suppressing printing results.
FLUXBIN	FLUX_BIN	A flag to turn on generating a collapsed cross section file for TRITON.
WUNIT	WGTD	The logical unit number on which to write an AMPX weighted library of the 1-D neutron cross sections.

A sample data block is given below.

```
READ INITIAL KUNIT=35 XUNIT=4 END INITIAL
```

One of the next two blocks is required, but both can be specified if desired. If both are entered, either one can be first. The next data block specified is named ACTIVITY, and the input starts with the keywords READ ACTIVITY. It contains the data specifying which activities are to be calculated. The activities are specified by pairs of numbers giving the nuclide identifier and the reaction type identifier desired. A list of reaction types, also known as MT numbers, can be found in Appendix A of the XSLib chapter. These pairs are repeated until all the desired activities have been specified. If the nuclides are identified by the SCALE scheme, then the nuclide can be specified most explicitly by following the nuclide by the keyword MIX= and the mixture number the nuclide is in. By specifying a mixture of zero the activity will be calculated for each region in which the nuclide occurs. If the nuclide specifies a natural element identifier (1000*Z) and individual isotopes occur on the cross-section library, the isotope activities will be summed to produce the total activity for the element. If the nuclide is a special nuclide, i.e., identified with a prefix id times a million + a ZA, then MIX= must be specified as a mixture the nuclide occurs in. The data pair is described below.

Keyword	Variable	Description
	NUCLIDE	The nuclide identification number on the cross-section library for this activity request.
MIX	MIXTURE	Mixture number of the nuclide for this activity request. This is an optional entry, and defaults to 0.
	REACTION	The reaction type identifier for this activity request.

If no activities are desired, then the block can be omitted. A sample block is given below.

```
READ ACTIVITY 92235 18 92235 27 92235 1452 END ACTIVITY
```

The other input block is named COLLAPSE, and starts with the keywords READ COLLAPSE. There are two keyword entries that may be input in this block. A flux factor to normalize the fluxes by can be specified. It defaults to 1. The last fine group in the current broad group is the other entry. The broad groups are specified sequentially starting with group one. If the flux factor is specified more than once, the last value given is used. The data is specified as below.

Keyword	Variable	Description
FACTOR	FACTOR	A flux multiplier used to scale the fluxes before printing (default 1.0).
LASTG=	LAST_GROUP	The last fine group to be included in the current broad group. The broad groups are input sequentially starting with group one.

If no collapsed fluxes are desired, then the block can be omitted. A sample block is given below.

```
READ COLLAPSE FACTOR 1.0 LASTG=10 LASTG=20 LASTG=30 LASTG=56
 END COLLAPSE
```

2.5.3 KMART SAMPLE INPUT

Sample input data for KMART5 is given in Example 2.5.1.

Example 2.5.1: KMART5 sample input.

```
=kmart5
read initial
  kunit=35 xunit=4 actbygrp rrpvol  keno3d  40  kmart5
end initial

2.6 C5TOC6: INPUT FILE CONVERSION PROGRAMS FOR CSAS

K. Bekar

2.6.1 INTRODUCTION

Program C5TOC6 can be used to automatically convert a CSAS5 input file to a CSAS6 input file. This functionality can be useful when converting a KENO V.a validation sequence to a KENO-VI validation sequence. It removes the problem of introducing a mistake or inadvertently changing the data when remodeling a geometry to the KENO-VI format. For some cases, however, the converted model may be a very inefficient KENO-VI model.

2.6.2 DESCRIPTION AND INPUT GUIDE

C5TOC6 is a utility program that can be used to automatically convert a CSAS5 input file to a CSAS6 input file. For C5TOC6, the "=CSAS*BB*" record in the input stream (where the *BB* is 5, 25, or 2x) is replaced by "=C5TOC6 PARM=CSAS5." The output file is named _geom*nnnnnnn* where *nnnnnnn* is a unique 7-digit number.

Important: The conversion makes no attempt to optimize the output file, so it almost surely will be inefficient in its use of storage, and in its use of bodies. This can lead to models that are very inefficient in their running time also.

The input/output (I/O) units for C5TOC6 are given below.

Unit Number	Function
5	CSAS5 input file
6	Output
7	Input file generated for CSAS6)

A sample C5TOC6 sample input file and corresponding converted CSAS6 input file are shown in Example 2.6.1 and Example 2.6.2, respectively.

Example 2.6.1: Sample C5TOC6 problem.

3. REACTOR PHYSICS

Introduction by M. A. Jessee and F. Bostelmann

SCALE supports a wide range of reactor physics analysis capabilities. SCALE reactor physics calculations couple neutron transport calculations with ORIGEN to simulate the time-dependent transmutation of various materials of interest. The two reactor physics analysis tools within SCALE are TRITON and Polaris. TRITON is SCALE's modular reactor physics sequence for a wide variety of system types; Polaris is SCALE's light water reactor (LWR) lattice physics sequence.

The primary function of TRITON is to simulate the time-dependent evolution of nuclide inventories of a reactor system through a series of multigroup transport calculations and depletion/decay calculations. Before each multigroup transport calculation, TRITON executes the XSProc module to calculate multigroup cross sections for each user-designated depletion material. The XSProc calculation is performed based on the time-dependent material compositions and the user-defined cross section processing definitions. TRITON provides maximum modeling flexibility, supporting the full range of cross section processing options in XSProc along with support for four different multigroup transport modules available in SCALE. These transport modules include the following:

- XSDRN: one-dimensional discrete ordinates (S_N) transport module for modeling simple slab, cylindrical, and spherical geometries,
- NEWT: two-dimensional (2D) S_N polygon-mesh deterministic transport module with arbitrary geometry model definitions, and
- KENO-V.a and KENO-VI and Shift: three-dimensional Monte Carlo transport modules with arbitrary geometry model definitions.

In addition to the multigroup-based calculation sequences, TRITON supports continuous-energy (CE) transport calculations with KENO-V.a and KENO-VI and Shift. For each depletion material, the CE Monte Carlo calculation tallies energy-integrated nuclide-dependent reaction rates to couple the transport solution to the ORIGEN depletion calculation. Both the multigroup- and CE-based depletion calculations are parallelizable and can run on an arbitrary number of processors.

TRITON provides easy-to-use input options to define the time-dependent reactor condition, including power history, material temperatures, and material compositions. TRITON also provides the option to perform lattice physics calculations, with input options to define branch calculations, homogenization edits, few-group energy structures, and assembly discontinuity factors. The homogenized few-group cross sections are archived onto auxiliary data files for subsequent in-reactor core calculations.

TRITON generates several data files for follow-on SCALE analysis. It creates the ORIGEN binary concentration file (.f71 extension) that stores all of the material inventories at each depletion/decay step. This file can be used as input to ORIGEN, ORIGAMI, and MAVRIC to support spent fuel characterization and shielding analysis. TRITON also creates the ORIGEN binary library file (.f33 extension) that stores the ORIGEN transition matrix for each depletion material at each depletion/decay step. The ORIGEN library files can be used as input to ORIGEN or ORIGAMI for rapid assessment of spent fuel inventories. Finally, TRITON also generates the aforementioned lattice physics few-group cross section archive (xfile016) for reactor core calculations.

In addition to the TRITON reactor physics sequence, SCALE supports an alternative easy-to-use LWR depletion sequence for generating lattice physics data for full-core reactor calculations. The Polaris lattice

physics sequence couples 2D multigroup transport calculations with ORIGEN depletion to simulate LWR fuel assemblies. Polaris provides easy-to-use input definitions for defining the primary inputs necessary for lattice physics analysis, namely the pin and lattice geometry, the material compositions, and specifications for the power history and branch calculations. Polaris supports systematic input defaults for analysis of both fuel and reflector models for both pressurized water reactor (PWR) and boiling water reactor (BWR) geometries. It uses a novel approach for cross section processing called the Embedded Self Shielding Method (ESSM). The hallmark feature of ESSM is that the self-shielding calculation is performed on the 2D fuel assembly geometry, eliminating the need for user-defined cross section processing definitions. The ESSM calculation and the keff calculation are performed with a deterministic transport module based on the Method of Characteristics (MOC) approach. The Polaris sequence generates the lattice physics archive file (.t16 and .x16 extension), the ORIGEN binary concentration file (.f71 extension), the ORIGEN binary library file (.f33 extension), and a geometry plot file (.png extension).

3.1 TRITON: A MULTIPURPOSE TRANSPORT, DEPLETION, AND SENSITIVITY AND UNCERTAINTY ANALYSIS MODULE

F. Bostelmann, M. A. Jessee, D. Wiarda, K. T. Clarno, U. Mertyurek, K. Bekar

ABSTRACT

The TRITON computer code is a multipurpose SCALE control sequence for transport, depletion, and sensitivity and uncertainty analysis. TRITON automates the processing of cross sections, the neutron transport calculations for one-, two-, and three-dimensional (1D, 2D, and 3D) configurations, and the depletion calculations to estimate the neutron flux, mixture-wise powers, isotopic concentrations, source terms, decay heat and other quantities as well as few-group homogenized cross sections for nodal core calculations as a function of burnup.

TRITON can be used in combination with any one of SCALE's neutron transport kernels. Deterministic multigroup transport calculations for 1D and 2D geometries are performed using XSDRNPM and NEWT, respectively. The application of the Monte Carlo codes KENO V.a, KENO-VI, and Shift enables depletion calculations of 3D geometries in either multigroup or in continuous-energy mode. In MG mode, TRITON automates the preparation of problem-dependent MG cross sections for use in MG neutron transport calculations using SCALE's cross section processing module XSProc. The depletion calculations are performed by the ORIGEN depletion module.

The SAMS module is used to determine the sensitivity of the calculated value of responses to the nuclear data used in the calculation as a function of nuclide, reaction type, and energy. The uncertainty in the calculated value of the response, resulting from uncertainties in the basic nuclear data used in the calculation, is estimated using energy-dependent cross section covariance matrices. The implicit effects of the cross section processing calculations are also treated.

3.1.1 INTRODUCTION

TRITON (Transport Rigor Implemented with Time-dependent Operation for Neutronic depletion) is a multipurpose SCALE control sequence for transport and depletion analysis for reactor physics applications. By calling the appropriate SCALE modules, TRITON automates the processing of cross sections, the neutron transport calculations for one-, two-, and three-dimensional (1D, 2D, and 3D) configurations, and the depletion calculations to estimate the neutron flux, mixture-wise powers, isotopic concentrations, source terms, decay heat and other quantities as a function of burnup. An overview can be found in [TRITONDB11].

The choice of the neutron transport kernel determines whether TRITON is run in multi-group (MG) or in continuous-energy (CE) mode. TRITON can be used in combination with any one of SCALE's neutron

transport kernels. Deterministic MG transport calculations for 1D and 2D geometries are performed using XSDRNPM and NEWT, respectively. The application of the Monte Carlo codes KENO V.a, KENO-VI, and Shift enables depletion calculations of 3D geometries in either MG or in CE mode. In MG mode, TRITON automates the preparation of problem-dependent MG cross sections for use by the MG neutron transport kernels (see Fig. 3.1.1). Nodal data for use in nodal core simulations can be generated with the TRITON sequence that uses the NEWT deterministic transport code and with the TRITON sequences using the Shift Monte Carlo code.

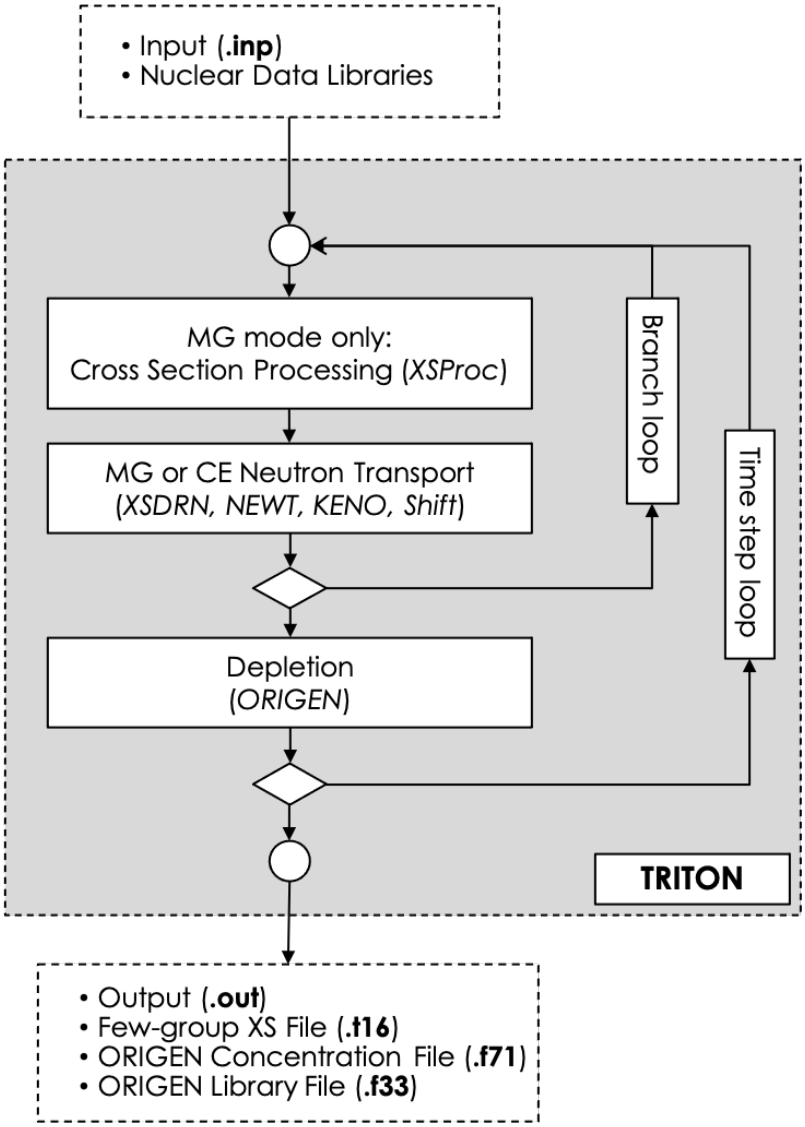

Fig. 3.1.1: General flowchart of the TRITON reactor physics sequence.

The SAMS module is used to determine the sensitivity of the calculated value of the response to the nuclear data used in the calculation as a function of nuclide, reaction type, and energy. The uncertainty in the calculated value of the response, resulting from uncertainties in the basic nuclear data used in the calculation, is estimated using energy-dependent cross section covariance matrices. The implicit effects of the cross section processing calculations are predicted using SENLIB and BONAMIST.

As a SCALE control module, TRITON automates execution of SCALE functional modules and manages data

transfer and input/output processes for multiple analysis sequences. Each of TRITON's eleven calculational sequences is provided in Table 3.1.1, which lists the sequence name keyword, the sequence description, and the function modules invoked within each sequence. The method for cross section processing is selected using a separate "*parm*=" keyword, which is described in more detail in the next section.

Table 3.1.1: Overview of TRITON sequences.

Sequence keyword	**Primary SCALE modules**	**parm= options**	**Sequence function**
Cross section processing sequences			
=T-XSEC	XSProc	bonami centrm[a] xslevel=1/2/3/4	Preparation of multigroup (MG) cross section library.
Transport sequences			
=T-XSDRN	XSProc, XSDRNPM	bonami centrm[a] xslevel=1/2/3/4 weight[b]	1D MG deterministic transport calculation.
=T-NEWT	XSProc, NEWT		2D MG deterministic transport calculation.
Depletion sequences			
=T-DEPL-1D	XSProc, XSDRNPM, ORIGEN, OPUS	bonami centrm xslevel=1/2/3*a*/4 addnux=0/1/2[a]/3/4 weight[b]	1D MG deterministic transport, coupled with ORIGEN depletion.
=T-DEPL	XSProc, NEWT, ORIGEN, OPUS		2D MG deterministic transport, coupled with ORIGEN depletion.
=T5-DEPL	XSProc[c] KENO-V.a, ORIGEN, OPUS		3D, Monte Carlo transport (KENO-V.a), coupled with ORIGEN depletion.
=T6-DEPL	XSProc[c] KENOVI, ORIGEN, OPUS		3D, Monte Carlo transport (KENO-VI), coupled with ORIGEN depletion.
=T5-DEPL-SHIFT	XSProc[c] Shift, ORIGEN, OPUS		3D, Monte Carlo transport (Shift, coupled with ORIGEN depletion.
=T6-DEPL-SHIFT	XSProc[c] Shift, ORIGEN, OPUS		3D, Monte Carlo transport (Shift), coupled with ORIGEN depletion.

[a]Default parm value.
[b]parm=weight is used to generate a broad group cross section library. This parm option is only available for the T-DEPL sequence.
[c]T5-DEPL and T6-DEPL are also available in CE-mode, which does not invoke XSProc for cross section processing.

3.1.2 OVERVIEW OF TRITON SEQUENCES

The TRITON control module supports eleven calculational sequences, each with its own design and applications. Each of these sequences is described in the following subsections.

The first subsection covers the basic cross section processing sequence T-XSEC. The T-XSEC sequence prepares problem-dependent multigroup cross sections for subsequent transport analysis. The second subsection covers TRITON's transport analysis sequences, while the third subsection discusses TRITON's depletion analysis sequences.

3.1.2.1 Cross section processing sequence (T-XSEC)

The T-XSEC sequence provides the ability to prepare a problem-dependent multigroup cross section library using SCALE cross section processing modules to appropriately account for spatial and energy self-shielding effects. The problem-dependent cross section library contains microscopic cross sections for each nuclide for each material composition defined in the TRITON input. SCALE provides several unit cell types (e.g., a lattice of pins, an infinite medium, a multiregion problem, or a doubly heterogeneous cell) to correct the cross sections for spatial and energy self-shielding. Multiple cell calculations can be used in the same calculation. The calculation of multigroup cross sections is executed by XSProc).

3.1.2.2 Transport sequences (T-XSDRN, T-NEWT)

The TRITON transport sequences build upon the cross section processing sequence by automating a transport calculation after cross section processing. Both 1D and 2D discrete-ordinates transport calculations can be performed using XSDRNPM and NEWT, respectively. The T-XSDRN sequence calls XSDRNPM for transport analysis in slab, sphere, or cylindrical geometries, while the T-NEWT sequence calls NEWT for analyses in 2D *xy*-geometries. In addition to the input necessary for cross section processing, an XSDRN or NEWT input model is also required. The XSDRN model input is discussed in Appendix A of TRITON; the NEWT model input requirements are described in the NEWT chapter. Similar capabilities and applications for KENO-V.a and KENO-VI are handled through the CSAS5 and CSAS6 sequences, respectively.

3.1.2.3 Depletion sequences (T-DEPL, T-DEPL-1D, T5-DEPL, T6-DEPL, T5-DEPL-SHIFT, T6-DEPL-SHIFT)

The TRITON depletion sequences build upon the transport sequences by automating depletion/decay calculations after the transport calculations for each material designated for depletion. One or more materials in the model can be designated for depletion. Each designated material is depleted using region-averaged reaction rates, accounting for all regions in the model associated with a given depletion material. The TRITON depletion calculation procedure is described further in the next subsection. TRITON automates the various computational processes-cross section processing, transport, and depletion-over a series of depletion and decay intervals supplied by the user. The depletion procedure is discussed in Sect. 3.1.2.3.1. The 2D TRITON depletion sequence (T-DEPL), which uses NEWT for the transport calculations and the 3D TRITON depletion sequences which use Shift in CE mode for the transport calculations (T5-DEPL-Shift, T6-DEPL-SHIFT) provide the capability to generate lattice-physics data for nodal core calculations.

Within TRITON depletion calculations, TRITON invokes the ORIGEN depletion module for the time-dependent transmutation of each user-defined material. TRITON provides ORIGEN the neutron flux space-energy distribution, the multigroup cross sections, material concentrations, and material volumes. ORIGEN performs the flux normalization, cross section collapse, and multi-material depletion/decay operations to determine new isotopic concentrations for the next calculation.

Predictor-corrector depletion process

For all depletion sequences, TRITON automates cross section processing, transport, and depletion calculations over a series of depletion-decay intervals supplied by the user. A **depletion interval** represents a time interval in which the model power level is assumed constant. A depletion model that exhibits various power level changes will require multiple depletion intervals to accurately model the changes in power. Each depletion interval can be followed by a decay calculation over a user-specified **decay interval**.

Within a given depletion interval (e.g., an LWR operating at constant power for a 12-month fuel cycle), the isotope concentrations of different depletion materials change, which induces changes in the problem-dependent multigroup cross sections (through spatial and energy self-shielding effects) as well as the neutron flux distribution, leading to different power distributions and transmutation rates in depletion materials. This requires TRITON to represent each depletion interval as a series of smaller time intervals in which cross section processing and transport solutions are recomputed to accurately model these time-dependent effects. A **depletion subinterval** represents a time interval in which TRITON performs cross section processing and transport calculations to determine cross sections and flux distributions used in the depletion calculations. All depletion subintervals for a given depletion interval have the same length-for example, one 12-month depletion interval can be represented as a series of 12 one-month depletion subintervals, or as 6 two-month depletion subintervals. Alternatively, the 12-month depletion interval can be modeled as two consecutive 6-month depletion intervals, each one having a different number of subintervals. Therefore the formulation of a **depletion scheme** in TRITON is highly flexible. A depletion scheme is the set of user-defined depletion and decay intervals with associated power levels and number of subintervals.

Caution: TRITON does not provide automated means to determine the appropriate depletion scheme for a given application. The user must determine the accurate depletion scheme specific to his or her application.

TRITON uses a predictor-corrector approach to process the user-defined depletion scheme. The predictor-corrector approach performs cross section processing and transport calculations based on anticipated isotope concentrations at the *midpoint* of a depletion subinterval. Depletion calculations are then performed over the full subinterval using cross sections and flux distributions predicted at the midpoint. Depletion calculations are then extended to the midpoint of the next subinterval (possibly through a decay interval and into a new depletion interval), followed by cross section processing and transport calculations at the new midpoint. The iterative process is repeated until all depletion subintervals are processed. In order to start the calculation, a "bootstrap case" is required using initial isotope concentrations for the initial cross section processing and transport calculation. The bootstrap calculation is used to determine the anticipated isotope concentrations at the midpoint of the first depletion subinterval.

The predictor-corrector approach is best explained by an example. Fig. 3.1.2 illustrates the predictor-corrector process for a hypothetical depletion scheme with two depletion intervals. The first depletion interval contains two subintervals, followed by a decay interval. The second depletion interval contains one subinterval and is also followed by a decay interval. In Fig. 3.1.2, cross section processing and transport calculations are represented by the 'T' label, and depletion calculations are represented by the 'D' label. For this example, four sets of calculations would be necessary: one for each of the three depletion subintervals, and one for the initial "bootstrap case." These calculations are represented in the following eight steps.

- **Step 1**
  - T_0: Cross section processing and transport calculation using initial (i.e., time-zero) isotope concentrations.

- **Step 2**
  - D_1: Depletion calculation from time-zero to the midpoint of the first depletion subinterval. The dashed horizontal arrow denotes a "predictor" depletion step.
- **Step 3**
  - T_1: Cross section processing and transport calculation at the midpoint of the first depletion subinterval.
- **Step 4**
  - D_1: Depletion calculation for the first depletion subinterval. The solid horizontal arrow across the subinterval denotes a "corrector" depletion step. *Corrector steps use cross sections and flux distribution computed at the subinterval midpoint.* This is represented by a solid arrow from T_1 to D_1.
  - D_2: Predictor depletion calculation for the second depletion subinterval. *Predictor steps use cross sections and flux distribution computed at the***previous***subinterval midpoint.* This is represented as the dashed arrow from T_1 to D_2.
- **Step 5**
  - T_2: Cross section processing and transport calculation at the midpoint of the second depletion subinterval.
- **Step 6:**
  - D_2: Corrector depletion calculation for the second depletion subinterval, followed by the decay calculation at the end of the first depletion interval.
  - D_3: Predictor depletion calculation for the third depletion subinterval. The third depletion subinterval is the first and only subinterval associated with the second depletion interval.
- **Step 7**
  - T_3: Cross section processing and transport calculation at the midpoint of the third depletion subinterval.
- **Step 8**
  - D_3: Corrector depletion calculation for the third depletion subinterval. This calculation is followed by a second decay calculation.

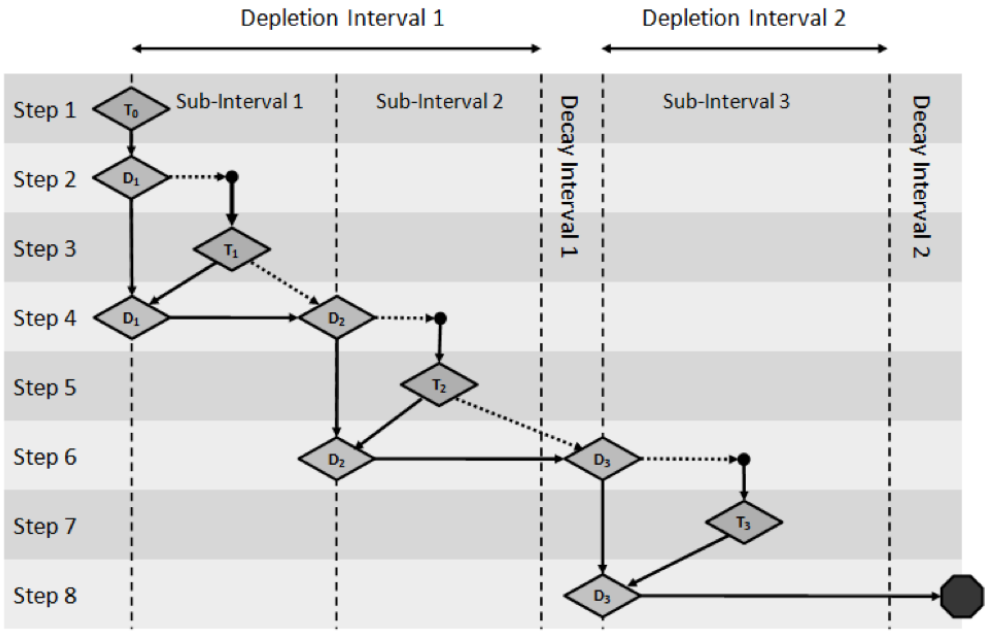

Fig. 3.1.2: Predictor/corrector depletion algorithm used by TRITON.

The depletion calculations are performed by ORIGEN and span either the first half of a subinterval (predictor step) or the full subinterval (corrector step). ORIGEN performs these depletion calculations and possible decay calculations over a series of smaller time intervals. The **ORIGEN time intervals** are automatically determined by TRITON depending on the length of the depletion subinterval and decay interval. Additionally, TRITON will automatically adjust the number of subintervals per depletion interval if the time length of the user-defined subinterval is large (i.e., >400 days). TRITON writes the utilized depletion scheme near the top of the output file. The depletion scheme output edit is further described in Sect. 3.1.5.4.1.

Lattice physics analysis

The 2D depletion sequence (T-DEPL) may be used to generate lattice physics data for subsequent core analysis calculations using core simulator software. Core simulators typically employ few-group nodal diffusion theory for neutronic calculations, coupled with other calculation methods for thermal hydraulics, fuel performance, and plant operation (e.g., soluble boron letdown or control rod movement). Core simulation requires the use of pretabulated **lattice physics data** for the neutronic calculations-that is, few-group homogenized cross sections, with appropriate discontinuity factors, pin powers, and kinetic parameters, functionalized in terms of burnup and other system conditions such as fuel temperature and moderator density.

To support lattice physics database preparation, the NEWT transport module contains flexible input options to define the few-group energy structure, spatial homogenization regions, and discontinuity factors. After the transport calculation at the midpoint of each depletion subinterval, NEWT computes the lattice physics data and stores this data on a temporary file. TRITON reads the temporary file and archives the lattice physics data onto a separate database file. In addition, the *T-DEPL* sequence supports branch calculations in which perturbations may be applied to certain system conditions such as fuel temperatures and moderator density. TRITON automates the cross section processing and transport calculations for each branch condition at the midpoint of the depletion subinterval. NEWT computes the lattice physics data for the branch calculations, and TRITON archives this data onto the lattice physics database file.

The TRITON input options for branch calculations are described in Sect. 3.1.3.3.2, and the file format of the lattice physics database is provided in the Appendix B of TRITON.

Note: The TRITON input options for branch calculations are designed to be highly flexible to support a large range of core analyses; therefore, TRITON does not provide automated means to determine the branch calculations. The user must determine the necessary branch calculations for his or her core analysis and be knowledgeable of the capabilities and limitations of the cross section treatment of the core simulator. The TRITON Lattice Physics Primer has been developed to provide guidance on appropriate TRITON branch calculations for LWR core analysis (NUREG/CR-7041) and in "Cross Section Generation Guidelines for TRACE-PARCS" (NUREG/CR-7164).

3.1.3 INPUT DESCRIPTION

TRITON input is free-form and keyword based, similar in form to many other modules in SCALE. With a few exceptions, the following formatting rules apply:

- Data is limited to 255 columns but may wrap into as many lines as are needed.
- Comment lines start with a tick mark (') in the first column of a line and may be placed anywhere in the input.
- The keyword-based input is case insensitive.
- TRITON input is organized into blocks of data. Each data block begins with *read blockname* and terminates with *end blockname*.
- Blocks of data may appear in any order. Each block of data may appear only once in the input.
- Input can be redirected from an auxiliary file by using the open angle bracket (<) and the name of the file-for example, *</path/to/auxiliary_input_file*.

The first three lines of input and the last line of the input are unique. The first line of input contains the TRITON sequence name along with parameter specifications, e.g., *parm=centrm*. The second line contains the case title (up to 80 characters), and the third line contains the cross section library identifier. The last line of the input contains the end keyword and terminates the input file. An example TRITON input is as follows:

```
=t-xsec         parm=(centrm,check)
TRITON Input Example
V7-252
...
end
```

In this example, the first line of input declares this calculation to use the T-XSEC sequence. The name of the sequence is preceded by the "=" sign. After the sequence name, two parameter options are specified. Parameters are optional. If specified, the keyword *parm=* must precede the parameter options. Multiple parameter options can be provided in a comma-separated list enclosed in parentheses. In this example, the *centrm* option specifies the CENTRM-based discrete-ordinates sequence is used by default. The *check* option implies that TRITON will read all input and ensure that no input errors are present, without running additional calculations. The second input line provides the case title: *TRITON Input Example*. The third input line provides the cross section library: *V7-252*. This example input file is terminated at the *end* keyword. The *end* keyword must appear by itself at the beginning of the final line of the input file.

The TRITON input section is organized by sequences. The first section summarizes the input requirements for the cross section processing sequence T-XSEC, which includes discussion of the *COMPOSITION* and

CELLDATA block. The second section summarizes the input requirements for the TRITON transport sequences T-XSDRN and T-NEWT. The *XSDRN MODEL* block is described in Appendix B of TRITON. The third section summarizes the input for TRITON depletion sequences: T-DEPL-1D, T-DEPL, T5-DEPL, and T6-DEPL. The depletion sequence input section includes discussion of the *DEPLETION, BURNDATA, TIMETABLE, BRANCH,* and *OPUS* blocks.

The input requirements for the depletion sequences and the S/U sequences build upon the input requirements for the cross section processing sequence and the transport sequences, so the user should be familiar with these first two sections. However, the input requirements for the depletion and S/U sequences are independent, so the user can skip over these sections as needed.

The fifth and sixth section of the input description is dedicated to two TRITON-specific blocks of data to simplify model development and output control: the *ALIAS* block and the *KEEP_OUTPUT* block, respectively. The final section describes TRITON control parameters used in the *parm*= specification.

3.1.3.1 Cross section processing

An example input structure for a cross section processing sequence calculation is the following:

```
=t-xsec parm=(options)
title-goes-here
xslib-goes-here
read alias
[List of user-defined aliases (optional)]
end alias
read comp
[List of material specifications (standard SCALE format)]
end comp
read celldata
[Unit cell specifications for self-shielding calculation (optional)]
end celldata
end
```

In this input, the title can be any descriptive title, and the cross section library *x-sect_lib_name* can be any multigroup SCALE cross section library (or continuous-energy library if KENO is used). The three blocks of data highlighted in red-*ALIAS, COMPOSITION,* and *CELLDATA*-**must** appear in the order shown above. However, the *ALIAS* and *CELLDATA* blocks are optional. If the *ALIAS* block is not used, the *COMPOSITION* block follows the cross section library line. If the *CELLDATA* block is not used, the input is terminated after the *COMPOSITION* block.

The input requirements for the *ALIAS* block are deferred to Sect. 3.1.3.4 as the *ALIAS* block impacts many different blocks of data for all TRITON sequences. The *COMPOSITION* block is used to define material compositions and temperatures. The *CELLDATA* block is used to specify unit cell calculations used to generate problem-dependent multigroup cross sections. The input requirements for the *COMPOSITION* and *CELLDATA* blocks are comprehensively described in the XSProc manual and are not repeated here. Fig. 3.1.3 shows an example input for a cross section processing calculation. In this input file, cross section processing calculations are performed for two different square-pitched UO_2 fuel pins surrounded by Zircaloy-4 cladding and borated H_2O moderator. The first fuel pin (material 1) is 2.5% enriched in ^{235}U. The second fuel pin (material 4) is 4.5% enriched in ^{235}U. These materials are used in two separate unit cell definitions in the *CELLDATA* block.

```
=t-xsec
Simple T-XSEC input
v7.1-252n
read composition
'cell 1
  uo2   1 den=9.550 1 750 92235 2.5 92238 97.5 end
  zirc4 2 1 600 end
  h2o   3 den=0.75 1 550 end
  boron 3 den=0.75 600e-6 550 end
'cell 2
  uo2   4 den=9.550 1 750 92235 4.5 92238 95.5 end
  zirc4 5 1 600 end
  h2o   6 den=0.75 1 550 end
  boron 6 den=0.75 600e-6 550 end
end composition
read celldata
   latticecell squarepitch fueld=0.95 1 cladd=1.05 2 pitch=1.4 3 end
   latticecell squarepitch fueld=0.95 4 cladd=1.05 5 pitch=1.4 6 end
end celldata
end
```

Fig. 3.1.3: Example T-XSEC input.

One key observation in this example is the duplicate definitions for the clad material (materials 2 and 5) and the moderator material (materials 3 and 6). For practical use in subsequent transport calculations, only four material compositions need to be defined: one each for the different fuel pin enrichments and one definition each for the clad and moderator material compositions. However, as described in the XSProc manual, the same material identifier cannot be used in multiple unit cell definitions. Because this example requires two separate unit cell definitions to appropriately generate cross sections for each fuel pin enrichment, duplicate definitions are required for the clad and moderator compositions. The unique mixture number input requirement can lead to many duplicate definitions of clad and moderator materials, depending on model complexity. To simplify model development, duplicate material compositions and similar unit cell definitions can be defined simultaneously through the use of aliases. The *ALIAS* block is discussed further in Sect. 3.1.3.4.

Combined two-region and S_N cross section processing

It is possible to use the both the CENTRM-based two-region method and the CENTRM-based S_N method within the same input file. Fig. 3.1.4 shows a modified input file of the previous example in which the first unit cell uses S_N cross section processing and the second unit cell uses two-region cross section processing. Each unit cell contains a *centrmdata* keyword specification after the *latticecell* specification. The *centrmdata* specification contains a set of additional keyword specifications used to identify the S_N and the two-region options in CENTRM.

The input centrmdata npxs=1 end centrmdata instructs TRITON to use S_N cross section processing, whereas the input centrmdata npxs=5 end centrmdata instructs TRITON to use two-region cross section processing. These keyword options are described in detail in the XSProc manual. The default cross section option for TRITON is S_N; therefore, the first *centrmdata* specification is not needed (but still acceptable). If *parm=centrm* was specified, the first *centrmdata* specification would not be needed (but still acceptable), whereas the second *centrmdata* specification would be required to activate the two-region option. Conversely,

if *parm=2region* was specified, the second *centrmdata* specification is not needed (but still acceptable), whereas the first *centrmdata* specification would be required to activate the S_N option.

The *centrmdata* specifications may also be applied to other unit cell types (e.g., multiregion); however, the two-region method is only valid for specific unit cell configurations described in the XSProc manual. The user should determine the applicability of the two-region method by comparing calculation results with continuous-energy calculations or multigroup calculations using the CENTRM-based S_N method.

```
=t-xsec
Simple T-XSEC input
v7.1-252n
read composition
'cell 1
  uo2   1 den=9.550 1 750 92235 2.5 92238 97.5 end
  zirc4 2 1 600 end
  h2o   3 den=0.75 1 550 end
  boron 3 den=0.75 600e-6 550 end
'cell 2
  uo2   4 den=9.550 1 750 92235 4.5 92238 95.5 end

   centrmdata npxs=5 end centrmdata
end celldata
end
```

Fig. 3.1.4: T-XSEC input with multiple cross section processing options.

User-defined Dancoff factors

Like other SCALE calculations, TRITON uses Dancoff factors as part of its cross section processing calculations. The user can specify Dancoff factors for various materials by using the *centrmdata* specification and the *dan2pitch* keyword. Here is an example.

```
read celldata
   latticecell squarepitch fueld=0.95 1 cladd=1.05 2 pitch=1.4 3 end
   centrmdata dan2pitch=0.51 end centrmdata
   latticecell squarepitch fueld=0.95 4 cladd=1.05 5 pitch=1.4 6 end
   centrmdata dan2pitch=0.65 end centrmdata
end celldata
```

In this example, fuel materials 1 and 4 were assigned a Dancoff factor of 0.51 and 0.65, respectively. These Dancoff factor values can be computed using the SCALE MCDANCOFF sequence. Only one *dan2pitch* keyword is allowed for a given *centrmdata* specification.

3.1.3.2 Transport sequences

An example input structure for a transport sequence calculation is the following:

```
=t-newt (or =t-xsdrn) parm=(options)
title-goes-here
xslib-goes-here
read alias
[List of user-defined aliases (optional)]
end alias
read comp
[List of material specifications (standard SCALE format)]
end comp
read celldata
[Unit cell specifications for self-shielding calculation (optional)]
end celldata
read keep_output
[keep output options (optional)]
end keep_output
read model
[specification of XSDRN or NEWT model]
end model
end
```

The *MODEL* block contains a full transport model input description and is required for both the T-NEWT and T-XSDRN sequences. *The MODEL block must be the last block of data in the input file.* The *MODEL* block provides the physical layout of the configuration for which the transport calculation is to be performed, along with general control parameters. The nature of data embedded within the MODEL block depends on the sequence selected. For the T-NEWT sequence, the *MODEL* block contains a complete NEWT input listing. NEWT input is fully described in the NEWT chapter and is not repeated here. For the T-XSDRN sequence, the *MODEL* block is described in the Appendix B of TRITON. Sample problems for both the T-NEWT and T-XSDRN sequences are provided in Sect. 3.1.6. The optional *KEEP_OUTPUT* block is described in Sect. 3.1.3.4.7.

3.1.3.3 Depletion sequences input

An example input structure for a depletion calculation is provided in the following:

```
=t-depl (or =t-depl-1d or =t5-depl or =t6-depl) parm=(options)
title-goes-here
xslib-goes-here
read alias
[List of user-defined aliases (optional)]
end alias
read comp
[List of material specifications (standard SCALE format)]
end comp
read celldata
[Unit cell specifications for self-shielding calculation (optional)]
end celldata
read keep
[keep output options (optional)]
end keep
read burndata
[information about specific power, depletion/decay time and intervals]
end burndata
read depletion
[material depletion specifications]
end depletion
read branch
[branch calculation specifications (optional, t-depl only)]
end branch
```

(continues on next page)

(continued from previous page)

```
read timetable
[time-dependent parameter specifications (optional)]
end timetable
read opus
[opus specification (optional)]
end opus
read model
[specification of XSDRN, NEWT, KENO-V.a or KENO-VI model]
end model
end
```

The TRITON depletion sequences support the following data blocks: the *DEPLETION, BURNDATA, OPUS, BRANCH, and TIMETABLE* data blocks. These data blocks, along with the *KEEP_OUTPUT* block, may appear only once, in any order, and must follow the *COMPOSITION* and *CELLDATA* blocks and must precede the *MODEL* block. The *DEPLETION* and *BURNDATA* blocks are always required for depletion calculations.

The *MODEL* block contains a full transport model input description and is required for all depletion sequences. For the *T-DEPL* sequence, the *MODEL* block contains a complete NEWT input listing. NEWT input is fully described in NEWT chapter and is not repeated here. For the *T-DEPL-1D* sequence, the *MODEL* block is described in Appendix A of TRITON. For *T5-DEPL* and *T6-DEPL* sequences, the *MODEL* block contains input for KENO V.a and KENO-VI, respectively. The details of KENO V.a and KENO-VI input formats are described in the KENO V.a and KENO-VI chapters and are not repeated here. To use the Monte Carlo code Shift instead of KENO V.a or KENO-VI, only the sequence name has to be changed from *T5-DEPL* to *T5-DEPL-SHIFT*, or from *T6-DEPL-SHIFT* to *T6-DEPL* sequences, respectively. Note that the KENO geometry description ends with an additional *END DATA* before *END MODEL*.

TRITON reads the *MODEL* block at the beginning of the sequence to process the input and save data to appropriate data in memory (or on a restart file for KENO). Reading the *MODEL* block at the beginning of the sequence allows TRITON to check all transport module data and to terminate immediately if errors are found in the model input. When the transport module is eventually invoked by the sequence, TRITON uses the processed data in memory (or reads it from the restart file), allowing for transport iterations (XSDRN, NEWT) or neutron histories (KENO, Shift) to begin immediately, eliminating the need for recalculation of geometry data each time the transport module is invoked.

BURNDATA block

The *BURNDATA* data block allows specification of the **depletion scheme** for the model and is used only by the depletion sequences of TRITON for which this block is required. As described in Sect. 3.1.2.3.1, the depletion scheme consists of a series of **depletion intervals**—time intervals of constant power operation—which may be partitioned into many **depletion subintervals**—intervals over which cross section processing and transport calculations are performed to update cross sections and flux distributions used in the depletion calculation. Moreover, depletion intervals may be optionally followed by a **decay interval**—a time interval for zero-power decay.

The depletion intervals that define the depletion scheme are specified in the *BURNDATA* block in chronological order within the *BURNDATA* block, with the following format.

```
READ burndata
power=P burn=B down=D nlib=N end
power=P burn=B down=D nlib=N end
END burndata
```

where

P = average specific power in the basis material(s), in megawatts per metric tonne of initial heavy metal (MW/MTHM) (typically MW/MTU for uranium-only models);

B = length of depletion interval in days;

D = length of decay interval in days following the depletion interval (optional, default = 0.0);

N = number of depletion subintervals for the depletion interval (optional, default = 1).

The average specific power is provided for the basis material(s). In other words, localized power distributions are uniformly scaled accordingly in the transport solution such that the average power in the basis material(s) matches the power specified in input. By default, the basis consists of all materials in the model, so that local powers are scaled to obtain a problem-wide average power matching the power specified in input. The basis can be set as a single material or set of materials in the *DEPLETION* data block. The *DEPLETION* data block is described in Sect. 3.1.3.3.4.

Each depletion interval specification must be terminated by an end keyword. As many depletion intervals as necessary may be entered to model the depletion scheme. The number of depletion subintervals can be used to refine the temporal discretization to force more cross section processing and transport calculations per depletion interval, as discussed in Sect. 3.1.2.3.1.

An example of a *BURNDATA* block is shown below. The example case contains three depletion intervals, with the first interval at power 26.54 MW/MTHM in the basis materials (the basis is defined in the *DEPLETION* block), for an interval of 121 days. This is followed by a second depletion interval at power 38.01 MW/MTHM for 201.5 days and then 30 days of zero-power operation. In the third depletion interval, the basis materials are depleted at a 31.44 MW/MTHM power level for 386.25 days, followed by 5 years (1826.25 days) of decay. In this model, three, two, and one depletion subintervals are used for the first, second, and third depletion intervals, respectively.

Example 3.1.1: Example *BURNDATA* block input.

```
READ burndata
power=26.54 burn=121.0 nlib=3 end
power=38.01 burn=201.5 down=30 nlib=2 end
power=31.44 burn=386.25 down=1826.25 end
END burndata
```

While at least one depletion interval was required in TRITON input files up to SCALE 6.2, TRITON in SCALE 6.3 permits the specification of a depletion step of 0 days or the omission of the depletion step. A TRITON calculation without a depletion step enables a neutron transport-only calculation as in the CSAS sequence, but with TRITON default settings and with the additional TRITON output files (f71, f33, etc.). A 0 day interval is only permitted in the first and only *BURNDATA* entry. The following two examples are equivalent and cause a neutron transport calculation only at t=0.

```
READ burndata
power=26.54 burn=0 end
END burndata

READ burndata
power=26.54 end
END burndata
```

BRANCH block

The T-DEPL sequence in TRITON supports the ability to perform branch calculations during depletion calculations. Branch calculations are not supported for the 3D depletion sequences, nor are branch calculations supported for problems that require doubly heterogeneous cross section processing. A branch calculation is a recalculation of cross section processing and transport calculations with one or more of a limited set of input parameters modified. These calculations are performed at the same location in the depletion scheme as in the nominal cross section processing and transport calculations-that is, at t = 0 and at the midpoint of the depletion subintervals (see Sect. 3.1.2.3.1 for more details on the TRITON predictor-corrector depletion scheme). Branch calculations allow for the quantification of changes in system responses of interest (eigenvalue, pin powers, homogenized few-group cross sections, and kinetic parameters) due to changes in system parameters. TRITON saves the responses of interest for the nominal and each perturbed (branch) state, for each evaluation within the TRITON depletion scheme. These responses of interest-in particular, homogenized cross sections-may be subsequently extracted for use in nodal core simulation calculations.

Branch calculations represent a branch from the primary depletion scheme at each depletion subinterval. With branching enabled, selected properties or conditions (fuel temperature, moderator temperature, moderator density, soluble boron concentration, and control rod insertion, or any combination thereof) can be varied from the reference state for as many branches as are desired. Depletion calculations, however, are performed for reference-state conditions only. Fig. 3.1.1 illustrates the branch loop during a T-DEPL sequence calculation. Although not technically a branch state, the reference state is considered to be branch 0 for numbering purposes within TRITON. For each branch calculation >0, TRITON updates the appropriate parameters and re-executes the cross section processing and transport calculations. Responses of interest are saved to a database file (i.e., the txtfile16 file) for both the nominal and perturbed-state conditions, and TRITON reverts to cross sections and fluxes from the reference branch 0 to proceed with the depletion calculation. The process repeats following each depletion subinterval, until all depletion subintervals are simulated. Responses of interest are added to the database file for all branches at each depletion subinterval.

Branch perturbations may be applied to any of the following five parameters: fuel temperature, moderator temperature, moderator density, moderator soluble boron concentration, and control rod insertion. These properties may be varied individually or simultaneously. Branch calculations are specified in the TRITON *BRANCH* data block. The *BRANCH* data block has the following form.

```
READ branch
define deftype   I1 I2 ... In end
...
tf=fueltemp tm=modtemp dm=moddens sb=boronconc cr=inout end
...
END branch
```

where

deftype = ‘fuel,’ ‘mod,’ ‘crout’, or ‘crin’,

Ii = list of materials associated with type definition *deftype*,

fueltemp = branch fuel temperature (K),

modtemp = branch moderator temperature (K),

moddens = branch moderator density (g/cm^3),

boronconc = soluble boron concentrations (ppm),

inout = control rod/blade state (out = 0, in = 1).

The type definitions must come first within the *BRANCH* block, and at least one definition is always required. The 'fuel' type definition is used to specify which of the problem materials are considered to be fuel during branch calculations; similarly, the 'mod' type definition specifies the material or materials that are to be considered moderator. The 'crout' definition specifies the materials that are in place in the transport model when control structures are withdrawn, while the 'crin' definition specifies the materials that are present in the transport model when a control structure is inserted. The 'fuel' definition must be present if any fuel temperature branches are performed. The 'mod' type definition must be present whenever moderator temperature, moderator density, or soluble boron branches are performed. Both the 'crout' and 'crin' definitions must be present if control rod branches are requested. Definitions may not be repeated-for example, 'define fuel' may occur only once.

Type definitions are followed by branch specifications. For each branch, one or more branch specifications may be given; if a particular property is omitted, then the reference conditions of the original model and material specifications are used. **The first branch specification must describe the nominal conditions,** and all parameters must be specified for this branch. Each branch specification can optionally define up to five branch keywords before terminating with the *end* keyword. The five branch keywords are as follows.

tf = fuel temperature (K),

tm = moderator temperature (K),

dm = moderator density (g/cm^3),

sb = soluble boron concentration (ppm boron), and

cr = control rod state (out = 0, in = 1).

The format of a *BRANCH* block is best illustrated by an example. Fig. 3.1.5 shows a complete branch data block for a five-branch calculation, with embedded descriptions of each branch. Note that there are six entries; the first branch is the reference or branch 0 state.

In this example, materials 11 and 12 are specified as 'fuel', and fuel temperature perturbations will be applied to only these materials. The nominal temperature for both materials is determined from the branch 0 input (901 K). The nominal fuel temperature must be the same for all materials in the definition and must be consistent with the initial standard composition input. Similarly, materials 13 and 14 are defined as the moderator materials. The temperature (559 K), density (0.76 g/cm^3), and soluble boron concentrations (655 ppm) for the reference state must be identical to those of the initial material specifications and must be identical for all materials defined as moderator.

```

'moderator density + fuel temperature branch
tf=559 dm=0.8 end
END branch
```

Fig. 3.1.5: Example BRANCH block input.

In a reactor core, when a control structure (rod, blade, etc.) is withdrawn, the volume occupied by the structure is replaced by something else. Thus, in a branch calculation with rod insertion and withdrawal, the material(s) present for both states must be specified. If the reference condition is defined as control rods withdrawn (i.e., cr = 0), the NEWT geometry model must contain the materials defined by 'crout'. For a control rod insertion branch (cr = 1), TRITON exchanges the materials specified in the 'crin' definition (30, 31) with corresponding materials in the 'crout' definition (20, 21). Conversely, if the reference condition is defined as control rods inserted (i.e., cr = 1), the NEWT geometry model must contain the materials defined by 'crin'. For a control rod withdrawal branch (cr = 0), TRITON exchanges the materials specified in the 'crout' definition with corresponding materials in the 'crin' definition. For this reason, unique material numbers must be paired between crin and crout definitions. For example, consider a zirc-clad B_4C control rod inserted during a control rod insertion branch, with materials 30 and 31 representing the clad and rod materials, respectively. In the withdrawn position, both the clad and poison materials are replaced by the moderator. To have consistent definitions of 'crin' and 'crout', two moderator materials must be defined for the withdrawn state: one corresponding to the clad material and one corresponding to the rod material.

As mentioned earlier, only one condition keyword is required per branch, but all five may be used. However, the reference state (branch 0) entry must specify all five conditions. For subsequent branches, when a specific branch state is not specified, the reference state is used. In the above example, the first entry, branch zero, specifies the reference state with a fuel temperature of 901 K, moderator temperature of 559 K, moderator density of 0.4 g/cm^3, control rod withdrawn, and a soluble boron concentration of 655 ppm. The second entry (branch 1) specifies a moderator density of 0.80 g/cm^3 and the control rod state as withdrawn. Since the reference state is for a withdrawn control rod, the statement cr = 0 is redundant (but completely acceptable). The next branch is identical to the previous branch, except that in this case the control rod is inserted. For

both cases, reference fuel and moderator temperatures were used. In the following branch, the soluble boron concentration is changed to 20 ppm, and the moderator density is again set to a value of 0.8 g/cm^3. In fact, this moderator density is applied to all five branches. Along with the moderator density change, the soluble boron concentration is changed to 1300 ppm for the next branch. And finally, in the last branch, in addition to the moderator density change, the fuel temperature is changed to 559 K. For this case, reference conditions are used for boron concentration, moderator temperature, and control rod state.

Note that TRITON compares the reference values of fuel temperature, moderator temperature, moderator density, and soluble boron concentration with the data entered in the *COMPOSITION* block. TRITON prints warning messages if the data in the *COMPOSITION* block and *BRANCH* block are inconsistent. Also note that each branch calculation is independent of other branch calculations. Thus, the order in which branch calculations are computed is not important.

Branch calculations are usually requested for lattice physics analysis, where the objective is to generate a database of few-group homogenized cross sections for nodal core calculations. Thus, BRANCH blocks are used in tandem with the NEWT's *COLLAPSE, HOMOGENIZATION,* and *ADF* blocks. With these blocks of data, TRITON will archive lattice physics data-few-group homogenized cross sections, assembly discontinuity factors (ADFs), homogenized kinetic parameters, pin powers, and form factors-to a binary file called xfile016 in the SCALE temporary working directory. An auxiliary text-formatted data file called txtfile16 is also created in the SCALE temporary working directory. This file format is documented in Sect. 3.1.7.1.

BRANCH block with user-defined Dancoff factors

As previously mentioned in Sect. 3.1.3.1.2, TRITON uses Dancoff factors as part of its cross section processing calculations. Dancoff factors play an important role in characterizing spatial self-shielding effects. The XSProc module computes the Dancoff factors based on the *CELLDATA* input. For a square-pitched lattice cell example, Dancoff factors are computed by DANCOFF by assuming that the fuel pin is within an infinite lattice of identical fuel pins. The assumption of an infinite uniform lattice of fuel pins may lead to inaccurate Dancoff factors for certain configurations such as BWR assembly designs, leading to inappropriate problem-dependent multigroup cross sections. Moreover, the Dancoff factors may change significantly for certain branch conditions, such as changing the in-channel moderator density in a BWR assembly.

The TRITON BRANCH block allows the user to specify material-dependent Dancoff factors for various branch conditions. Branch-specific Dancoff factors may be utilized by defining a new set of material-dependent Dancoff factors using the *d2pset* type definition. The set of Dancoff factors may be included in a branch specification by using the *d2p=* keyword. The *BRANCH* block now has the following format.

```
READ branch
define deftype   I1 I2 ... In end
define d2pset id M1 D1 M2 D2 ... Mn Dn end
...
tf=fueltemp tm=modtemp dm=moddens sb=boronconc cr=inout d2p=d2pID end
...
END branch
```

In the type definition section, the *d2pset* keyword is followed by a positive integer identifier, which is subsequently followed by pairs of material identifiers and their user-defined Dancoff factor value. Multiple material/Dancoff pairs may be entered for a particular set definition, as long as the material identifiers are unique. Multiple set definitions are allowed, as long as the set identifiers are unique.

The *d2p=* keyword in the branch specification can be assigned to any set identifier defined in the branch definition section. If *d2p=* is utilized, the material/Dancoff pairs in the set definition are applied for the

given branch condition. The values *d2p=0* and *d2p=-1* have special meaning. If *d2p=* is set to 0, the material/Dancoff pairs defined in the *CELLDATA* block are utilized. If *d2p=* is set to -1, the default MIPLIB-computed Dancoff factors will be utilized, even if material/Dancoff pairs are defined in the *CELLDATA* block using the *dan2pitch* keyword available there. The nominal (branch 0) condition **must** use the material/Dancoff pairs (if defined) in the *CELLDATA* block; therefore, the first branch specification **must** not set the *d2p* keyword to anything other than zero. (Note: *d2p=0* need not be defined for the first branch condition since this is always the case.)

In Fig. 3.1.6, the *BRANCH* block from the previous example has been modified to use branch-specific Dancoff factors. In this example, the nominal branch defines the reference moderator density to be 0.4 g/cm^3, and five branches use a higher moderator density of 0.8 g/cm^3. The Dancoff factors for the higher moderator density condition are different from the reference moderator density. To account for the different Dancoff factors at the higher moderator density condition, a set of material/Dancoff pairs are defined with the set identifier of 400. In the set, fuel material 11 has a Dancoff factor of 0.4, and fuel material 12 has a Dancoff factor of 0.5. The set of Dancoff factors is used for the five branch states through the specification of the *d2p=* keyword to 400.

```
READ branch

tf=559 dm=0.8 d2p=400 end
END branch
```

Fig. 3.1.6: Example BRANCH block input with Dancoff factors.

DEPLETION block

The *DEPLETION* block, used by the four depletion sequences, is simple in concept but performs four important functions. First, this block specifies the materials for which depletion calculations are to be performed. In general, it is desirable to perform depletion calculations only for fuel and target materials of interest. Calculating the depletion of gas gaps, cladding, moderator, or coolant is usually of little value unless the material contains components that will be significantly depleted with burnup. Additionally, it is not usually desirable to deplete soluble poisons in reactor coolants. Therefore, the *DEPLETION* block requires that the user specify the materials to be depleted. There are no defaults; hence, the block is required for all depletion sequences.

The second function of the *DEPLETION* block is to specify the basis to which the model power is normalized. In general, the average time-dependent power to which an irradiated object is exposed is known. For example, an LWR fuel assembly discharged from a reactor is known to have operated at certain power levels for one or more time periods. The individual pins in the assembly will have varying power levels depending on position and assembly design. In such a case, the basis for the input power is the full assembly. Fluxes computed in the transport solution will be normalized by TRITON based on reaction rates and energies **in all problem materials** (depleted and nondepleted materials) such that the assembly-wide power will match the power given in *BURNDATA* block. However, it is often the case in radiochemical assay analysis that the burnup history of a specific pin is known and isotopic concentrations for that pin are desired. It is still necessary to model the full assembly in order to properly characterize the fluxes in that pin. In such a case, it would be advantageous to specify the operating history for the pin instead of the full assembly. When this is done, the average specific power of the full assembly will be different from that of the pin and will be computed automatically based on power distributions calculated for the assembly. In other words, powers for other materials in the assembly will be normalized such that the power in the pin of interest matches that specified in the *BURNDATA* block. The material of that pin becomes the *basis* for power normalization.

Sect. 3.1.3.3.5 below describes the general format of the *DEPLETION* block that is available to all four depletion sequences. The third function of the *DEPLETION* block is an optional function used to specify ORIGEN solver options and ORIGEN depletion mode for each depletion material. These options are further described in Sect. Sect. 3.1.3.3.6. The fourth function of the *DEPLETION* block is to define optional deletion instructions used to simplify cross section processing using the ASSIGN function. Special provisions have been made in the 1D and 2D depletion sequence (T-DEPL-1D and T-DEPL) to reduce the number of cross section processing calculations in order to decrease calculation run-time. The ASSIGN functionality is further described in Sect. Sect. 3.1.3.3.7.

Basic DEPLETION block format

The basic format of the DEPLETION block is as follows:

```
READ depletion M1 M2 M3... Mn END depletion
```

where M_i represents the SCALE material numbers for materials to be depleted. As discussed above, the *DEPLETION* block can also be used to specify the basis for the input power. Power normalization is accomplished by prefixing the material number(s) with a negative sign (-). For example, consider a problem in which materials 1, 2, and 3 are being depleted, but the power for material 1 is known. The *DEPLETION* block for this case is

```
READ depletion
  -1 2 3
END depletion
```

In this case, powers for all materials will be normalized such that the power in material 1 matches the input power specification in the *BURNDATA* block.

Note that multiple materials can be used as a power basis. Consider a fuel assembly with three fuel types represented by materials 1, 2, and 3, and also containing cladding as material 4 and water as material 5. The following illustrates multiple ways that the power basis for this assembly might be specified and describes the effect of each specification.

- The assembly-averaged power is normalized to match the input specific power. Power generated by moderator and clad is included but they are not depleted.

```
READ depletion
  1 2 3
END depletion
```

- The assembly-averaged power is normalized such that the power of material 1 matches the input specific power.

```
READ depletion
  -1 2 3
END depletion
```

- The assembly-averaged power is normalized such that the average power in materials 1 and 2 matches the input specific power.

```
READ depletion
  -1 -2 3
END depletion
```

- The assembly-averaged power is normalized to match input specific powers. TRITON will attempt to do depletion in cladding and moderator materials too. (Note that cladding and moderator materials should be depleted using the deplete-by-flux option described in the next subsection).

```
READ depletion
  1 2 3 4 5
END depletion
```

- The assembly-averaged power is normalized such that the average power in materials 1–3 matches the input specific power. This is not the same as the normalizing specification for an assembly average, because it neglects contributions of, for example, (n, γ) sources in moderator and cladding materials.

```
READ depletion
  -1 -2 -3
END depletion
```

ORIGEN depletion options

ORIGEN provides two input options for the flux used in the depletion calculation: direct specification of fluxes (i.e., deplete by flux) or indirect specification of fluxes in terms of power (i.e., deplete by power). The ORIGEN depletion is based on a known flux; however, it is more often the case that one knows the specific power in a depletion region rather than the actual flux. When ORIGEN is used in deplete-by-power mode, ORIGEN will internally determine the corresponding flux from the input-specific power and internal tables of fission and capture energy releases for the nuclides present and the macroscopic cross sections of those nuclides. Additionally, at each ORIGEN time interval, ORIGEN recalculates the material power density as nuclide inventories change. Hence, the deplete-by-power mode will result in a time-varying flux, whereas the

deplete-by-flux mode will result in a constant flux over the calculation time interval. Since reactors typically operate at a constant (or nearly so) power level, with varying local fluxes, the deplete-by-power option is closer to reality. However, the choice of approach is generally not an issue. Significant differences between calculation results between the two depletion modes would indicate that the TRITON depletion subintervals are too large.

By default, all TRITON depletion materials use the deplete-by-power mode. However, there exist some circumstances where deplete-by-flux is more appropriate. In deplete-by-power mode, ORIGEN will often halt when an attempt to maintain constant power results in a large change in flux between ORIGEN time intervals. Large changes in flux can occur in media where isotope contents are changing rapidly with time, such as in a gadolinium-bearing burnable absorber rod, where gadolinium is being rapidly depleted with time. Another circumstance pertains to activation analysis of nonfuel materials. The flux for these materials is typically governed by external power sources (i.e., fuel materials located elsewhere in the problem domain) rather than by internal power sources. Therefore, the deplete-by-flux option is recommended for these materials.

TRITON provides the option to specify deplete-by-flux mode for selected depletion materials using a modified form of the depletion specification:

```
READ depletion M1 M2 M3...Mi-1 flux Mi Mi+1... Mn END depletion
```

Materials preceding the *flux* keyword are depleted using the deplete-by-power mode; materials following the flux keyword are depleted using the deplete-by-flux mode. For example, consider a problem in which materials 1–6 are to be depleted, but materials 3 and 4 represent nonfuel materials that do not contribute significantly to the total power and are therefore to be depleted assuming constant flux. The *DEPLETION* block for this situation could be specified as follows.

```
READ depletion 1 2 5 6 flux 3 4 END depletion
```

The DEPLETION block also supports the specification of the ORIGEN calculation method. The default option is solver=matrex, which represents the matrix exponential option. The other option is solver=cram, which represents the new CRAM solver option in ORIGEN. An example depletion specification for the cram solver is as follows.

```
READ depletion 1 2 5 6 flux 3 4 solver=cram END depletion
```

Cross section processing simplification using ASSIGN

When depleting a large number of fuel materials, considerable time may be spent in the cross section processing calculations prior to the multigroup transport calculation. Fuel assembly designs may require 20-200 unique depletion materials across the different fuel pins in the assembly. In such cases, an assembly model may require hours of run-time for each pin-wise cross section processing calculation in order to perform a 10-minute transport solution.

Although highly rigorous, such a cross section processing process is extremely burdensome for depletion calculations, especially if branch calculations are requested. To reduce run-time, the 2D depletion sequence (*T-DEPL*) provides the option to group depletion materials together such that they are tracked independently in the depletion calculation but use a common set of microscopic cross sections. The microscopic cross sections for a given depletion group are computed using the average composition of all the depletion materials within the group. Typically, this grouping is applied to fuel pins of identical initial composition. Although the nuclide number densities of such pins will diverge with burnup as a function of location within an assembly, the cross sections of these pins are well represented by a single pin cell calculation with an average composition representative of all these pins.

Although the material grouping option introduces approximations in the cross section processing calculations, which in turn affects the transport and depletion calculations, internal investigations have shown that solution accuracy can be maintained for a wide range of assembly designs while significantly improving the run-time.

The alternate format of the *DEPLETION* block for simplified cross section processing is as follows.

```
READ depletion M1 M2 M3... Mz END
assign N1 Ma Mb ... Mx end
assign N2 Mf Mg ... My end
...
assign Nn Mj Mk ... Mz end
END depletion
```

Similar to the basic format, each material designated for depletion (M_i) is listed after *READ* depletion and before the *END* keyword. Each designated depletion material must be present in the 2D NEWT model. After the first *END* keyword, the alternate format contains a list of material "assignments" used to simplify cross section processing for a group of depletion materials. The material assignments begin with the *assign* keyword and terminate with the *end* keyword. After the *assign* keyword, a unique representative material identifier (N_j) is defined. The representative material is associated with the group of depletion materials that immediately follows in the *assign* definition. The representative material identifier is used in the *COMPOSITION* and *CELLDATA* blocks to define the initial composition, temperature, and cell definition for the group of depletion materials. Thus, the *assign* definitions in *TRITON* are currently constrained such that each depletion material group must have the same initial composition. After the last *assign* definition, the depletion block is terminated with *END depletion*.

Only depletion materials may be assigned to representative materials. The group of depletion materials assigned to a particular representative material must **not** appear in the *COMPOSITION* and *CELLDATA* blocks.

The use of material assignments is best illustrated by an example. Fig. 3.1.7 shows a complete T-DEPL input that uses material assignments. A 2D plot of the model is shown in Fig. 3.1.8. In this example, two fuel materials are defined as materials 1 and 2 in the *COMPOSITON* block. In the *DEPLETION* block, the list of depletion materials includes materials 1, 20, 30, and 40. Depletion materials 20, 30, and 40 are "assigned" to representative material 2. Material 2 does not appear in the depletion list or the transport model; materials 20, 30, and 40 do. But only material 2 is defined in the *COMPOSITION* and *CELLDATA* blocks. In the transport model, four units are defined, one for each material. An array is used to place each unit in its own location.

The initial calculation uses material 2 to define the compositions of materials 20, 30, and 40, since all are initially identical. Microscopic cross sections computed for material 2 are used for each of the three assigned depletion materials during the transport calculation and the depletion calculation. After the first depletion calculation, materials 20, 30, and 40 will have different isotopic concentrations because of different locations in the nonsymmetric transport model. At this time, the number densities in each of these three materials are averaged and used to update the concentration of representative material 2. A new set of cell calculations will be performed for materials 1 and 2; this will be followed by a transport calculation that uses the microscopic cross sections for material 2 along with local nuclide number densities for materials 20, 30, and 40 to calculate new and unique macroscopic cross sections for each. The transport and subsequent depletion calculation are then run. The iterative process will continue until all depletion steps have been completed.

Fig. 3.1.7: Example input with material assignments.

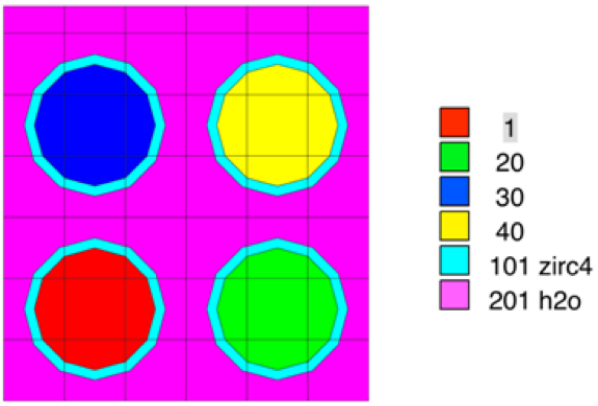

Fig. 3.1.8: Example 2D model plot of material assignments.

The use of assignments can make a considerable difference in run-time performance with minimal sacrifice in accuracy. The above example ran 1.8 times faster using the assignment of three similar pins to one initial specification. A larger BWR calculation, in which 41 pin positions were depleted independently, was run in an assessment of the accuracy of the method. Using this approach, the simplified representation ran 20 depletion steps in 20% of the time required for the explicitly modeled cells. Fig. 3.1.9 shows a comparison of the eigenvalues using the simplified (with assignments) and explicit (without assignments) models. Also shown on the figure is the percent difference between the approximate and explicit models. For this model, the error in k_{eff} remains well below 0.05%.

Note that one can combine depletion mode control with material assignments, as follows.

```
READ depletion 1 2 5 6
          flux 3 4 end
         assign 11 1 2 end
         assign 12 3 4 end
         assign 13 5 6 end
END depletion
```

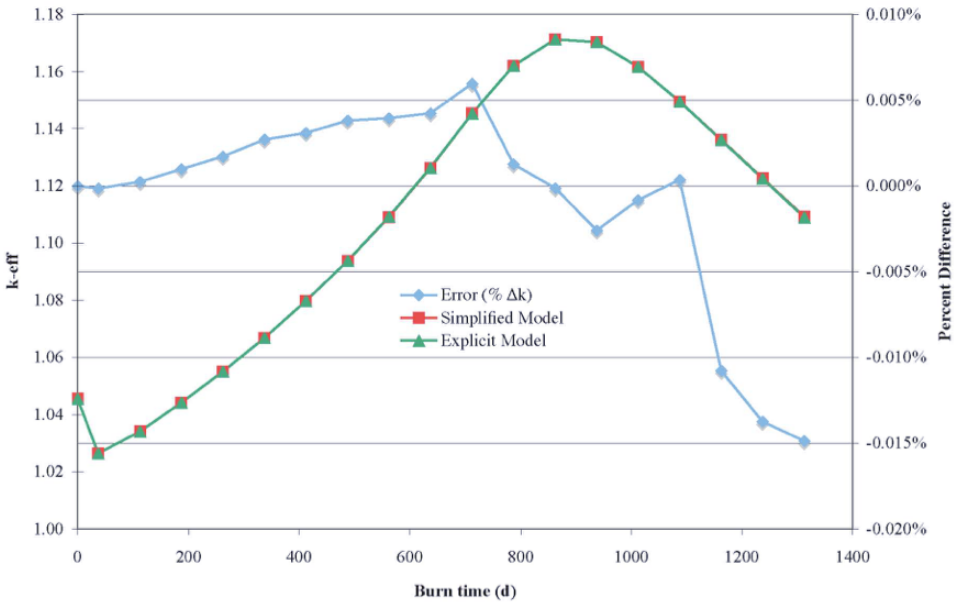

Fig. 3.1.9: Eigenvalue comparison of simplified cross section processing example.

TIMETABLE block

In many depletion analyses, material properties can change due to influences outside the depletion process (e.g., boron letdown in pressurized water reactors [PWRs], the insertion or removal of poisons during or between fuel cycles, or changes in temperatures of materials with time). The *TIMETABLE* block has been provided to allow modification of properties during a depletion calculation. Timetables may be entered for any material or for selected nuclides within a material and allow changes in number densities or temperatures. Timetables may also be entered to swap a material in and out of the geometry during depletion. Continuous feed and/or removal to/from mixtures during depletion can be enabled for analysis of systems with flowing fuel.

The *TIMETABLE* block takes the following general format.

```
READ timetable
[time dependent specifications for a given material]
[time dependent specifications for a given material]
[time dependent specifications for a given material]
END timetable
```

Four different material specifications are allowed to modify temperature, density, swap materials, or fractional removal/continuous feed of nuclides from/to materials.

Temperature and density

Temperature timetable entries are specified in the format

```
temperature I t1 K1 t2 K2 t3 K3...tC KC end
```

where

I = material ID number;

t_i = time (days) in calculation where temperature K_i is set, i = 1 to C;

K_i = temperature (in K) of specified materials at time t_i, i = 1 to C;

C = number of time steps.

Density entries have an analogous specification, with the addition of a couple of extra terms:

```
density  I  M N1 N2 N3 ... NM   t1 D1 t2 D2 t3 D3...tC DC end
```

where

I = material ID number;

M = number of nuclides to which this change is applied;

N_i = nuclide ID for the i_{th} nuclide in the list, i = 1 to M;

t_j = time (days) in calculation where density multiplier D_j is set, i = 1 to C;

D_j = density multiplier (fractional change) of specified nuclides at time t_j, i = 1 to C;

C = number of time steps.

In both formats, time and data (temperature or density multiplier) must be entered in pairs. Note that density changes may be applied to specific nuclides, while for temperature the change must be applied to all nuclides within the material simultaneously. If M (the number of nuclides for which the density is to be modified) is specified as 0 and no nuclide IDs are entered, then the timetable values are applied to all nuclides in the material.

Note that timetable entries are specified at distinct times in the calculation. These times are measured relative to the beginning of the calculation and are *continuous* (as opposed to *BURNDATA* entries, which give burn times or down times in increments per depletion interval). The initial timetable entry should always begin at t=0 days. To allow for time-dependent changes in properties, *TRITON applies linear interpolation between data pairs.* To hold a parameter constant over a time interval, that parameter should be specified at the same value at both the beginning and the end of this time interval.

The application of timetable entries is best illustrated by example. Consider the depletion scheme described by the following *BURNDATA* block which contains three depletion intervals:

```
READ burndata
power=26.54 burn=121.0 nlib=3 end
power=38.01 burn=201.5 down=30 nlib=2 end
power=31.44 burn=386.25 down=1826.25 end
END burndata
```

Assume that the moderator, material 3, has temperatures and boron concentrations that vary over the three depletion intervals in the following manner:

Interval	Boron concentration (ppm)		Temperature (K)
	BOC	EOC	
1	1000	100	615
2	1250	130	685
3	980	100	610

```
READ timetable
temperature 3
0.0     615
121.0   615
121.01  685
322.5   685
352.5   610
738.75  610 end
density 3 2 5010 5011
0.0     1.0
121.0   0.1
121.01  1.25
322.5   0.13
352.5   0.98
738.75  0.1 end
END timetable
```

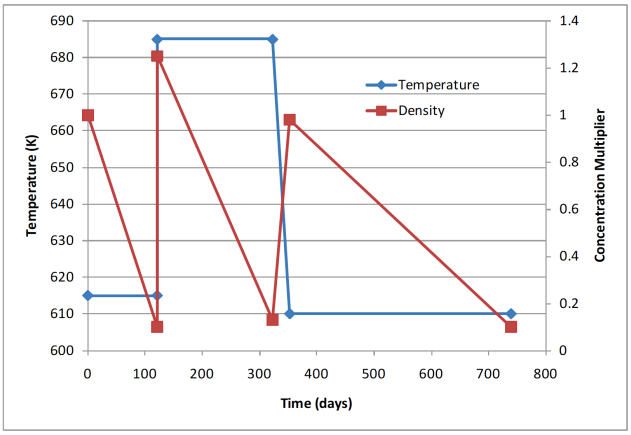

Fig. 3.1.10: Example temperature and density *TIMETABLE* block input.

Note: It is important to note that time-dependent changes to temperatures and number densities are not applied continuously over the depletion calculation, but instead are applied only at the times at which cross section processing and transport calculations are performed - that is, the midpoint of the depletion subintervals. *The user must determine the accurate depletion scheme specific to his or her application to accurately model time-dependent changes in system properties.*

Density timetable specifications can be used to effectively exchange compositions of a single material. One may construct a compound material comprised of two distinct materials at their design densities; a timetable specification can be used to set the density multiplier to 1.0 for the nuclides initially present and to use a multiplier of 0.0 for all nuclides in materials that are not intended to be present at time zero. The timetable can then affect the exchange by changing the multipliers from 0 to 1, and from 1 to 0, at the time of the material exchange. One must bear in mind that timetable processing within TRITON performs linear interpolation between time points; if the exchange is intended to occur at a specific moment in time, then the timetable should be set up with the exchange occurring within a very short period. Moreover, it is important to note that material exchanges for two materials that have common nuclides are more difficult to model. For example, a B_4C absorber material and borated H_2O moderator material both contain boron nuclides in common. In order to exchange the B_4C absorber material and the borated H_2O moderator material, the carbon, oxygen, and hydrogen density multipliers would be 0 or 1, but the boron density multipliers would need to be derived from the boron concentrations in both materials.

Material swap

Material exchange timetables offer another option to users to exchange one material with another material during depletion calculations.

Material exchange timetable has a similar format to temperature timetables:

```
swap I1 I2 t1 S1 t2 S2 t3 S3...tC SC end
```

where

I1 = first material ID

I2 = second material ID

t_j = time (days) in calculation where swap ID is set, i = 1 to C;

S_j = swap value 0/1 at time t_j, i = 1 to C;

C = number of time steps.

The first two entries in the timetable specify the material IDs for swap materials. The remaining entries are entered in pairs: the first pair value is a time value, the second pair value is either "0" or "1". "0" instructs TRITON to model the swap materials as defined in the nominal model. "1" instructs TRITON to swap the materials (swap every *I1* for every *I2* and swap every *I2* for every *I1*). The swap state persists until the next time entry in the timetable. For the last time entry in the timetable, the swap state persists for the duration of the calculation. For example:

```
read timetable
  swap 5 6  0 0  100 1  200 0 end
read timetable
```

- Do not perform the material swap on the interval [0, 100],
- Perform the material swap on the interval [100, 200], and
- Return to the nominal state at time 200 days until the duration of the calculation.

Depending on the *BURNDATA* specification, there may be one or more depletion/decay steps between timetable entries. Moreover, for accurate depletion modeling, material exchanges must not occur during a depletion subinterval. If a material exchange occurs during a depletion interval, TRITON will subdivide the depletion subinterval at the time of the material exchange. Extending the example above, assume the *BURNDATA* block is as follows:

```
read timetable
  swap 5 6  0 0  100 1  200 0 end
read timetable
read burndata
 power=40 burn=300 nlib=4 end
end burndata
```

Without the material exchange table, the depletion subintervals are [0, 75], [75, 150], [150, 225], and [225, 300]. With the material exchange table, the subintervals are:

- [0, 75] – Swap value is 0
- [75, 100] – Swap value is 0
- [100–150] – Swap value is 1, i.e. materials 5 and 6 swap definitions

- [150–200] – Swap value is 1, i.e. materials 5 and 6 swap definitions
- [200–225] – Swap value is 0, materials 5 and 6 return to their original definitions
- [225–300] – Swap value is 0

As a limitation of the material exchange timetable, if a depletion material is removed from the geometry, the isotope concentrations at the time of removal are stored in-memory, and then reused upon re-entry into the geometry. In other words, the depletion material does not undergo radioactive decay for the period of time outside the problem geometry.

Material flow

To allow modeling of systems with flowing fuel, TRITON offers a *FLOW* block which permits fractional removal and continuous feed from/to mixture. When this block is requested, TRITON makes use of ORIGEN's capability for feed and removal from/to mixtures, including the decay of nuclides removed from the system. Detailed information about the feed and removal to simulate flowing fuel can be found in [TRITONVBWF20], [TRITONBPW17], [TRITONBPBR17].

Eq. (5.1.1) from the ORIGEN part of the manual (Sect. 5.1.3) is as follows when explicitly adding a removal rate $\lambda_{i,rem}$ and acknowledging the feed rate S_i:

$$\frac{dN_i}{\mathrm{dt}} = \sum_{j \neq i} (l_{\mathrm{ij}} \lambda_j + f_{\mathrm{ij}} \sigma_j \Phi) N_j(t) - (\lambda_i + \lambda_{i,rem} + \sigma_i \Phi) N_i(t) + S_i(t) \tag{3.1.1}$$

where

- N_i = amount of nuclide i (atoms),
- λ_i = decay constant of nuclide i (1/s),
- $\lambda_{i,rem}$ = **removal constant** defining the continuous removal of nuclide i (1/s),
- l_{ij} = fractional yield of nuclide i from decay of nuclide j,
- σ_i = spectrum-averaged removal cross section for nuclide i (barn),
- f_{ij} = fractional yield of nuclide i from neutron-induced removal of nuclide j,
- Φ = angle- and energy-integrated time-dependent neutron flux (neutrons/cm^2-s), and
- S_i = time-dependent **source/feed term** (atoms/s).

The *FLOW* block can consider two scenarios: (1) continuous feed into a mixture and (2) fractional removal from one mixture into another. In the case of the continuous feed, the feed rate (source) must be specified by the user. In the case of the fractional removal of a nuclide from material 1 to material 2, the removal rate (removal constant) for material 1 is specified. The removed nuclides from material 1 are then considered as source for material 2.

The following *FLOW* block enables continuous feed of nuclides into a mixture:

```
read timetable
  flow
    to I2
    type continuous_feed
    units [pers or gpers]
    nuclides [N1 N2 ... NM] end
    rates    [R1 R2 ... RM] end
    time       [t1 t2 ... tC] end
    multiplier [f1 f2 ... fC] end
  end flow
end timetable
```

The following *FLOW* block enables fractional removal of nuclides from one mixture to another:

```
read timetable
  flow
    from I1 to I2
    type fractional_removal
    units [pers or gpers]
    nuclides [N1 N2 ... NM] end
    rates    [R1 R2 ... RM] end
    time       [t1 t2 ... tC] end
    multiplier [f1 f2 ... fC] end
  end flow
end timetable
```

The input parameters are as follows:

- I = mixture ID
- *from (to)* = identifier from which mixture nuclides are removed (from I1) and to which mixture they are added (to I2)
- *type* = type of addition or removal of nuclides from/to mixture:
  - *fractional_removal* requires *from* and *to*
  - *continuous_feed* requires *to* and does not permit *from*
- *units* = *pers* or *gpers* unit of the flow rate constant used:
  - for flow blocks with flow *from* a mixture *to* another mixture: pers (1/second)
  - only flow *to* a mixture: gpers (grams/second)
- M = number of nuclides to which change is applied
- N_i = nuclide ID for the i_{th} nuclide in the list, i = 1 to M
- R_i = rates for the i_{th} nuclide in the list, i = 1 to M
- t_j = time (days) in calculation where multiplier f_j is set, i = 1 to C, t1 must be 0.0
- f_j = multiplier to vary specified flow rate (based off the initial flow rate) at time t_j, i = 1 to C
- C = number of time steps.

If nuclides are transferred from mixture 1 into mixture 2, but mixture 2 is not part of the system (e.g., contained in a loop outside the reactor), then the decay of the nuclides in this mixture can still be considered by specifying keyword *decayonly* in the *DEPLETION* block.

The following is an example in which xenon is transfered from mixture 1 to mixture 2, and the decay of nuclides in mixture 2 is enabled in the *DEPLETION* block:

```
read depletion
-1 decayonly 2
end depletion

read timetable
  flow
   from 1
   to 2
   type continuous_feed
   units pers
```

(continues on next page)

(continued from previous page)

```
   nuclides    xe end
   rates     2e-2 end
   time       0.0 end
   multiplier 1.0 end
 end flow
end timetable
```

OPUS block

The OPUS module of SCALE is fully documented in the OPUS chapter of the SCALE manual. OPUS provides the ability to extract specific data from ORIGEN output libraries, perform unit conversions, and generate plot data for post-calculation analysis. In essence, OPUS is an ORIGEN post-processor that provides data in the desired form for a desired subset of nuclides. TRITON by default calls OPUS to extract nuclide concentrations for selected nuclides for all depletion materials and for the most important nuclides. TRITON provides the capability to specify the full set of OPUS commands to tailor OPUS calculations to obtain specific information. TRITON allows a stacked set of OPUS calculations in order to retrieve selected data for selected nuclides.

The content of the *OPUS* block is based on standard OPUS input parameters, as described in the OPUS chapter; the details of OPUS control and use are not repeated here. However, additional input is necessary to support TRITON operations with OPUS, because TRITON enables additional capabilities beyond those provided for in standard OPUS input. For example, OPUS is designed to process the output file from a single ORIGEN calculation; because ORIGEN is a point depletion solver, the output represents data from a single material. TRITON is typically used to perform multiple depletion calculations at each depletion step-one calculation for each material being depleted. Hence, multiple OPUS calculations are needed to obtain results from multiple materials. The OPUS calculations are performed automatically by TRITON but require the user to specify the materials for which OPUS processing is desired. Additionally, TRITON supports stacked OPUS cases within the *READ OPUS* data block; hence, keywords are introduced to separate stacked cases.

There are two alternatives available to SCALE users that are complimentary to the OPUS block within TRITON. First, standalone OPUS case(s) can be used to post process the ORIGEN binary concentration file (.f71 extension). This file is automatically saved in the output directory with the file name `${OUTBASENAME}.f71`. (e.g. if the input file is reactor.inp, the concentration file is saved in the output directory as reactor.f71) Second, the user may also open the concentration file within Fulcrum to enable similar post-processing capabilities.

Selection of materials for OPUS processing

Beyond standard OPUS input keywords (see OPUS chapter), TRITON reads a *matl*= keyword to allow specification of ID number(s) for the material(s) in the problem for which outputs are desired. The *matl*=. . . *end* input keyword accepts one or more materials from the *DEPLETION* data block for which OPUS processing is desired. If omitted, OPUS processing will be performed for all materials in the *DEPLETION* block. For example, consider the following *DEPLETION* and *OPUS* data blocks:

```
READ depletion 1 2 3 4 5 6 END depletion
READ opus
units=gram symnuc=u-234 u-235 u-236 u-238 pu-238 pu-239
pu-240 pu-241 pu-242 pu-243 np-237 end
time=year
END opus
```

In this example, OPUS processing will be performed for all depletion materials, 1–6. Adding a subset of materials using the *matl*= keyword, for example.

```
READ depletion 1 2 3 4 5 6 END depletion
READ opus
units=gram symnuc=u-234 u-235 u-236 u-238 pu-238 pu-239
pu-240 pu-241 pu-242 pu-243 np-237 end
time=year
matl=1 2 3 end
END opus
```

will result in OPUS calculations for materials 1, 2, and 3 only.

Although ORIGEN calculations are performed only for individual materials, TRITON provides the capability of combining the results of all or a subset of all depletion materials to get a multimaterial average set of ORIGEN responses. TRITON provides two special ID numbers for combining material results. Specification of material ID 0 will return system-averaged results for the entire set of depletion materials (typically, all fuel elements in a depletion model). Specification of material -1 returns the average of only those materials with ID > 0 present in the *matl*= list. Again, this is best illustrated by example. Specification of the data blocks

```
READ depletion 1 2 3 4 5 6 END depletion
READ opus
units=gram symnuc=u-234 u-235 u-236 u-238 pu-238 pu-239
pu-240 pu-241 pu-242 pu-243 np-237 end
time=year
matl=1 2 3 0 -1 end
END opus
```

will result in five OPUS calculations and five sets of results-one for each of materials 1, 2, and 3, one for the average of materials 1–6 (due to input of material ID 0), and one for the average of materials 1–3 (due to input of material ID –1).

Specification of stacked OPUS cases

In a given calculation, multiple output units may be desired (e.g., grams, curies, and watts), or multiple time scales (e.g., seconds and years), or a combination of these or other parameters. TRITON provides the ability to stack inputs such that multiple cases may be run within a single TRITON calculation. In order to stack cases, the keywords *new case* are entered in the input stream. Any parameters following these keywords are used to define a new OPUS case.

There is no limit on the number of stacked cases that may be input; however, the *matl*= specification may be used only in the first case. OPUS calculations are run for each of the materials in this list, for all cases.

Consider a depletion calculation where gadolinium pins are present in the assembly design. One may wish to determine the quantities of gadolinium nuclides from the initial poison rods (tracked as a light element by ORIGEN within TRITON) and from fission (tracked as a fission product by ORIGEN). One may also need masses of selected actinides as well as the total (α,n) reaction rate. Fig. 3.1.11 shows how the *new case* keyword set is used to define unique OPUS calculations. In this example, the *new case* keywords are shown in upper case and on a line by themselves, but this has been done only for readability. The text may be entered in lower case and on the same line as other keywords. Note, however, that the *matl*= specification is given only in the first case. All OPUS calculations will be performed for materials 1, 2, and 3 and for the average of these three materials.

```
READ opus
  matl=1 2 3 -1 end
  units=grams  time=year  typarms=nucl  libtyp=lite

```

Fig. 3.1.11: Example OPUS block input.

FGXS block

The 3D TRITON depletion sequences which use Shift in CE mode for the transport calculations (T5-DEPL-Shift, T6-DEPL-SHIFT) provide the capability to generate lattice-physics data for nodal core calculations based on complex 3D geometries. The use of CE data avoids any approximations due to MG cross section processing and it allows the generation of nodal data in arbitrary group structures.

The generation of nodal data in a TRITON-Shift input is requested through the *FGXS* block. The general input format of this block is as follows:

```
read fgxs
    energy       id=<NUM> <E0> <E1> ... <EN> <EN+1> end
    <tallytype>  id=<NUM> [options]
    shape <type> id=<NUM> [dimensions]
  [ mesh <type>  id=<NUM> [definition] ]
end fgxs
```

- **id**: Integer identifier of the requested nodal data set. Multiple sets of data can be requested, and the id allows the association of parameters to one specific set.
- **energy**: Energy group boundaries [eV] in increasing order, including the uppermost and lowermost boundaries. For an N-group structure, N+1 boundaries need to be provided.
- **<tallytype>**: The type of requested tally. The only supported type is currently *tallyset t16* to request the full set of nodal data.
- **shape**: Either the name of one of the permitted cell shapes [*cuboid*, *rhexprism*] or keyword *global* to request data on a mesh over the entire geometry. The use of *global* requires a *mesh* record. All dimensions are provided in cm.

- **mesh**: Gobal mesh definition in case of a *global* shape. See details below.

Global energy and tallytype definition

If multiple sets of nodal are requested within one *FGXS* block, and if the same type of tally in the same energy group structure is desired for *all* tallies, a global *energy* definition and the *tallytype* can be defined. The energy and tallytype id can be set to 0 (*id=0*) and is then valid for all other defined tallies. The energy and tallytype definition can then be skipped for the individual tallies (see Example 5 below).

Shapes

The supported shapes follow the following input syntax:

1. **cuboid**:

```
shape cuboid id=<NUM> <xmax> <xmin> <ymax> <ymin> <zmax> <zmin>
```

2. **rhexprism**:

```
shape rhexprism id=<NUM> hpitch=<hpitch> <zmax> <zmin> origin x=<x0> y=<y0>
```

3. **global**:

```
shape global id=<NUM>
```

with the following parameters:

- *<xmax>, <xmin>, <ymax>, <ymin>, <zmax>, <zmin>*: minimum and maximum x-, y-, or z-coordinates [cm]
- *hpitch=<p>*: half-pitch [cm] in case of the hexagon
- *origin x=<x0> y=<y0>*: coordinates in the global unit coordinate system for the center of the defined shape [cm]

Meshes

Global meshes are superimposed over the entire geometry. The half pitches of the mesh needs to be provided, the origin of the mesh (the origin of the central mesh cell), and the axial discretization.

At this point, only square lattices and **rotated** hexagonal lattices are supported:

1. **square**:

```
mesh square id=<NUM> hpitch=<p> origin x=<x0> y=<y0> dz <z1> ... <zM> end
```

2. **hexagonal**

```
mesh hexagonal id=<NUM> hpitch=<hpitch> origin x=<x0> y=<y0> dz <z1> ... <zM> end
```

with the following parameters:

- *hpitch=<p>*: half-pitch of the lattice [cm]
- *origin x=<x0> y=<y0>*: <x0> and <y0> are coordinates in the global unit coordinate system in which to place the center of a lattice element [cm]. Lattice elements are repeated in the negative-x, negative-y, positive-x, and positive-y directions to fill the global unit.

- *dz <z1> ... <zM>*: definition of the relative axial mesh widths. Each <*zi*> value must be positive, and the sum of all <*zi*> values must be 1.0. M entries in the dz-list will create M axial zones. The axial zone boundaries is determined by the relative mesh widths and the bottom and top axial boundaries of the global unit.

Output

On overview of the requested nodal data is provided in the output file:

```
================================================================================================
Nodal FGXS Tally Summary
================================================================================================

  Tally ID=30
    tally spatial type: MESH
    tally boundary: RHEXPRISM
    energy grid: 2e+07,0.625,1e-05
    volume mesh inscribed radius: 0.500000
    volume mesh center: -0.288675,-0.5
    volume mesh planes z: -1e-06,0.9,1
    volume tallies: absorption,fission,flux,kappa_sigma,nu_delayed_fission,nu_fission,transfer_1n,transfer_2n,
↪transfer_3n,transfer_4n
    volume tallies on isotopes (nuclide id/reaction mt): 1001/18, ... , 96245/1018
    fine energy grid: 2e+07,... , 1e-05
    fine energy grid volume tallies: flux,absorption,fission,transfer_1n,transfer_2n,transfer_3n,transfer_4n
    volume tally name (shift): mesh_nodal_tally_t16_30
    num tally energy groups: 2
    num tally mesh rings: 2
    num tally fine energy groups: 1000

  Tally ID=40
   ...
```

The t16 output file names are composed of the ${BASENAME} of the input file, the tally id, the mesh ids in case of global meshes, and they have the ending t16.

Example 1:

The following block requests nodal data in a cuboid within the interval *x=[2, -5]*, *y=[8, -5]*, *z=[2.5, 0]*.

```
read fgxs
  energy          id=1 1e-5 0.625 20E6 end
  tallyset t16    id=1
  shape cuboid    id=1 2 -5 8 -5 2.5 0
end fgxs
```

One output file with name *$ {BASENAME}.id1.t16* will be generated.

Example 2:

The following block requests nodal data in a rotated hexagon with half pitch of 1.25 cm, in the axial zone *z=[2,-2]*. The center of the hexagon is located at *(x,y,z) = (10.0, 0.5, 0.0)*.

```
read fgxs
  energy          id=2 1e-5 0.625 20E6 end
  tallyset t16    id=2
  shape rhexprism id=2 1.25 2.0 -2.0 origin x=10 y=0.5
end fgxs
```

One output file with name *$ {BASENAME}.id2.t16* will be generated.

Example 3:

The following block requests nodal data in a square lattice that stretches over the entire geometry. The half pitch of the square lattice is 0.8 cm and the origin is at (x,y) = (0,0). Nodal data is requested for 2 axial zones of equal height.

```
read fgxs
  energy          id=3 1e-10 0.625 20e6 end
  tallyset t16    id=3
  shape global    id=3
  mesh square     id=3 hpitch=0.8 origin x=0 y=0 dz 0.5 0.5 end
end fgxs
```

Multiple files named *$ {BASENAME}.id3-<x>-<y>-<z>.t16* will be generated.

Example 4:

The following block requests nodal data in a rotated hexagonal lattice that stretches over the entire geometry. The half pitch of the hexagonal lattice is 0.5 cm and the origin is at (x,y) = (-0.288675,-0.5). Nodal data is requested in two axial zones, the lower zone stretching over 90% of the geometry, the upper zone covering the upper 10% of the geometry.

```
read fgxs
  energy         id=4  1E-5 0.625 20E6 end
  tallyset t16   id=4
  shape global   id=4
  mesh hexagonal id=4 hpitch=0.5 origin x=-0.288675 y=-0.5 dz 0.9 0.1 end
end fgxs
```

Multiple files named *$ {BASENAME}.id3-<ii>-<jj>-<kk>.t16* will be generated. The output files contains an overview of all file names with the corresponding (x,y)-origin of the cells and the axial range. A visual representation of the mesh superimposed on the geometry indicates the centrl cell and the cells for which nodal data was generated.

#### mesh origin cell
**** tally cells
<II> cell column/x-index
<JJ> cell row/y-index
```

Example 5:

The following block requests three sets of nodal data for different cuboids. The energy group definition and the tallyset are only defined once and apply to all defined tallies.

```
read fgxs
  energy       id=0 1e-5 0.625 20E6 end
  tallyset t16 id=0
  shape cuboid id=10 1.0 -1.0 5.0 -5.0 1.0 0.1
  shape cuboid id=20 2.0 -2.0 6.0 -6.0 2.5 1.2
  shape cuboid id=30 3.0 -3.0 7.0 -7.0 5.0 2.0
end fgxs
```

TALLIES and DEFINITIONS block

Since SCALE 6.3, a *TALLIES* input block and a *DEFINITIONS* input block can be used with CSAS-Shift and TRITON-Shift for flexible definition and output control of mesh tallies. The mesh responses for neutron flux, the neutrons produced from fission, and the fission rate (new since 6.3) can be requested on different spatial and energy grids. The syntax is very similar to the corresponding blocks used in the MAVRIC sequence.

The input parameters previously used to request these responses (i.e., *gfx*, *cds*, and *fis*) are still permitted in SCALE 6.3, but it is recommended to use the new input. The new input further permits the mesh tally responses based on different spatial grids and energy grids within one calculation, whereas previously only one spatial and energy grid was permitted per calculation.

DEFINITIONS BLOCK

The new definitions input block allows multiple spatial grids to be defined using the *gridGeometry* keyword and multiple energy grids to be defined using the *energyBounds* keyword. The syntax for defining a *gridGeometry* inside a definitions block is the same as defining a standalone grid at the root level of input (see Sect. 8.1.3.14). The syntax for defining *energyBounds* is already used for defining energy grids in the MAVRIC sequence (see Table 8.2.12).

In addition to specifying a list of individual energy group boundaries, equal-width energy bins and equal-width lethargy bins can also be requested. In continuous-energy mode, a special *default* keyword allows modification of the default energy group structure previously defined with the *NGP* parameter and/or the standalone energy block. For example, TRITON-Shift can use these *energyBounds* to tally flux and cross sections for depletion calculations.

The following examples demonstrate how the *DEFINITIONS* block in TRITON is used.

```
read definitions

  read grid 1
      xlinear 30 -10 70
      ylinear 10 -20 60
      zlinear 50 -30 40
  end grid

  read grid 2
      numxcells=10 xmin=-18.5 xmax=+68.5
      numycells=25 ymin=-28.5 ymax=+58.5
      numzcells=10 zmin=-38.5 zmax=+48.5
  end grid

' global energy grid, default is 252g in CE mode, but can be modified here
  energyBounds default
      bounds 2e7 0.625 1e-5 end
  end energyBounds

' user specified energy grid
  energyBounds 1
      bounds 2e7 0.625 1e-5 end
  end energyBounds

' user specified energy grid using equal-energy bins
  energyBounds 2
      linear=10 1e-5 2e7
  end energyBounds

' user specified energy grid using equal-lethargy bins
  energyBounds 3
      logarithmic=10 1e-5 2e7
  end energyBounds

end definitions
```

TALLIES BLOCK

The new tallies input block allows mesh responses to be requested using any energy grid and/or spatial grid from the definitions block. TRITON-Shift also allows specifying a time input array to enable or disable these mesh tally responses for specific depletion steps. The last depletion step may be conveniently requested using the special *LAST* keyword, and the special *ALL* keyword may be used to request the tally for every depletion step.

Description	SCALE 6.2 parameter name	SCALE 6.3 parameter name
neutron flux	GFX	flux
fission rate	FIS	fission_density
neutrons produced from fission	CDS	fission_source

The following examples demonstrate how the *TALLIES* block in TRITON is used.

```
read tallies

  read mesh 1
      response = FLUX
      grid     = 1
      time       0 LAST end
      energy   = 1
  end mesh

  read mesh 2
      response = FISSION_DENSITY
      grid     = 2
      time       0 1 2 end
      energy   = 2
  end mesh

  read mesh 3
      response = FISSION_SOURCE
      grid     = 3
      time       ALL end
      energy   = default
  end mesh

end tallies
```

3.1.3.4 *ALIAS* block

The optional *ALIAS* block may be used to simplify model development within TRITON by defining a set of material numbers that will be inserted in place of the alias when that alias is used in subsequent data blocks. Aliases function as variables for which a user-defined set of materials are inserted; they are identified by a dollar character ($) preceding a single-word alphanumeric label. The *ALIAS* block is used to preprocess an input, creating a new, modified input deck with all alias variable substitutions included. TRITON then processes the modified input deck before proceeding with the calculation.

The use of an alias variable is best illustrated by a brief example. Assume that the alias `$fuel` is defined as materials 1, 2, and 3, and `$mod` as materials 4, 5, and 6. (The input format for defining aliases is described below.) The user wishes to create three identical sets of materials and use them in three identical pin cell specifications. In the *COMPOSITION* data block, specifications could be written in the following form

```
h2o $mod den=0.6616 1.0 595 end
wtpt-boron $mod 0.6616 1 5000 100 655e-6 595 end
```

TRITON would create a modified input with the alias expanded as follows:

```
uo2  1 den=10.29 0.9322 920 92235 3.0 92238 97.0 end
uo2  2 den=10.29 0.9322 920 92235 3.0 92238 97.0 end
uo2  3 den=10.29 0.9322 920 92235 3.0 92238 97.0 end
h2o 4 den=0.6616 1.0 595 end
h2o 5 den=0.6616 1.0 595 end
h2o 6 den=0.6616 1.0 595 end
wtpt-boron  4 0.6616 1 5000 100 655e-6 595 end
wtpt-boron  5 0.6616 1 5000 100 655e-6 595 end
wtpt-boron  6 0.6616 1 5000 100 655e-6 595 end
```

Similarly, if the alias were used in the *CELLDATA* block as

```
latticecell squarepitch pitch=1.26 $mod fuelr=0.4095 $fuel end
```

then TRITON would expand the aliases to

```
latticecell squarepitch pitch=1.26 4 fuelr=0.4095 1 end
latticecell squarepitch pitch=1.26 5 fuelr=0.4095 2 end
latticecell squarepitch pitch=1.26 6 fuelr=0.4095 3 end
```

In a depletion calculation, one may wish to deplete a large number of fuel rods independently because of different geometric locations in a fuel assembly. Even though each fuel rod may have the same initial composition, each must be specified as a unique material composition in order to be depleted independently. Furthermore, multiple cell specifications must all use unique material identifiers for each cell component. Thus, if one desired to deplete 25 fuel materials in a fuel/clad/moderator pin cell, one would need to set up material composition definitions for 25 fuels, 25 moderators, and 25 clads. Then one would need to provide 25 pin cell specifications. By using aliases, one need only specify the material identifiers corresponding to each alias and then provide only one material composition specification for each alias type, and then one pin cell specification. TRITON will automatically expand the aliases and create a revised input with all materials and cell specifications explicitly defined.

Note: Note that although this will simplify the pin cell input in the CELLDATA, 25 pin cell calculations would still be required. The number of pin cell calculations can be reduced by using the ASSIGN function described in Sect. 3.1.3.3.7.

The purpose of the *ALIAS* block is to define a set of alias variables to be used in subsequent data blocks. The *ALIAS* block is optional, but aliases may not be used in other blocks if an *ALIAS* block is not present to define the aliases. An *ALIAS* block may contain as many aliases as desired. Each alias specification consists of three parts: the alias name, consisting of a dollar sign followed by up to 11 alphanumeric characters with no embedded spaces; the material number or numbers; and an *end* keyword. Material numbers may be entered in any order and may be separated by spaces or commas (or both). Material numbers may also be separated by a dash (-), but this represents an inclusive list. In other words, a material specification of 1-3 (or 1 - 1) indicates materials 1, 2, and 3. The example *ALIAS* block below illustrates the various means for assigning a set of materials for an alias definition.

```
read alias
$fueltype1 1 2 3 end
$fueltype2 4,5,6, 31-33 end
$clad1 21,22,23 end
$clad2 24 25 26 34-36 end
$mod1 11    -   13 end
$mod2 14-16, 37-39 end
end alias
```

The *ALIAS* block simply serves to assign material identifiers to specific variables, and the variables are used in subsequent data blocks. The same material identifier can be used in more than one alias if desired. As indicated earlier, TRITON will preprocess any input deck containing an *ALIAS* block and replace instances of alias variables with the appropriate material identifiers. The following subsections describe how aliases are implemented in TRITON's various input blocks, as the form of alias variable substitution is block dependent. Aliases are processed only in these input blocks; aliases used in other blocks will result in an error.

COMPOSITION *block aliases*

The *COMPOSITION* block uses aliases to create multiple copies of each standard composition specification, replacing the alias variable with each material identifier associated with the alias definition. For example, consider the following alias definition in an *ALIAS* block:

```
read alias
$fuel 1 2 10 end
end alias
```

and the standard composition specification:

```
uo2 $fuel den=10.045 1 800 92235 2.5 92238 97.5 end
```

A modified TRITON input would be created with the standard composition specification replaced by

```
uo2  1 den=10.045 1 800 92235 2.5 92238 97.5 end
uo2  2 den=10.045 1 800 92235 2.5 92238 97.5 end
uo2 10 den=10.045 1 800 92235 2.5 92238 97.5 end
```

CELLDATA *block aliases*

CELLDATA block *latticecell* specifications typically contain more than one material; therefore, multiple aliases are permitted in each cell specification. However, this constrains the set of aliases used in the cell specification to have the same number of material identifiers associated with it.

Consider the *ALIAS* block:

```
read alias
$fuel 1-3 10 end
$clad 4,5,6,11 end
$mod 7 8-9 12 end
end alias
```

All three aliases contain four materials each. One could then create a single cell specification that uses one or more of these alias variables, such as

```
latticecell squarepitch pitch=1.26 $mod fuelr=0.41 $fuel cladr=0.50 $clad end
```

This would result in the following alias expansion by TRITON:

```
latticecell squarepitch pitch=1.26  7 fuelr=0.41  1 cladr=0.50  4 end
latticecell squarepitch pitch=1.26  8 fuelr=0.41  2 cladr=0.50  5 end
latticecell squarepitch pitch=1.26  9 fuelr=0.41  3 cladr=0.50  6 end
latticecell squarepitch pitch=1.26 12 fuelr=0.41 10 cladr=0.50 11 end
```

Material identifiers are substituted according to their position in the alias definition (i.e., the first substitution will use the first material associated with each alias, and the second expansion will use the second material associated with each alias, etc.)

Material numbers should not be entered manually in a cell specification; for example,

```
latticecell triangpitch pitch=1.26 $mod fuelr=0.4095 1 end
```

TRITON would allow this to occur and would create a set of cell specifications as follows:

```
latticecell triangpitch pitch=1.26 2 fuelr=0.4095 1 end
latticecell triangpitch pitch=1.26 3 fuelr=0.4095 1 end
```

where $mod was defined as materials 2 and 3. However, SCALE does not allow the same material identifier to occur in two different cell specifications, and the fact that material 1 occurs in two different cell specifications would result in TRITON ending with an error. *Note that alias expansions for* **multiregion** *and* **doublehet** *cell specifications are not supported. Also note that TRITON will not copy* **centrmdata** *and* **moredata** *specifications that follow a cell specification that uses an alias variable.*

DEPLETION *block aliases*

Aliases in the TRITON *DEPLETION* are simply replaced by the set of materials associated with the alias. For example, the *ALIAS* block

```
read alias
$fuel 1 2 10 end
end alias
```

and DEPLETION block

```
read depletion 7 8 9 $fuel end depletion
```

would be expanded to

```
read depletion 7 8 9 1 2 10 end depletion
```

Aliases may be mixed with actual material numbers in the depletion block, along with the flux and assign keywords. *However, the negative sign-used to define the basis for power normalization-cannot precede an alias definition.*

TIMETABLE *block aliases*

TIMETABLE block alias expansion is similar to that of the *COMPOSITION* block: TRITON will create a new timetable entry for each material associated with the alias used in the *TIMETABLE* definition. For the *TIMETABLE* block below, using the alias *$ allmod*, unique timetables will be created for each material identifier associated with this alias variable.

Note: Note that alias expansion of **density** timetable entries is not yet supported.

```
read timetable
temperature $allmod
0.0    615
121.0  615
121.01 685
322.5  685
352.5  610
738.75 610 end
end timetable
```

BRANCH *block aliases*

Aliases may be used within the *define* keyword definitions of the *BRANCH* block. Aliases are simply replaced by the list of materials associated with the alias, as is done for the *DEPLETIO*N block. Hence,

```
read alias
$fuel 1 2 10 end
end alias
```

used with

```
read branch
define fuel $fuel end
md=0.75 tm=559 tf=880 sb=0.0 cr=0 end
tf=1600 end
end branch
```

would be expanded to

```
read branch
define fuel 1 2 10 end
md=0.75 tm=559 tf=880 sb=0.0 cr=0 end
tf=1600 end
end branch
```

NEWT MATERIAL *block aliases*

The *MATERIAL* block within the NEWT model section of a TRITON input can also use aliases. As with *COMPOSITION* and *TIMETABLE* entries, TRITON will create a new material specification for each material represented by an alias. For the sample material block below, using the alias *$ fuel*, unique material block entries will be created for each material associated with the alias variable.

```
read materials
mix=$fuel pn=1  com="3.25 wo uo2 fuel" end
mix=21    pn=1  com="zirc cladding"    end
mix=31    pn=1  com="water"            end
end materials
```

If an alias were defined as

```
$fuel 10 11 12 end
```

then the *MATERIAL* block would be expanded to

```
read materials
mix=10 pn=1  com="3.25 wo uo2 fuel" end
mix=11 pn=1  com="3.25 wo uo2 fuel" end
mix=12 pn=1  com="3.25 wo uo2 fuel" end
mix=21    pn=1  com="zirc cladding"    end
mix=31    pn=1  com="water"            end
end materials
```

KEEP_OUTPUT *block*

When performing depletion calculations for a number of different materials, TRITON output can become quite voluminous. Often, much of that output is not needed for calculations that seek only eigenvalues, sources, or concentrations as a function of irradiation history. TRITON provides the ability to trim output to only those portions for which output is desired. Output produced directly by the TRITON module is always provided and cannot be disabled, but output from any other code in the sequence can be automatically removed from the output listing. Retaining certain output is accomplished using the *KEEP_OUTPUT* data block.

The *KEEP_OUTPUT* data block provides the ability to preserve only selected outputs. The format of this data block is

```
read keep_output
module_1 module_1 ... module_i ... module_N
end keep_output
```

where `module_i` represents any valid module name from the list of modules invoked by TRITON, as listed here:

xsproc xsdrn newt kenova kenovi couple origen

Without the *KEEP_OUTPUT* data block, the output from the neutron transport kernel (xsdrn, newt, kenova, kenovi) is retained and the output of all other modules (xsproc, couple, origen) is suppressed. Note that the output of SAMS and OPUS is not controlled by this block; the output of these modules is always retained.

If a *KEEP_OUTPUT* data block is included, then only the output of the specified modules is retained. If the output of the neutron transport kernel is desired, then the corresponding module has to be listed since the above mentioned default is no longer applicable. A *KEEP_OUTPUT* data block without any module name can be specified to suppress the output of all modules.

When using the TRITON-Shift sequence, the generation of Shift's HDF5 output files can be controlled through a time array in the *KEEP_OUTPUT* output. The special keywords "ALL" for all depletion steps and "LAST" for the last depletion step are supported.

Examples:

1. Only the output of the neutron transport kernel is retained:

The input does not contain a KEEP_OUTPUT data block.

2. Only the XSProc output is retained; the output of the neutron transport kernel is suppressed:

```
read keep_output
  xsproc
end keep_output
```

3. The output of both XSProc and the neutron transport kernel KENO-VI is retained:

```
read keep_output
  xsproc kenovi
end keep_output
```

4. The output of all modules is suppressed:

```
read keep_output
end keep_output
```

5. Shift's HDF5 output files are requested for the first, second and last depletion step:

```
read keep_output
  shift 0 1 LAST end
end keep_output
```

3.1.3.5 TRITON control parameters

TRITON supports the following of control parameter options:

parm= CHECK, CENTRM, 2REGION, XSLEVEL=N, WEIGHT, WEIGHT=N, ADDNUX=N, INFDCUTOFF=X, CXM=N, MAXDAYS=N

If an invalid control parameter option is specified, including misspelled keywords, an error message will be generated and execution terminated. TRITON also provides the ability to nest several control parameter keywords together; to combine keywords (where appropriate), a list may be entered, enclosed in parentheses, and separated by commas. For example, to specify CHECK, 2REGION, and ADDNUX=1 at the same time, input would begin with

```
=t-depl  parm=(check, 2region,addnux=1)
```

The following subsections provide more detail on each of the control parameters listed above.

Check mode: parm=check

Specification of *parm=check* will request that TRITON read all input and ensure that no input errors are present, without running additional calculations. In this mode, all input is set up as if a full calculation will be run, but the sequence exits without any functional module execution. The check mode is useful for debugging or obtaining processed standard composition data, without actually running a calculation. It can also be used to generate plot files for embedded NEWT and KENO inputs for additional review and checking of input specifications. Of course, some errors may be uncovered only by dynamically executing the functional modules; hence, there are rare occasions where a *parm=check* run will complete with no errors but will fail when run outside of check mode as the problem begins to run.

Multigroup cross section processing options

The most common use of *parm=* sequence control is in the selection of an alternate multigroup cross section processing mode.

By default, XSProc enables both the BONAMI and CENTRM modules for cross section processing. BONAMI-only XSProc calculations can be performed using the control parameter *parm=bonami*.

TRITON also supports the control parameter *parm=(xslevel=N)*. The *xslevel* parameter option initializes various CENTRM options for the XSProc calculations. The *xslevel* option is equivalent to initializing all unit cell calculations with the following *centrmdata* specifications:

```
parm=(xslevel=1):
centrmdata
  npxs=5 nfst=0 nthr=3 nmf6=-1 alump=0.3 demin=0.125 pmc_omit=1 pmc_dilute=5.0e5
end centrmdata
parm=(xslevel=2):
  centrmdata npxs=5 nfst=0 nthr=3 nmf6=-1 end centrmdata
```

(continues on next page)

(continued from previous page)

```
parm=(xslevel=3):
   centrmdata alump=0.3 demin=0.125 pmc_omit=1 pmc_dilute=5.0e5 end centrmdata
parm=(xslevel=4):
   [no centrmdata statement]
```

The option *parm=(xslevel=4)* is equivalent to *parm=centrm*. The option *parm=(xslevel=3)* is the default for depletion sequences and is equivalent to *parm=centrm* but with some minor approximations to decrease run time. The option *parm=(xslevel=2)* is equivalent to *parm=2region* for all sequences.

Note that the *xslevel=1* and *xslevel=3* options have additional specifications for keywords *alump*, *demin*, *pmc_omit*, and *pmc_dilute*. These keywords are further discussed in the XSProc chapter. The additional keyword specifications are used to decrease run-time for the CENTRM and PMC calculations. Internal investigations have shown that the approximations introduced by the additional keyword specifications have minimal impact on solution accuracy for a wide range of calculations. Therefore the additional keyword specifications are used by default for depletion calculations, where several CENTRM and PMC calculations are necessary. The additional keyword values are not used by default for nondepletion calculations to be consistent with the SCALE CSAS5 and CSAS6 criticality sequences.

***Creating a broad group library:* parm=weight, parm=(weight=N)**

Used in tandem with the TRITON T-NEWT sequence, the specification *parm=weight* extends the sequence by setting up and executing the MALOCS2 module to generate a weighted broad-group cross-library (AMPX master format). The spectrum generated in the NEWT transport calculation is used as the weighting function for the collapse. Additionally, the broad-group library energy structure is defined by the NEWT *COLLASPE* block.

The *parm=weight* option uses the problem-averaged flux spectrum for the weighting function in the collapse. The problem may be a simple pin cell or a full assembly. However, there may be cases where the flux in a specific region or material is most appropriate for the spectral collapse. TRITON allows identification of a specific material from which the collapsing spectrum should be used. When specified in the form *parm=(weight=N)*, the average flux determined for material N is used in place of the total domain spectrum to perform the collapse.

TRITON sample problem 1 (Sect. 3.1.6.1) provides an example of the use of T-NEWT to produce a new broad-group library. Note that the broad-group library produced in this calculation will reside in the SCALE temporary working directory with the name *newxnlib* at the end of the calculation. If the library will be needed for future calculations, the user should use a shell script to copy the library back to a more permanent location, and perhaps give it a more meaningful name. In sample problem 1, the SCALE 252-group master library is collapsed to 56 energy groups.

The process for creating a broad-group master library is also supported in the 2D depletion sequence T-DEPL. When *parm=weight* or *parm=(weight=N)* is specified in a depletion calculation, the input cross section library must be one of the SCALE 238-group or 252-group libraries, which will automatically be collapsed to the SCALE 49-group or 56-group structure, respectively. An initial fine group calculation is performed for the input configuration, and the flux from the solution is used to create the broad group library. The initial calculation is then repeated with the new broad group library, followed by the remainder of the depletion calculation. *Note that for lattice physics calculations, the NEWT* COLLAPSE *block will be based on the 49-group (or 56-group) energy structure, not the fine group structure.*

It is important to note that the 252-group library contains intermediate resonance parameters and other data that cannot be accurately collapsed into 56-group data with the collapsing procedures available in MALOCS2.

These parameters are important for bonami-only cross section processing calculations, i.e., *parm=bonami*. Therefore, the *parm=centrm* option is recommended for follow-on application of the collapsed 56-group collapsed library. The 238-group and 49-group libraries do not contain intermediate resonance parameter data, and bonami-only processing is available, provided that this cross section processing option and group structure is suitable for the intended application.

Inclusion of additional nuclides for depletion: **parm=(addnux=N)**

For depletion calculations, it is important to add trace quantities (1×10^{-20} at/b-cm) of certain nuclides to the inventories of depletion materials in order to accurately track the nuclides' impact on cross section processing and transport calculations as a function of burnup. By default, TRITON automatically adds to all fuel materials trace quantities of a set of nuclides that have been determined to be important in the characterization of spent fuel. TRITON recognizes fuel materials as any material containing quantities of heavy metals (Z > 89) in the standard composition specification.

TRITON provides user control of the set of nuclides added to a fuel material through the *parm=(addnux=N)* control parameter, where N is an integer value. For N = 0, no nuclides are added, which is generally a very poor approximation and should only be used when the ramifications are fully understood. For N = 1, a bare minimum set of 15 nuclides (actinides) are added; this will generate improved number density estimates for actinides in low-burnup fuels but will not update cross sections for fission products of primary importance. Again, use of this option is discouraged unless it addresses special modeling needs. For N = 2, the default setting for the TRITON depletion sequences, 95 nuclides are added. N = 3 and N = 4 add 231 and 388 nuclides, respectively. Note that in previous versions of TRITON, N = 2 would add 64 nuclides. The set of 64 nuclides is still supported by specifiying *parm=(addnux=-2)* in the input. The default in the SCALE 6.1 release remains *parm=(addnux=2).* Table 3.1.2 through Table 3.1.6 list the set of nuclides added in trace quantities for each value of *addnux*.

*158 additional nuclides in addition to the 15 nuclides in Table 3.1.2, 49 nuclides in Table 3.1.3, 30 nuclides in Table 3.1.4, and 136 nuclides in Table 3.1.5, for a total of 388.

Few-group reaction cross section calculation control for continuous energy depletion: **parm=(cxm=N)**

In continuous energy depletion calculations, few group reaction cross sections are computed by KENO directly rather than using a post-processing approach that TRITON uses for multigroup mode. In addition to these region averaged multigroup reaction cross sections, KENO also provides problem-dependent region-averaged multigroup fluxes to TRITON that will be used by COUPLE to generate one-group cross section library for each depletion material.

Option *parm=(cxm=N)* is used to setup continuous-energy depletion calculation with different modes of calculation, which tells KENO the details of the tallying process for the reaction cross sections and mixture fluxes. Available calculations modes and their descriptions are presented in Table 3.1.7.

Table 3.1.7: *cxm* values and their descriptions.

cxm	**cross sections**		**flux**	**description**
	reactions	number of energy groups	number of energy groups	
1	All	NGP	NGP	KENO uses default NGP-group energy group boundaries to generate region-averaged reaction cross sections for all available reactions of the nuclides in each depletion mixture. KENO also computes region-averaged multigroup fluxes using the default NGP-group energy bins. multigroup fluxes using the default NGP-group energy bins.
2	Transmutation (MT=16-18, 102-125)	NGP	NGP	KENO uses default NGP-group energy group boundaries to generate region-averaged reaction cross sections for only transmutation reactions of the nuclides in each depletion mixture. KENO also computes region-averaged multigroup fluxes using the default NGP-group energy bins. multigroup fluxes using the default NGP-group energy bins.

continues on next page

Table 3.1.7 – continued from previous page

3	All	1	NGP	KENO uses 1-group energy group boundaries to generate region-averaged reaction cross sections for all available reactions of the nuclides in each depletion mixture. KENO also computes region-averaged multigroup fluxes using the default NGP-group energy bins. multigroup fluxes using the default NGP-group energy bins.
4 (default)	Transmutation (MT=16-18, 102-125)	1	NGP	KENO uses 1-group energy group boundaries to generate region-averaged reaction cross sections for only transmutation reactions of the nuclides in each depletion mixture. KENO also computes region-averaged multigroup fluxes using the default NGP-group energy bins. multigroup fluxes using the default NGP-group energy bins.

Note: The energy group structure in KENO and associated number of energy groups, NGP, should be consistent with those from the ORIGEN library used in the problem.

Infinite dilution cutoff control: **parm=(infdcutoff=X)**

The addition of nuclides to depletion materials as described in the previous section can lead to increased run-times for CENTRM-based XSProc calculations. However, many nuclides (e.g., low-density nuclides) are effectively infinitely dilute and can be treated as such and omitted from the expensive point-wise cross section collapse operation. For the option *parm=(infdcutoff=sigma0)* sequence option, XSProc will compute an effective background microscopic cross section for each nuclide. If the computed background cross section is greater than the cutoff value *sigma0*, recommended as 5×10^5 barns, then the nuclide is considered infinitely dilute and the infinitely dilute multigroup cross section is utilized from the cross section library.

In general, a *sigma0* cutoff value of 5×10^5 barns will be acceptable for most applications. However, TRITON and the centrmdata card in the *CELLDATA* block provide a means for the user to control the cutoff value. The cutoff value may be assigned in either of two ways. A single global value may be assigned to all cells using the TRITON *parm=* specifier with the keyword *infdcutoff*, for example, *parm=(infdcutoff=1e10)*. Addition of the specifier with a value of 1×10^{10} will set the cutoff value to 1×10^{10} for all cells in the problem, which is generally appropriate for most calculations. However, a provision is made to specify a unique cutoff value to each cell using the *pmc_dilute* keyword in a *centrmdata* specification. An example of this is shown in the description of *parm=xslevel* in Sect. 3.1.3.5.2.

The default value of *sigma0* depends on the sequence and cross section processing option. For nondepletion sequences that use *parm=centrm*, the default is 0. The default value of 0 instructs PMC to include all nuclides for PMC processing. For depletion sequences that use *parm=centrm* or for any sequence that uses *parm=2region*, the default value is 5×10^5 barns.

Override of the maximum number of days per depletion subinterval: **PARM=(MAXDAYS=N)**

TRITON is set to limit ORIGEN time intervals to no more than 40 days to avoid potential numerical error that would be introduced if depletion were performed over a long time interval. For depletion subintervals of more than 400 days (10 time intervals of 40 days), TRITON will automatically increase the number of depletion subintervals in a depletion interval. The depletion subinterval is based on a rule of thumb for ORIGEN depletion. However, the rule breaks down when burning at very low powers for extended time intervals. Thus, TRITON allows the user to override the default behavior by specifying a new value for the maximum number of days per ORIGEN time interval. A 100-day limit per ORIGEN time interval may be set using *parm=(maxdays=100)*. In overriding the default behavior, the user must be aware of any potential errors introduced in the approximation.

3.1.4 OUTPUT FILES CREATED BY TRITON

TRITON produces a variety of output files that may be of use in related calculations. Of those files, only certain files are copied back to the return directory: the TRITON output file (.out); plot files generated by NEWT, KENO, or OPUS (.plt); SAMS sensitivity data files (.sdf), in the case of an S/U calculation; ORIGEN binary concentration files (.f71) and HTML-formatted output (.html), where available. The TRITON output file is a concatenated listing of outputs from TRITON and all modules for which output is kept. Other files of potential interest are not copied, and the user should be aware of these files and their names so that they may be retrieved using a SHELL script after TRITON execution is complete. The following subsections list those files and their purposes.

3.1.4.1 Standard composition restart files

At the end of all depletion calculations, standard composition files are automatically produced for each material, listing the nuclides and number densities of the materials at the time the transport calculation (i.e., XSDRN, NEWT, KENO) is performed. Only nuclides for which cross section data are available in the master cross section library are saved in these files. Files are saved using the file naming convention StdCmpMix*NNNNN*, where *NNNNN* is the material identifier. The file contains compositions at the final time of the calculation. Additional files are saved with the file naming convention StdCmpMix*NNNNN_MMMMM*, where *MMMMM* is an index to a particular time step in the depletion calculation. For example, if a calculation is completed with materials 1 and 40 for two depletion steps, then the following files will be created in the temporary working directory.

```
StdCmpMix00001_00000 (t=0)
StdCmpMix00001_00001 (midpoint of 1st depletion step)
StdCmpMix00001_00002 (midpoint of 2nd depletion step)
StdCmpMix00001_00003 (final compositions, end of 2nd depletion step)
StdCmpMix00001 (same as StdCmpMix00001_00003)
StdCmpMix00040_00000 (t=0)
StdCmpMix00040_00001 (midpoint of 1st depletion step)
StdCmpMix00040_00002 (midpoint of 2nd depletion step)
StdCmpMix00040_00003 (final compositions, end of 2nd depletion step)
StdCmpMix00040 (same as StdCmpMix00040_00003)
```

The contents of these files will be a standard composition description of each material by atomic contents-that is, SCALE standard nuclide IDs (e.g., U-235), number density, and temperature (using the temperature of the original material). Using SCALE's external file read capability, these outputs may be automatically included in a follow-on calculation that relies on depleted/decayed number densities. TRITON sample problem 7 (Sect. 3.1.6.6) provides an example of the use of these restart files.

These files are not automatically copied back to the output directory. Users can use a shell block to manually copy back the files, for example:

```
read shell
  cp ${TMPDIR}/StdCmpMix* ${OUTDIR}
end shell
```

Important: Standard composition restart files should be used only for follow-on criticality or shielding calculations.

3.1.4.2 Lattice physics parameters

During T-DEPL depletion calculations that use branch states and homogenization, a database of few-group cross sections is saved for each branch state and at each depletion step containing homogenized cross section data and other lattice physics parameters (e.g., discontinuity factors, pin power peaking factors, diffusion coefficients, etc.). The *xfile016* file is intended for post-processing, to be read and written in the desired format for subsequent nodal diffusion core simulator calculations. The *xfile016* file is a binary-formatted file, which is described in detail in Appendix A of TRITON. An auxiliary text-formatted database file (*txtfile16*) is also created that contains the same data as the binary-formatted file.

3.1.4.3 ORIGEN binary library files (.f33)

During depletion calculations, ORIGEN binary library files are created to archive cross sections for each depletion material at each depletion subinterval. These files can be used in future depletion calculations in ORIGEN, ORIGAMI, and ARP. For each depletion material, the ORIGEN binary library file is named *$ {BASENAME}.mixNNNNNN.f33*, where *NNNNN* is the material number for each depleted material. Additionally, the system-average cross section file is saved with the name *$ {BASENAME}.system.f33*. All f33-files are automatically copied back into the output directory.

Note that in SCALE versions up to 6.2, these files were named *ft33f001_mixNNNNN* and *f33f001_cmbined*. They had to be copied manually from the temporary working directory *$ {TMPDIR}* into the output directory through a shell block following the TRITON input. Since SCALE 6.3, the files are automatically copied back and have more intuitive names.

3.1.4.4 ORIGEN binary concentration file (.f71)

During depletion calculations, TRITON creates the ORIGEN binary concentration file (.f71). This file is created in the temporary directory as *ft71f001* and is copied back at the end of the SCALE calculation to the return directory with the name ${OUTBASENAME}.f71. TRITON archives computed concentrations for each depletion material at the beginning and end of each depletion subinterval or decay interval. These files include concentrations and also decay heat term, photon and neutron data, and other quantities or interest computed by ORIGEN. These data may be post-processed by the OPUS module.

The .f71 file contains concentrations for each individual material, and it also contains the combined concentrations of the individual material results (i.e., the net response for the entire system). The TRITON output contains an index of the contents of this file (see Sect. 3.1.5.4.5).

3.1.4.5 Binary mesh response files (.3dmap)

If mesh responses are requested, the corresponding binary 3dmap files are generated. If the TRITON-Shift sequences with the definitions and tallies block was used to request mesh responses, the output files follow the following syntax:

- flux: *$ {BASENAME}.flux_time$ {STEP}_3dmap*
- fission_density: *$ {BASENAME}.fission_density_time$ {STEP}.3dmap*
- fission_source: *$ {BASENAME}.fission_source_time$ {STEP}.3dmap*

3.1.4.6 Binary Shift output file (.h5)

If the TRITON-Shift sequence was used, detailed results of the Shift calculation can be found in Shift's hdf5 output file. The HDF5 filename follow the following syntax: *$ {basename}_time$ {step}.shift-output.h5*. The generation of these files for only selected depletion steps can be controled through the *KEEP_OUTPUT* block.

3.1.5 OUTPUT DESCRIPTION

This section contains a brief description and explanation of TRITON output. As with any SCALE module, TRITON output begins with the SCALE header, the job information, the input file, and the program verification information. These outputs are common to all SCALE modules. Likewise, all SCALE calculations report a run-time summary at the end of the output file.

3.1.5.1 Control parameter edit

When TRITON control parameters are specified using the parm= command (see Sect. 3.1.3.5), all specified parameters are echoed following the above output, with an explanation of the meaning of the parameter, as shown below. If no parameters are specified, no edit is provided.

```
The following TRITON control parameters were requested:

   WEIGHT - Weighted collapsed master library
            option selected for t-newt calculation, based
            on system-averaged flux.
   ADDNUX - specifies the set of additional nuclides added
            in trace quantities for depletion
            calculations. Set 1 was selected.
            See TRITON manual for more information.
```

3.1.5.2 T-XSEC output

The T-XSEC sequence performs only cross section processing functions. The XSProc output is written to the output file as the calculation proceeds.

3.1.5.3 T-NEWT and T-XSDRN output

By default, the T-NEWT and T-XSDRN outputs include only the NEWT and XSDRN output respectively. The XSProc output can be included by using the *KEEP_OUTPUT* block (see Sect. 3.1.3.4.7).

3.1.5.4 Depletion sequence output

The output of TRITON depletion sequences contains several depletion edits. The edits are described in the following subsections. These output edits are written to the output file in the order in which they are computed during the calculation.

Burnup history summary (all depletion sequences)

TRITON generates the burnup history summary table after processing the *BURNDATA* block. An example of this table is as follows:

```
*******************************************************************************************
Based on the supplied burnup history, triton will use the following time history to perform
depletion calculations.  This breakdown has been calculated so as to permit burn steps of
no more than 40 days, and decay times using the rule of threes with a maximum first decay
period of no more than 75 days.
*******************************************************************************************

  7 Time-dependent libraries will be created

NOTE: Library Burnup is the cumulative burnup computed at the midpoint of the depletion sub-interval.
      Specific Power and Library Burnup depend on basis mixture(s) selected in DEPLETION block.
-------------------------------------------------------------------------------------------------
```

This table shows the results of a burnup history using one depletion interval with 5 depletion subintervals. Column 1 is the cumulative depletion subinterval number. Column 2 is the depletion interval number, and column 3 is the depletion subinterval number within the current depletion interval. Columns 4–6 echo the specific power, depletion interval, and decay interval specified in the *BURNDATA* block. The final column shows the cumulative burnup at the midpoint of each depletion subinterval.

Embedded transport model output

The output from the initial transport calculation follows the burnup history edit. The output edits for NEWT, XSDRN, KENO-V.a, and KENO-VI are described in their respective manual sections.

System mass balance table

After the initial transport calculation output, a summary of system mass information is printed, an example of which is provided as follows.

```
*****************************************************************************
** System total mass is  1.8684e+01 grams heavy metal per unit length.       **
** Masses will be normalized by a factor of  5.3521e+04 cm to obtain a total  **
** system mass of  1.0000e+06 g of heavy metal                                **
*****************************************************************************

```

This table provides mass and density data for each material used in the transport model. Column 1 provides the material identifier, and columns 5 and 6 provide the material density and material heavy metal density, respectively, in units of grams per cubic centimeter. Heavy metal mass is determined from masses of all nuclides with an atomic number greater than 89. The final column provides the depletion mode for each material (see Sect. 3.1.3.3.6). Column 2 provides the "prenormalized" heavy metal mass of each material. The units for this mass value depend on the transport model. For 2D *xy* NEWT models, the units are grams per centimeter since there is no *z*- dimension in the model. Similarly, the units are grams per centimeter for 1D cylinder XSDRN models, grams per square centimeter for 1D slab XSDRN models, and grams for 1D spherical XSDRN models and 3D KENO models. The total prenormalized heavy metal mass is printed in the final row of the table as well as in the table header. The heavy metal mass is normalized such that a total system mass of 1 MTHM is present. The volume scaling factor used to normalize the system mass is also printed in the table banner. The units of the volume scaling factor depend on the transport model. Column 3 prints the normalized material heavy metal mass in units of grams, which is equal to the prenormalized material heavy metal mass in column 2 multiplied by the volume scaling factor in the table header. The total normalized mass is printed in the final row and also in the table header. The fourth column shows the fractional heavy metal mass of all materials, which is equal to the normalized heavy metal mass in column 3, divided by the total normalized system heavy metal mass in the table header.

Power balance tables

As the TRITON calculation proceeds, the results of the cross section processing and transport calculations are used to calculate fluxes and powers in each mixture. The output segments listed in the next two tables show the results for the first calculation based on the initial mixture compositions. The total power (column 2) represents the mixture-specific power in units of MW/MTHM of initial **system** mass. The fractional power (column 3) is equal to the total power for a mixture divided by the total system power. The mixture power (column 4) represents mixture-specific power in units of MW/MTHM of initial **mixture** mass. The mixture power is equal to the total power of the mixture divided by the fractional heavy metal mass of the mixture, which is provided in the system mass balance table (Sect. 3.1.5.4.3). Column 5 presents the burnup of the individual mixture. If a mixture does not contain heavy metal, then "N/A" is printed in the mixture power and burnup columns. Columns 6 and 7 show the mixture thermal and total flux values, respectively, in units of neutrons/cm^2-sec. The thermal flux is determined by integrating multigroup flux values for energy groups below 0.625 eV.

If the specific power is normalized to the total system power, the summation of the mixture powers in column 1 should match the input specification in the *BURNDATA* block (in the example given here, 37.883 MW/MTHM):

```
--- Mixture powers for depletion pass no.   1 (MW/MITHM) ---
     Time =    21.25 days (   0.058 y), Burnup =    0.805     GWd/MTIHM, Transport k=  1.2783

                 Total    Fractional  Mixture      Mixture     Mixture       Mixture
      Mixture    Power      Power      Power       Burnup      Thermal Flux  Total Flux
       Number (MW/MTIHM)    (---)   (MW/MTIHM)   (GWd/MTIHM)   n/(cm^2*sec)  n/(cm^2*sec)
          1      37.799    0.99779     37.799         0.803    3.2106e+13    3.1724e+14
         25       0.041    0.00109     N/A           N/A       3.4431e+13    3.1682e+14
         26       0.042    0.00112     N/A           N/A       3.5114e+13    3.1832e+14
      Total      37.883    1.00000

  NOTE:    Total Power is the Mixture Power per 1 metric ton of HM of the initial  system mass.
         Mixture Power is the Mixture Power per 1 metric ton of HM of the initial mixture mass.
         Mixture Burnup is the Mixture Burnup per 1 metric ton of HM of the initial mixture mass.
         Mixture Thermal Flux determined using 0.625 eV cutoff: Groups 214 through 252.
 ------------------------------------------------------------
```

If the specific power is normalized to the power to one or more specific mixtures, the mixture powers are slightly different. For the case above, if depletion was performed with input power normalized to mixture 1, then mixture 1 has the input-specified power (37.883 MW/MTHM), and the power in the remainder of the model mixtures is normalized according to this basis mixture:

```
--- Mixture powers for depletion pass no.   1 (MW/MITHM) ---
     Time =    21.25 days (   0.058 y), Burnup =    0.805     GWd/MTIHM, Transport k=  1.2783

                 Total    Fractional  Mixture      Mixture     Mixture       Mixture
       Mixture   Power      Power      Power       Burnup      Thermal Flux  Total Flux
        Number (MW/MTIHM)    (---)   (MW/MTIHM)   (GWd/MTIHM)   n/(cm^2*sec)  n/(cm^2*sec)
           1  *   37.883    0.99779     37.883         0.805    3.2176e+13    3.1795e+14
          25       0.041    0.00109     N/A           N/A       3.4507e+13    3.1753e+14
          26       0.042    0.00112     N/A           N/A       3.5191e+13    3.1903e+14
       Total      37.967    1.00000

      * - Power normalized to this mixture.

  NOTE:    Total Power is the Mixture Power per 1 metric ton of HM of the initial  system mass.
         Mixture Power is the Mixture Power per 1 metric ton of HM of the initial mixture mass.
         Mixture Burnup is the Mixture Burnup per 1 metric ton of HM of the initial mixture mass.
         Mixture Thermal Flux determined using 0.625 eV cutoff: Groups 214 through 252.
 ---------------------------------------------------------------
```

Note: Note that the above two power balance tables refer to results at the time of the neutron transport calculation, i.e. the middle of a depletion subinterval.

Additionally, *after* every depletion subinterval, a summary of the mixture-wise power, flux, fluence, burnup, and initial heavy metal is provided. This is the result from ORIGEN, i.e. results noramlized to 1 ton of initial heavy metal.

```
end-of-step summary at time =    42.500  days (    0.116  y), system-average burnup* =    1.606  GWd/MTIHM

mixture        power         flux      fluence      burnup*    initialhm
    (-)         (MW)    (n/cm2-s)      (n/cm2)  (MWd/MTIHM)      (MTIHM)

      1  3.77957e+01  3.16389e+14  1.16178e+21  1.60632e+03  1.00000e+00

* Burnup is only calculated for mixtures with initial HM mass fraction greater than 1e-6.
```

ORIGEN binary concentration file listing

After all depletion calculations are completed, TRITON creates an ORIGEN binary concentration file (.f71) with isotopic concentrations for each depletion material. The order and content of the .f71 file is provided in the TRITON output. An example of this edit is shown below. For each depletion material, the output gives the location in the file, the ORIGEN time interval number, the depletion interval time in days, the cumulative time in years, and a title. After all materials are added to the library, the system average of all libraries and the average of all fuel mixtures are computed and added to the library. The file *case* numbers correspond to the mixture ids. Special cases are 0, -1, and -2 as indicated in the table below.

```
File ft71f001 is the ORIGEN binary concentration file, containing concentrations for
  - each of the 2 depletion mixtures,
  - a set for the sum of all depletion mixtures,
  - a set for the sum of selected mixtures (from optional opus block),
  - a set for the sum of all fuel mixtures
for always 7 time steps.
```

(continues on next page)

(continued from previous page)

```
Isotopic data locations are listed according to the following table.

Position  Time Step  Cycle Time (d)  Cumulative Time (y)

The requested OPUS output edits follow this .f71 file summary edit.

3.1.6 TRITON SAMPLE CASES

This section provides descriptions of the 13 TRITON sample problems included with SCALE. Note that all of these problems (along with all other SCALE sample problems) are typically executed in the initial SCALE installation to test the performance of various codes and options, for validation of the installation process. Because of the number of problems that are executed, these sample problems are adjusted to run as fast as possible so that all test problems may be completed in relatively short order. To accomplish this, crude modeling approximations (reduced convergence, few histories, simplified cross section processing, low-order quadrature and scattering approximations, coarse computational grids, reduced numbers of libraries per depletion cycle, etc.) may be used. Hence, although these problems provide guidance in setting up and executing TRITON problems, it is generally a good idea to review all control settings to ensure sufficient accuracy in one's own calculations.

Additional TRITON input files for several reactor types can be generated with the SCALE/ORIGEN Library Generator (SLIG). The SLIB documentation is available as Appendix B of the ORIGEN chapter.

3.1.6.1 TRITON sample problem 1: triton1.inp

Sample problem triton1.inp is an example of a T-NEWT transport calculation sequence. Input begins (as with all SCALE sequences) with a title card and cross section library specification; this calculation is performed using the 252-group ENDF/B-7.1 library. After the library specification, three materials are defined in the composition block, followed by a cell specification and the NEWT transport model.

This example includes an axial height of 37.1 cm and will therefore do a buckled calculation based on this height. The geometric model consists of a simple pin cell, with cylindrical fuel and clad regions inside a square moderator region, with a 6×6 base grid. The NEWT *BOUNDS* block specifies that periodic boundary conditions are used for this model.

This simple problem also demonstrates the use of TRITON's automatic cross section collapse capability-*parm=weight*. For *T-NEWT* calculations, TRITON uses the NEWT *COLLAPSE* block to define the broad-group energy structure. For this sample problem, the cross sections are collapsed to a 56-group format. The new broad-group library will be identified as filename *newxnlib* in the temporary working directory, which can be used in follow-up SCALE calculations.

```
' THIS SAMPLE PROBLEM TEST THE FOLLOWING:
'  ** t-newt sequence
'  ** v7-252 group library
'  ** centrm cross section processing (default for t-newt calculations)
'  ** parm=weight option for the t-newt sequence, which uses the NEWT collapse block to specify a 252 -> 56␣
↪group collapse.
'  ** latticecell cross section processing option

3.1.6.2 TRITON sample problem 2: triton2.inp

Sample problem triton2.inp is an example of a T-XSDRN transport calculation sequence. In this case, the parameter specification *parm=2region* instructs TRITON to perform cross section processing using the CENTRM-based two-region option in place of the default CENTRM-based S_N option (see Sect. 3.1.2.1). As in sample problem 1, a simple square-pitched pin cell is modeled but in this case using an XSDRN model block rather than the NEWT model block. The moderator radius was defined in order to preserve the volume of the moderator region.

3.1.6.3 TRITON sample problem 3: triton3.inp

Sample problem 3 illustrates the input format for a T-DEPL-1D depletion calculation. In this case, a single square-pitched pin-cell model is depleted, where the fuel composition is comprised of UO_2 fuel homogenized with aluminum and B_4C. Although this is not representative of real fuel, it does allow one to observe the effect of boron depletion during burnup; results will show an increasing multiplication factor as boron is depleted, followed by a decreasing eigenvalue after the fuel depletion becomes the dominant contributor to reactivity change. Three depletion intervals are specified with the same power and no decay intervals. Two depletion subintervals are specified for the first two depletion intervals, with only one depletion subinterval for the final depletion interval. Note that this may be insufficient to capture the effect of boron depletion early in life; fewer depletion subintervals are used here only to reduce the run-time for this sample problem. In this model, power is normalized such that material 1 has a power density of 21.22 MW/MTHM (or MT/MTU for UO_2 fuel), and OPUS output is requested for 35 nuclides. The problem is run using the addnux=3 option set to add trace quantities of 231 nuclides to depletion materials.

TRITON sample problem 4: triton4.inp

Sample problem *triton4.inp* performs a large-scale depletion calculation for a one-fourth PWR assembly, taking advantage of symmetry to reduce the problem size. The same fuel material is used in each fuel rod, which will result in assembly-averaged isotopic compositions for all fuel rods. If one wanted to obtain an isotopic estimate for one or more unique fuel rod locations, then different materials would be specified for different rod positions. Even though all fuel is identical at the beginning of life, unique materials must be specified if one desires to perform tracking of the unique response of each unique fuel position.

The problem parameter specification *parm=(weight)* instructs TRITON to perform an automated cross section library collapse. For library collapse automation within depletion calculations (see Sect. 3.1.3.5.3), TRITON will perform a single 252-group calculation at t = 0 to generate the 56-group cross section library. TRITON will restart the depletion calculation at t = 0 using the broad-group library after it is created. Because *parm=weight* is specified, the *NEWT COLLAPSE* block must comply with the 56-group energy structure and not the 252-group energy structure. The *COLLAPSE* block input is slightly different for the library collapse automation for *T-NEWT* calculations, where the *NEWT COLLAPSE* block must comply with the 252-group energy structure.

Problem 4 also uses a timetable to specify boron letdown in the moderator. The initially specified boron concentration in the *COMP* (or *COMPOSITION*) data block is multiplied by a density multiplier at the

time of each cross section processing and transport calculation (i.e., the midpoint of depletion subinterval). Linear interpolation is performed between values on the timetable to obtain the multiplier for a given time. Typically a multiplier of 1.0 is used for t = 0, and the beginning-of-life boron concentration is input in the *COMPOSITION* block, but this example demonstrates that this is not necessary. For this calculation, a 500 ppm boron concentration is specified in the standard composition description, and a concentration of (500 ppm)*(1.832), or 916 ppm, would be used in the t = 0 transport calculation.

Problem 4 is also an example of a lattice physics calculation for a full fuel assembly. The NEWT model employs coarse-mesh finite-difference acceleration, whole-assembly homogenization, 2-energy-group collapse, and a pin-power print, and computes assembly discontinuity factors. Although this sample problem will create the cross section database file for core calculations, this sample problem does not contain branching calculations, nor do lattice physics calculations typically use boron letdown curves. Additional guidance for TRITON lattice physics calculations can be found in the lattice physics primer.

Because only one fuel material is used, only one cell specification is necessary. If multiple fuel materials were used, then a corresponding cell specification would be required for each fuel, with a unique clad and moderator material identifier for each cell. To apply boron letdown properly, the moderator present in each cell specification would need to have the same letdown curve specified. Hence, a letdown timetable would need to be specified for each moderator (even if the moderators are not all used in the NEWT *model* block). If multiple fuel materials are used, requiring corresponding multiple clad, moderation, cell, and timetable specifications, the use of an *alias* specification can simplify input. Aliases are described in Sect. 3.1.3.4; sample problems triton6.inp (Sect. 3.1.6.5), triton8.inp (Sect. 3.1.6.7), and triton12.inp (Sect. 3.1.6.10) demonstrate the use of aliases.

This case also illustrates the use of stacked OPUS cases within a single TRITON input file. Here, an OPUS calculation is requested to obtain the mass in grams of 26 actinides and fission products for material 1 and for the entire system; since material 1 is the entire set of depletion materials, the system output will be identical to the material 1 output. A second OPUS calculation is also specified, which requests a ranked output of the top 20 nuclides in terms of decay heat (in watts).), TRITON will perform a single 252-group calculation at t = 0 to generate the 56-group cross section library. TRITON will restart the depletion calculation at t = 0 using the broad-group library after it is created. Because *parm=weight* is specified, the *NEWT COLLAPSE* block must comply with the 56-group energy structure and not the 252-group energy structure. The *COLLAPSE* block input is slightly different for the library collapse automation for *T-NEWT* calculations, where the *NEWT COLLAPSE* block must comply with the 252-group energy structure.

Problem 4 also uses a timetable to specify boron letdown in the moderator. The initially specified boron concentration in the *COMP* (or *COMPOSITION*) data block is multiplied by a density multiplier at the time of each cross section processing and transport calculation (i.e., the midpoint of depletion subinterval). Linear interpolation is performed between values on the timetable to obtain the multiplier for a given time. Typically a multiplier of 1.0 is used for t = 0, and the beginning-of-life boron concentration is input in the *COMPOSITION* block, but this example demonstrates that this is not necessary. For this calculation, a 500 ppm boron concentration is specified in the standard composition description, and a concentration of (500 ppm)*(1.832), or 916 ppm, would be used in the t = 0 transport calculation.

Problem 4 is also an example of a lattice physics calculation for a full fuel assembly. The NEWT model employs coarse-mesh finite-difference acceleration, whole-assembly homogenization, 2-energy-group collapse, and a pin-power print, and computes assembly discontinuity factors. Although this sample problem will create the cross section database file for core calculations, this sample problem does not contain branching calculations, nor do lattice physics calculations typically use boron letdown curves. Additional guidance for TRITON lattice physics calculations can be found in the lattice physics primer.

Because only one fuel material is used, only one cell specification is necessary. If multiple fuel materials were used, then a corresponding cell specification would be required for each fuel, with a unique clad and moderator material identifier for each cell. To apply boron letdown properly, the moderator present in each cell specification would need to have the same letdown curve specified. Hence, a letdown timetable would need to be specified for each moderator (even if the moderators are not all used in the NEWT *model* block). If multiple fuel materials are used, requiring corresponding multiple clad, moderation, cell, and timetable specifications, the use of an *alias* specification can simplify input. Aliases are described in Sect. 3.1.3.4; sample problems triton6.inp (Sect. 3.1.6.5), triton8.inp (Sect. 3.1.6.7), and triton12.inp (Sect. 3.1.6.10) demonstrate the use of aliases.

This case also illustrates the use of stacked OPUS cases within a single TRITON input file. Here, an OPUS calculation is requested to obtain the mass in grams of 26 actinides and fission products for material 1 and for the entire system; since material 1 is the entire set of depletion materials, the system output will be identical to the material 1 output. 3.1.6.4 TRITON sample problem 5: triton5.inp

Sample problem *triton5.inp* is similar to *triton4.inp*, except that it is a T5-DEPL case; thus, a KENO V.a transport model is used in place of the NEWT model of the earlier case. The KENO V.a model, although 3D, is axially uniform with reflecting boundary conditions, so it is effectively the same model as the 2D model of *triton4.inp*. Moreover, the KENO V.a model represents the full assembly rather than a one-fourth model. Hence, both cases will generate similar results. In the KENO model, only 300,000 neutron histories are retained, which is somewhat low to obtain good statistics on fluxes. The 238 ENDF/B-VII library is used for this sample problem compared to the 252 ENDF/B-VII.1 library utilized in *triton4.inp*.

3.1.6.5 TRITON sample problem 6: triton6.inp

Sample problem *triton6.inp* performs T-DEPL depletion in a pin cell model; however, the pin is discretized into five equal-volume rings of fuel. Thus, CENTRM-based S_N cross section processing is necessary to capture the radial burnup of the pin cell. A *multiregion* cell specification is given to allow specification of the varying radii for the fuel regions. Because the multiregion cell is cylindrical, the moderator volume is represented in terms of a radius that corresponds to the volume associated with the pin pitch. The right boundary condition for the cell is set to *white*; this is important, as the default right boundary condition for a multiregion cylinder is vacuum. In this case, addnux=1 is also requested in the parameter specification, simply for a faster (but less accurate) calculation. Material aliases are used to simplify input. The calculation is performed with the 238 ENDF/B-VII library. The TRITON *TIMETABLE* block is used to demonstrate time-dependent temperature changes to the moderator material.

3.1.6.6 TRITON sample problem 7: triton7.inp

Sample problem triton7.inp is an example of a T-DEPL depletion calculation for a full PWR fuel assembly model. Depletion is performed on the basis of material 7, which is located in a single fuel pin for which destructive assay measurements were performed. All other fuel is modeled as a single (average) material, material 1. The parameter specification *parm=(2region,addnux=1,weight)* was chosen to reduce the run-time of the sample problem.

This sample problem also demonstrates the use of TRITON's standard composition restart files and SCALE external file reading capabilities to represent the time-dependent behavior of an assembly in which burnable poisons are removed after the first cycle of operation.

This problem consists of two TRITON 2D depletion cases. In the first case, the full assembly model contains borosilicate glass burnable poison rods (BPRs), material 4, which are included in the list of materials to be depleted. The calculation is run for the entirety of the first operational cycle, which included a 40-day mid-cycle decay interval. The model also includes a 64-day decay interval after the end of the operational cycle. When this calculation is completed, TRITON creates in the temporary working directory a standard composition file for each material containing the isotopic inventories for each depletion material at the end of the 64-day decay interval. The second TRITON calculation reads the standard composition specifications for materials 1 and 7 as part of the input to provide the fuel state for the second calculation. In the second model, the BPRs are removed and replaced with the moderator in the embedded NEWT model. The initial depletion calculation uses the 252 ENDF/B-VII.1 library. With the *parm=(...,weight)* option, a 56 group library is created in the temporary directory called *newxnlib*. This library is used for the second *T-NEWT* calculation.

3.1.6.7 TRITON sample problem 8: triton8.inp

Sample problem *triton8.inp* is an example of TRITON's simplified cross section processing scheme in a BWR-like configuration. It uses the T-DEPL extended format for the *DEPLETION* block to allow material assignments to be made to reduce the number of cross section processing calculations required in a multimaterial depletion model. In this sample problem, the lower-left quadrant of a 6×6 fuel assembly is modeled (see Fig. 3.1.12). The fuel pin layout is as follows: one 2.3% ^{235}U-enriched fuel pin in the southwest corner (red pin), one-fourth of a water rod in the northeast corner, five 3.6% ^{235}U-enriched fuel pins (2 green, 1 yellow, and 2 blue pins), and two gadolinium-bearing pins each modeled with three fuel rings. (Gadolinium-bearing pins are typically modeled with multiple fuel rings due to the strong spatial dependence of the flux.) Due to diagonal symmetry, only seven depletion material regions need to be defined: the red, green, yellow, and blue pins along with three regions for the gadolinium-bearing pins. Although seven depletion materials are defined, only three cell specifications are used: one for the gadolinium-bearing pin cell and one each for the 2.3% and 3.6% ^{235}U-enriched pin cells. This model makes extensive use of aliases. The sequence is run with *parm=(addnux=0,...)*, which includes no extra nuclides, for an accelerated solution; however, this is an extremely poor approximation unless important nuclides are manually specified. This example also illustrates the use of the keyword *flux* in the *DEPLETION* data block to force flux-based ORIGEN calculations in place of power-based calculation for all three rings of the gadolinium-bearing fuel pins. Finally, this case uses the *parm=(...,weight,...)* directive to request the automatic collapse of the input 238 ENDF/B-VII library to a 49 group library (collapsed using the 238-group system-averaged flux), which is then used for depletion calculations.

```

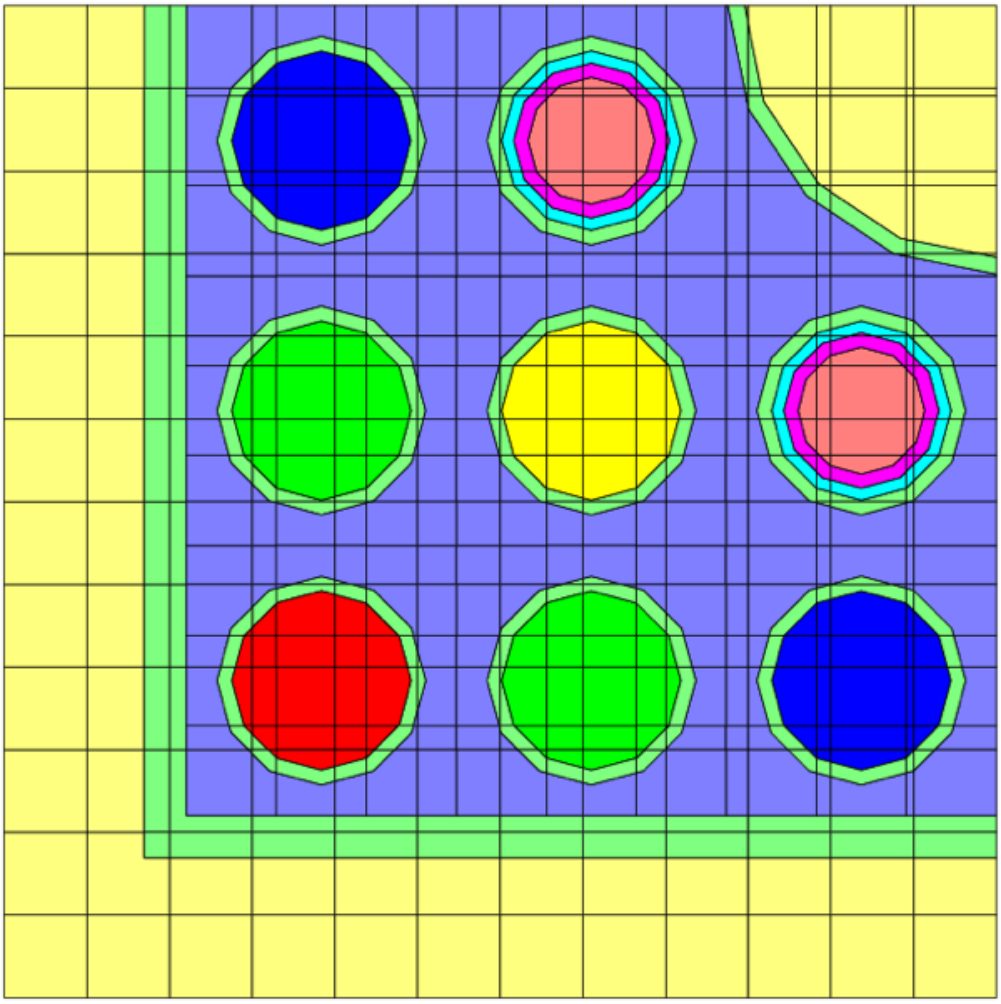

Fig. 3.1.12: BWR-like assembly design for triton8.

3.1.6.8 TRITON sample problem 10: triton10.inp

Sample problem *triton10.inp* performs NEWT-based depletion of a one-fourth symmetric assembly model. The primary intent of this sample problem is to test and to demonstrate the use of branches and archival of computed cross sections for a depletion case. The model includes two branch calculations-in addition to the nominal condition-that demonstrate the different perturbation outputs available in the *BRANCH* block. A two-group collapse is requested in the NEWT input, along with homogenization over all materials. (Note that the parameter specification *parm=(addnux=1)* is only used to reduce run-time of the sample problem.) At the end of the calculation, the binary file "xfile016" and text file "txtfile16" will exist in the temporary working directory and will contain all lattice physics parameters for all branches at all depletion states. These files are often copied back from the SCALE temporary working directory to another more permanent directory for subsequent post-processing.

```

3.1.6.9 TRITON sample problem 11: triton11.inp

Sample problem *triton11.inp* demonstrates the use of determining Dancoff factors for a BWR fuel assembly. The BWR assembly design contains a 7×7 array of fuel pins enclosed by a channel box (see Fig. 3.1.13). The in-channel moderator void fraction is 40%, and the bypass moderator void fraction is 0%. The input file contains an MCDANCOFF input file that calculates the Dancoff factors for each fuel pin (See the MCDANCOFF chapter). The MCDANCOFF input is essentially the equivalent of the KENO-VI model of the 2D assembly design. Following the MCDANCOFF input, the T-NEWT input is provided that shows how the computed Dancoff factors are inserted into the TRITON model. The Dancoff factors are inserted into the model via the *centrmdata* keyword entry in the *CELLDATA* block.

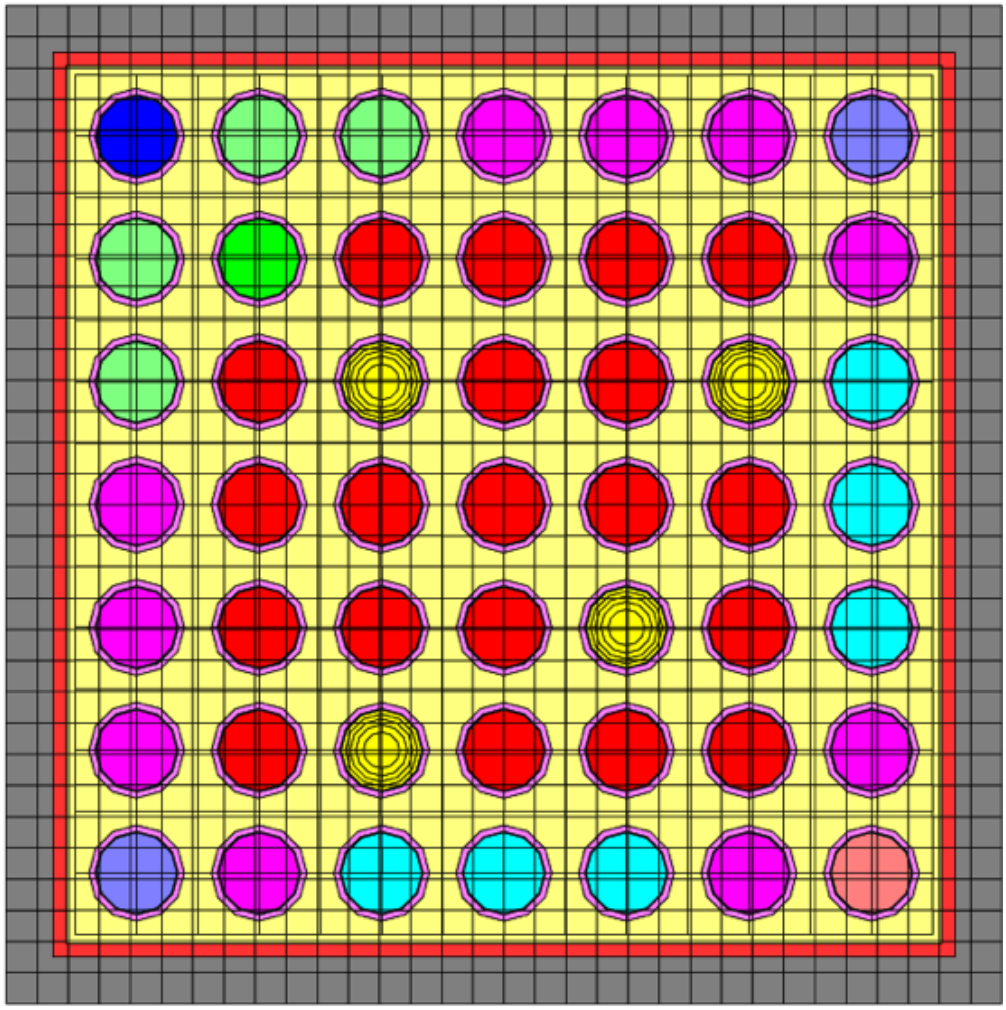

Fig. 3.1.13: triton11 BWR assembly design.

3.1.6.10 TRITON sample problem 12: triton12.inp

Sample problem triton12.inp illustrates the use of the TRITON-NEWT with a model with numerous mixtures and aliases. Sample problem 11 demonstrates how MCDANCOFF is used to compute fuel pin Dancoff factors for designs where nonuniform lattice effects play a critical role in cross section processing. The Dancoff factors are inserted into the follow-on T-NEWT model through the centrmdata keyword in the CELLDATA block. The output for the T-NEWT model in sample problem 11 provides an adjusted moderator pitch needed to preserve the user-specified Dancoff factor. As common in other sample problems, several input options were used to reduce the run-time—and therefore solution accuracy—of the sample problem.

3.1.6.11 TRITON6 sample problem 1: triton6-1.inp

Sample problem *triton6-1.inp* is an example of KENO-VI-based depletion for an infinite lattice of cylinders fabricated with particulate TRISO fuel dispersed in a graphite matrix. This provides an example of the cross section processing specification of a doubly heterogeneous (*DOUBLEHET*) media and use of the resultant homogenized media in a depletion calculation.

```
' THIS SAMPLE PROBLEM TEST THE FOLLOWING:
'  ** t6-depl sequence
'  ** v7-252 group library
'  ** centrm cross section processing
'  ** double-heterogeneous cross section processing option
'  ** deplete-by-constant power and flux
'  ** system power normalization
=t6-depl      parm=centrm

3.1.7 APPENDICES

3.1.7.1 XSDRN Model Block Description

The model data block for *T-XSDRN* and *T-DEPL-1D* calculations allows specification of the 1D geometry model and various control parameters used in the transport solution. The XSDRN *MODEL* block input is arranged in blocks of data that are similar to the NEWT *MODEL* block input described in Sect. 9.2. The XSDRN model input starts with an optional 80-character title, followed by a *PARAMETER* block, and then the following three data blocks in any order: the *GEOMETRY* data block, the *MATERIAL* data block, and the optional *COLLAPSE* data block. If the *PARAMETER*, *GEOMETRY*, and *MATERIAL* data block are not specified, an error message is printed and the problem is terminated. Sample input files for *T-XSDRN* and *T-DEPL-1D* calculations are provided in TRITON sample problems 2 and 3, respectively.

XSDRN* PARAMETER *block

PARAMETER Block keyword = parm, para, parameter, or parameters

Valid *PARAMETER* block specifications are described below. For each keyword, allowable values are listed in parentheses, and the default is listed in brackets. Input that can take an arbitrary integer value is indicated by an IN; similarly, any parameter that can take an arbitrary real/floating point value is indicated by RN as the allowable value. SCALE read routines allow the input of integers for real numbers, and vice versa, and the number will be converted accordingly. The order of the parameters within the block is arbitrary and may be skipped if a default value is desired for that parameter. If a parameter is listed multiple times, the final specified value is used.

bf=(RN) - Buckling factor, equal to twice the extrapolation distance multiplier used to determine the zero point of the asymptotic flux. [1.420892]

collapse=(yes/no) - If collapse=yes is specified, a flux-weighted collapse is performed by material number; cross sections for each nuclide in each material in the problem are collapsed to a specified (or default) group structure based on the average flux in that material. If collapse=yes, TRITON will look for the *COLLAPSE* block; if not found, TRITON will generate cross sections based on the original group structure. [no]

deltay=(RN) - The first transverse dimension in centimeters used in a buckling correction to calculate

leakage normal to the principal calculation direction (i.e., the height of a slab or a cylinder).

deltaz=(RN) - The second transverse dimension in centimeters used in a buckling correction (i.e., the width of a slab).

difftreatment=(mg_1d_sigtr/mg_0d_diff/mg_0d_sigtr/1g_0d_sigtr) - Diffusion treatment option for transverse leakage corrections. The mg_1d_sigtr option uses zone-dependent transport cross-sections for the transverse leakage correction. The mg_0d_diff option uses flux-volume-weighted homogenized diffusion coefficients. The mg_0d_sigtr option uses flux-volume weighted homogenized transport cross-sections. The 1g_0d_sigtr option uses a one-group homogenized transport cross-section. [1g_0d_sigtr]

epsglobal=(RN) - Overall problem convergence criteria. [1.0e-6]

epsouter=(RN) - Scalar flux convergence criteria. [1.0e-6]

inners=(IN) - Maximum number of inner iterations in an energy group. [20]

outers=(IN) - Maximum number of outer iterations. [100]

prtflux=(yes/no) - Flag indicating whether or not scalar flux values are should be printed in problem output. [no]

prtangflux=(yes/no) - Flag indicating whether or not angular flux values should be printed in problem output. [no]

prtbalnc=(yes/no) - Flag indicating whether or not fine-group material balance tables should be printed in problem output. [no]

prtmxsec=(yes/no/1d) - Flag indicating whether or not material macroscopic cross sections should be printed in problem output. The 1D option indicates that 2D scattering tables are not to be printed. [no]

sn=(2/4/6/8/16/32) - Sn quadrature order for the transport calculations.

XSDRN *GEOMETRY* block

GEOMETRY Block keyword = geom, geometry

The *GEOMETRY* block is used to specify the geometry type (e.g., slab, cylinder, or sphere), the boundary conditions, the 1D material mesh (i.e., zone mesh), and the 1D spatial mesh used in the transport calculation. The order of the parameters entered in the *GEOMETRY* block is arbitrary and can be any of the following supported keyword specifications or keyword array specifications.

geom=(slab/cylinder/sphere) - Problem geometry. Keywords geometry=, ige=, and cyl for cylinder are also allowed. [slab]

leftbc=(vaccum/periodic/white/albedo/mirror) - Left-hand boundary condition. Keywords ibl=, vac for vacuum, refl for mirror, and reflected for mirror are also allowed. [mirror]

rightbc=(vaccum/periodic/white/albedo/mirror) - Right-hand boundary condition. Keywords ibr=, vac for vacuum, refl for mirror, and reflected for mirror are also allowed. [mirror]

left_albedo RN1 RN2 ... RNN **end left_albedo -** The left-hand boundary albedo values as a function of energy group. The left_albedo array is ignored if leftbc= is vacuum, periodic, white, or mirror. If the left_albedo array is omitted and leftbc=albedo, white boundary conditions are used. If the number of entries in the left_albedo array does not equal the number of energy groups in the cross-section library, an error message is printed and the problem is terminated.

right_albedo RN1 RN2 ... RNN **end right_albedo -** The right-hand boundary albedo values as a function of energy group. The right_albedo array is ignored if rightbc= is vacuum, periodic, white, or mirror. If the right_albedo array is omitted and rightbc=albedo, white boundary conditions are used. If the number of entries in the right_albedo array does not equal the number of energy groups in the cross-section library, an error message is printed and the problem is terminated.

zoneids IN1 IN2 ... INN **end zoneids -** Material composition number by zone. The number of entries in the zoneids array defines the number of zones for the problem. If the zoneids array is not defined, an error message is printed and the problem is terminated.

zonedimensions RN1 RN2 ... RNN **end zonedimensions -** The right-hand boundary for each zone is given in centimeters. Note that the left-hand boundary of the first zone is 0.0 and must not be entered. If the zonedimensions array is not defined or the number of entries does not equal the number of entries in the zoneids array, then an error message is printed and the problem is terminated.

zoneintervals IN1 IN2 ... INN **end zoneintervals -** Number of spatial mesh of constant width per each problem zone. If specified, the number of entries of the zonedimensions array must equal the number of entries in the zoneids array. Otherwise, an error message is printed and the problem is terminated.

mesh RN1 RN2 ... RNN **end mesh -** The right-hand boundary for each spatial mesh in centimeters. The spatial mesh is the discretization used in the transport calculation. Note that the left-hand boundary of the first spatial mesh is 0.0 and must not be entered. The zone boundaries in the zonedimensions array must be a subset of the spatial mesh boundaries in the mesh array. Otherwise, an error message is printed and the problem is terminated. The mesh array is optional and is not used if the zoneintervals array is specified. If neither the zoneintervals array nor the mesh array is specified, an error message is printed and the problem is terminated.

XSDRN* MATERIAL *block

MATERIAL Block keyword = matl, mat, material, materials

The *MATERIAL* block is used to specify the material numbers for each material used in the calculation in the order of scattering cross section to be used for each material. The format of the *MATERIAL* block is identical to the NEWT *MATERIAL* block that is described in detail in (Sect. 9.2). Although source and description specifications are allowed, these options are not used by XSDRN.

XSDRN* COLLAPSE *block

COLLAPSE Block keyword = collapse, coll

The *COLLAPSE* block is used to define the energy group collapsing operation to calculate broad group cross-section libraries using the XSDRN flux solution. The format of the *COLLAPSE* block is identical to the NEWT *COLLAPSE* block that is described in detail in Sect. 9.2.

3.1.7.2 Data Structure for Cross Section Database File xfile016

When branch calculations are performed, TRITON archives collapsed homogenized cross sections in an unformatted, direct-access FORTRAN file called *xfile016*. The contents and format of this file are described in this appendix.

TRITON uses a library of SCALE subroutines to read and write blocks of data to direct-access FORTRAN files. The SCALE subroutine library allows the blocks of data to have variable length, even though direct-access FORTRAN files have a fixed record length. The data blocks can be retrieved from the file at random, provided the block length and block starting record position are known. The block length is expressed in terms of 4-byte words. For example, a block of 3-group macroscopic cross sections that contained the total, fission, capture, chi, and nubar cross sections would have a block length of 15 (3×5), assuming that the cross sections are stored in single precision 4-byte format.

The *xfile016* file supports 11 different block types. The first seven block types appear only once in the file, each block type occupying one of the first seven record positions. The remaining four block types, types 8-11, are repeated for each branch, at each depletion step, starting at the eighth record position.

Branch-specific blocks, i.e., block types 8-11, are written in the following order, for N branch calculations over M depletion steps:

First (t=0) transport calculation, branch 0 (reference state)

First (t=0) transport calculation, branch 1

First (t=0) transport calculation, branch 2

...

First (t=0) transport calculation, branch N

Second transport calculation, branch 0 (reference state)

Second transport calculation, branch 1

Second transport calculation, branch 2

...

Second transport calculation, branch N

...

...

...

$(M + 1)^{th}$ transport calculation, branch 0 (reference state)

$(M + 1)^{th}$ transport calculation, branch 1

$(M + 1)^{th}$ transport calculation, branch 2

...

$(M + 1)^{th}$ transport calculation, branch N

Note that $(M + 1) \times (N + 1)$ sets are saved for M depletion steps and N branches. For each set, block types 8 and 9 are always written, whereas block types 10 and 11 are written only if pin data output was requested ($nx \neq 0$).

Block Type 1: block length data

Length: 13

Position: 1

Type: integer.

Data: datlen(13)

datlen(1) Length of block type 1 (this array), which is 13.

datlen(2) Number of blocks allocated for this file (1000). Currently not used.

datlen(3) Length of FORTRAN record for this file (512).

datlen(4) Length of block type 2: general dimensioning data.

datlen(5) Length of block type 3: depletion data.

datlen(6) Length of block type 4: branching data.

datlen(7) Length of block type 5: branching data for advanced branch block (not yet supported).

datlen(8) Length of block type 6: currently not used.

datlen(9) Length of block type 7: energy group boundaries.

datlen(10) Length of block type 8: cross sections and misc data.

datlen(11) Length of block type 9: corner discontinuity factors.

datlen(12) Length of block type 10: pin power factors.

datlen(13) Length of block type 11: groupwise form factors.

Block Type 2: general dimensioning data

Length: datlen(4)

Position: 2

Type: integer, unless specified otherwise

Data: brnchdepl, nobranch, nsets, igm, iftg, ndelay, nadf, ncdf, ipin, nxpin, nypin, ivers, adftype, branchflag

brnchdepl Number of depletion steps + 1.

nobranch Number of branches.

nsets Number of cross-section sets on library (typically 1).

igm Number of energy groups in collapsed cross sections.

iftg First thermal energy group (max upscatter group).

ndelay Number of delayed neutron precursor groups (6).

nadf Number of assembly discontinuity factors (ADFs).

ncdf Number of corner discontinuity factors (CDFs).

ipin Flag for pin data (0 = no pin data, 1 = pin data included).

nxpin Number of pins in x-direction (0 if ipin = 0).

nypin Number of pins in y-direction (0 if ipin = 0).

ivers Format version number. This appendix describes version 5 of the database structure.

adftype ADF type: (1= single-assembly, 2= reflector, 3= single-assembly on arbitrary grid lines).

branchflag (logical) TRUE for simple BRANCH block format, FALSE for advanced format.

Block Type 3: depletion data

Length: datlen(5)

Position: 3

Type: real

Data: burnup(brnchdepl), time(brnchdepl), power(brnchdepl), sysHMdens

burnup(brnchdepl) Burnup (GWd/MTHM) at each transport step.

time(brnchdepl) Cumulative cycle time (days) at each transport step.

power(brnchdepl) Specific power (MW/MTHM) at each transport step.

sysHMdens System heavy metal mass density (g/cm^3).

Block Type 4: branching data

Length: datlen(6)

Position: 4

Type: integer, unless specified otherwise

Data: fuelused, modused, crused, fuelcount, modcount, crcount, crref, tfref, tmref, mdref, sbref, fuelmix(fuelcount), modmix(modcount), crinmix(crcount), croutmix(crcount), crstate(nobranch), tfuel(nobranch), tmod(nobranch), dmod(nobranch), sboron(nobranch)

fuelused (logical) TRUE if fuel mixtures were specified for branches.

modused (logical) TRUE if moderator mixtures were specified for branches.

crused (logical) TRUE if control rod mixtures were specified for branches.

fuelcount Number of mixtures in fuel definition.

modcount Number of mixtures in moderator definition.

crcount Number of mixture pairs in control rod definition.

crref Reference control rod state (0/1).

tfref (real) Reference fuel temperature (K).

tmref (real) Reference moderator temperature (K).

mdref (real) Referenced moderator density (g/cm^3).

sbref (real) Reference soluble boron concentration (ppm).

fuelmix(fuelcount) Mixtures defined as fuel.

modmix(modcount) Mixtures defined as moderator.

crinmix(crcount) Mixtures defined for the control-rod in state.

croutmix(crcount) Mixtures defined for the control-rod out state.

crstate(nobranch) Control rod state (0=withdrawn/1=inserted) for each branch.

tfuel(nobranch) (real) Fuel temperature (K) for each branch.

tmod(nobranch) (real) Moderator temperature (K) for each branch.

dmod(nobranch) (real) Moderator density (g/cm^3) for each branch.

sboron(nobranch) (real) Soluble boron concentration (ppm) for each branch.

Block Type 5: advanced branching data

Length: datlen(7)

Position: 5

Type: integer

Data: Stores data for advanced branch block (not yet supported)

Block Type 6: currently not used

Block Type 7: energy group boundary data

Length: datlen(9)

Position: 7

Type: real

Data: ebnds(igm+1)

ebnds(igm+1) Energy group boundaries

Blocks 1–7 are written only once. Blocks 8 and 9 (plus 10 and 11 if pin power data is output) are written for each branch case at each depletion step.

Block Type 8: cross-section data

Length: datlen(10)

Position: 8 + (igm + 3) [i * (nobranch + 1) + j]) , i = 0,. . . , brnchdepl, j = 0,. . . , nobranch

Type: real

Data: {kinf(i), beta_eff(1:ndelay, i), lam_eff(1:ndelay, i) , y_i135(i), y_xe135(i), y_pm149(i), id(i), nden(i), aden(i), [sigt(i,j), siga(i,j), xemac(i,j), smmac(i,j), sigc(i,j), sigf(i,j), sign2n(i,j), sigtr(i,j), nusigf(i,j), kappaf(i,j), nu(i,j), chi(i,j), diffcoef(i,j), flux(i,j), sigselas(i,j), sig_xe(i,j), sig_sm (i,j), detfis(i,j), detflx(i,j), invvel(i,j), sigtr2(i,j), sigtr(i,j), [(adf(i,j,k), k=1,nadf),(0,k=nadf+1,12), (current(i,j,k), k=1,nadf),(0,k=nadf+1,12)], (sigs(i,j,k), k=1,igm), j=1,igm], i=1,nsets}

Data is saved for i = 1,nsets (number of homogenized regions):

kinf(i) k-infinity

beta_eff(1:ndelay,i) Approximate delayed neutron fractions.

lam_eff(1:ndelay,i) Approximate delayed neutron decay constants (sec^{-1}).

y_i135(i) Fission product yield for ^{135}I.

y_xe135(i) Fission product yield for ^{135}Xe.

y_pm149(i) Fission product yield for ^{149}Pm.

Data is saved for j = 1, igm (number of energy groups):

sigt(i,j) Total cross section (cm^{-1}).

siga(i,j) Effective absorption cross section (cm^{-1}).

xemac(i,j) Macroscopic ^{135}Xe cross section (cm^{-1})

smmac(i,j) Macroscopic ^{149}Sm cross section (cm^{-1}).

sigc(i,j) Capture cross section (cm^{-1}).

sigf(i,j) Fission cross section (cm^{-1}).

sign2n(i,j) Effective n2n cross section (cm^{-1}).

sigtr(i,j) Transport cross section (cm^{-1}), determined by outscatter approximation.

nusigf(i,j) Average total number of neutrons/fission $\times$ fission cross section (cm^{-1}).

kappaf(i,j) Energy released per capture × capture cross section + Energy released per fission × fission cross section (J/cm).

nu(i,j) Average total number of neutrons released per fission (delayed + prompt).

chi(i,j) Fission spectrum (delayed + prompt).

diffcoef(i,j) Diffusion coefficient (cm), 1 / (3 × sigtr(i,j)).

flux(i,j) Average flux (n/cm^2-sec).

sigselas(i,j) Total elastic scattering cross section (cm^{-1}).

sig_xe(i,j) Microscopic cross section for ^{135}Xe (barns).

sig_sm (i,j) Microscopic cross section for ^{149}Sm (barns).

detfis(i,j) Microscopic ^{235}U cross section at detector location (barns).

detflx(i,j) Average flux in detector mixture (n/cm^2-sec).

invvel(i,j) Inverse neutron velocity (sec/cm).

sigtr2(i,j) Transport cross section (cm^{-1}), determined by inscatter approximation.

sigtr(i,j) Transport cross section (cm^{-1}), determined by outscatter approximation.

adf(1:nadf,i,j) Assembly discontinuity factors for up to 12 faces.

current(1:nadf,i,j) Net current for up to 12 faces (n/cm^2-sec), adftype = 3 only.

sigs(i,j,k), k=1,igm Macroscopic scattering cross section, j k (cm^{-1}).

End of data saved for j = 1, igm

End of data saved for i = 1,nsets

Block Type 9: corner discontinuity factors

Length: datlen(11)

Position: 9 + (igm + 3) [i * (nobranch + 1) + j]) , i = 0,. . . , brnchdepl, j = 0,. . . , nobranch

Type: real

Data: ((cdf(i,j), i=1,ncdf), j=1,igm)

Data is saved for i = 1,ncdf (number of “corner” discontinuity factors):

Data is saved for j = 1, igm (number of energy groups):

cdf(i,j) Corner discontinuity factors

End of data saved for j = 1, igm

End of data saved for i = 1,ncdf

Block Type 10: pin power peaking factors

Length: datlen(12)

Position: 10 + (igm + 3) [i * (nobranch + 1) + j]) , i = 0,. . . , brnchdepl, j = 0,. . . , nobranch

Type: double precision

Data: ((ppf(i,j), i=1,nx), j=1,ny)

Data is saved for j = 1, ny (number of pins in y direction):

Data is saved for i = 1,nx (number of pins in x direction):

ppf(i,j) Pin power (peaking) factors

End of data saved for i = 1, nx

End of data saved for j = 1, ny

Block Type 11: group form factors

Length: datlen(13)

Position: 10 + k + (igm + 3) [i * (nobranch + 1) + j]) ,

k = 1,. . . , igm, i = 0,. . . , brnchdepl, j = 0,. . . , nobranch

Type: double precision

Data: ((gff(i,j), i=1,nx), j=1,ny)

Data is saved for j = 1,ny (number of pins in y direction):

Data is saved for j = 1, nx (number of pins in x direction):

gff(i,j,k) Groupwise form factors

End of data saved for i = 1, nx

End of data saved for j = 1, ny

NOTE: Block Type 11 is repeated igm times where igm is the number of energy groups.

It is recommended that code written to process *xfile016* include the SCALE subroutine library. Although possible to link in the appropriate files in the scalelib object library in SCALE, it may be more practical to copy the appropriate SCALE routines into a new FORTRAN code used in reading *xfile016*. All direct-access operations needed to operate on this file are contained in the file direct_access_M.f90 in the scale src/scalelib directory. This file has dependencies and requires the following additional subroutines, all in the `src/scalelib` directory, in order to compile:

Error_functions_M.f90

common_unit_C.f90

Vast_kind_param_M.f90

separator_character_M.f90

Y0trns_M.f90

f_exit.c

The single C routine can be eliminated by eliminating the call to f_exit in subroutine stop of Error_function.f90, e.g., change

```
if ( stopcode == 0 ) return
write(npr,'(1x,a,i10)') 'stop code ',stopcode
call f_exit(npr)

end subroutine stop
```

to

```
if ( stopcode == 0 ) return
write(npr,'(1x,a,i10)') 'stop code ',stopcode
write(standard_output,'(a)')npr
stop

end subroutine stop
```

Alternatively, one can utilize the module listed on the following pages, developed by Mr. Benjamin Collins of the University of Michigan, which includes all necessary coding wrapped into a single Fortran module. Although developed from SCALE 5.1 routines, the format of SCALE direct access does not change and this source should remain compatible with later versions of SCALE.

```
module direct_access

3.1.7.3 The Flexible Branch Block

In support of various projects, the "flexible branch block" was developed to enable a broader set of perturbations than are available in the typical TRITON branch capability. The typical branch block allows the user to define a single set of mixtures for 'fuel,' 'mod,' 'crout', or 'crin'. Having only four material set definitions limits user's ability to specify more complex perturbations that may be possible in some reactors, especially under transient conditions. The flexible branch block was developed such that the user can specify any number of material sets, and then apply separate perturbations to those sets. This capability, for example, enables specification of bypass flow density branches in BWRs in which the in-channel coolant and out-channel moderator can set to different densities in the same branch calculation.

The flexible branch block was developed in the SCALE 6.1 implementation of TRITON and was not modernized for SCALE 6.2. As a result, the flexible branch block is available in SCALE 6.1 and in the legacy mode in SCALE 6.2. The legacy mode can be accessed using *t-d* as the sequence name, rather than the more typical *t-depl*. The flexible branch block can be accessed using **branchblock** as the block name, rather than **branch** that is used for the typical branch block.

The following section of the manual explains the syntax of the **branchblock** and contains short examples of each element within the the **branchblock**. At the end of this section, a full example of a **branchblock** is provided so that users can gain an understanding of how to use all of the parts of the **branchblock** in order to define needed calculation branches.

SYNTAX:

```
read branchblock
  [block keyword specifications]
end branchblock
```

The advanced **branchblock** supports five different keyword specifications described below.

- **mixset** — used to define a set of mixtures which can be used in **swap** and **perturbset** definition,
- **systemchange** — used to define a system change to, temperatures, nuclide concentrations, and Dancoff factors,
- **swap** - used to define a set of mixtures to swap,
- **perturbset** — used to define a set of perturbations which apply the system changes defined by **systemchange** to a set of mixtures, and
- **branch** — used to define a branch calculation, composed of various **swaps** and **perturbsets**. Additional perturbations may also be defined.

Note: Several keywords in the*__branchblock__* are defined using strings. These strings must be must be delimited, i.e. starts and ends with an identifying marker. (Examples: `title="cold"`, `title=#hot Doppler#`, `title=!40%void!`, `title=(80%void)`). As shown in the following examples, the string can optionally start with open angle bracket < and end with a closing angle bracket > (Example: `title=<cold>`). All string-value inputs in the ***branchblock*** are delimited, alphanumeric strings with a maximum length of 80 characters. It is recommended that users choose a single type of delimiter, and then use that delimiter throughout the **branchblock**

---

systemchange

SYNTAX:

```
read branchblock
  [...]
  systemchange title
    [systemchange keyword specifications]
  end systemchange
  [...]
end branchblock
```

systemchange supports the following keyword specifications:

```
title
dancoff=(real value)
temperature=(real value)
dendiv N1 f1 N2 f2 end
denmult N1 f1 N2 f2 end
```

title is required string input and must follow **systemchange**. Only one title keyword may be specified. Multiple **systemchange** specifications are allowed, so each specification must have a unique **title**.

dancoff is optional and is used to set a dancoff factor value in the interval [0,1]. Only one dancoff specification is allowed and can appear anywhere in the **systemchange** specification following the title.

temperature is optional and is used to set a system temperature in Kelvin. It must be nonnegative. Only one temperature specification is allowed and can appear anywhere in the **systemchange** specification following the title.

dendiv and **denmult** are keyword arrays used to define nuclide concentration dividers and multipliers respectively. The arrays must be terminated with the **end** keyword. Each array is defined by a series of nuclide/factor pairs where nuclide is the ZZZAAA identifier and factor is either a multiply or divide factor applied to that nuclide concentration (Note that the particular mixture for which the factor is applied is defined in the **perturb** specification described below). Multiply factors must be >=0. Divide factors must be >0. A nuclide identifier set to zero implies that the factor is applied to all nuclides that are not explicitly listed in the array. Multiple dendiv and denmult arrays are allowed and can appear anywhere in the **systemchange** specification following the title. TRITON applies the concentration factors in the order in which they are entered in the systemchange specification.

Multiple **systemchange** specifications are allowed in the branch block. They can appear in any order, but must have a unique title.

EXAMPLE:

Define a temperature change to 60 kelvin. (The temperature change will be applied to a set of mixtures defined in the **perturbset** specification defined later.)

```
systemchange <60C>
  temperature=333.15
end systemchange
```

swap

SYNTAX:

```
read branchblock
  [...]
  swap title
    [swap keyword specifications]
  end swap
  [...]
end branchblock
```

swap supports the following keyword specifications:

```
title
group1 [mixture specifications] end
group2 [mixture specifications] end
```

title is required string and must follow **swap**. Only one title keyword may be specified. Multiple **swap** specifications are allowed, so each specification must have a unique **title**.

group1 and **group2** are used to define a set of mixtures to exchange. **group1** must follow the **swap** title. **group2** must follow **group1**. Only one specification for each group is allowed and they must have the same number of mixtures.

The **group1** and **group2** keywords support the following keyword specifications:

```
mixture=(integer value)
mixtures I1 I2 ... IN end
mixset=(string value)
```

mixture is used to define a single mixture. **mixtures** is used to define an array of mixtures and is terminated with the **end** keyword. **mixset** is used to substitute a **mixset** specification defined elsewhere in the branchblock. Multiple **mixture**, **mixtures**, and **mixset** are allowed and can be placed in any order. TRITON will remove any duplicated mixture identifier, however each mixture must be defined in the model input.

EXAMPLES:

Exchange material 1 for 4.

```
swap <1 for 4>
  group1 mixture=1 end
  group2 mixtures 4 end end
end swap
```

Exchange a set of mixtures:

```
swap <RodInsertion>
  group1 mixset=<crout> end
  group2 mixset=<crin> end
end swap
```

branch

SYNTAX:

```
read branchblock
  [...]
  branch title
    [branch keyword specifications]
  end branch
  [...]
end branchblock
```

branch supports the following keyword specifications.

```
title
swap=(string value)
perturbset=(string value)
perturb [perturb specification] end
```

title is required string and must follow **branch**. Only one title keyword may be specified. Multiple **branch** specifications are allowed, so each specification must have a unique **title**.

swap is used to swap different sets of mixtures. The swap value is a string which is the title of a **swap** specification defined elsewhere in the branchblock. (The **swap** specification is described below). Multiple **swap** specifications are allowed and can appear anywhere in the **branch** specification following the title.

perturbset is used to apply a series of system perturbations. The perturbset value is a string which is the title of a **perturbset** specification defined elsewhere in the branchblock. (The **perturbset** specification is described below). Multiple **perturbset** specifications are allowed and can appear anywhere in the **branch** specification following the title.

perturb is used to apply a system perturbation that is not defined through the use of a **perturbset** specification. **perturb** specifications must terminate with the **end** keyword.

perturb supports the following keyword specifications.

```
change=(string value)
mixture=(integer value)
mixtures I1 I2 ... IN end
mixset=(string value)
```

change is a string which is the title of a **systemchange** specification defined elsewhere in the branchblock. Only one **change** specification is allowed and may appear anywhere in the **perturb** specification.

The system change is applied to a set of mixtures defined by the **mixture**, **mixtures**, and **mixset** specifications. Only one of each of these keywords is allowed (however all three may be used in the same **perturb** specification). **mixture**, **mixtures**, and **mixset** may be placed in any order. TRITON will remove any duplicated mixture, however each mixture must be defined in the model input. TRITON will perform **swap** and **perturb** operations in the order they appear in the input.

EXAMPLES:

Define a branch to charactize the rodded, cold-zero-power condition. This requires the use of mixture swap entitled <CRodIn> along with the perturbset definition <ColdMod> which perturbs all of the moderator mixtures to a cold temperature and density. The fuel mixtures (defined as <FuelMix>) must also be set to a temperature of 300K.

```
read branchblock
  [...]  (contains definitions for <CRodIn>, <FuelMix>, and <ColdMod>)
  branch <CZP,rodded>
    perturbset=<ColdMod> swap=<CRodIn>
    perturb change=<300K> mixset=<FuelMix> end
  end branch
  systemchange <300K> temperature=300 end systemchange
end branchblock
```

Define a branch to characterize the BWR instantaneous 100% void branch. This requires that:

- in-channel moderator mixtures (<ChannelMod>) are perturbed from 40% void to 100% void (defined by systemchange <40vf-100vf>).

- Water-rod moderator mixtures (<WaterRodMod>) are perturbed from 0% void to 5% void (<0vf-5vf>)
- Bypass moderator mixtures (<BypassMod>) are perturbed from 0% void to 3% void (<0vf-3vf>)
- Corner Rod Fuel mixture (mixture 1) dancoff factor changes (described by <100vf-cornerDF>)
- Edge Fuel Rod Mixtures (3,4,5,6,7,10) dancoff factor changes (described by <100vf-edgeDF>)

```
read branchblock
  [...]   (contains all other definitions)
  branch <100VF>
    perturb change=<40vf-100vf> mixset=<ChannelMod>  end
    perturb change=<0vf-5vf>    mixset=<WaterRodMod> end
    perturb change=<0vf-3vf>    mixset=<BypassMod> end
    perturb mixture=1 change=<100vf-cornerDF> end
    perturb mixtures 3 4 5 6 7 10 end change=<100vf-edgeDF> end
  end branch
end branchblock
```

mixset

mixset — used to define a set of mixtures used in **swap**, **perturbset**, and **perturb** specifications.

SYNTAX:

```
read branchblock
  [...]
  mixset title
    [mixset keyword specifications]
  end mixset
  [...]
end branchblock
```

mixset supports the following keyword specifications:

```
title
mixture=(integer value)
mixtures I1 I2 ... IN end
mixset=(string value)
```

title is required string and must follow **mixset**. Only one title keyword may be specified. Multiple **mixset** specifications are allowed, so each specification must have a unique **title**.

mixture is used to define a single mixture. **mixtures** is used to define an array of mixtures and is terminated with the **end** keyword. **mixset** is used to substitute a **mixset** specification defined elsewhere in the branchblock. Multiple **mixture**, **mixtures**, and **mixset** are allowed and can be placed in any order. TRITON will remove any duplicated mixture identifier, however each mixture must be defined in the model input. If **mixset** is used to, the mixture set must be *previously* defined in the branchblock.

EXAMPLE:

In previous example for 100% void fraction, define a mixture set to be used for the edge rod dancoff factor perturbation.

```
read branchblock
  [...]   !contains all other definitions
  branch <100VF>
    perturb change=<40vf-100vf> mixset=<ChannelMod>  end
    perturb change=<0vf-5vf>    mixset=<WaterRodMod> end
    perturb change=<0vf-3vf>    mixset=<BypassMod> end
```

(continues on next page)

(continued from previous page)

```
    perturb mixture=1 change=<100vf-cornerDF> end
    perturb change=<100vf-edgeDF> mixset=<edge-fuel> end
  end branch
  mixset <edge-fuel>
    mixtures 3 4 5 6 7 10 end
  end mixset
end branchblock
```

perturbset — used to define a set of system perturbations that can be used in **branch** specifications.

SYNTAX:

```
read branchblock
  [...]
  perturbset title
    [perturbset keyword specifications]
  end perturbset
  [...]
end branchblock
```

perturbset supports the following keyword specifications:

```
title
perturb [perturb specification] end
```

title is required string and must follow **perturbset**. Only one title keyword may be specified. Multiple **perturbset** specifications are allowed, so each specification must have a unique **title**.

After title, multiple **perturb** specifications can be used to defined a set of perturbations. The **perturbset** can then be used in **branch** specifications to simplify the **branch** input. TRITON will apply the perturbations in the order in which they appear in the **perturbset** specification.

EXAMPLE:

In previous example for 100% void fraction, define a perturbset for the moderator perturbations, and a separate perturbset for the fuel perturbations.

```
read branchblock
  [...]   !contains all other definitions
  perturbset <modChange>
    perturb change=<40vf-100vf> mixset=<ChannelMod>  end
    perturb change=<0vf-5vf>    mixset=<WaterRodMod> end
    perturb change=<0vf-3vf>    mixset=<BypassMod> end
  end perturbset
  branch <100VF> perturbset=<modChange> perturbset=<fuelChange>  end branch
  perturbset <fuelChange>
    perturb mixture=1 change=<100vf-cornerDF> end
    perturb change=<100vf-edgeDF> mixset=<edge-fuel> end
  end perturbset
  mixset <edge-fuel>
    mixtures 3 4 5 6 7 10 end
  end mixset
end branchblock
```

branchblock Full Example

Because the **branchblock** input is so flexible, it may be difficult for users to know where to begin. For that reason, we have provided a sample **branchblock** that is typical to a BWR analysis. In this example, the open and close parentheses are using instead of angle brackets. In the example provided, the **branchblock** is separated into ### different sections: definition of **mixsets**, definition of **systemchanges**, definition of **swaps**,

definition of **perturbsets** (which are composed of multiple **systemchanges**), and definition of **branches**. This example may appear complicated, but in essence, it is quite straightforward. First, all of the mixture IDs in the problem are defined into logical **mixsets**. Then, other large **mixsets** are composed of the individual **mixsets**. The first two **systemchanges**, (1/nom) and (1/liq), are a very important items. These **systemchanges** are density divisors that divide the number densities of a specified moderator mixture by the nominal or liquid density, making the resulting density 1.0. Then, **systemchanges** that are density multipliers are specified as the actual density, which make the **branchblock** much easier to read and understand. By using the special density divisors, an almost identical **branchblock** can be use for different nominal densities — only the density specified in (1/nom) needs to be modified for a different nominal density.

Following the **systemchanges**, a number of **perturbsets** are defined to make multiple perturbations to the collant or moderator density. For example, the (00%Void353) **perturbset** shown below makes six changes: (1) divide all coolant (in-channel) mixtures by the nominal density, then (2) multiple all coolant mixtures by the specified density, (3) divide all liquid water moderator (out-channel) features by the saturated liquid density, then (4) multiple all liquid water features by the specified density, and then, (5) and (6) change the Dancoff factors to their appropriate values corresponding to the coolant and moderator densities.

```
perturbset (00%Void353)
 perturb mixset=(coolant)    change=(1/nom)             end
 perturb mixset=(coolant)    change=(00V-353)           end
 perturb mixset=(solidmod)   change=(1/liq)             end
 perturb mixset=(solidmod)   change=(00V-353)           end
 perturb mixset=(cornerfuel) change=(00VCold-dfC0)      end
 perturb mixset=(edgefuel)   change=(00VCold-dfE0)      end
end perturbset
```

To end the file, all branch calculations are specified in a single block using the previously defined **perturbsets**. Note that unlike the typical **branch** block, the flexible **branchblock** does not need the first branch to correspond to the nominal conditions. It is important to note that in the *xfile016* and *txtfile16* files, the branch conditions (moderator density, temperature, soluble boron, and CR state) will not be listed correctly in the file header as they are for the typical **branch** block. When using the **branchblock** input, TRITON no longer knows the condition for any given branch, however, the branch order specified in the input file is maintained in the *xfile016* and *txtfile16* files.

Also note that in the example provided, no soluble boron changes have been specified (as this is a BWR example). However, soluble poisons (boron or other), are also fairly straightforward to specify using the density divisors and density multipliers.

BWR branchblock Example

```
read branchblock
  mixset (1f127E)      mixtures   701                 end   end mixset
  mixset (1f127C)      mixtures   702                 end   end mixset
  mixset (1f169C)      mixtures   703                 end   end mixset
  mixset (1f169E)      mixtures   704                 end   end mixset
  mixset (1f194)       mixtures   705                 end   end mixset
  mixset (1f194C)      mixtures   706                 end   end mixset
  mixset (1f194E)      mixtures   707                 end   end mixset
  mixset (1f279)       mixtures   708                 end   end mixset
  mixset (1f279E)      mixtures   709                 end   end mixset
  mixset (1f279gd40)   mixtures   710 711 712 713 714  end   end mixset

  mixset (gap)       mixtures   800 801 802 803 804 805 806 807 808 809 end   end mixset
  mixset (clad)      mixtures   825 826 827 828 829 830 831 832 833 834 end   end mixset
  mixset (coolant)   mixtures   850 851 852 853 854 855 856 857 858 859 end   end mixset
```

3.2 POLARIS - 2D LIGHT WATER REACTOR LATTICE PHYSICS MODULE

M. A. Jessee, W. A. Wieselquist, A. M. Holcomb, S. W. Hart, J. W. Bae, K. S. Kim, C. A. Gentry

ABSTRACT

Polaris is an easy-to-use light water reactor (LWR) lattice physics capability for SCALE. Originally released in SCALE 6.2, Polaris uses the Embedded Self Shielding Method (ESSM) for multigroup cross section processing and a transport solver based on the Method of Characteristics (MOC). The ESSM computes multigroup self-shielded cross sections using Bondarenko interpolation methods. The background cross section used in the interpolation is determined by iterative 2D MOC fixed-source transport calculations. Polaris is integrated with ORIGEN for depletion calculations. Each pin-or each radial subregion of the pin-is depleted based on the local power distribution. An optional critical spectrum calculation is incorporated into the depletion calculation and the output edits of few-group homogenized cross sections. Few-group cross sections are archived to the lattice physics archive (`.t16` and `.x16` extension) file, which can be used in subsequent core simulator calculations. Nuclide inventories are archived to the ORIGEN binary concentration file (`.f71` extension), which can be used in subsequent SCALE calculations for source term characterization or radition shielding. Depletion and decay data are archived to the ORIGEN binary library file (`.f33` extension), and can also be used in subsequent source term calculations.

ACKNOWLEDGMENTS

The authors express gratitude to the US Nuclear Regulatory Commission (NRC) for funding Polaris development. The author acknowledges Don Algama and Mourad Aissa of the NRC for their support of the project.

3.2.1 INTRODUCTION

Polaris was introduced in SCALE 6.2 to provide 2D lattice physics analysis capability for light water reactor (LWR) fuel designs. For multigroup cross section processing, Polaris uses the Embedded Self-Shielding Method (ESSM) [POLARISWK12]. Unlike SCALE multigroup sequences that use XSProc, ESSM does not require user-defined unit cell definitions. ESSM computes multigroup cross sections using Bondarenko interpolation methods. The background cross section used in the interpolation is determined by iterative 2D fixed source transport calculations. Both the ESSM fixed-source calculations and the keff calculation utilize a Method of Characteristics (MoC) transport solver developed in the Exnihilo computational package.

Polaris is integrated with ORIGEN for depletion calculations. Each pin-or each radial subregion of the pin-is depleted based on the local power distribution. An optional critical spectrum calculation is incorporated into the depletion calculation for computing depletion reaction rates and/or few-group homogenized cross sections. A complete description of the Polaris computational methods is provided in [POLARISJWM+21].

Polaris provides an easy-to-use input format to allow users to set up lattice models with minimal lines of input. All recognized Polaris commands are shown in Table 3.2.1. Note that many commands support short and

long forms. The allowed basic *Types* for input are described in Table 3.2.2. The special Polaris *TYPES* are shown in Table 3.2.3. The convention used in this manual is that basic types appear italicized and capitalized (*Type*), while special Polaris types appear in all caps (*TYPE*).

Table 3.2.1: Polaris commands.

card	*long command*	*short command(s)*
system	system	sys
geometry	geometry	geom
composition	composition	comp
property	property	prop
material	material	mat
burnup	bu or dbu	-
power	power	pow

Real	any number	565 10.257 1.5e-6	yes bor_water
String	a single or double quoted string	"INFMED" "Includes spaces" 'NONE'	Includes spaces
Value	any non-word		*Int*|*Bool*|*Real*|*String*

Table 3.2.3: Special Polaris Types.

Polaris type	description	variants
STYPE	system type	*PWR* | *BWR*
GTYPE	geometry type	*ASSM* | *REFL*
CTYPE	composition type	*NUM* | *WT* | *FORM* | *CONC* | *LW* | *UOX* | *ENRU* | *UN* | *USI*
PTYPE	property type	*SOLP* | *DOPANT*
ETYPE	control element type	*RODLET*|*BLADE*
OTYPE	option type	*KEFF* | *BOND* | *ESSM* | *CRITS PEC* | *FG* | *DEPL* | *RUN* | *PRINT* | *GAMMA* | *GEOM* | *DATA*

The Polaris input supports a very flexible input scheme that allows some elements to be suppressed for better readability. With *key=value* type input, when the standard order of keys is used, the keys may be suppressed. Consider the following input specification as an example.

```
geometry GNAME : ASSM npins=Int ppitch=Real [sym=<FULL>|SE]
```

The geometry card requires a geometry name (GNAME) in the first group, then a geometry type (*GTYPE*) which is *ASSM* here indicating an assembly geometry. The remaining arguments have keys: "npins" with an integer value, "ppitch" with a real value, and the optional "sym" with either *FULL* or *SE* values (optional arguments are always shown in square brackets: [sym=<*FULL*>|*SE*]. The default value is in angle brackets: <FULL>. The pipe "|" shows an *or* relation (i.e., *FULL* or *SE* is an acceptable value). With the flexible input processing, the following inputs are all valid and identical.

```
geometry FuelNode : ASSM npins=15 ppitch=1.43 sym=FULL
geometry FuelNode : ASSM 15 1.43 FULL
geometry FuelNode : ASSM sym=FULL ppitch=1.43 npins=15
geometry FuelNode : ASSM 15 1.43
geometry FuelNode ASSM 15 1.43
```

The group separator ":" is suppressed in the last variant. This is possible in any situation where (1) the group is implicitly terminated by running out of arguments or (2) the next type does not match the expected type in the current group. For example, consider the hgap card:

```
hgap [ d ] [: M ]
```

In this card, d and M are values (without keys) defined as *Real* and material name (MNAME), respectively. The following form would automatically bypass the *Real* value, which allows a default, and set the interassembly gap material name as COOL.2.

```
hgap COOL.2
```

3.2.2 SCALE 6.3 POLARIS INPUT UPDATES

For the release of SCALE 6.2.3, several new input cards were implemented into Polaris to model boiling water reactor (BWR) geometries and neutron/gamma detectors, which requires a gamma transport calculation. Moreover, improvements to existing input cards were implemented, along with the ability to specify time-dependent state properties and the ability to specify one or more depletion histories. This section describes the new and modified input cards that are included in the Polaris input format for SCALE 6.3, which are accessible as part of the release of SCALE 6.2.3.

To maximize backwards compatibility for input files developed with the original SCALE 6.2.0 release, the new and modified input cards are not available *by default* with SCALE 6.2.3. The new and modified input cards were activated if the input file begins with =polaris_6.3 rather than =polaris. The suffix "_6.3" is an indicator to the Polaris input processor to use the SCALE 6.3 input format. For the SCALE 6.3 release, the original input cards supported in the SCALE 6.2 input format will be available if the input file begins with =polaris_6.2, with the new SCALE 6.3 defaults being used for inputs with =polaris.

The new input cards to model BWR geometries include:

- **cross** – define the interior water cross geometry of SVEA assembly designs;
- **dxmap** (or **dymap**) – define displacement maps that indicate that translation of the pin center in the x- (or y-) direction;
- **control <BLADE>** – define the control blade geometry;
- **mesh** – define advanced spatial meshing options for different materials; and
- **option <GEOM>** – define geometry tolerances, advance meshing options, and plotting options.

The modified input cards to model BWR geometries include:

- **pin** – define circular and square-based geometry zones, as well as arbitrarily sized pins, e.g. size=1.5 water rod in some 9x9 BWR lattice designs; and
- **box** – define channel box geometry with arbitrary number of zones and cutout regions.

For neutron/gamma detector modeling, there is a new **detector** card and an addition to the existing **option <FG>** card to enable output to the few-group cross section output (T16) file.

To control the gamma calculation, an **option <GAMMA>** has been added.

The new input cards for time-dependent modeling include:

- **history** – define one or more operating histories in the input file; and

- **bui** (or **ti**) – define restart cumulative burnup (or time) values.

The modified input cards for time-dependent modeling include:

- **state** – define one or more time-independent or time-dependent state properties;
- **bu** (or **t**) – define cumulative burnup (or time) values; and
- **dbu** (or **dt**) – define incremental burnup (or time) values.

Example input files are included in the ${SCALE}/regression/input directory:

- polaris.6.3.atrium9x9.inp and polaris.6.3.atrium10x10.inp – prototypic ATRIUM models;
- polaris.6.3.blade1.inp and polaris.6.3.blade2.inp – control <BLADE> examples;
- polaris.6.3.ge7x7.inp through polaris.6.3.ge10x10.inp – prototypic GE models;
- polaris.6.3.svea100.inp and polaris.6.3.svea64.inp – prototypic SVEA models; and
- polarisHistory.inp: history example.

3.2.3 SETUP

The cards in this section generally appear at the beginning of an input file. Note that the manual is organized with each card starting a new page. This is especially convenient when printing a few cards across different sections.

3.2.3.1 title - case title lines

title Line_1 Line_2 ... Line_i ... Line_N

param	type	name	details	default
Line_i	*String*	line	used in output file headers	"DEFAULT TITLE"

Examples:

```
title "Westinghouse 15x15"

title "Westinghouse 15x15"
       "Condition: Hot Full Power"
       "Date: 10/18/2012"
```

Comments:

The **title** card gives a title to this Polaris case, which appears as a descriptive header on the output file. The additional lines may be used to document a subcase or to embed additional information in the output file in an orderly way (e.g., author, date, project identifier).

The **title** card is optional.

See also:

lib

3.2.3.2 library - nuclear data libraries

lib [mg=*String*]

param	type	name	details	default
mg	*String*	multigroup library	multigroup cross section library	"fine_n"

Examples:

```
% a name of library in the DATA directory
% use SCALE 252g ENDF/B-VII.1 library
lib "fine_therm"   % Alias for the V7.1 252g-neutron 47g-gamma library

% use SCALE 56g ENDF/B-VII.1 library
lib mg="broad_lwr"   % Alias for the V7.1 56g-neutron 19g-gamma library

% a name of a local library in the temporary working directory
% (useful in SAMPLER calculations)
lib "perturbed_xs_library"

% fully specified path
lib "C:\scale6.3\data\scale.rev05.xn252v7.1"
```

Comments:

The **lib** card specifies the multigroup library location. See SCALE's FileNameAliases.txt file in the installation directory for up-to-date library aliases for the fine and broad group libraries provided in SCALE's data directory. Only the 252-group and the 56-group cross section libraries are recommended to be used in Polaris. Full specification of the file path is acceptable, as in the final example shown above.

The **lib** card is optional.

title

3.2.4 GEOMETRY

The highest level structures in the model are named and defined with a **geometry** card. The general outline for a geometry definition is shown below. Two types of geometry are currently supported, *ASSM* for pressurized water reactor (PWR) or boiling water reactor (BWR) assemblies with fuel elements in a square-pitch, and *REFL* for an assembly-adjacent reflector.

geom GNAME : GTYPE *arguments*

param	type	name	details	default
GNAME	*Word*	geometry name		
GTYPE	-	geometry type		
	ASSM	assembly	see **pin** & **pinmap**	
	REFL	reflector	see **slab**	
arguments	-	remaining arguments	depends on *GTYPE*	

The control element geometry is also enumerated with types, as shown below. To model PWR-type rod cluster control assemblies (RCCAs), the *RODLET* element type is used in conjunction with **pin** definitions. In future releases of Polaris, other control element types, such as BWR-type control blades will be supported..

control INAME : ETYPE *arguments*

param	type	name	details	default
INAME	*Word*	control element name		
ETYPE	-	control element type		
	RODLET	PWR-type RCCA	requires PINIDs	
arguments	-	remaining arguments	depends on *ETYPE*	

3.2.4.1 geometry<ASSM> – assembly

geom GNAME : *ASSM*
npins=*Int*
ppitch=*Real*
[sym=<*FULL*>|*SE*]

param	type	name	details	default
GNAME	*Word*	assembly name		
GTYPE	*ASSM*			
npins	*Int*	number of pins	on each side of the assembly	
ppitch	*Real*	pin pitch	units: cm	
sym	FULL|SE	symmetry	assembly symmetry, FULL: no symmetry, SE: south-east quarter	FULL

Examples:

```
% simple pincell
geom MyPin : ASSM 1 1.5

% 17x17 Westinghouse with 1.26 cm pin pitch in quarter symmetry
geom FuelNode : ASSM 17 1.26 sym=SE
```

Comments:

Examples:

% simple pincell

geom MyPin : ASSM 1 1.5

% 17x17 Westinghouse with 1.26 cm pin pitch in quarter symmetry

geom FuelNode : ASSM 17 1.26 sym=SE

Comments:

The assembly geometry describes the basic elements of an assembly. The **pin** and **pinmap** cards are required to finalize the assembly geometry. The **hgap** card specifies the interassembly half gap, and the **channel** specifies the channel material for the assembly.

See also:

pinmap, **pin, hgap, box, channel, control**, **insert**

3.2.4.2 geometry<REFL> - reflector

geom GNAME : *REFL*
thick=*REAL*

param	type	name	details	default
GNAME	*Word*	reflector name		
GTYPE	*REFL*			
thick	*Real*	thickness	units: cm	

Examples:

```
% defines a 20 cm reflector
geom ReflectorNode : REFL 20.0
```

Comments:

The reflector geometry describes the basic elements of a simple slab-type reflector. The **slab** card can be used to define geometric dimensions and mesh for the reflector geometry.

See also:

slab

3.2.4.3 channel - coolant channel

channel [M_{chan} =MCLASS]

param	type	name	details	default
M_{chan}	MCLASS	material class	initializes materials in outermost **pin** zone	*
*By default, M_{chan} will be set to COOL by "system PWR" and "system BWR." Otherwise, M_{chan} is required.				

Examples:

```
% define the channel material class to be COOL
channel COOL
```

Comments:

The **channel** card is used to set the default channel material class for the outermost region of each pin, typically containing reactor coolant. See the **material** card for a description of material classes.

See also:

pin, material, geometry<ASSM>

3.2.4.4 hgap - half distance between assemblies

hgap [d_E d_N d_W d_S]
[: M_E M_N M_W M_S]
[: nf_E nf_N nf_W nf_S]
[: nd_E nd_N nd_W nd_S]

param	type	name	details	default
d_i	*Real*	list of widths *with i*: *E:* east *N:* north *W:* west *S*: south	accepts 1, 2, or 4 values E: all hgaps are same E+N: d_E =d:sub: *S* and d_N =d_W units: cm	0.0
M_i	MNAME	list of material names	requires same # as d_i	*
meshing options				
nf_i	*Int*	list of number of faces per pin	requires same # as d_i	2
nd_i	*Int*	list of number of divisions	requires same # as d_i	1

*By default, **hgap** material will be set to COOL.1 by "system PWR." For "system BWR," the east and south **hgap** materials will be set to MOD.2, and the west and north **hgap** materials will be set to MOD.1. Otherwise **hgap** material is required.

Examples:

```
% defines a 17x17 Westinghouse assembly with 1.26 cm pin pitch
% with 0.04 cm half-gap filled with material COOL.1
geom w17x17 : ASSM 17 1.26 sym=SE
hgap 0.04 COOL.1

% defines a GE 7x7 assembly with 1.88 cm pin pitch
```

(continues on next page)

(continued from previous page)

```
%   0.48 cm narrow gap on east and south edge
%   0.95 cm wide gap on north and west edge
%   narrow gap mesh is 3
%   wide gap mesh is 4
%   faces per pin is 2 for both narrow and wide gap
geom ge7x7 : ASSM 7 1.88
hgap 0.48 0.95 : MOD.1 MOD.1 : 2 2 : 3 4
```

Comments:

The **hgap** specifies the outermost geometry region in an assembly. If a channel **box** exists, then **hgap** specifies the material and mesh from outer channel box edge to the problem boundary. Otherwise**, hgap** specifies the material and mesh from the edge of the fuel array to the problem boundary. In both cases, **hgap** represents the half-distance between adjacent assemblies for single assembly calculations. Fig. 3.2.1 shows some of the hgap meshing options. Referring to the south edge of the assembly, the number of faces per pin refers to the extra cells introduced by "splitting" the pin cell boundary, and the number of divisions refers to extra horizontal lines dividing half gap into smaller width cells.

See also:

pinmap, **control**, **insert**, **geometry<ASSM>, channel, box**

3.2.4.5 box - channel box geometry

box thick=*Real* [rad=*Real*] [hspan=*Real*] [Mbox=MNAME] [cothick=*Real*] [cobtm=*Real*] [cotop=*Real*]

[: t_2 t_3 … t_i … t_N
[: a_2 a_3 … a_i … a_N
[: b_2 b_3 … b_i … b_N
[: M_2 M_3 … M_i … M_N

[: r_2 r_3 ... r_i ... r_{N+1}]]]]]

param	type	name	details	default
thick	*Real*	nominal thickness (cm)	must be > 0.0	
rad	*Real*	inner corner radius (cm)	must be ≥ 0.0	0.0
hspan	*Real*	half inner span (cm)	———-See comments——-	
Mbox	*MNAME*	box material		*
cothick	*Real*	interior cutout region thickness (cm)	thick > cothick ≥ 0.0	0.0
cobtm	*Real*	distance from box centerline to bottom of interior cutout region (cm)	hspan-rad > cobtm ≥ 0.0	0.0
cotop	*Real*	distance from box centerline to top of interior cutout region (cm)	cobtm ≥ cotop ≥ 0.0	cobtm
options for additional box zones				
t_i	*Real*	zone thickness (cm)	must be ≥ 0	
a_i	*Real*	distance from box centerline to bottom of zone cutout region (cm)	——See comments——	
b_i	*Real*	distance from box centerline to top of zone cutout region (cm)	——See comments——	
M_i	*MNAME*	zone material	——See comments——	
ri	*Real*	zone inner corner radius (cm)	——See comments——	

*By default, **box** material will be set to CAN.1 by "system BWR." Otherwise **box** material is required.

Examples:

```
% simple
box 0.2

% rounded corner, rad 0.9
box 0.2 0.9
```

(continues on next page)

(continued from previous page)

```
% rounded corner and user-defined inner span
box 0.2 0.9 6.7

% two zones
box 0.2 0.9 6.7
  : 0.2
  : 4.0
  : 4.3
```

Comments:

The **box** specifies the channel box geometry that surrounds the **pinmap**. The three primary dimensions of the channel box are the thickness (thick), the inner corner radius (rad), and the half inner span (hspan). Several additional dimensions for both **box** and **cross** are defined with respect to the channel box center. The channel box center is not to be confused with the lattice center: the former is the centroid of the inner channel box square boundary and the latter will depend on the wide and narrow gap dimensions provided on the **hgap** card. By default, the half inner span is equal to the half pin pitch multiplied by the number of pins on each side of the assembly (see npins and ppitch on the **geometry<ASSM>** card). If a **cross** card is applied, the default half inner span is increased by the half width of the interior cross buffer region (see hwidth on the **cross** card).

Additional channel box zones can be specified on the **box** card. The additional zones are useful for defining thick corner regions of the channel box. Each additional zone must have a user-defined thickness (t_i, i = 2 to N). Note that the starting index begins at "2" rather than "1" because the zone 1 thickness has already been defined by the "thick" input field.

"Cutout regions" may be defined in which a portion of the channel box zone is replaced by the corresponding **hgap** material along the horizontal and vertical centerlines of the channel box. The cutout region is defined by the distance from the channel box centerline to the bottom additional channel box zone (a_i) and the top of the channel box zone (b_i). The values of a_i and b_i determine the size of trapezoidal cutout region centered along each face of the channel box. The b_i value must be greater than or equal to the a_i value. The a_i value must be greater than or equal to the previous zone's b_i value, i.e., b_{i-1}. By default, a_2 and b_2 are zero. If only M cutout regions are specified for N additional zones, i.e., M < N, both a_i and b_i is set to b_M for i = M+1 to N.

Additional zones can also have a different inner corner radius ($r_2 \ldots r_N$). The outer corner radius of the last zone may also be specified (r_{N+1}). By default, r_2 is zero if rad is zero. If rad is greater than zero, the default value of r_2 is rad+thick. Similar rules apply for determining the default corner radii for additional zones if they are omitted in the input specification.

Additional zones can also have a different material (M_i). By default, M_2 is M_{box}. If additional materials are omitted in the input, the default value of M_i is M_{i-1} for i = 3 to N.

The spatial mesh along each face of the channel box will be determined by the nf values specified on the hgap card.

The four examples listed above are displayed in Fig. 3.2.2. For additional examples, see the polaris.6.3 regression input files described at the beginning of Sect. 3.2.2.

geometry<ASSM>, hgap, cross

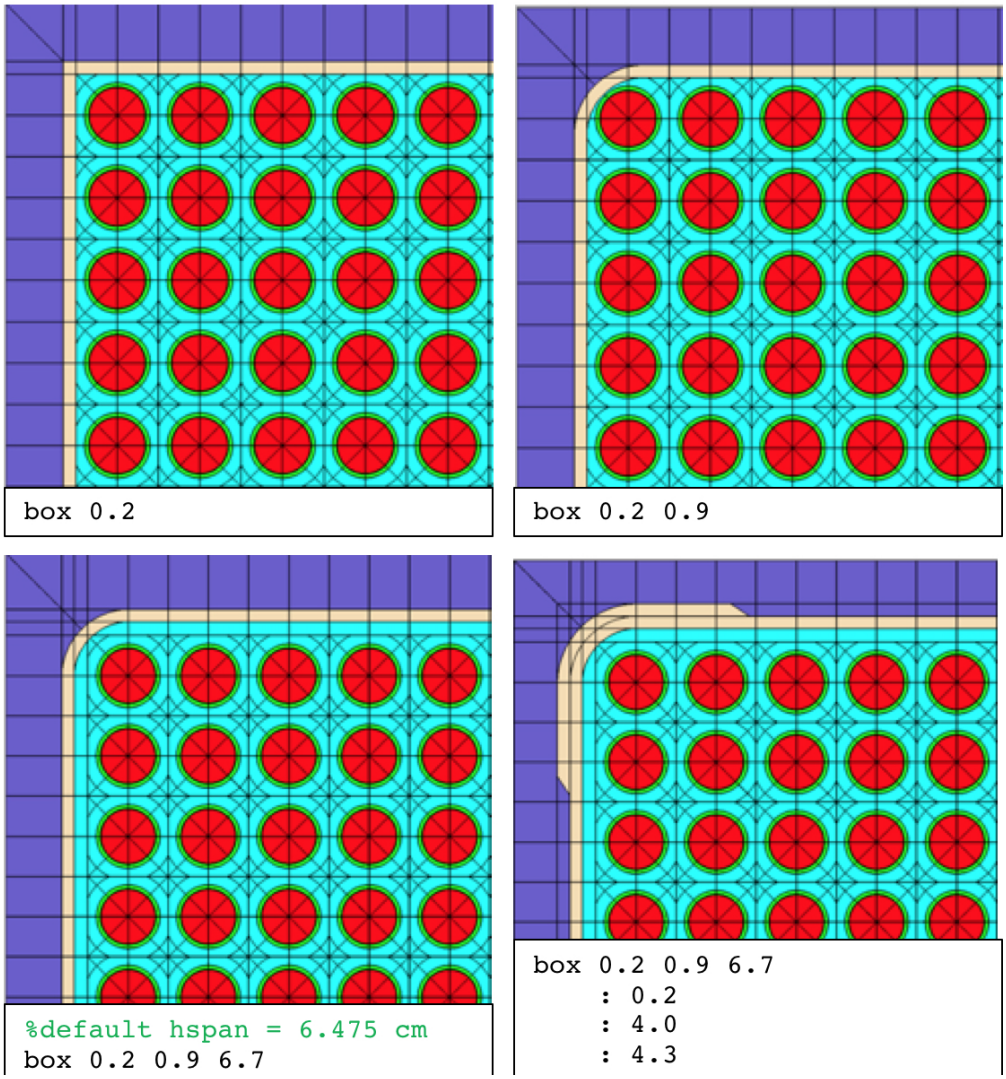

Fig. 3.2.2: Box card examples.

3.2.4.6 pin - pincell comprised of nested geometry zones of variable shape

pin PINID [size=*Real*]

: r_1 r_2 ... r_i ... r_N

: M_1 M_2 ... M_i ... M_N [M_{out}]

[: S_1 S_2 ... S_i ... S_N]

param	type	name	details	default
PINID	*Word|Int*	pin identifier		
size	*Real*	pin size multiplication factor	must be ≥ 1.0	1.0

continues on next page

Table 3.2.13 – continued from previous page

r_i	*Real*	zone interior radius (cm)	r_1 must be > 0. Additional zones must be > r_{i-1}	
M_i	*MNAME*	zone material	.1 added if given MCLASS, e.g., FUEL-FUEL.1	
M_{out}	*MNAME*	outermost zone material	.1 added if given MCLASS	*
S_i		CIR or SQR or SQR(X)	circular zone or square zone with optional corner radius, X ≥ 0.0	CIR X=0.0

*If not specified, the material class MCLASS is taken from the **channel** card (M_{chan}) and set to the first member of that class, "M_{chan}.1." For example if M_{chan}="COOL," then M_{out}= "COOL.1."

Examples:

```
%standard fuel pin
pin 1 : 0.4096 0.418 0.475 : FUEL.1 GAP.1 CLAD.1

%2x2 water rod
pin W 2.0 : 1.6   1.7 : MOD.1 TUBE.1

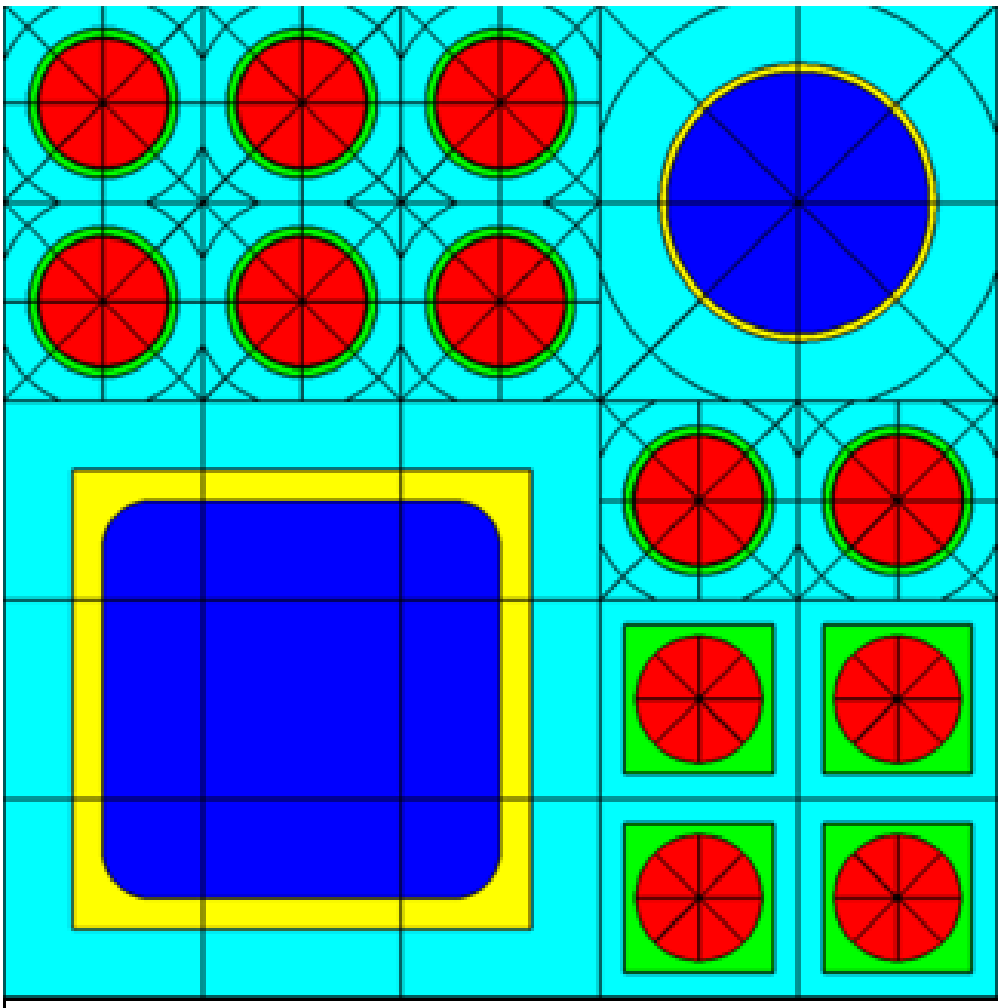
%3x3 square water box (ATRIUM)
pin W 3.0 : 1.68 1.75 : MOD.1 TUBE.1 : SQR SQR

%noninteger size water rod (GE9x9)
pin W 1.76 : 1.16 1.259 : MOD.1 TUBE.1 COOL.2
```

Comments:

The **pin** card is one of the basic building blocks of the assembly model. **pin** and **slab** are the only geometry components which allows an integer (*Int*) identifier as well as a *Word*-all other geometric identifiers use *Word*. Note that the materials are required, except for the last M_{out}, which can be used to overwrite the material given by a **channel** for the outermost region in the pincell. The **pin** geometry is constructed from the inside out, using either circle zones (defined by the radius) or square zones (defined by the half-width, and optional corner radius). Different examples of pin geometries are displayed in Fig. 3.2.3. All meshing options for the **pin** are provided through the **mesh** card.

If the pin size is an integer value, the pin consumes a size × size subarray in the **pinmap** (e.g. 1 × 1, 2 ×times` 3, etc). If the pin size is noninteger, the pin consumes a *ceil*(size) × *ceil*(size) subarray in the **pinmap**. *ceil(x)* represents the ceiling function to round the value of x to the nearest integer greater than or equal to x. For size equal to 1.3, each instance of the pin will consume a 2 × 2 subarray in the **pinmap**. Each instance of a noninteger-sized pin must share a location with another instance of a noninteger-sized pin, but not necessarily the same pin. The shared location must be set to "_" in the **pinmap**. The identification of the shared location is necessary to determine the center of each pin. The pin center is at a distance of size*half pitch*sqrt(2) from the opposite corner of the shared location, along the diagonal of the pin boundary. An example of an integer-sized pins is displayed in Fig. 3.2.3. An example of noninteger-sized pins is displayed in Fig. 3.2.4.



```

pinmap
F F F F F F
F F F F F F
F F W W F F
F F W W F F
F F F F F F
F F F F F F
```

Comments:

The **pinmap** card defines the layout of pin cells in the assembly. The symmetry is determined by the number of pin identifiers given on the card and must not be more general than the symmetry option given on the assembly **geometry** card (i.e., do not define a full pin map for a *sym*=SE assembly model). If the **pin** has a large size specifier, *size>1*, then the pinmap must reflect that with those pins occurring in blocks of size × size.

B _ _ B
_ _ _ _ _
_ _ _ _ _ B
B _ _ B _ _ _
_ _ _ _ _ _ _ _
_ _ _ _ _ _ _ _ _
```

Comments:

Note that control elements and inserts share the INAME identifiers, so an insert and a control element cannot have the same name. Different control rod banks may be included in a single input file using more than one **control** card with unique INAMEs. The main difference between the inserts defined by **control** element and **insert** cards is that by default, *control element materials are not depleted,* whereas *insert materials are depleted*.

The outer dimensions of the tube must be included in the **pin** card that is inserted.

N_i	*Real*	# of pins or slabs in section i	——- See comments ———-	
*Default values for shtmat and csmat are set by "system BWR." If "system BWR" is omitted, the material definitions are required.				

Comments:

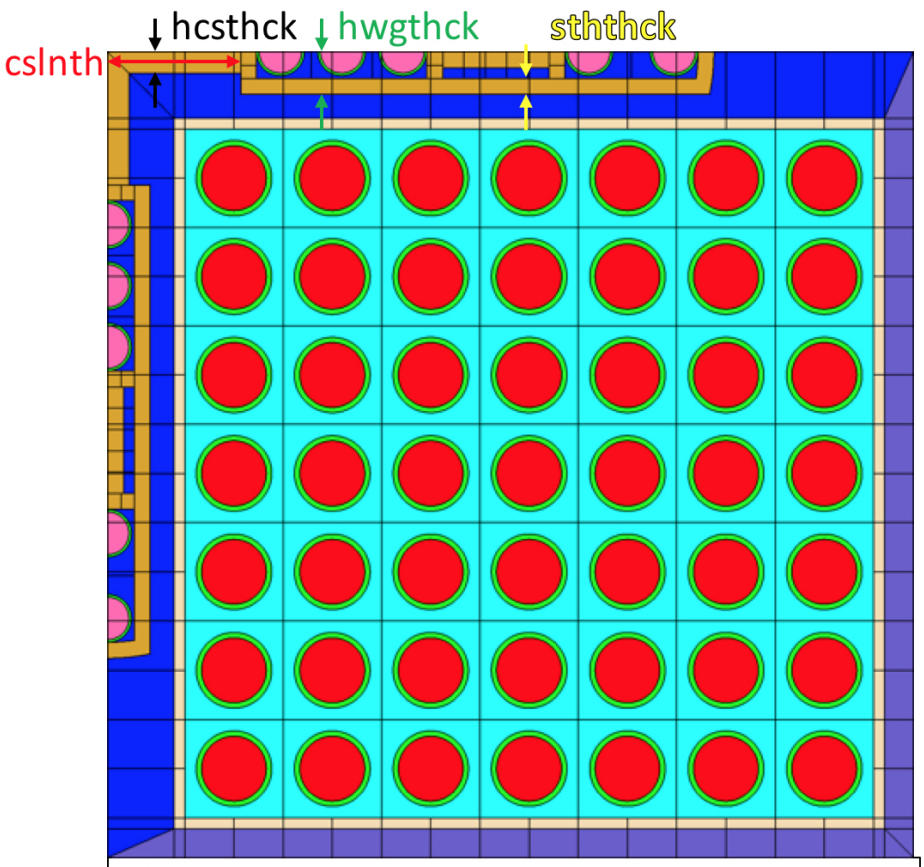
The **blade** card defines a control blade geometry. The control blade identifier (INAME) can be used to insert the control blade using **state** or **add** statements to define histories or branches respectively. INAME=yes inserts the control blade into the northwest corner of the lattice.

The control blade geometry is described with reference to the blade wing on the northern edge of the lattice in Fig. 3.2.5. The blade wing on the west edge is a reflection of the northern edge wing along the diagonal symmetry line that extends from the northwest corner to the southeast corner of the lattice.

The two primary regions of the blade are the central support and the active blade wing. The central support has a length (cslnth), half width (hcsthck), and material (csmat). The central support half width is the vertical distance between the north face of the lattice and the south boundary of the central support. The central support length is the horizontal distance from west face of the lattice to the east boundary of the central support. See Fig. 3.2.5 for details.

The active portion of the blade wing begins at the east boundary of the central support. The active portion has a half width (hwgthck), sheath thickness (shthck), sheath material (sthmat), and wing tip radius (wgcrv). The half width is the vertical distance between the north face of the lattice and the southern boundary of the active blade wing, including the sheath. The wing tip radius can be any nonnegative number. If the radius is zero, the wing tip is a straight edge.

The active portion of the blade wing is subdivided into sections. Each section has a length (L_i), and identifier associated with a pin or slab (ID_i), and the number of pins or slabs for each section (N_i). The list of section lengths and section identifiers is required and must have consistent list lengths. The final list for number of pin/slabs per section is optional. If omitted, the default number of pin or slabs per section is one.



```

slab S : 0.5 : STRUCT.1 : 2 : 1
slab Z : 0.3 0.2 : STRUCT.1 MOD.1
control blade1 : BLADE 0.8 0.3 2.5
                   hcsthck=0.4 wgcrv=4.0
                 : S   A   S   Z   S   A
                 : 0.3 3.2 0.3 2.0 0.3 2.5
                 : 1   3   1   5   1   2

state blade1 : in=yes
```

Fig. 3.2.5: Control blade example.

If there is only one **pin** in a pin section, the pin is placed in the section center. If there are multiple pins, the first and last pin are positioned flush against the west and east section boundary respectively, and the interior pins are uniformly spaced between the two edge pins. Slab sections are built from the blade centerline in the vertical direction towards the interior sheath boundary. Each slab zone has width equal to the section length. Each slab zone can be subdivided in the vertical direction by the zone nx parameter on the **slab** card. The slab zone can be subdivided in the horizontal direction by the product of the zone ny parameter and the number of slabs in the blade wing section.

The blade is further subdivided by the **mesh** nf/nd settings for **hgap** material in the north and west bypass region, typically MOD.1 for models that include **system BWR.**

3.2.4.10 insert - insert layout

insert INAME:

PINID$_1$

PINID$_2$ ...

PINID$_i$ ... PINID$_N$

param	type	name	details	default
INAME	*Word*	insert name		
PINID$_i$	*Word|Int*	list of pin identifiers	same format as **pinmap** "_" indicate empty locations	

Examples:

```
%pyrex inserts
pin P : 0.214  0.231 0.241 0.427 0.437 0.484 0.561 0.602
      : GAS    TUBE  GAS   BP.3  GAS   TUBE  COOL  CLAD

insert PyrexInserts :
  _
  _ _
  _ _ _
  P _ _ P
  _ _ _ _ _
  _ _ _ _ _ P
  P _ _ P _ _ _
  _ _ _ _ _ _ _ _
  _ _ _ _ _ _ _ _ _
```

Comments:

The **insert** card defines a set of pins to be used to model inserts such as WABA. When the **insert** is "in," the insert pins replace *overlapping regions* of the pins defined on the assembly **pinmap**. An underscore (_) is used to indicate locations without inserts. See the notes on the **control<RODLET>** card for additional guidelines.

pinmap, **control**, **insert**

3.2.4.11 slab - slab geometry

slab [SLABID]

: t_1 t_2 ... t_i ... t_N

: M_1 M_2 ... M_i ... M_N

[: nx_1 nx_2 ... nx_i ... nx_N]

[: ny_1 ny_2 ... ny_i ... ny_N]

param	type	name	details	default
SLABID	*Word*	slab geometry identifier		reflector GNAME
t_i	*Real*	list of slab thicknesses	units: cm	
M_i	MNAME	list of material names		
meshing options				
nx_i	*Int*	list of number of x-divisions		1
ny_i	*Int*	list of number of y-divisions		1

Examples:

```
% a reflector definition
% 2.22 cm of baffle
% 15 cm of moderator
geom ReflectorNode : REFL 17.22
  slab 2.22 15 : BAFFLE.1  MOD.1
```

Comments:

The **slab** card may be used to define three things: (1) the materials and thicknesses of a reflector initiated on a **geometry** card, (2) slabs in a control blade, and (3) spacer grids. If the first argument identifier is *not present,* then the first purpose of describing the various material thicknesses in a reflector is assumed. The meshing options allow each material slab to be spatially refined in x and y, increasing the number of cells in the transport problem. The meshing option for the number of x divisions creates the equivalent of additional "sub-slabs" in each user-defined slab thickness. The y-divisions create additional cells vertically. The default of one y-division corresponds to the entire assembly.

[: x_1 x_2 ... x_N]

[: y_1 y_2 ... y_N]

[: yin_1 yin_2 ... yin_N]

[: nx_1 nx_2 ... nx_{N-1}]

[: ny_1 ny_2 ... ny_{N-1}]

param	*type*	*Name*	*details*	*default*
hwidth	*Real*	half width of interior cross region (cm)	must be >=0	
lthick	*Real*	cross liner thickness (cm)	must be >=0	
Mcross	*MNAME*	cross liner material		CAN.1*
row	*Int*	row to insert cross	must be >1 and < npins	npins/2
Min	*MNAME*	cross interior material		MOD.2*
ld	*Int*	number of liner divisions		1
Mout	*MNAME*	cross outer fill material		COOL.1*
x_i	*Real*	x coordinate of vertex i	------- See comments ----------	
y_i	*Real*	y coordinate of vertex i	------- See comments ----------	
yin_i	*Real*	y “inner” coordinate of vertex i	------- See comments ----------	
nx_i	*Int*	# of x subdivisions b/w vertices [i,i+1]	must be >0	1
ny_i	*Int*	# of y subdivisions b/w vertices [i,i+1]	must be >0	1

*Default values for Mcross, Min, and Mout set by “system BWR.” If “system BWR” is omitted, the material definitions are required.

Comments:

The cross card performs two tasks. First, it subdivides the pinmap into four subarrays, optionally adding a horizontal and vertical gap between the subarrays. The row parameter is uses to subdivide the pinmap. If the pinmap is 10×10 and row=5, each of the four subarrays is 5×5. If the pinmap is 10×10 and row=4, the northwest subarray is 4 ×times`6, the southwest subarray is 6×4, and the southeast subarray is 6×6. The hwidth parameter controls the half-spacing of the horizontal and vertical gap in between the subarrays. The hwidth parameter must be ≥ 0.0 and if hwidth is > 0.0, the gap is filled with material M_{out} (default is COOL.2 with system BWR).

The second task is the insertion of the cross structure into the lattice geometry. The process is described with reference to the example in Fig. Fig. 3.2.6. In the example, the **pinmap** is 9×9 and row=3, hwidth=1.5, and hspan=10.5. The top left plot contains the four following lines:

1. the line in the center of the vertical cross gap,
2. the line in the center of the horizontal cross gap,
3. the diagonal line from the northwest (NW) channel box corner to the southeast (SE) corner, and

4. the diagonal line, perpendicular to line 3, passing through the intersection of line 1 and line 2.

These four lines intersect and form 8 separate regions, i.e., octants, within the channel box interior. The intersection point, i.e., cross center, is not necessarily equal to the box center as shown in this example. In the top left plot, the red triangle represents the WNW octant. In the bottom left plot, the red triangle represents the SSE octant.

                     : 1 .5 .5 1  1
```

Fig. 3.2.6: Construction of the BWR cross geometry (full example shown later).

The cross structure is defined be a series of vertices (x_i, y_i). Shown as yellow points in the top left plot, the **cross** vertices are defined based on an origin displayed as the red point, which is the intersection of the inner

west edge of the channel box and the horizontal line in that passes through the cross center.

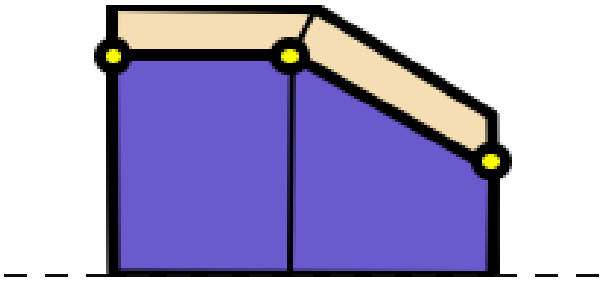
The top plots demonstrate how Polaris inserts a section of the cross into the WNW octant. In the top left plot, the blue polygon is constructed based on the first two vertices defined on the **cross** card: (0.0,1.0) and (4.0,0.5). The intersection of the blue polygon and red polygon is inserted into the lattice and filled with cross interior material (M_{in}). The liner is then inserted **above** the blue polygon, padded by the liner thickness (lthick), and clipped by WNW red polygon if needed.

Similarly, the bottom plots demonstrate insertion into the SSE octant. For SSE insertions, the origin and the **cross** vertices are rotated 90 degrees about the cross center. The blue polygon is constructed from the second and third vertices on the **cross** card: (4.0,0.5) and (11,0.5). The intersection of the blue polygon and red polygon is inserted into the lattice and filled with cross interior material (M_{in}). The liner is then inserted **above** the blue polygon, padded by the liner thickness (lthick), and clipped by SSE red polygon if needed.

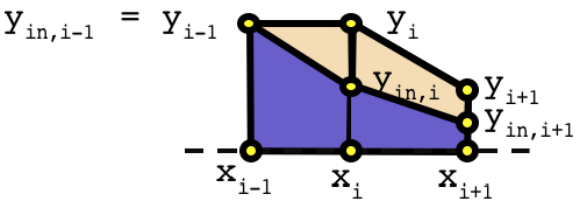
For each consecutive set of **cross** vertices, Polaris inserts a polygonal region into each of the 8 octants. The **cross** vertices are entered in the input as an x-values list followed by a y-values list of the same length. The coordinate system of the x- and y- lists is displayed in the top left plot of Fig. 3.2.6. The coordinate system is transformed based on the following rules for each octant:

- WNW, ENE: no transform,
- NNW, SSW: reflected across the diagonal line from NW to SE channel box corners,
- NNE, SSE: rotated 90 degrees about the cross center, and
- ESE, WSW: reflected across the line in the center of the horizontal cross gap.

The cross liner is inserted above the cross vertex values. The liner has a uniform thickness (lthick) and uniform material (M_{cross}). The uniform liner thickness is constructed with a miter joint at each cross vertex as shown in the following diagram:



After the set of y-values on the **cross** card, an optional list of interior y-values can be specified. The length of the interior y-values list must be equal to the length of the x- and y- lists. The optional interior y-values list is used to split the polygons into two material regions as shown in the following diagram:

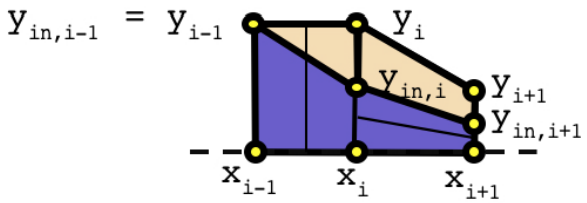


For the left-hand polygon, $y_{in,i-1}$ is the same as y_{i-1}, but $y_{in,i}$ is less than y_i. In this scenario, the trapezoid region is filled with M_{in}, and the triangular region is filled with M_{cross}. Similarly for the right-hand polygon,

the lower trapezoid is filled with M_{in} and the upper trapezoid is filled with M_{cross}. Note that the uniform liner above the y-values is not shown for simplicity.

The interior y-list values can be specified in one of two ways. First, a positive value may be entered that is greater than or equal to zero and less than or equal to the corresponding y-value. Second, a negative value may be entered that represents the relative distance of the interior y-value below the corresponding y-value. Note the Polaris input processor interprets "-0" different than "0". "-0" implies that the internal y-value is the same as the y-value. "0" implies that the internal y-value is zero. If the interior y-list is omitted, the default for all internal y-values is "-0", i.e., the polygon regions defined are completely filled with M_{in}.

In addition to the interior y-values list, two additional lists can be used to refine the spatial mesh in the x- and y- directions. The list of nx- and ny- values subdivide the polygon regions along the x- and y- directions respectively. Both lists must have one less entry than the x-, y-, and y_{in}- lists. If omitted, the default values for both the nx- and ny- lists are 1, i.e., no additional spatial refinement is applied to the polygon regions. For refinement in the y-direction, only the M_{in} material is refined. The following diagram shows nx=2 refinement for the left polygon and ny=2 refinement for the right polygon:



The full cross example from Fig. 3.2.6 is displayed in the top left plot of Fig. 3.2.7. The bottom plot shows a centered cross structure with a diamond water box and empty pins surrounding the water box.

For additional examples, see the polaris.6.3 regression input files described at the beginning of Sect. 3.2.2.

3.2.4.13 dxmap and dymap - pin-by-pin displacement maps

dxmap d_1 d_2 ... d_i ... d_N
dymap d_1 d_2 ... d_i ... d_N

param	type	details	default
d_i	*Real*	pin center displacement value in the x or y direction (cm)	0.0

Comments:

The dxmap and dymap cards displace pins from their natural position in the geometry (see comments for the pin card). If displacement maps are required, both the dxmap and dymap must be specified in the input and they must have the same length. However, the length of the displacement maps does not have to equal

of length of the pinmap if the displacement maps have reduced symmetry. For integer-sized pins greater than 1, the displacement value should be entered in the northwest corner element of the size × size subarray. For noninteger-sized pins, the displacement value should be in the corner element opposite of shared corner location. Note the following symmetry restrictions for the displacement maps:

- dy_i value must be zero on a horizontal symmetry line for an odd × odd pinmap,
- dx_i value must be zero on a vertical symmetry line for an odd × odd pinmap, and
- dx_i must equal dy_i for an element on a diagonal symmetry line.

Examples:

```
dxmap
  0.0  0.0  0.0  0.0  0.0
  0.0  0.2  0.0  0.0 -0.2

3.2.4.14 mesh - advanced material dependent meshing options

mesh MSPEC : [m=*Real*] [nx=*Int*] [ny=*Int*] [mx=*Real*] [my=*Real*]
[nr=*Int*] [ns=*Int*] [mr=*Real*] [ms=*Real*]
[nf=*Int*] [nd=*Int*] [mf=*Real*] [md=*Real*]

param	**type**	**name**	**details**	**default**
MSPEC	*MCLASS* |*MNAME*	material identifier		
nx	*Int*	# of x divisions	must be >0	MeshNumX*
ny	*Int*	# of y divisions	must be >0	MeshNumY*
nr	*Int*	# of radial rings	must be >0	MeshNumRings*
ns	*Int*	# of radial sectors	must be nonzero	MeshNumSectors*
nf	*Int*	# of faces/pin	must be >0	2**
nd	*Int*	# of gap divisions	must be >0	1
meshing multipliers				
m	*Real*	global multiplier	must be >0	1.0
mx	*Real*	x divisions	must be >0	1.0
my	*Real*	y divisions	must be >0	1.0
mr	*Real*	radial rings	must be >0	1.0
ms	*Real*	radial sectors	must be >0	1.0
mf	*Real*	faces/pin	must be >0	1.0
md	*Real*	gap divisions	must be >0	1.0

* The global mesh default values are set on the **option <GEOM>** card using the parameter name in the table above.

** Default number of faces per pin is 1. Default is 2 for **system BWR** or **system PWR.**

Examples:

```
mesh COOL : nr=3 ns=4 nx=2 ny=2 %coolant mesh: 3 ring, 4 sectors, 2 in x and y

mesh MOD.1 : nf=2 nd=4          %mesh used for wide gap (MOD.1): nf=2 nd=4

mesh MOD.2 : nf=2 nd=3          %mesh used for narrow gap (MOD.2): nf=2 nd=3

mesh FUEL : mr=2.0              %double the fuel radial mesh

mesh FUEL.2 : m=3.0             %triple all mesh values for FUEL.2

mesh CLAD : ms=0.5              %coarsen the clad sector mesh by a factor of 1/2.
```

Comments:

Polaris supports three different mesh types: 1) cylindrical mesh for CIR shapes in the pin card, 2) Cartesian mesh for SQR shapes in the pin card, and 3) a special Cartesian mesh for the region external to the pinmap region. As shown in the examples above, the mesh card is used to define, refine, or coarsen the mesh parameters for one or more of the mesh types associated with a given material class or material name. The default values for mesh parameters are defined through the option<GEOM> card and the system card. The

default values on the option<GEOM> card are nr=1, ns=1, nx=1, ny=1, nf=1, nd=1, and MeshMult=1.0. The “MeshMult” multiplier from the option<GEOM> is a global mesh multiplier applied in conjunction with any material-specific multiplier (see option<GEOM> example for details). If system BWR or system PWR is applied, new default values include nf=2, ns=8, and nr=2 (only for the channel material class). If the final mesh value is noninteger, Polaris rounds down to determine the applied value.

3.2.4.15 detector - insert a detector geometry

det DNAME : PINID at=PINID|GNAME loc=*String*
: rx=RSPEC fmat=*MNAME* rmat=*MNAME*

param	*type*	*Name*	*details*	*default*
DNAME	*Word*	detector name		*none*
PINID	*Word|Int*	detector geometry	currently only pin geometry is supported	*none*
at	*PINID|GNAME*	parent geometry	detector may be inserted either into an existing pin or assembly geometry	*none*
loc	*String*	location within parent	location is either "CENTER": center (only valid for placing within a pin geometry) "SE": southeast corner (only valid for placing within an assembly geometry)	*none*
rx	*RSPEC*	reaction specifier	has the form Units(Inc,Type) "Units": reaction units either "R" for a reaction rate or "E" for an energy deposition "Inc": incident particle type either "N" for a neutron or "G" for a gamma/photon "Type": reaction type either "CAP" for capture, "FIS" for fission, "ABS" for absorption (FIS+CAP), or “TOT” for total (gamma/photon only)	*none*
fmat	*MNAME*	flux material	material whose flux is used to calculate the reation rate (must exist in the detector geometry)	*none*
rmat	*MNAME*	reaction material	material whose reaction cross sections are to be used instead of fmat (must **not** exist in the detector geometry)	*fmat*

Examples:

```
% declare detector materials
mat DET.2 : SS304 %transmitter
```

(continues on next page)

(continued from previous page)

```
mat DET.3 : Al 2.7 %active material matrix (with u235 dopant not modeled)

% declare detector geometry
% - transmitting wire
% - active material
% - sheath
pin PD : 0.03 0.04 0.0787
: DET.2 DET.3 TUBE.1

%u235 for reaction rate material
mat DET.1 : detu 1e-5
   comp detu : WT u235=99.9 u238=0.1

% place detector D1, described by pin PD
% into instrument tube pin.IT, at the center
% with signal proportional to fission in material DET.1
% but with flux inside material matrix DET.3
det D1 : pin.PD at=pin.IT loc=CENTER
: R(n,FIS) fmat=DET.3 rmat=DET.1

% enable detector output in XFile16
opt FG DetectorEdit=D1
```

Comments:

The **detector** card is not intended to produce arbitrary reaction rates, but model a simple, discrete detector inserted into the geometry. The first line of detector input defines the detector and where it should be placed. The second line of input defines the "signal" the detector produces. The most complex piece of the input is the reaction specificer (RSPEC) which denotes the units (reaction rate or energy rate), incident particle, and type of reaction. For example, neutron absorption rate would be denoted "R(n,ABS)" and gamma energy deposition rate "E(g,CAP)".

The detector signal is collected for the material specified as the flux material, "fmat". In some cases, e.g. PWR fission detector modeling, it is desirable to model a reaction rate for fissile material that does not exist, e.g. a U-235 fission rate in an gaseous fission chamber that does not have trace amounts of U-235 present in the composition definition. The optional reaction material, "rmat", gives a way to specify this type of scenario. In this case the "fmat" would be a physical material in the model like the detector fill gas whereas the "rmat" would be another material (not present in the model) with composition and temperature defined appropriately.

3.2.5 MATERIALS

A material contains two main types of information: (1) the *composition*, or distribution of nuclides, and (2) *the properties* which include basic (required) properties like density and temperature, and as well as (optional) properties like soluble poison content, void, or grid spacer smearing. The composition is defined by a **composition** card. The basic specification for a material is shown below.

[**mat** MNAME : CNAME [dens=*Real*] [temp=*Real*] [: *properties*]]

argument	type	name	details	default
MNAME= MCLASS.MSUB	*Word. Int*	material name	used to reference this material	
CNAME	Word	composition name		

continues on next page

Table 3.2.21 – continued from previous page

dens	Real	density	basic property units: g/cm^3	composition reference density, if defined
temp	Real	temperature	basic property units: K	293
properties	Word=Value	properties	extra properties are defined with **property** cards	no extra properties

A material name has two parts, the material class, or MCLASS, and a member identifier, or MSUB. For example, FUEL.2 has an MCLASS=FUEL and an MSUB=2. **All properties are defined by MCLASS.** The composition referenced by CNAME is created with a **composition** card, as shown below.

[**comp** CNAME : CTYPE *arguments*]

Table 3.2.22: :class: longtable

argument	**type**	**name**	**details**	**default**
CNAME	*Word*	composition name	used to reference this composition later in materials and property definitions	
CTYPE	-	composition type		
	General Composition Constructors			
	NUM	number fraction		
	WT	weight fraction		
	FORM	Formula		
	CONC	Concentrations		
	Reactor Composition Constructors			
	LW	borated light water		
	UOX	uranium oxide fuel		
arguments	-	remaining arguments	depends on *CTYPE*	

Additional properties are defined with the **property** card, which defines the property PNAME for a material class MCLASS**.** The property type, *PTYPE,* determines the remaining arguments.

prop PNAME MCLASS : PTYPE *arguments*

argument	**type**	**name**	**details**	**default**
PNAME	*Word*	property name	used to reference this property

Table 3.2.23 – continued from previous page

	SOLP	soluble poison	used to define soluble boron content	
arguments	-	remaining arguments	depends on *PTYPE*	

3.2.5.1 material - material initialization

mat MNAME : CNAME [dens=*Real*] [temp=*Real*]
[: p_1=val_1 p_2=val_2 ... p_i=val_i ... p_N=val_N]

argument	**type**	**name**	**details**	**default**
MNAME	*Word. Int*	material name	uses form MCLASS.MSUB	
CNAME	*Word*	composition name		
dens	*Real*	density	*basic property* units: g/cm^3	composition reference density
temp	*Real*	temperature	*basic property* units: K	293
p_i =val_i	PNAME=Value	properties	*additional properties*	0

Examples:

```
% define a gas gap material
mat GAP.1  : FILLGAS

% define a 3.5% enriched fuel material
comp uox_e350 : UOX 3.5
mat FUEL.1 : uox_e350 dens=10.257 temp=900

% define a cladding material
mat CLAD.1 : ZIRC4

% define a guide tube material
mat TUBE.1 : SS304

% define a control rod material
mat CNTL.1 : AIC
```

Comments:

Material properties may be set on either a **material** card or on a **state** card. If a temperature is specified rather than a density, the "temp=" key must be used to skip over the density argument.

3.2.5.2 composition<NUM|WT> – general atom/wt fraction

comp CNAME: *NUM|WT*
[scale=<*PCT*>|*ABS*|*PPM*]
[norm=*Bool*]
[refdens=*Real*]
[structure=*Function*]
id_1=val_1 id_2=val_2 … id_i=val_i … id_N=val_N

---

param	*type*	*name*	*details*	*default*
CNAME	*Word*	composition name		
CTYPE	*NUM*	number fraction		
	WT	weight fraction		
scale	*PCT*|*ABS*|*PPM*	scaling factor	all values are divided by this factor PCT: percentage (divide by 100) PPM: parts per million (divide by 1e6) ABS: absolute (divide by 1)	PCT
norm	*Bool*	normalize	normalize values to 1	false
refdens	*Real*	reference density	default density for materials using this composition units: g/cm^3	*
structure	*Function*	structure	see Structure names	FREE
id_i=val_i	Word|Int=*Real*	id/value pairs	value<0 fills the remainder up to value see acceptable id forms below	

*The density property must be defined for each *material* either explicitly on the material card itself or implicitly through the "reference density" of the material's composition.

Examples:

```
% create a plutonium vector and then plutonium oxide
comp puvec : WT scale=PCT
  Pu238=1.2
  Pu239=63.3
  Pu240=21.0
  Pu241=8.6
  Pu242=5.9
comp puox : FORM puvec=1 O=2

% create an 85/10/5 Ag/In/Cd composition
```

(continues on next page)

(continued from previous page)

```
% using 10% In, 5% Cd,
% and filling the remainder up to 100% with Ag
comp aic : WT In=10 Cd=5 Ag=-100
```

Comments:

IDs in weight or number fraction-based compositions may be any of the following:

- nuclide IDs (*Int*), e.g., 92235,
- nuclide names (*Word*), e.g., U235 or u235,
- element Z numbers (*Int*), e.g., 92,
- element names (*Word*), e.g., U or u, or
- other composition names (CNAME).

See also:

composition<FORM>

3.2.5.3 composition<FORM> - general chemical formula

comp CNAME : *FORM*
[refdens=*Real*]
[structure=*Function*]
id_1=val_1 id_2=val_2 ... id_i=val_i ... id_N=val_N

param	type	name	details	default
CNAME	*Word*	composition name		
CTYPE	*FORM*	formula		
refdens	*Real*	reference density	default density for materials using this composition units: g/cm^3	*
structure	*Function*	structure	see Structure names	FREE
id_i =val_i	Word|Int=*Real*	id/value pairs	see acceptable id forms below values in atoms per molecule (e.g., H_2O is given as "H"=2 "O"=1)	

*The density property must be defined for each *material* either explicitly on the material card itself or implicitly through the "reference density" of the material's composition.

Examples:

```
% define Gd2O3 using element names
% (using elements implies natural abundances used in isotopics)
comp gd2o3 : FORM Gd=2 O=3

% define Gd2O3 using 100% Gd 155
comp gd2o3 : FORM Gd155=2 O=3

% define D2O using nuclide IDs and element names
comp d2o : FORM 1002=2 8000=3
comp d2o : FORM H2=2 O=3
```

Comments:

IDs in formula-based composition may be any of the following:

- nuclide IDs (*Int*), e.g., 92235,
- nuclide names (*Word*), e.g., U235 or u235,
- element Z numbers (*Int*), e.g., 92,
- element names (*Word*), e.g., U or u, or

         8016=5.85563E-02
        13027=3.90223E-02
```

Comments:

IDs in concentration-based composition may be any of the following:

- nuclide IDs (*Int*), e.g., 92235;
- nuclide names (*Word*), e.g., U235 or u235;
- element Z numbers (*Int*), e.g., 92;
- element names (*Word*), e.g., U or u; and
- SCALE-specific Nuclide IDs (*Int*), e.g., 3006000 (Only available for comp(CONC) card).

Other composition names (CNAME) *cannot* be used in a concentration definition. To easily ensure consistency of input when comparing codes, the composition input should be used in the concentrations described here. In all other cases, the other **composition** constructors are recommended because they are much simpler and easier to use.

composition<ENRU>, composition<FORM>

3.2.5.7 composition<UN> - UN fuel

comp CNAME : UN enr=*Real* [n15enr=*Real*][bu=*Real*] [refdens=*Real*]

param	type	name	details	default
CNAME	*Word*	composition name		
CTYPE	*UN*	uranium nitride		
enr n15enr	*Real* *Real*	enrichment nitrogen enrichment	U-235 wt. % (see **composition<ENRU>** for formula) N-15 wt. %	100%*
bu	*Real*	burnup	only available for $0 \leq bu \leq 100$ units: GWd/MTU	0**
refdens	*Real*	reference density	default density for materials using this composition units: g/cm^3	***

* Natural nitrogen is 0.4 wt. % ^{15}N, but the reactivity penalty of ^{14}N warrants using the highest ^{15}N composition possible.

**Note that the burnup parameter should not be specified. It is a future option to create a fixed, representative, burned fuel composition. The composition is interpolated using linear interpolation from an internal burnup- and enrichment-dependent data matrix.

***The density property must be defined for each *material* either explicitly on the material card itself or implicitly through the "reference density" of the material's composition.

Examples:

```
% define a 4.95% enriched fuel composition with a reference density
comp usi_495 : UN 4.95 refdens=11.3

% same result as above
comp u_495  : ENRU 4.95
comp un_495 : FORM u_495=1 7015=1

% define a 3.25% enriched fuel composition with a reference density and
% specify natural 15N composition
Comp un_495 : UN 3.25 refdens=11.3 n15enr=0.4
```

Comments:

Internally, the uranium nitride composition is built from **composition<FORM>**, **composition<WT>**, and **composition<ENRU>** cards.

See also:

composition<ENRU>, composition<FORM>

3.2.5.8 composition<ENRU> – enriched uranium

comp CNAME : ENRU enr=*Real* [refdens=*Real*]

param	**type**	**name**	**details**	**default**
CNAME	*Word*	composition name		
CTYPE	*UOX*	uranium dioxide		
enr	*Real*	enrichment	*U-235 wt. %	
refdens	*Real*	reference density	default density for materials using this composition units: g/cm^3	**

*The following formula from [POLARISGod14] is used to determine the ^{234}U and ^{236}U wt% from the ^{235}U enrichment. Note that this formula is only valid for U-235 enrichments less than 10 wt%.

$w_{u234} = 0.007731*(enr)^{1.0837}$

$w_{u236} = 0.0046*enr$

$w_{u238} = 100 - w_{u234} - enr - w_{u236}$

**The density property must be defined for each *material* either explicitly on the material card itself or implicitly through the "reference density" of the material's composition.

Examples:

```
% 5% enriched metal fuel
comp umetal : ENRU 5
```

Comments:

This composition for enriched uranium is used internally to create uranium oxide, silicide, and nitride fuels using the **composition<UOX>**, **composition<USI>**, and **composition<UN>** cards.

See also:

composition<UOX>, **composition<USI>**, **composition<UN>**

3.2.5.9 composition library (pre-defined)

The Polaris composition library contains predefined compositions that may be used without a constructor by simply referencing the CNAME below. Each predefined library composition has a reference density, so it can be used directly on a material card.

Table 3.2.32: Standard molecular compositions

CNAME	*Description*
H2O	light water with structure=BOND(H2O)
B4C	Boron carbide burnable poison material
Er2O3	Erbium oxide burnable poison material
Gd2O3	Gadolinium oxide burnable poison material
SiC	Silicon carbide
ZrH	zirconium hydride alloy with structure=CRYS(orthorhombic_zrh)
Zr5H8	zirconium hydride alloy with structure=CRYS(cubic_zrh)
ZrH2	zirconium hydride alloy with structure=CRYS(tetragonal_zrh)
fillgas	Helium gas
Cr2O3	Chromium dioxide (chromia, Cr_2O_3)
Al2O3	Aluminum dioxide (alumina, Al_2O_3)
BeO	Beryllium dioxide (beryllia, BeO)

Table 3.2.33: Standard reactor mixtures and alloys

CNAME	*Description*
aic	Ag-In-Cd control rod absorber material
pyrex	Pyrex glass
zirc2	Zircaloy-2 clad material
zirc4	Zircaloy-4 clad material
ss304	Stainless Steel 304
ss316	Stainless Steel 316
inc718	Inconel 718
water	H2O with trace amount of boron
pyroc	Pyrolytic carbon, C with structure=CRYS(pyrolytic_c)
graphite	Graphite, C with structure=CRYS(hexagonal_c)

Table 3.2.34: Structure names.

structure	*Description*	*Nuclide* *Cross section ID**
BOND(H2O)	H,O in liquid water	H-1 → 1001 H-2 → 1002
FREE	atoms allowed to orient freely (no structure)	H-1 → 8001001 H-2 → 8001002
CRYS(orthorhombic_zrh)	Zr,H in zirconium hydride alloy with orthorhombic crystal structure (gamma phase)	H-1 → 7001001 Zr-90 → 1040090 Zr-91 → 1040091 Zr-92 → 1040092 Zr-93 → 1040093 Zr-94 → 1040094 Zr-95 → 1040095 Zr-95 → 1040096
CRYS(cubic_zrh)	Zr,H in zirconium hydride alloy with cubic crystal structure (delta phase)	H-1 → 7001001 Zr-90 → 1040090 Zr-91 → 1040091 Zr-92 → 1040092 Zr-93 → 1040093 Zr-94 → 1040094 Zr-95 → 1040095 Zr-95 → 1040096
CRYS(tetragonal_zrh)	Zr,H in zirconium hydride alloy with tetragonal crystal structure (epsilon phase)	H-1 → 7001001 Zr-90 → 1040090 Zr-91 → 1040091 Zr-92 →1040092 Zr-93 → 1040093 Zr-94 → 1040094 Zr-95 → 1040095 Zr-95 → 1040096
CRYS(pyrolytic_c)	C in pyrolytic crystal structure (graphite)	C → 3006000
CRYS(hexagonal_c)	C in pyrolytic carbon (additional covalent bonds compared to graphite)	C → 3006000
CRYS(hexagonal_beo)	Be,O in beryllium oxide with hexagonal structure	Be-9 → 5004009 O-16 → 5008016

Note: The cross section IDs can only be used on composition cards with the CONC variant to input number densities directly.

3.2.5.10 property<SOLP> - soluble poison by weight

prop PNAME M1 ... : SOLP poison [scale=<*PPM*>|*PCT*|*ABS*]

param	type	name	details	default
PNAME	*Word*	property name	property value p ≥ 0	
M1 ...	MCLASS	material class	one or more material classes to gain this property	
PTYPE	*SOLP*	soluble poison		
poison	CNAME	soluble poison composition name		
scale	PCT|ABS|PPM	scaling factor	all values are divided by this factor PCT: percentage (divide by 100) PPM: parts per million (divide by 1e6) ABS: absolute (divide by 1)	PPM

Examples:

```
% define a soluble boron property for moderator
% and coolant material classes
% using natural boron
prop boron MOD COOL : SOLP B

% investigate coolant crud/impurity activation
%  1. define a general impurity property to mix in coolant,
  comp crud : NUM Ni=12.7 Cr=2.3 Fe=-100 %mostly Fe
  prop impurity COOL : SOLP crud
% 2. create coolant material with 100ppm of crud
  mat COOL.1 : LW dens=0.75 : impurity=100
% 3. make sure to "deplete" coolant so crud gets activated
  deplete COOL=true
```

Comments:

None

solp

3.2.5.12 property<TWOPHASE> - density property used to control two phase mixtures

property PNAME MCLASS : TWOPHASE liqden=*Real* vapden=*Real*

param	type	name	details	default
PNAME	*String*	name for this property	Name with which to refer to this TWOPHASE property in other cards.	
MCLASS	*MCLASS*	material class(es) for which this property is valid	Generally COOL or MOD but can be any material.	
liqden vapden	*Real* *Real*	density of the liquid density of the vapor	In g/cm^3. In g/cm^3.	

Examples:

```
% define a TWOPHASE combination for moderator and coolant
prop vf MOD COOL : TWOPHASE 0.7 0.04
```

Comments:

The two-phase property is used to model materials that exist in two phases, such as water existing in a liquid or gas. This is typically used for water in BWR systems where the density of the water changes as one moves axially through the core. This property is defined by the liquid and vapor density. Later, in the state or history cards, a number between 0% and 100% is entered and the final density is calculated by interpolating between the liquid and vapor density values. The only requirement is that the liquid density must be greater than the vapor density.

3.2.5.13 deplete - material depletion and decay

deplete M_1=*Bool* M_2=*Bool* ... M_i=*Bool* ... M_N=*Bool*

param	type	name	details	default
M_i	MNAME|MCLASS	list of material names or material classes	use ALL for all materials	

Note: Only one deplete card is allowed in an input. ALL only applies in the first position.

Examples:

```
% turn on depletion/decay for two new materials
sys PWR
deplete MyMaterial=true MyOtherMaterial=true

% activate/deplete/decay every material
deplete ALL=true
```

(continues on next page)

(continued from previous page)

```
% impose strict conditions
sys PWR
deplete ALL=false FUEL=true CLAD=true
```

Comments:

The **deplete** card not only instructs Polaris to deplete a material, but also to solve the Bateman equations with ORIGEN for that material. Thus if the flux/power is zero, only materials that are flagged to "deplete" will undergo decay. The **deplete** card modifies the depletables included in a **system** card to avoid the situation in which "deplete MyMaterial=true" would make only MyMaterial depletable. Thus to completely re-specify the depletable materials, "ALL=false" should be used as the first argument. This is in contrast to the **basis** card, which completely specifies a new power basis.

See also:

material, shield, basis

3.2.5.14 basis - power basis materials

basis M_1=*Bool* M_2=*Bool* ... M_i=*Bool* ... M_N= *Bool*

param	type	name	details	default
M_i	MNAME|MCLASS	List of material names or material classes	use ALL for all materials	ALL

Note: Only one basis card is allowed per input. ALL is only allowed in the first position.

Examples:

```
% use only FUEL materials as the basis
basis ALL=no FUEL=YES

% Specify FUEL.3 as the basis
basis ALL=no FUEL.3=YES
```

Comments:

The **basis** card is used to specify the materials to use in power normalization. By default, the energy release from all materials is taken into account, including (n,gamma) reactions in structural materials such as cladding. It is not recommended to change the default of ALL in most situations. Exceptions include (1) when comparing results to other codes that only use fuel in the basis and (2) fixing the power in a specific pin is known-a material should be created only for that pin, and the power basis should be specified for that material only. The **basis** card overrides any power basis imposed by a **system** card. Thus it behaves differently than a **deplete** card, which is combined with depletable materials imposed by a system card.

See also:

material, shield, deplete

3.2.5.15 shield - cross section self-shielding expansion specification

shield M_1=*XTYPE* M_2=*XTYPE* ... M_i=*XTYPE* ... M_N= *XTYPE*

param	type	name	Details	default
M_i	MNAME| MCLASS	list of material names or material classes	use ALL for all materials	
XTYPE	N|P|R|S	self-shield ing expansion type	shield across various mesh elements N: no expansion P: pins R: rings (P implicit)	R

Note: Only one shield card is allowed per input. ALL is only allowed in the first position.

Examples:

```
%create a unique self-shielded FUEL cross sections in each pin
%consider all other materials to have a single self-shielded cross section
shield ALL=N FUEL=P

%assess effect of self-shielding each pin's cladding
shield CLAD=P

%re-specify self-shielding to be P by default, R for the FUEL
shield ALL=P FUEL=R
```

Comments:

The **shield** card controls how materials are internally expanded for self-shielding purposes. By default, Polaris expands all materials across pins and rings (R). For example, a fuel region defined on a **pin** card as having 10 rings will be expanded internally to have 10 different self-shielded cross sections. Because the R option also implicitly includes the P option, each instance of that pin will also get different cross sections.

When using specific systems (e.g., **system** *PWR*), this card is generally not needed. The **shield** card modifies the self-shielding options included in a **system** card. Thus, to completely re-specify the expansion, use "ALL=N" as the first argument. This is in contrast to the **basis** card, which completely specifies a new power basis.

material, deplete, system

3.2.6 STATE

The idea of a "state" or "statepoint" is a standard concept in lattice physics calculations. In Polaris, the concept of state is mostly tied to the values of material properties. The *base state* for a calculation is determined as follows:

1. The base state is initialized with any property values set on **material** cards.
2. The base state is updated with any **state** cards that apply to ALL.

3. The base state is updated with any other **state** cards, and the **power** card is used to set the base state power.

This sequence ensures that the state does not change, even if the order of inputs changes. A **time** or **burnup** card is then used to initiate a calculation as a function of time or burnup, thus producing a sequence of states. A **branch** block is used to perform branches off the base state at specific times or burnups.

single value mode:

state NAME : p_1=val_1 p_2=val_2 ... p_i=val_i ... p_N=val_N
[NAME : p_1=val_1 p_2=val_2 ... p_i=val_i ... p_N=val_N ...]

array mode with M burnup/time values, only in **history** *block:*

state NAME : p_1=val_1 [val_2 ... val_i ... val_M]
p_2=val_2 [val_2 ... val_i ... val_M]
...
p_i=val_1 ...
p_N=val_1 ...
[NAME : p_1=val_1 ...]

param	type	name	details	default
NAME	MNAME|MCLASS, or INAME, or GNAME	material name/class insert/cont rol geometry	use ALL for all materials in=yes|no pres=yes|no	
p_i	*PNAME*	property name		
val_i	*Value*	property value		

Examples:

```
state ALL : temp=293
     COOL : dens=1.0 boron=1100
    BPMAP : in=yes

read history
  %--------------------------------------%
  % cycle 1
  %--------------------------------------%
  pow 39
  state   ALL :  temp=600
         COOL : boron=900 850 700 600 400
                dens =0.6
         FUEL : temp =900 910 920 890 880
  dt                  50  50 100 100 200
  pow 0
  dt 70
```

(continues on next page)

(continued from previous page)

```
  %-------------------------------------%
  % cycle 2
  %-------------------------------------%
  state  BPMAP :    in= no
          COOL : boron=900 850 700 600 300
          FUEL : temp =900 910 920 890 880
  pow                   42  41  38  39  37
  dt                    50  50  50 100 250
  pow 0
  dt 80
end history
```

Comments:

The **state** card is used to specify properties for different materials, control maps, control blades, and insert maps. The **state** card can specify one or multiple properties simultaneously. The property specifications can either be a single value or multiple values, each value corresponding to a burnup/time step in the burnup/time input card (**bu|bui|dbu|t|ti|dt**).

The **state** card can be used outside a **history** block or inside a **history** block. Outside the history block, i.e., at the "root" input level, a single **state** card can initialize property values to a single value. If one or more power histories are defined at the root input level, the state properties are constant throughout the calculation. The state properties are only modified for **branch** calculations.

Time-dependent state properties are allowed through the **history** block. One or more power histories are allowed inside a history block. Each power history contains a **power** card (single value or array value) and a burnup/time card (**bu|bui|dbu|t|ti|dt**). Before the burnup/time card, a **state** card can be used to define one or more state properties. The property specifications are either a single value or an array of values that correspond to each burnup/time step. If a property is omitted in a **state** card, the value is defined based on the following precedence:

- the last value specified through the closest preceding **state** card in a given **history** block, or
- the value specified in the **state** card at the root input level, or
- the default property value.

By default, all control or insert geometries are not inserted (in=no). Material property defaults are defined on the **material** card or through the **system** card.

history, system

3.2.6.1 power - total power

pow [: p_1 p_2 ... p_i ... p_N]

param	type	name	details	default
p_i	Real	list of specific powers in W/g initial heavy metal		0

Examples:

```
% set power to 35 W/gIHM
power 35.0

% provide a power history
% must have same number of values as following time/burnup card
power : 35.0 40.0 45.0 45.0 40.0 5.0 0.0
time  : 10   20   30   40   50   60  70
```

Comments:

The **power** card specifies the total power of the basis materials specified by a **basis** card. The **power** value may be specified only once.

See also:

t, bu, history, basis, state<MNAME>

3.2.6.2 bu - initiate calculation with cumulative burnups

bu [b_1 b_2 ... b_i ... b_N]
[: units=<*GWD/MTIHM*>|*MWD/MTIHM*]

param	type	name	default
b_i	*Real*	list of burnups	0
units	GWD/MTIHM|MWD/MTIHM	burnup units	GWD/MTIHM

Examples:

```
% simple depletion case with constant power and absolute/cumulative burnups
power 40
bu     5 10 15 20 30 40 50 60 80

% using MWd/MTIHM units with variable power
% 40 W/gIHM for 0→5000 MWD/MTIHM, then 30 W/gIHM for 5000→10000 MWD/MTIHM
power  40    30
bu    5000 10000 MWD/MTIHM

% combine burnup and time cards
% 20 W/gIHM for 0→5 then 5→10 GWD/MTIHM steps, then
% 40 W/gIHM for a 5-day step then 30 W/gIHM for a 5-day step
power 20
bu     5 10 GWD/MTIHM
power 40 30
dt     5  5 DAYS
```

Comments:

The **bu** card initiates a calculation for a given sequence of cumulative/absolute burnups. A burnup or time card usually follows a **power** card, the two effectively specifying the power history. If multiple burnups are given, then the **power** card must have either a single power or a list of powers the same size as the list times. A value of 0 is implicit at the beginning of the first burnup list. Multiple burnup/time cards may be specified in an input. This can be convenient for switching units or changing from burnup-based to time-based depletion. Internal automatic substeps are always in effect unless modified with the **option<DEPL>** card.

See also:

t, dt, ti, bui, dbu, power, option<DEPL>, branch, deplete

3.2.6.3 bui - initiate calculation with cumulative burnups (with restart)

bui [b_1 b_2 … b_i … b_N]
[: units=<*GWD/MTIHM*>|*MWD/MTIHM*]

param	type	name	default
b_i	*Real*	list of burnups	0
units	GWD/MTIHM|MWD/MTIHM	burnup units	GWD/MTIHM

Examples:

```
power 30
  bui    5 10   %equivalent to: bu 5 10

  power 40
  bui    5 10   %equivalent to: bu 15 20
```

Comments:

The **bui** card initiates a calculation for a given sequence of cumulative burnups. If only one burnup list is provided, the **bui** card is identical to the **bu** card. For any subsequent burnup list, the **bui** card specifies cumulative burnups that restart at zero at the beginning of each list (see example above).

See also:

t, dt, ti, bu, dbu, power, option<DEPL>, branch, deplete

3.2.6.4 dbu - initiate calculation with incremental burnups

dbu [b_1 b_2 … b_i … b_N]
[: units=<*GWD/MTIHM*>|*MWD/MTIHM*]

param	type	name	details	default
b_i	*Real*	list of incremental burnups		0
units	GWD/MTIHM|MWD/MTIHM	burnup units		GWD/MTIHM

Examples:

```
% incremental burnups equivalent to
%   power 40
```

(continues on next page)

(continued from previous page)

```
%   bu 0 5 10 15 20 30 40 50 60 80
power 40
dbu 5 5 5 5 10 10 10 10 20
```

Comments:

The **dbu** card initiates a calculation for a given sequence of *incremental* burnups. Otherwise, it is identical to the **bu** card for specifying cumulative burnups.

See also:

t, dt, ti, bu, bui, power, option<DEPL>, branch, deplete

3.2.6.5 t - initiate calculation by cumulative time

t [t_1 t_2 ... t_i ... t_N]
[:units=*SECONDS*|*MINUTES*|*HOURS*|<*DAYS*>|*YEARS*]

param	type	name	details	default
t_i	*Real*	list of times	0	0
units	*SECONDS* | *MINUTES* | *HOURS* | *DAYS* | *YEARS*	time units		*DAYS*

Examples:

```
% burn with 40 W/gIHM for 300 days in 100-day increments
power 40
t 100 200 300

% simulate 2 cycles of time-dependent irradiation with shutdown cooling
% note that time defaults to DAYs
%
% cycle 1
power 40   30   30   30
t    100  200  300  400
power  0
t    415
%
% cycle 2
power 30   20   20   20
t    515  615  715  815
power  0
t    830
```

Comments:

The **t** card initiates a calculation for a given sequence of cumulative/absolute times. One of the time cards (**t**, **dt**, or **ti**) is required to model periods of decay in conjunction with **power** 0. Otherwise, the time card **t** is similar in functionality to the burnup **bu** card but with different units.

See also:

ti, dt, bu, bui, dbu, power, option<DEPL>, branch, deplete

3.2.6.6 ti - initiate calculation by cumulative time (with restart)

t [t_1 t_2 ... t_i ... t_N]
[:units=*SECONDS*|*MINUTES*|*HOURS*|<*DAYS*>|*YEARS*]

param	type	name	details	default
t_i	*Real*	list of times	0	0
units	*SECONDS*|*MINUTES*|*HOURS*|*DAYS*|*YEARS*	time units		DAYS

Example with t card:

```
% cycle 1
power 40
t 100 200 300 400

power  0
t    415

% cycle 2
power 30
t 515  615  715  815

power  0
t    830
```

Equivalent example with ti card:

```
% cycle 1
power 40
ti 100 200 300 400

power  0
ti    15

% cycle 2
power 30
ti    100 100 100 100

power  0
ti    15
```

Comments:

The **ti** card initiates a calculation for a given sequence of cumulative times. If only one time list is provided, the **ti** card is identical to the **t** card. For any subsequent time list, the **ti** card specifies cumulative times that restart at zero at the beginning of each list (see example above).

See also:

t, dt, bu, bui, dbu, power, option<DEPL>, branch, deplete

dt - initiate calculation by incremental time

t [t_1 t_2 ... t_i ... t_N]
[:units=*SECONDS*|*MINUTES*|*HOURS*|<*DAYS*>|*YEARS*]

param	type	name	details	default
t_i	*Real*	list of times		0
units	*SECONDS*|*MINUTES*|*HOURS*|*DAYS*|*YEARS*	time units		DAYS

Examples:

```
% burn with 40 W/gIHM for 300 days in 100-day increments equivalent to
%     power 40
%     t 100 200 300
power 40
dt 100 100 100

% decay for 30 minutes
power 0
dt 30 MINUTES
```

Comments:

The **dt** card is identical to the cumulative time card **t** except that the values given are incremental.

See also:

t, ti, bu, bui, dbu, power, option<DEPL>, branch, deplete

3.2.6.7 branch - instantaneous change

read branch [BNAME]
add ...
[**add** ...]
end branch

param	type	name	details	default
BNAME	*Word*	branch name		DEFAULT
allowed cards in branch block				
add	-	-	adds a list of states to branch on	

Examples:

```
% fuel temperature and boron branches (results in 7 total states)
read branch
  add FUEL : temp=800 1000 1200
  add COOL : boron=0 400 800 1400
end branch

% branch to different
% fuel temp/coolant temp/coolant density, synchronizing
% states (results in 3 total states)
read branch
  %            state 1    2    3
  add FUEL : temp=800  1000 1200
      COOL : temp=565   585  620
      COOL : dens=0.73 0.71 0.68
end branch
```

Comments:

The **branch** card initiates so-called "branch" calculations, i.e., instantaneous changes of state at specific burnups/times during the base depletion sequence of calculations. The syntax for the **add** card is identical to the **state** card except, instead of taking a list of different properties and their values, it takes *a single property* and a list of values. Note that a **time** or **burnup** card is not necessary-if not found, branches will be performed at every burnup/time specified in the base state. The initial state for *any* **branch** card is the base state as specified in the main file. This means **branch** cards have no knowledge of one another.

See also:

add, bu, t, title

3.2.6.8 history - time-dependent history

read history [HNAME]

power . . .

[state . . .]

bu|bui|dbu|t|ti|dt . . .

[power . . .

[state . . .]

bu|bui|dbu|t|ti|dt . . .]

. . .

end history

param	**type**	**name**	**details**	**default**
HNAME	*Word*	history name		DEFAULT
allowed cards in history block				
power	-	-	specific power	
state	-	-	state properties	
bu|bui|dbu|t|ti|dt	-	-	burnup or time	

Examples:

```
state ALL : temp=293
     COOL : dens=1.0 boron=1100
    BPMAP : in=yes

read history
  %-------------------------------------%
  % cycle 1
  %-------------------------------------%
  pow 39
  state   ALL :  temp=600
         COOL : boron=900 850 700 600 400
                dens =0.6
         FUEL : temp =900 910 920 890 880
  dt                   50  50 100 100 200
  pow 0
  dt 70
  %-------------------------------------%
  % cycle 2
  %-------------------------------------%
  state  BPMAP :    in= no
          COOL : boron=900 850 700 600 300
          FUEL : temp =900 910 920 890 880
  pow                   42  41  38  39  37
  dt                    50  50  50 100 250
  pow 0
  dt 80
end history
```

Comments:

The **history** card initiates a time-dependent calculation with user defined power history and time-dependent material or geometry properties. Each history block is independent from one another. Each history calculation generates an ORIGEN binary concentration file with the name *filename_hname.f71* where *filename* is the root name of the input file and *hname* is the name for the history. Similarly, if few-group cross section files are requested, the filenames are *filename.hname.t16*. If ORIGEN binary library files are requested, the names are *filename.hname.XXX.f33* where *XXX* is the name of the material (or system) for the corresponding library.

History calculations are also allowed in conjunction with branch calculation. At this time, all history calculations will perform all branch calculations defined in the input file. Selection of the burnup values for branch calculations is available on the **option <FG>** card.

See also:

state, branch, option<FG>, power, bu, bui, dbu, t, ti, dt

3.2.6.9 add<MNAME> - material branch

add MNAME|MCLASS

[incr=*Bool*]

[scale=<*ABS*>|*PCT*] :

PNAME=val_1 val_2 ... val_i ... val_N

[MNAME|MCLASS

...]

param	type	name	details	default
MNAME|MCLASS	-	material name or material class	use ALL for all materials	
incr	*Bool*	increment	values are added to reference value	false
scale	*ABS|PCT*	Scaling	scaling ABS: absolute units PCT: percentage units	*ABS*
PNAME	-	property name		
val_i	*Value*	list of property values		

Examples:

```
% fuel temperature branches using incremental
% changes from the base state of 900 K
state FUEL : temp=900
read branch
  add FUEL incr=true : temp=-200 -100 +100 +200 +500
end branch

% material properties may be varied together (synchronized)
% by chaining additional material/properties together
% the first block below results in 2 states
% the second is 6 states
read branch
  add FUEL : temp=900 1200
       FUEL : dens=10.4 10.3
       COOL : dens=0.7  0.65
end branch
read branch
  add FUEL : temp=900 1200
  add FUEL : dens=10.4 10.3
  add COOL : dens=0.7  0.65
end branch
```

Comments:

The **add** card is only valid inside a **branch** block. This version adds a set of branches for a specific material name (MNAME) or class (MCLASS). Branches are always with respect to the base state. Although similar to the **state** card, the **add** card has a single property name and a list of values. The **state** card has a list of *property=value* pairs.

See also:

material, state<MNAME>

3.2.6.10 add<INAME> - insert/control branch

add INAME : in=*Bool1*[*Bool2*]

Table 3.2.52: Options for control element insertion branch cases

param	type	name	details	default
INAME	-	insert name or control element name		
in	Bool	list of insertion states	"in=" is required	

Examples:

```
% branch to remove WABA inserts
state InsWABA4 : in=true
read branch
  add InsWABA4 : in=false
end branch

% synchronize rods in with material branches (5 states)
read branch
  add BankD : in=true false false false true
      FUEL  : temp=600 900 1200 2000 2000
end branch

% swap control banks
read branch
  add BankB : in=true  false false
      BankC : in=false true  false
      BankD : in=false false true
end branch
```

Comments:

This form of the **add** card is required to add branches to insert/remove control elements or inserts. Given that only two possible states exist, specifying "true false" will result in a calculation at the *other* state not specified by the *base state*.

See also:

insert, control, state<INAME>

3.2.6.11 add<GNAME> - geometry branch

add GNAME : pres=*Bool1*[*Bool2*]

param	type	name	details	default
GNAME	-	geometry name		
pres	Bool	list of geometry states	"pres=" is required	

Examples:

```
% perform a reflector calculation on a branch
state ReflectorNode : pres=no
read branch
  add ReflectorNode : pres=yes
end branch
```

Comments:

This form of the **add** card is required to add branches for new geometry, such as reflector calculations. Given that only two possible states exist, specifying "true false" will result in a calculation at the *other* state not specified by the *base state*.

See also:

geometry, state<GNAME>

3.2.7 OPTIONS

An extensive set of options is provided for manipulating the solvers and output. Most **option** cards support a *key*=*value* style of input, with reasonable defaults in place for all parameters.

3.2.7.1 option<KEFF> - eigenvalue

opt *KEFF* [key_1=val_1 key_2=val_2 ... key_i=val_i ... key_N=val_N]

key	*value type*	*details*	*default*
NumAzim	*Int*	number of azimuthal angles per octant	20
NumPolar	*Int*	number of polar angles per octant	3
PnOrder	*Int*	scattering order	2
RaySpacing	*Real*	spacing between MoC rays	0.04 cm
developer options (generally should not change)			
PolarScheme	*String*	polar quadrature “TY”: Tabuchi-Yamamoto quadrature “DECART”: DeCART quadrature “LO”: Leonard optimal quadrature “CACTUS”: Cactus quadrature	“TY”
EigSolver	*String*	eigenvalue solver type “CMFD” (single-assembly default) “POWER” (reflector default)	
UpscatterSolver	*String*	upscatter solver type “GAUSS_SEIDEL”, (default if EigSolver=”CMFD”) “BICGSTAB” (default if EigSolver=”POWER”) “GMRES”	
DownscatterSolver, UpscatterInnerSolver	*String*	within-group solver type “SOURCE”, (default if EigSolver=”CMFD”) “BICGSTAB” (default if EigSolver=”POWER”) “GMRES”	
EigMaxIterations	*Int*	maximum number of eigenvalue iterations	1000
DownscatterMaxIterations, UpscatterMaxIterations, UpscatterInnerMaxIterations	*Int*	maximum iterations for multigroup solves default is 1 for EigSolver=”CMFD” default is 1000 for EigSolver=”POWER”	
EigTolerance	*Real*	eigenvector L_2 residual tolerance	1.0
EigFissionTolerance	*Real*	eigenvector $L_¥$ relative fission error tolerance	3e-4
DownscatterTolerance, UpscatterTolerance, UpscatterInnerTolerance	*Real*	L_2 residual tolerance for multigroup solve	3e-6
EigVerbosity	*String*	msg file print level for eigenvalue iterations “NONE”, “LOW”, “HIGH”	“LOW”
DownscatterVerbosity, UpscatterVerbosity, UpscatterInnerVerbosity	*String*	msg file print level for multigroup iterations “NONE”, “LOW”, “HIGH”	“NONE”
CmfdRelaxation	*Real*	relaxation parameter for CMFD solution update	1.0
UpscatterSuperGroup	*Int*	number of energy groups in the inner iteration in the upscatter calculation	1
DownscatterSuperGroup	*Int*	number of energy groups in the inner iteration in the downscatter calculation	1
PartitionUpscatter	*Bool*	Partition problem into downscatter and upscatter energy regions default is true for EigSolver=”POWER” default is false for EigSolver="CMFD"	
ReverseRay	*Bool*	true – store attenuation coefficients from forward ray calculation and reuse in reverse ray calculation false – recompute attenuation coefficients for reverse ray	true
CyclicRay	*Bool*	true – continue particle tracks after reaching the boundary false – separate particle tracks	true
Accumulator	*String*	angle-to-moment flux calculation “SEGMENT”: during sweep (P_0 default) “SWEEP”: after sweep (P_N default)	
TransportCorrection	*Bool*	true: use P1 transport correction false: do not perform correction (Only applies for P_0 calculation)	true

Examples:

```
% change the MOC ray spacing for the
% eigenvalue calculation to 0.01 cm
opt KEFF RaySpacing=0.01

%P3 scattering
opt KEFF PnOrder=3
```

3.2.7.2 option<ESSM> - embedded self-shielding

opt *ESSM*

[key_1=val_1 key_2=val_2 ... key_i=val_i ... key_N=val_N]

[: MG_1=met_1 MG_2=met_2 ... MG_i=met_i ... MG_M=met_M]

[: E_1 E_2 ... E_i ... E_K]

key	*value type*	*details*	*default*
WithinGroupSolver	*String*	solver method "BICGSTAB": Bi-conjugate gradient stabilized "GMRES": general minimized residual "SOURCE": source iteration	"BICGSTAB"
MaxIterations	*Int*	maximum number of solver iterations	20
developer options (generally should not change)			
NumAzim	*Int*	number of azimuthal angles	8
NumPolar	*Int*	number of polar angles	3
RaySpacing	*Real*	spacing between MOC rays	0.02 cm
SolverTolerance	*Real*	solver tolerance	1e-4
EscapeXSConvergenceCriteria	*Real*		1e-3
ZeroEscapeXsTolerance	*Real*		1e-10
FluxMaxValue	*Real*		0.999999
LargeEscapeXs	*Real*		1e9
MinEnergy	*Real*	Full ESSM band lower energy bound in eV. The associated bounding energy group will have a lower boundary less than or equal to MinEnergy and an upper boundary greater than MinEnergy	1.25
MaxEnergy	*Real*	Full ESSM band upper energy bound in eV. The associated bounding energy group will have a lower boundary less than MaxEnergy and an upper boundary greater than or equal to MaxEnergy	50,000
PolarScheme	*String*	polar quadrature “TY”: Tabuchi-Yamamoto quadrature “DECART”: DeCART quadrature “LO”: Leonard optimal quadrature “CACTUS”: Cactus quadrature	DECART

param	type	details	default
MG_i	*String*	Material group name for ESSM group i. All materials in the model with a material ID which contains the material group name will have their ESSM escape cross-section calculations performed together. The method used to performed these calculations will be designated by met_i	ALL
met_i	*String*	The ESSM calculation method to be used by material group MG_i. Acceptable values are either "G" for full "Group-wise" treatment, or "I" for the Enhanced Neutron Current based tabular "Interpolation" approximation method.	G
E_i	*Real*	Energy values in units of eV which specify the energies to be used for tabular Interpolation. These values must be provided in ascending order.	0.1 1 10

Examples:

```
% change within group solver to use source iterations
opt ESSM WithinGroupSolver=SOURCE

% change all CLAD to use the interpolation
% self-shielding method (faster)
opt ESSM RaySpacing=0.08
         NumAzim=1
         NumPolar=1
         MinEnergy=1e3
         MaxEnergy=1e7
         : CLAD=I FUEL=G
         : 10 100 1000 10000
```

3.2.7.3 option<BOND> - Bondarenko search

opt *BOND* [key_1=val_1 key_2=val_2 … key_i=val_i … key_N=val_N]

key	value type	details	default
MaxIterations	*Int*	number of Bondarenko iterations (0 is disabled)	0*
ConvergenceXS	*String*	cross section used in Bondarenko convergence iterations "SIGA": absorption "SIGT": total	"SIGA"**
developer options (generally should not change)			
IterationCriteria	*Real*		1e-3
TempSearchMaxIterations	*Int*		20
TempSearchCriteria	*Real*		1e-8
TempSearchEqualTolerance	*Real*		1e-3

continues on next page

Table 3.2.55 – continued from previous page

key	value type	details	default
TempSearchMax-Power	*Real*		35.0
Sig0SearchMaxIterations	*Int*		20
Sig0SearchCriteria	*Real*		1e-8
Sig0SearchEqual Tolerance	*Real*		1e-3
Sig0SearchMaxPower	*Real*		35.0

* By setting the Bondarenko iterations >0, resonance interference effects may be taken into account. The default MaxIterations=0 effectively disables the Bondarenko resonance interference model.

**In SCALE, the transport cross section ("SIGT") has historically been used in Bondarenko iterations.

Examples:

```
% introduce Bondarenko iterations on total cross section
opt BOND
   MaxIterations=10
   ConvergenceXS="SIGT"
```

3.2.7.4 option<DEPL> - depletion

opt DEPL [key_1=val_1 key_2=val_2 ... key_i=val_i ... key_N=val_N]

key	value type.	details	default
TrackingSet	*String*	set of nuclides tracked in depletion calculations "None": set of nuclides present in user input "Complete": complete set of all nuclides available on ORIGEN data libraries	"Complete"
Solver	*String*	"MATREX": legacy ORIGEN solution method "CRAM": Chebyshev Rational Approximation Method	"MATREX"
Method	*String*	"PREDICTOR" "PREDICTOR_CORR ECTOR"	"PREDICTOR_CORR ECTOR"
StepRefinement	*Int*	divide the user input steps by this factor>0, i.e., refinement of 2 divides all steps by 2 (NOT ENABLED)	1
NumSubsteps	*Int*	Number of internal substeps for depletion calculations	4
DepleteMode	*String*	"BOSS" or "MOSS." The depletion power renormalization is done at the beginning of each substep (BOSS) or the middle of each substep (MOSS)	"BOSS"

continues on next page

Table 3.2.56 – continued from previous page

key	value type.	details	default
ArchiveF71	ALL|NONE	Archive all of materials on the .f71 file, or do not archive any isotope inventories	ALL
ArchiveF33	ALL |NONE|SYSTEM	Archive all of materials on the .f33 file, or no materials, or just the system average.	SYSTEM

Examples:

```
% Set the number of origen substeps per time steps to 2
% (may be useful for convergence studies)
opt DEPL
   NumSubsteps=2

% disable the addition of depletion nuclides to input materials
opt DEPL TrackingSet="NONE"

% use CRAM solver
opt DEPL Solver="CRAM"
```

3.2.7.5 option<CRITSPEC> - critical spectrum

opt *CRITSPEC* [key_1=val_1 key_2=val_2 ... key_i=val_i ... key_N=val_N]

key	value type	details	default
Mode	*String*	critical spectrum mode "SEARCH": search for critical mode (k-eff=1) "SPECIFIED": provide B2 below "NONE": do not use critical spectrum	"SEARCH"
B2	*Real*	value of critical buckling if Mode="SPECIFIED " units: cm^{-2}	0.0
Method	*String*	critical spectrum system "B1": solve the B_1 equations "P1": solve the P_1 equations	"P1"

Examples:

```
% enable critical buckling search using B1 equations for a buckling of 1e-3
opt CRITSPEC
  Mode="SPECIFIED"
  B2=1e-3
  Method="B1"
```

3.2.7.6 option<PRINT> - printing

opt *PRINT* [key_1=val_1 key_2=val_2 ... key_i=val_i ... key_N=val_N]

key	value type	details	default
XSSummary	*Bool*	print a cross section summary in the output file	yes

opt DATA
  KineticsResource="kinetics_Tuttle.h5"
  ReactionResource="n302.reaction.data"
```

3.2.8 SYSTEM

The **system** cards provide a way to initialize a set of defaults to simplify input and add robustness for a well-known and well-characterized system.

system *STYPE*

argument	type	name
STYPE		system type
	PWR	pressurized water reactor
	BWR	boiling water reac-tor

The **system** card performs the following actions:

1. defines a set of materials and properties, imposing standard names for the materials and properties;
2. warns user of potential mistakes; and

3. uses heuristics to modify *unspecified* mesh and solver options for robust results.

3.2.8.1 system<PWR> - pressurized water reactor

miscellaneous

type	*purpose*	*introduced*
deplete	depletion materials	deplete ALL=N FUEL=R BP=R
shield	material self-shielding	shield ALL=N FUEL=R BP=R CNTL=R

Description

Twelve reactor materials are initialized with compositions and densities from the predefined composition set. In most cases, all that remains is to define fuel materials, all material temperatures, and properties such as COOL/MOD soluble boron and density. Note that some rules are based on naming conventions. For example, burnable poisons (the material class BP) are declared to be depletable materials, whereas the CNTL (control elements) class of materials is not.

Examples:

```
% a complete input file for a PWR pincell model
=polaris
system PWR

3.2.9 SAMPLE PROBLEMS

Within the SCALE distribution, 31 Polaris sample problems are provided to demonstrate the differences in calculation and geometry options, and 21 sample problems consider the Consortium for Advanced Simulation of Light Water Reactors (CASL) Virtual Environment for Reactor Applications (VERA) benchmark problems for pin cell and lattice configurations described in [POLARISRE13]. The VERA pin cell problems are identified as `polaris_1a.inp` through `polaris_1e.inp`. The VERA lattice problems are identified as `polaris_2a.inp` through `polaris_2p.inp`.

The remaining ten sample problems are described as follows:

- polaris_TMI1_Cycle1-2.inp – 15 × 15 PWR geometry model with branch block definition for lattice physics calculations
- polaris_bench_taka3_sf97-4_assm.inp, polaris_bench_taka3_sf97-4_pin.inp – Takahama UOX depletion benchmark for radiochemical assay NT3G24-SF97-4 described in [POLARISBS96].
- polaris.6.3_rca_pwr.inp – Additional Takahama UOX depletion benchmark with time-dependent boron concentraion defined in a **history** block.
- polaris_bwr10x10.inp, polaris_bwr7×7.inp – example BWR geometry models for 10 × 10 and 7 x 7 fuel.
- polaris_dv1a.inp – simple PWR pin cell depletion calculation.
- polaris_twophase.inp – simple BWR 8 x 8 fuel example to demonstrate the TWOPHASE property.
- polaris_dopants.inp – pin cell demonstrations of built-in dopant properties for LWR fuel.
- polarisHatchT1ASimple.inp - BWR model with detector model in narrow-narrow corner.

3.2.10 APPENDICES

3.2.10.1 SCALE 6.2 Polaris Input Format

For the release of SCALE 6.2.3, several new input cards were implemented into Polaris to model boiling water reactor (BWR) geometries and neutron/gamma detectors, which requires a gamma transport calculation. Moreover, improvements to existing input cards were implemented, along with the ability to specify time-dependent state properties and the ability to specify one or more depletion histories. This appendix documents the SCALE 6.2 input cards that were included in the Polaris input format which are accessible as part of the release of SCALE 6.3.

The old input cards are not available *by default* with SCALE 6.3, and should be considered deprecated. To maximize backwards compatibility for input files developed with the original SCALE 6.2.0 release, the old input options are available if the input file begins with =polaris_6.2.

The following input cards were introduced in SCALE 6.3 and are not available by default in SCALE 6.2:

- **cross** – define the interior water cross geometry of SVEA assembly designs;
- **dxmap** (or **dymap**) – define displacement maps that indicate that translation of the pin center in the x- (or y-) direction;
- **control <BLADE>** – define the control blade geometry;
- **mesh** – define advanced spatial meshing options for different materials; and

- **option <GEOM>** – define geometry tolerances, advance meshing options, and plotting options.
- **option <GAMMA>** – gamma transport calculation
- **detector** – insert a detector geometry
- **history** – time dependent history
- **bui [ti]** – initiate calculation with cumulative burnups [time] (with restart)
- **property<GRAIN>** – used to model stochastic media
- **state** – the generalized state input is preceded by the state<MNAME>, state<INAME>, state<GNAME> variants

box – channel box

box [thick=*Real*] [rad=*Real*] [icdist=*Real*] [xrad=*Real*] [xlen=*Real*] [Mbox=MNAME]

param	**type**	**name**	**details**	**default**
thick	*Real*	nominal thickness (cm)	must be >0	none
rad	*Real*	inner corner radius (cm)	must be >0, additional constraints listed below	none
icdist	*Real*	in-channel distance (cm)	must be >0	none
xrad	*Real*	extra corner thickness (cm)	must be >= 0	0
xlen	*Real*	extra corner length (cm)	excludes rounded corner length	0
M_{box}	MNAME	box material		*

*By default, **box** material will be set to CAN.1 by "system BWR." Otherwise **box** material is required.

```
% GE 7x7 assembly with 1.88 cm pin pitch
%   0.48 cm narrow gap
%   0.95 cm wide gap
system BWR
geom ge7x7 : ASSM 7 1.88
hgap 0.48 0.95

% Box geometry
%   0.2 thickness
%   0.97 inner corner radius

pin – pin or pincell

pin PINID [nsect=*Int*] [nring=*Int*] [size=*Int*]

: r_1 r_2 … r_i … r_N

: M_1 M_2 … M_i … M_N [M_{out}]

[: nr_1 nr_2 … nr_i … nr_N nr_{out}]

[: ns_1 ns_2 … ns_i … ns_N ns_{out}]

param	*type*	*name*	*details*	*default*
PINID	*Word|Int*	pin identifier		
size	*Int*	pin will be placed in a size x size pincell grid	used to create large water rods in CE PWRs and GE BWRs (see pinmap)	
r_i	*Real*	list of radii	for each radial zone from center out units: cm	
M_i	*MNAME*	list of pin materials	material in each radial zone .1 added if given MCLASS, e.g., FUEL→FUEL.1	
M_{out}	*MNAME*	material in outermost zone	material in outermost zone .1 added if given MCLASS, e.g., FUEL→FUEL.1	*
meshing options				
nsect	*Int*	number of sectors	azimuthal sections of the pin cell, value applies to all ns_i and ns_{out}	
nring	*Int*	number of rings	value applies to all nr_i and nr_{out}	
nr_i	*Int*	number of rings	number of rings in each radial zone	1
nr_{out}	*Int*	number of rings in outermost zone	number of rings in the outermost zone	1
ns_i	*Int*	number of sectors	number of sectors in each radial zone	1
ns_{out}	*Int*	number of sectors in outermost zone	number of sectors in the outermost zone	1

*If not specified, the material class MCLASS is taken from the **channel** card (M_{chan}) and set to the first member of that class, "M_{chan}.1." For example if M_{chan}="COOL," then M_{out}= "COOL.1."

Examples:

```
%standard fuel pin
pin 1 : 0.4096 0.418 0.475
      : FUEL   GAS   CLAD

%empty guide tube
pin E :        0.561 0.602

      : GAS   TUBE  GAS   BP.3  GAS   TUBE  COOL  CLAD

%standard fuel pin with explicit material in the outermost region
pin 1 : 0.4096 0.418 0.475
      : FUEL   GAS   CLAD   COOL.6

%standard fuel pin with explicit ring and sector mesh
pin 1 : 0.4096 0.418 0.475
      : FUEL   GAS   CLAD
      : 5      1     1      0   %5 rings in fuel
      : 8      1     1      1   %8 sectors only in fuel
```

(continues on next page)

(continued from previous page)

```
%large central 2x2 water rod in 4x4 assembly
pin W size=2 : 0.8
             : COOL

%pinmap must show adjacent Ws
pinmap
F F F F
F W W F
F W W F
F F F F
```

Comments:

The **pin** card is one of the basic building blocks of the assembly model. It is the only geometry component which allows an integer (*Int*) identifier as well as a *Word*-all other geometric identifiers use *Word*. Note that the materials are required, except for the last M_{out}, which can be used to overwrite the material given by a **channel** for the outermost region in the pincell. The various pin cell meshing options are displayed in Fig. 3.2.10. Note that extra rings in the radial zones create equal area regions, whereas rings in the outermost region create equal distance divisions between the last radius and the pincell boundary. Extra sectors create additional azimuthal divisions. A negative value of sectors is allowed and can be used to rotate the sector mesh by a half angle, e.g., ns=4 looks like ⊗ and ns=-4 looks like ⊗.

The total number of cells used in the transport calculation is determined from both the number of rings and the number of sectors. With the MoC transport solver, the fidelity of the solution is also dictated by the number of azimuthal and polar angles and ray spacing. These parameters are changed on the **option<KEFF>** card.

Due to self-shielding and depletion, each cell could be modeled as a unique material with its own cross section data. However, this is prohibitively memory intensive and typically not necessary. The **shield** card provides the mechanism to control the additional self-shielded materials introduced.

% using MWd/MTIHM units with variable power
% 40 W/gIHM for 0→5000 MWD/MTIHM, then 30 W/gIHM for 5000→10000 MWD/MTIHM
power  40    30
bu MWD/MTIHM: 0 5000 10000
```

(continues on next page)

(continued from previous page)

```
% combine burn/time cards
% 20 W/gIHM for 0→5 then 5→10 GWD/MTIHM steps, then
% 40 W/gIHM for a 5-day step then 30 W/gIHM for a 5-day step
power 20
bu   GWD/MTIHM :  5 10 GWD/MTIHM
power 40 30
dt  DAYS :   5  5
```

Comments:

The **bu** card initiates a calculation for a given sequence of cumulative burnups. A burnup or time card usually follows a **power** card, the two effectively specifying the power history. If multiple burnups are given, then the **power** card must have either a single power or a list of powers the same size as the list times. A value of 0 is implicit at the beginning of the first burnup list. Multiple burnup/time cards may be specified in an input. This can be convenient for switching units or changing from burnup-based to time-based depletion. Internal automatic substeps are always in effect unless modified with the **option<DEPL>** card.

t, dt, bu, power, option<DEPL>, branch, deplete

t – initiate calculation by cumulative time

t [units=*SECONDS*|*MINUTES*|*HOURS*|<*DAYS*>|*YEARS*] : [t_1 t_2 … t_i … t_N]

param	Type	name	details	default
units	*SECONDS*| *MINUTES*| *HOURS*| <*DAYS*>| *YEARS*	time units		DAYS
t_i	*Real*	list of times	0	0

Examples:

```
% burn with 40 W/gIHM for 300 days in 100-day increments
power 40
t 100 200 300

% simulate 2 cycles of time-dependent irradiation with shutdown cooling
% note that time defaults to DAYs
%
% cycle 1
power 40   30   30   30
t    100  200  300  400
power  0
t    415
%
% cycle 2
power 30   20   20   20
t    515  615  715  815
power  0
t    830
```

Comments:

The **t** card initiates a calculation for a given sequence of cumulative/absolute times. One of the time cards (**t**, **dt**, or **ti**) is required to model periods of decay in conjunction with **power** 0. Otherwise, the time card **t** is similar in functionality to the burnup **bu** card but with different units.

4. RADIATION SHIELDING

Introduction by D. E. Peplow and B. T. Rearden

The Monaco with Automated Variance Reduction using Importance Calculations (MAVRIC) fixed-source radiation transport sequence is designed to apply the multigroup and continuous energy fixed-source Monte Carlo code Monaco to solve problems too challenging for standard, unbiased Monte Carlo methods.i The intention of the sequence is to calculate fluxes and dose rates with low uncertainties in reasonable times even for deep penetration problems. MAVRIC is based on the Consistent Adjoint Driven Importance Sampling (CADIS) methodology, which uses an importance map and biased source that are derived to work together. MAVRIC generates problem-dependent cross section data and then automatically performs a coarse mesh 3D discrete ordinates transport calculation using Denovo to determine the adjoint flux as a function of position and energy. MAVRIC then applies the information to optimize the shielding calculation in Monaco. In the Forward-Weighted CADIS (FW-CADIS) methodology, an additional Denovo calculation is performed to further optimize the Monaco model to obtain uniform uncertainties for multiple tally locations. Sources can be input using many spatial and energy distributions, or they can be imported from a previously generated mesh file. Responses can be generated from cross section reaction rates, flux-to-dose conversion factors, or user-defined functions; responses are tallied on geometry regions, Cartesian or cylindrical grids, or as point detectors.

MAVRIC enables users to import spent fuel isotopics from ORIGEN binary concentrations files such as those generated with ORIGAMI and to import gamma emission spectral data directly from the ORIGEN nuclear data files to streamline analysis and reduce the opportunity for human error.

Several utility modules are also provided for data introspection and conversion.

4.1 MAVRIC: MONACO WITH AUTOMATED VARIANCE REDUCTION USING IMPORTANCE CALCULATIONS

D. E. Peplow and C. Celik

4.1.1 INTRODUCTION

Monte Carlo particle transport calculations for deep penetration problems can require very long run times in order to achieve an acceptable level of statistical uncertainty in the final answers. Discrete-ordinates codes can be faster but have limitations relative to the discretization of space, energy, and direction. Monte Carlo calculations can be modified (biased) to produce results with the same variance in less time if an approximate answer or some other additional information is already known about the problem. If importances can be assigned to different particles based on how much they will contribute to the final answer, then more time can be spent on important particles, with less time devoted to unimportant particles. One of the best ways to bias a Monte Carlo code for a particular tally is to form an importance map from the adjoint flux based on that tally. Unfortunately, determining the exact adjoint flux could be just as difficult as computing the original problem itself. However, an approximate adjoint can still be very useful in biasing the Monte Carlo solution [MAVRIC-Wag97]. Discrete ordinates can be used to quickly compute that approximate adjoint. Together, Monte Carlo and discrete ordinates can be used to find solutions to thick shielding problems in reasonable times.

The MAVRIC (Monaco with Automated Variance Reduction using Importance Calculations) sequence is based on the CADIS (Consistent Adjoint Driven Importance Sampling) and FW-CADIS (Forward-Weighted CADIS) methodologies [MAVRIC-HW03, MAVRIC-Wag02, MAVRIC-WBP07, MAVRIC-WH98,

MAVRIC-WPE20]. MAVRIC automatically performs a three-dimensional, discrete-ordinates calculation using Denovo to compute the adjoint flux as a function of position and energy. This adjoint flux information is then used to construct an importance map (i.e., target weights for weight windows) and a biased source distribution that work together-particles are born with a weight matching the target weight of the cell into which they are born. The fixed-source Monte Carlo radiation transport Monaco [MAVRIC-Pep11] then uses the importance map for biasing during particle transport, and it uses the biased source distribution as its source. During transport, the particle weight is compared with the importance map after each particle interaction and whenever a particle crosses into a new importance cell in the map.

For problems that do not require variance reduction to complete in a reasonable time, execution of MAVRIC without the importance map calculation provides an easy way to run Monaco. For problems that do require variance reduction to complete in a reasonable time, MAVRIC removes the burden of setting weight windows from the user and performs it automatically with a minimal amount of additional input. Note that the MAVRIC sequence can be used with the final Monaco calculation as either a multigroup (MG) or a continuous-energy (CE) calculation.

Monaco has a wide variety of tally options: it can calculate fluxes (by group) at a point in space, over any geometrical region, or for a user-defined, three-dimensional, rectangular grid. These tallies can also integrate the fluxes with either standard response functions from the cross section library or user-defined response functions. All of these tallies are available in the MAVRIC sequence.

Although it was originally designed for CADIS, the MAVRIC sequence is also capable of creating importance maps using both forward and adjoint deterministic estimates. The FW-CADIS method [MAVRIC-WPM14] can be used for optimizing several tallies at once, a mesh tally over a large region, or a mesh tally over the entire problem. Several other methods for producing importance maps are also available in MAVRIC and are explored in Sect. 4.4.

4.1.2 CADIS METHODOLOGY

MAVRIC is an implementation of CADIS (Consistent Adjoint Driven Importance Sampling) using the Denovo SN and Monaco Monte Carlo functional modules. Source biasing and a mesh-based importance map, overlaying the physical geometry, are the basic methods of variance reduction. To make the best use of an importance map, the map must be made consistent with the source biasing. If the source biasing is inconsistent with the weight windows that will be used during the transport process, then source particles will undergo Russian roulette or splitting immediately, wasting computational time and negating the intent of the biasing.

4.1.2.1 Overview of CADIS

CADIS is well described in the literature, so only a brief overview is given here. Consider a class source-detector problem described by a unit source with emission probability distribution function $q\left(\overrightarrow{r}, E\right)$ and a detector response function $\sigma_d\left(\overrightarrow{r}, E\right)$. To determine the total detector response, R, the forward scalar flux $\phi\left(\overrightarrow{r}, E\right)$ must be known. The response is found by integrating the product of the detector response function and the flux over the detector volume V_d:

$$R = \int_{V_d} \int_E \sigma_d\left(\overrightarrow{r}, E\right) \phi\left(\overrightarrow{r}, E\right) dE\, dV. \tag{4.1.1}$$

Alternatively, if the adjoint scalar flux, $\phi^+\left(\overrightarrow{r}, E\right)$, is known from the corresponding adjoint problem with adjoint source $q^+\left(\overrightarrow{r}, E\right) = \sigma_d\left(\overrightarrow{r}, E\right)$, then the total detector response could be found by integrating the

product of the forward source and the adjoint flux over the source volume, V_s:

$$R = \int_{V_s} \int_E q\left(\vec{r}, E\right)\phi^+\left(\vec{r}, E\right) dE\, dV. \tag{4.1.2}$$

Unfortunately, the exact adjoint flux may be just as difficult to determine as the forward flux, but an approximation of the adjoint flux can still be used to form an importance map and a biased source distribution for use in the forward Monte Carlo calculation.

Wagner [MAVRIC-Wag97] showed that if an estimate of the adjoint scalar flux for the corresponding adjoint problem can be found, then an estimate of the response R can be made using Eq. (4.1.2). The adjoint source for the adjoint problem is typically separable and corresponds to the detector response and spatial area of the tally to be optimized: $q^+\left(\vec{r}, E\right) = \sigma_d\left(E\right) g\left(\vec{r}\right)$, where $\sigma_d\left(E\right)$ is a flux-to-dose conversion factor and $g\left(\vec{r}\right)$ is 1 in the tally volume and is 0 otherwise. Then, from the adjoint flux $\phi^+\left(\vec{r}, E\right)$ and response estimate R, a biased source distribution, $\widehat{q}\left(\vec{r}, E\right)$, for source sampling of the form

$$\widehat{q}\left(\vec{r}, E\right) = \frac{1}{R} q\left(\vec{r}, E\right)\phi^+\left(\vec{r}, E\right) \tag{4.1.3}$$

and weight window target values, $\overline{w}\left(\vec{r}, E\right)$, for particle transport of the form

$$\overline{w}\left(\vec{r}, E\right) = \frac{R}{\phi^+\left(\vec{r}, E\right)} \tag{4.1.4}$$

can be constructed, which minimizes the variance in the forward Monte Carlo calculation of R.

When a particle is sampled from the biased source distribution $\widehat{q}\left(\vec{r}, E\right)$, to preserve a fair game, its initial weight is set to

$$w_0\left(\vec{r}, E\right) = \frac{q\left(\vec{r}, E\right)}{\widehat{q}\left(\vec{r}, E\right)} = \frac{R}{\phi^+\left(\vec{r}, E\right)} \tag{4.1.5}$$

which exactly matches the target weight for that particle's position and energy. This is the "consistent" part of CADIS-source particles are born with a weight matching the weight window of the region/energy into which they are born. The source biasing and the weight windows work together.

CADIS has been applied to many problems-including reactor ex-core detectors, well-logging instruments, cask shielding studies, and independent spent fuel storage facility models-and has demonstrated very significant speed-ups in calculation time compared to analog simulations.

4.1.2.2 Multiple sources with CADIS

For a typical Monte Carlo calculation with multiple sources—each with a probability distribution function $q_i\left(\vec{r}, E\right)$ and a strength S_i, giving a total source strength of $S = \sum S_i$—the source is sampled in two steps. First, the specific source i is sampled with probability $p\left(i\right) = S_i/S$, and then the particle is sampled from the specific source distribution $q_i\left(\vec{r}, E\right)$.

The source sampling can be biased at both levels: from which source to sample and how to sample each source. For example, the specific source can be sampled using some arbitrary distribution, $\widehat{p}\left(i\right)$, and then the individual sources can be sampled using distributions $\widehat{q}_i\left(\vec{r}, E\right)$. Particles would then have a birth weight of

$$w_0 \equiv \left(\frac{p\left(i\right)}{\widehat{p}\left(i\right)}\right)\left(\frac{q_i\left(\vec{r}, E\right)}{\widehat{q}_i\left(\vec{r}, E\right)}\right). \tag{4.1.6}$$

For CADIS, a biased multiple source needs to be developed so that the birth weights of sampled particles still match the target weights of the importance map. For a problem with multiple sources—each with a distribution $q_i\left(\overrightarrow{r},E\right)$ and a strength S_i—the goal of the Monte Carlo calculation is to compute some response R for a response function $\sigma_d\left(\overrightarrow{r},E\right)$ at a given detector,

$$R = \int_V \int_E \sigma_d\left(\overrightarrow{r},E\right)\phi\left(\overrightarrow{r},E\right) dE\, dV. \tag{4.1.7}$$

Note that the flux $\phi\left(\overrightarrow{r},E\right)$ has contributions from each source. The response, R_i, from each specific source (S_i with $q_i\left(\overrightarrow{r},E\right)$) can be expressed using just the flux from that source, $\phi_i\left(\overrightarrow{r},E\right)$, as

$$R_i = \int_V \int_E \sigma_d\left(\overrightarrow{r},E\right)\ \phi_i\left(\overrightarrow{r},E\right) dE\, dV\,. \tag{4.1.8}$$

The total response is then found as $R = \sum_i R_i$.

For the adjoint problem, using the adjoint source of $q^+\left(\overrightarrow{r},E\right) = \sigma_d\left(\overrightarrow{r},E\right)$, the response R can also be calculated as

$$R = \int_V \int_E \left[\sum_i S_i q_i\left(\overrightarrow{r},E\right)\right] \phi^+\left(\overrightarrow{r},E\right) dE\, dV, \tag{4.1.9}$$

with the response contribution from each specific source being

$$R_i = \int_V \int_E S_i q_i\left(\overrightarrow{r},E\right)\phi^+\left(\overrightarrow{r},E\right) dE\, dV. \tag{4.1.10}$$

The target weights $\overline{w}\left(\overrightarrow{r},E\right)$ of the importance map are found using

$$\overline{w}\left(\overrightarrow{r},E\right) = \frac{R/S}{\phi^+\left(\overrightarrow{r},E\right)}. \tag{4.1.11}$$

Each biased source $\widehat{q}_i\left(\overrightarrow{r},E\right)$ pdf is found using

$$\widehat{q}_i\left(\overrightarrow{r},E\right) = \frac{S_i}{R_i} q_i\left(\overrightarrow{r},E\right)\phi^+\left(\overrightarrow{r},E\right)\ , \tag{4.1.12}$$

and the biased distribution used to select an individual source is $\widehat{p}\,(i) = R_i/\sum R_i = R_i/R$.

When using the biased distribution used to select an individual source, $\widehat{p}\,(i)$, and the biased source distribution, $\widehat{q}_i\left(\overrightarrow{r},E\right)$, the birth weight of the sampled particle will be

$$\begin{aligned} w_0 &\equiv \left(\frac{p(i)}{\widehat{p}(i)}\right)\left(\frac{q_i\left(\overrightarrow{r},E\right)}{\widehat{q}_i\left(\overrightarrow{r},E\right)}\right) \\ &= \left(\frac{\frac{S_i}{S}}{\frac{R_i}{R}}\right)\left(\frac{q_i\left(\overrightarrow{r},E\right)}{\frac{S_i}{R_i} q_i\left(\overrightarrow{r},E\right)\phi^+\left(\overrightarrow{r},E\right)}\right) \\ &= \frac{R/S}{\phi^+\left(\overrightarrow{r},E\right)}, \end{aligned} \tag{4.1.13}$$

which matches the target weight, $\overline{w}\left(\overrightarrow{r},E\right)$.

4.1.2.3 Multiple tallies with CADIS

The CADIS methodology works quite well for classic source/detector problems. The statistical uncertainty of the tally that serves as the adjoint source is greatly reduced since the Monte Carlo transport is optimized to spend more simulation time on those particles that contribute to the tally, at the expense of tracking particles in other parts of phase space. However, more recently, Monte Carlo has been applied to problems in which multiple tallies need to all be found with low statistical uncertainties. The extension of this idea is the mesh tally-where each voxel is a tally for which the user desires low statistical uncertainties. For these problems, the user must accept a total simulation time that is controlled by the tally with the slowest convergence and simulation results where the tallies have a wide range of relative uncertainties.

The obvious way around this problem is to create a separate problem for each tally and use CADIS to optimize each. Each simulation can then be run until the tally reaches the level of acceptable uncertainty. For more than a few tallies, this approach becomes complicated and time-consuming for the user. For large mesh tallies, this approach is not reasonable.

Another approach to treat several tallies, if they are in close proximity to each other, or a mesh tally covering a small portion of the physical problem, is to use the CADIS methodology with the adjoint source near the middle of the tallies to be optimized. Since particles in the forward Monte Carlo simulation are optimized to reach the location of the adjoint source, all the tallies surrounding that adjoint source should converge quickly. This approach requires the difficult question of "how close." If the tallies are too far apart, then certain energies or regions that are needed for one tally may be of low importance for getting particles to the central adjoint source. This may under-predict the flux or dose at the tally sites far from the adjoint source.

MAVRIC has the capability to have multiple adjoint sources with this problem in mind. For several tallies that are far from each other, multiple adjoint sources could be used. In the forward Monte Carlo, particles would be drawn to one of those adjoint sources. The difficulty with this approach is that typically the tally that is closest to the true physical source converges faster than the other tallies—showing that the closest adjoint source seems to attract more particles than the others. Assigning more strength to the adjoint source further from the true physical source helps to address this issue, but finding the correct strengths so that all of the tallies converge to the same relative uncertainty in one simulation is an iterative process for the user.

4.1.2.4 Forward-weighted CADIS

To converge several tallies to the same relative uncertainty in one simulation, the adjoint source corresponding to each of those tallies must be weighted inversely by the expected tally value. To calculate the dose rate at two points—say one near a reactor and one far from a reactor—in one simulation, then the total adjoint source used to develop the weight windows and biased source must have two parts. The adjoint source far from the reactor must have more strength than the adjoint source near the reactor by a factor equal to the ratio of the expected near dose rate to the expected far dose rate.

This concept can be extended to mesh tallies, as well. Instead of using a uniform adjoint source strength over the entire mesh tally volume, each voxel of the adjoint source should be weighted inversely by the expected forward tally value for that voxel. Areas of low flux or low dose rate would have more adjoint source strength than areas of high flux or high dose rate.

An estimate of the expected tally results can be found by using a quick discrete-ordinates calculation. This leads to an extension of the CADIS method: forward-weighted CADIS (FW-CADIS). First, a forward S_N calculation is performed to estimate the expected tally results. A total adjoint source is constructed so that the adjoint source corresponding to each tally is weighted inversely by those forward tally estimates. Then the standard CADIS approach is used-an importance map (target weight windows) and a biased source are made using the adjoint flux computed from the adjoint S_N calculation.

For example, if the goal is to calculate a detector response function $\sigma_d(E)$ (such as dose rate using flux-to-dose-rate conversion factors) over a volume (defined by $g\left(\overrightarrow{r}\right)$) corresponding to mesh tally, then instead of simply using $q^+\left(\overrightarrow{r},E\right) = \sigma_d(E)\ g(\overrightarrow{r})$, the adjoint source would be

$$q^+\left(\overrightarrow{r},E\right) = \frac{\sigma_d(E)\,\mathrm{g}\left(\overrightarrow{r}\right)}{\int \sigma_d(E)\,\phi\left(\overrightarrow{r},E\right)dE}\,, \tag{4.1.14}$$

where $\phi\left(\overrightarrow{r},E\right)$ is an estimate of the forward flux, and the energy integral is over the voxel at $\overrightarrow{r}$. The adjoint source is nonzero only where the mesh tally is defined ($g\left(\overrightarrow{r}\right)$), and its strength is inversely proportional to the forward estimate of dose rate.

The relative uncertainty of a tally is controlled by two components: (1) the number of tracks contributing to the tally and (2) the shape of the distribution of scores contributing to that tally. In the Monte Carlo game, the number of simulated particles, $m\left(\overrightarrow{r},E\right)$, can be related to the true physical particle density, $n\left(\overrightarrow{r},E\right)$, by the average Monte Carlo weight of scoring particles, $\overline{w}\left(\overrightarrow{r},E\right)$, by

$$n\left(\overrightarrow{r},E\right) = \overline{w}\left(\overrightarrow{r},E\right)\mathrm{m}\left(\overrightarrow{r},E\right). \tag{4.1.15}$$

In a typical Monte Carlo calculation, tallies are made by adding some score, multiplied by the current particle weight, to an accumulator. To calculate a similar quantity related to the Monte Carlo particle density would be very close to calculating any other quantity but without including the particle weight. The goal of FW-CADIS is to make the Monte Carlo particle density, $m\left(\overrightarrow{r},E\right)$, uniform over the tally areas, so an importance map must be developed that represents the importance of achieving uniform Monte Carlo particle density. By attempting to keep the Monte Carlo particle density more uniform, more uniform relative errors for the tallies should be realized.

Two options for forward weighting are possible. For tallies over some area where the entire group-wise flux is needed with low relative uncertainties, the adjoint source should be weighted inversely by the forward flux, $\phi\left(\overrightarrow{r},E\right)$. The other option, for a tally in which only an energy-integrated quantity is desired, is to weight the adjoint inversely by that energy-integrated quantity, $\int \sigma_d(E)\,\phi\left(\overrightarrow{r},E\right)$ dE. For a tally in which the total flux is desired, then the response in the adjoint source is simply $\sigma_d(E) = 1$.

To optimize the forward Monte Carlo simulation for the calculation of some quantity at multiple tally locations or across a mesh tally, the adjoint source must be weighted by the estimate of that quantity. For a tally defined by its spatial location $g\left(\overrightarrow{r}\right)$ and its optional response $\sigma_d(E)$, the standard adjoint source would be $q^+\left(\overrightarrow{r},E\right) = \sigma_d(E)\,\mathrm{g}\left(\overrightarrow{r}\right)$. The forward-weighted adjoint source, $q^+\left(\overrightarrow{r},E\right)$, depending on what quantity is to be optimized, is listed below.

For the calculation of		Adjoint source
Energy and spatially dependent flux	$\phi\left(\overrightarrow{r},E\right)$	$\frac{g\left(\overrightarrow{r}\right)}{\phi\left(\overrightarrow{r},E\right)}$
Spatially dependent total flux	$\int \phi\left(\overrightarrow{r},E\right)dE$	$\frac{g\left(\overrightarrow{r}\right)}{\int \phi\left(\overrightarrow{r},E\right)dE}$
Spatially dependent total response	$\int \sigma_d(E)\,\phi\left(\overrightarrow{r},E\right)dE$	$\frac{\sigma_d(E)\mathrm{g}\left(\overrightarrow{r}\right)}{\int \sigma_d(E)\phi\left(\overrightarrow{r},E\right)dE}$

The bottom line of FW-CADIS is that in order to calculate a quantity at multiple tally locations (or across a mesh tally) with more uniform relative uncertainties, an adjoint source must be developed for an objective

function that keeps some non-physical quantity-related to the Monte Carlo particle density and similar in form to the desired quantity-constant. FW-CADIS uses the solution of a forward discrete-ordinates calculation to properly weight the adjoint source. After that, the standard CADIS approach is used.

4.1.2.5 MAVRIC Implementation of CADIS

With MAVRIC, as with other shielding codes, the user defines the problem as a set of physical models-the material compositions, the geometry, the source, and the detectors (locations and response functions)-as well as some mathematical parameters on how to solve the problem (number of histories, etc.). For the variance reduction portion of MAVRIC, the only additional inputs required are (1) the mesh planes to use in the discrete-ordinates calculation(s) and (2) the adjoint source description—basically the location and the response of each tally to optimize in the forward Monte Carlo calculation. MAVRIC uses this information to construct a Denovo adjoint problem. (The adjoint source is weighted by a Denovo forward flux or response estimate for FW-CADIS applications.) MAVRIC then uses the CADIS methodology: it combines the adjoint flux from the Denovo calculation with the source description and creates the importance map (weight window targets) and the mesh-based biased source. Monaco is then run using the CADIS biased source distribution and the weight window targets.

Denovo

Denovo is a parallel three-dimensional SN code that is used to generate adjoint (and, for FW-CADIS, forward) scalar fluxes for the CADIS methods in MAVRIC. For use in MAVRIC/CADIS, it is highly desirable that the SN code be fast, positive, and robust. The phase-space shape of the forward and adjoint fluxes, as opposed to a highly accurate solution, is the most important quality for Monte Carlo weight-window generation. Accordingly, Denovo provides a step-characteristics spatial differencing option that produces positive scalar fluxes as long as the source (volume plus in-scatter) is positive. Denovo uses an orthogonal, nonuniform mesh that is ideal for CADIS applications because of the speed and robustness of calculations on this mesh type.

Denovo uses the highly robust GMRES (Generalized Minimum Residual) Krylov method to solve the SN equations in each group. GMRES has been shown to be more robust and efficient than traditional source (fixed-point) iteration. The in-group discrete SN equations are defined as

$$\mathbf{L}\psi = \mathrm{MS}\phi + q \tag{4.1.16}$$

where $\mathbf{L}$ is the differential transport operator, $\mathbf{M}$ is the moment-to-discrete operator, $\mathbf{S}$ is the matrix of scattering cross section moments, q is the external and in-scatter source, ϕ is the vector of angular flux moments, and ψ is the vector of angular fluxes at discrete angles. Applying the operator $\mathbf{D}$, where $\phi = \mathbf{D}\psi$, and rearranging terms, casts the in-group equations in the form of a traditional linear system, $\mathbf{A}x = b$,

$$\left(\mathbf{I} - \mathbf{D}\mathbf{L}^{-1}\mathrm{MS}\right) = \mathbf{D}\mathbf{L}^{-1}q. \tag{4.1.17}$$

The operation $\mathbf{L}^{-1}\nu$, where ν is an iteration vector, is performed using a traditional wave-front solve (transport sweep). The parallel implementation of the Denovo wave-front solver uses the well-known Koch-Baker-Alcouffe (KBA) algorithm, which is a two-dimensional block-spatial decomposition of a three-dimensional orthogonal mesh [MAVRIC-BK98]. The Trilinos package is used for the GMRES implementation [MAVRIC-WH03] Denovo stores the mesh-based scalar fluxes in a double precision binary file (*.dff) called a *Denovo flux file*. Past versions of SCALE/Denovo used the TORT [MAVRIC-RS97] *.varscl file format (DOORS package [MAVRIC-RC98]), but this was limited to single precision. Since the rest of the MAVRIC sequence has not yet been parallelized, Denovo is currently used only in serial mode within MAVRIC.

Monaco

The forward Monte Carlo transport is performed using Monaco, a fixed-source shielding code that uses the SCALE General Geometry Package (SGGP, the same as used by the criticality code KENO-VI) and the standard SCALE material information processor. Monaco can use either MG or CE cross section libraries. Monaco was originally based on the MORSE Monte Carlo code but has been extensively modified to modernize the coding, incorporate more flexibility in terms of sources/tallies, and read a user-friendly block/keyword style input.

Much of the input to MAVRIC is the same as Monaco. More details can be found in the Monaco chapter of the SCALE manual (Sect. 8.2).

Running MAVRIC

The objective of a SCALE sequence is to execute several codes, passing the output from one to the input of the next, in order to perform some analysis—tasks that users typically had to do in the past. MAVRIC does this for difficult shielding problems by running approximate discrete-ordinates calculations, constructing an importance map and biased source for one or more tallies that the user wants to optimize in the Monte Carlo calculation, and then using those in a forward Monaco Monte Carlo calculation. MAVRIC also prepares the forward and adjoint cross sections when needed. The steps of a MAVRIC sequence are listed in Table 4.1.1. The user can instruct MAVRIC to run this whole sequence of steps or just some subset of the steps to verify the intermediate steps or to reuse previously calculated quantities in a new analyses.

The MAVRIC sequence can be stopped after key points by using the "parm= *parameter* " operator on the "=mavric" command line, which is the first line of the input file. The various parameters are listed in Table Table 4.1.2. These parameters allow the user to perform checks and make changes to the importance map calculation before the actual Monte Carlo calculation in Monaco.

MAVRIC also allows the sequence to start at several different points. If an importance map and biased source have already been computed, they can then be used directly. If the adjoint scalar fluxes are known, they can quickly be used to create the importance map and biased source and then begin the forward Monte Carlo calculation. All of the different combinations of starting MAVRIC with some previously calculated quantities are listed in the following section detailing the input options.

When using MG cross section libraries that do not have flux-to-dose-rate conversion factors, use "parm=nodose" to prevent the cross section processing codes from trying to move these values into the working library.

MAVRIC creates many files that use the base problem name from the output file. For an output file called "c:path1path2*outputName*.out" or "/home/path1/path2/ *outputName*.inp", spaces in the output name will cause trouble and should not be used.

Cross section calculation	XSProc is used to calculate the adjoint cross sections for Denovo
Adjoint flux calculation	Denovo calculates the estimate of the adjoint flux
CADIS (optional)	The scalar flux file from Denovo is then used to create the biased source distribution and transport weight windows
Monte Carlo calculation	Monaco uses the biased source distribution and transport weight windows to calculate the various tallies

Table 4.1.2: Parameters for the MAVRIC command line ("parm=...")

Parameter	MAVRIC will stop after
check	input checking
forinp	Forward Denovo input construction (makes `xkba_b.inp` in the tmp area)
forward	The forward Denovo calculation
adjinp	Adjoint Denovo input construction (makes `xkba_b.inp` in the tmp area)
adjoint	The adjoint Denovo calculation
impmap	Calculation of importance map and biased source

4.1.3 MAVRIC INPUT

The input file for MAVRIC consists of three lines of text ("=mavric" command line with optional parameters, the problem title, and SCALE cross section library name) and then several blocks, with each block starting with "read xxxx" and ending with "end xxxx". There are three required blocks and nine optional blocks. Material and geometry blocks must be listed first and in the specified order. Other blocks may be listed in any order.

Blocks (must be in this order):

- Composition – (required) SCALE standard composition, list of materials used in the problem
- Celldata – SCALE resonance self-shielding
- Geometry – (required) SCALE general geometry description
- Array – optional addition to the above geometry description
- Volume – optional calculation or listing of region volumes
- Plot – create 2D slices of the SGGP geometry

Other Blocks (in any order, following the blocks listed above):

- Definitions – defines locations, response functions, and grid geometries used by other blocks
- Sources – (required) description of the particle source spatial, energy, and directional distributions
- Tallies – description of what to calculate: point detector tallies, region tallies, or mesh tallies
- Parameters – how to perform the simulation (random number seed, how many histories, etc.)
- Biasing – data for reducing the variance of the simulation
- ImportanceMap – instructions for creating an importance map based on a discrete-ordinates calculation

The material blocks (Composition and Celldata) and the physical model blocks (Geometry, Array, Volume, and Plot) follow the standard SCALE format. See the other SCALE references as noted in the following sections for details. The Biasing block and ImportanceMap block cannot both be used.

For the other six blocks, scalar variables are set by "keyword=value", fixed-length arrays are set with "keyword $value_1$ ... $value_N$", variable-length arrays are set with "keyword $value_1$ ... $value_N$ end", and some text and filenames are read in as quoted strings. Single keywords to set options are also used in some instances. The indention, comment lines, and upper/lowercase shown in this document are not required-they are used in the examples only for clarity. Except for strings in quotes (like filenames), SCALE is case insensitive.

After all input blocks are listed, a single line with "end data" should be listed. A final "end" should also be listed, to signify the end of all MAVRIC input. Nine of the blocks are the same input blocks as those used by the functional module Monaco, with a few extra keywords only for use with MAVRIC. These extra keywords are highlighted here, but without relisting all of the standard Monaco keywords for those blocks. See Example 4.1.1 for an overview of MAVRIC input file structure.

4.1.3.1 Composition block

Material information input follows the standard SCALE format for material input. Basic materials known to the SCALE library may be used as well as completely user-defined materials (using isotopes with known cross sections). Input instructions are located in the XSProc chapter (Sect. 7.1) in the SCALE manual. The Standard Composition Library chapter (Sect. 7.2) lists the different cross section libraries and the names of standard materials. An example is as follows:

```
read composition

    uo2 1 0.2 293.0 92234 0.0055 92235 3.5 92238 96.4945 end

    orconcrete 2 1.0 293.0 end

    ss304 3 1.0 293.0 end

end composition
```

Details on the cell data block are also included in the XSProc chapter (Sect. 7.1). When using different libraries for the importance map production (listed at the top of the input) and the final Monte Carlo calculation (listed in the parameters block, if different), make sure that the materials are present in both libraries.

Example 4.1.1: Overall input format for MAVRIC

```
=mavric                          % name of sequence
Some title for this problem      % title
v7-27n19g                        % cross section library name
read composition                 % SCALE material compositions
   ...                           %     [required block]
end composition                  %
read celldata                    % SCALE resonance self-shielding
   ...                           %     [optional block]
end celldata                     %
read geometry                    % SCALE SGGP geometry
   ...                           %     [required block]
end geometry                     %
read array                       % SCALE SGGP arrays
   ...                           %     [optional block]
end array                        %
read volume                      % SCALE SGGP volume calc
```

(continues on next page)

(continued from previous page)

```
   ...                          %     [optional block]
end volume                      %
read plot                       % SGGP Plots
   ...                          %     [optional block]
end plot                        %
read definitions                % Definitions
   ...                          %     [possibly required]
end definitions                 %
read sources                    % Sources definition
   ...                          %     [required block]
end sources                     %
read tallies                    % Tally specifications
   ...                          %     [optional block]
end tallies                     %
read parameters                 % Monte Carlo parameters
   ...                          %     [optional block]
end parameters                  %
read biasing                    % Biasing information
   ...                          %     [optional block]
end biasing                     %
read importanceMap              % Importance map
   ...                          %     [optional block]
end importanceMap               %
end data                        % end of all blocks
end                             % end of MAVRIC input
```

4.1.3.2 SGGP geometry blocks

MAVRIC uses the functional module Monaco for the forward Monte Carlo calculation. Monaco tracks particles through the physical geometry described by the SGGP input blocks, as well as through the mesh importance map and any mesh tallies, which are defined in the global coordinates and overlay the physical geometry. Because Monaco must track through all of these geometries at the same time, users should not use the reflective boundary capability in the SGGP geometry.

For more details on each SGGP geometry block, see the following sections of the KENO-VI chapter Sect. 8.1 of the SCALE Manual.

Geometry – *Geometry Data*

Array – *Array Data*

Volume – *Volume Data*

Plot – *Plot Data*

4.1.3.3 Other blocks shared with Monaco

The definitions, sources, tallies, and biasing blocks are all the same as Monaco. They are all fully described in the Monaco chapter (Sect. 8.2) of the SCALE Manual.

Definitions — *Definitions Block*

Sources — *Sources Block*

Tallies — *Tallies Block*

Biasing — *Biasing Block*

The parameters block includes several keywords that are not included in Monaco (see the *Parameter Block* section of the Monaco chapter (Sect. 8.2) which are used when the cross section library used in the importance

calculations differs from the library used in the final forward Monaco Monte Carlo calculation. The library listed at the beginning of the MAVRIC input file will be used for the importance calculations (forward and adjoint Denovo calculation, formation of the importance map, and biased sources). To use a different MG library in the final Monaco simulation, use the keyword "library=" with the cross section library name in quotes. A cross section library for Monaco will be made using csas-mg. If there are any extra parameters to use ("parm=" in the "=csas-mg" line of the csas-mg input), they can be passed along using the keyword "parmString=" with the extra information in quotes. For example, the following input file would use a coarse-group library for the importance calculations and a fine-group library for the final Monaco, each with CENTRM processing.

```
=mavric parm=centrm
v7-27n19g
...

read parameters

    library="v7-200n47g" parmString="centrm"

    ...

end parameters

...

end data

end
```

To use a CE cross section in the final Monaco step, use the keyword "ceLibrary=" with the cross section library name in quotes. When the "library=" or "ceLibrary=" keywords are used, they should precede the "neutron", "photon", "noNeutron", and "noPhoton" keywords. Table 4.1.3 summarizes all of the keywords in the MAVRIC parameter block.

When using two different cross section libraries, be sure that the responses and distributions are defined in ways that do not depend on the cross section library. For example, any response that is just a list of n values (corresponding to a cross section library of n groups) needs to have the group energies specifically listed so that it can be evaluated properly on the other group structure.

Table 4.1.3: Extra keywords for the parameters block

block	keyword	type	length	default	required	restrictions/comments
read parameters						
	All of the keywords listed in the Monaco manual still apply					
	Final Monaco Monte Carlo calculation is multi-group					
	library=	character		not present	no	multi-group library for final Monaco run, if different than MAVRIC
	parmString=	character		not present	no	parm for MG cross section processing using CSAS-MG
	Final Monaco Monte Carlo calculation is continuous energy					
	ceLibrary=	character		not present	no	continuous energy library name
end parameters						

4.1.3.4 Importance map block

The importance map block is the "heart and soul" of MAVRIC. This block lists the parameters for creating an importance map and biased source from one (adjoint) or two (forward, followed by adjoint) Denovo discrete-ordinates calculations. Without an importance map block, MAVRIC can be used to run Monaco and use its conventional types of variance reduction. If both the importance map and biasing blocks are specified, then only the importance map block will be used. The various ways to use the importance map block are explained in the subsections below. Keywords for this block are summarized at the end of this section, in Table 4.1.4.

Constructing a mesh for the S_N calculation

All uses of the importance map block that run the discrete-ordinates code require the use of a grid geometry that overlays the physical geometry. Grid geometries are defined in the definitions block of the MAVRIC input. The extent and level of detail needed in a grid geometry are discussed in the following paragraphs.

When using S_N methods alone for solving radiation transport in shielding problems, a good rule of thumb is to use mesh cell sizes on the order of a meanfree path of the particle. In complex shielding problems, this could lead to an extremely large number of mesh cells, especially when considering the size of the meanfree path of the lowest energy neutrons and photons in common shielding materials.

In MAVRIC, the goal is to use the S_N calculation for a quick approximate solution. Accuracy is not paramount-just getting an idea of the overall shape of the true importance map will help accelerate the convergence of the forward Monte Carlo calculation. The more accurate the importance map, the better the forward Monte Carlo acceleration will be. At some point there is a time trade-off when the computational time for calculating the importance map followed by the time to perform the Monte Carlo calculation exceeds that of a standard analog Monte Carlo calculation. Large numbers of mesh cells that result from using very small mesh sizes for S_N calculations also use a great deal of computer memory.

Because the deterministic solution(s) for CADIS and FW-CADIS can have moderate fidelity and still provide variance reduction parameters that substantially accelerate the Monte Carlo solution, mesh cell sizes in MAVRIC applications can be larger than what most S_N practioners would typically use. The use of relatively coarse mesh reduces memory requirements and the run time of the deterministic solution(s). Some general guidelines to keep in mind when creating a mesh for the importance map/biased source are as follows:

- The true source regions should be included in the mesh with mesh planes at their boundaries.
- Place point or very small sources in the center of a mesh cell, not on the mesh planes.
- Any region of the geometry where particles could eventually contribute to the tallies (the "important" areas) should be included in the mesh.
- Point adjoint sources (corresponding to point detector locations) in standard CADIS calculations do not have to be included inside the mesh. For FW-CADIS, they must be in the mesh and should be located at a mesh cell center, not on any of the mesh planes.
- Volumetric adjoint sources should be included in the mesh with mesh planes at their boundaries.
- Mesh planes should be placed at significant material boundaries.
- Neighboring cell sizes should not be drastically different.
- Smaller cell sizes should be used where the adjoint flux is changing rapidly, such as toward the surfaces of adjoint sources and shields (rather than in their interiors).

Another aspect to keep in mind is that the source in the forward Monaco Monte Carlo calculation will be a biased mesh-based source. Source particles will be selected by first sampling which mesh cell to use and then sampling a position uniformly within that mesh cell that meets the user criteria of "unit=", "region=", or "mixture=" if specified. The mesh should have enough resolution that the mesh source will be an accurate representation of the true source.

The geometry for the Denovo calculation is specified using the keyword "gridGeometryID=" and the identification number of a grid geometry that was defined in the definitions block. The material assigned to each voxel of the mesh is determined by testing the center point in the SGGP geometry (unless the macro-material option is used-see below).

Macromaterials for S_N geometries

Part of the advantage of the CADIS method is that the adjoint discrete-ordinates calculation only needs to be approximate in order to form a reasonable importance map and biased source. This usually means that the mesh used is much coarser than the mesh that would be used if the problem were to be solved only with a discrete-ordinates code. This coarse mesh may miss significant details (especially curves) in the geometry and produce a less-than-optimal importance map.

To get more accurate solutions from a coarse-mesh discrete-ordinates calculation, Denovo can represent the material in each voxel of the mesh as a volume-weighted mixture of the real materials, called *macromaterials*, in the problem. When constructing the Denovo input, the Denovo EigenValue Calculation (DEVC, see section Sect. 2.4) sequence can estimate the volume fraction occupied by using each real material in each voxel by a sampling method. The user can specify parameters for how to sample the geometry. Note that finer sampling makes more accurate estimates of the material fraction but requires more setup time to create the Denovo input. Users should understand how the macromaterials are sampled and should consider this when constructing a mesh grid. This is especially important for geometries that contain arrays. Careful consideration should be given when overlaying a mesh on a geometry that contains arrays of arrays.

Because the list of macromaterials could become large, the user can also specify a tolerance for how close two different macromaterials can be in order to be considered the same, thereby reducing the total number of macromaterials. The macromaterial tolerance, "`mmTolerance=`", is used for creating a different macromaterial from the those already created by looking at the infinity norm between two macromaterials. The number of macromaterials does not appreciably impact Denovo run time or memory requirements.

Two different sampling methods are available-point testing [MAVRIC-IPE+09] with the keyword `mmPointTest` and ray tracing [MAVRIC-Joh13] with the keyword `mmRayTest`.

Ray Tracing

This method estimates the volume of different materials in the Denovo mesh grid elements by tracing rays through the SGGP geometry and computing the average track lengths through each material. Rays are traced in all three dimensions to better estimate the volume fractions of materials within each voxel. The mmSubCell parameter controls how many rays will be traced in each voxel in each dimension. For example, if mmSubCell= n, then when tracing rays in the z dimension, each column of voxels uses a set of n × n rays starting uniformly spaced in the x and y dimensions. With rays being cast from all three orthogonal directions, a total of 3n2 rays are used to sample each voxel. One can think of subcells as an equally spaced sub-mesh with a single ray positioned at each center. The number of subcells in each direction, and hence the number of rays, can be explicitly given with mmSubCells ny nz nx nz nx ny end keyword for rays parallel to the x axis, y axis, and z axis. Fig. 4.1.1 shows different subcell configurations (in two dimensions) for a given voxel.

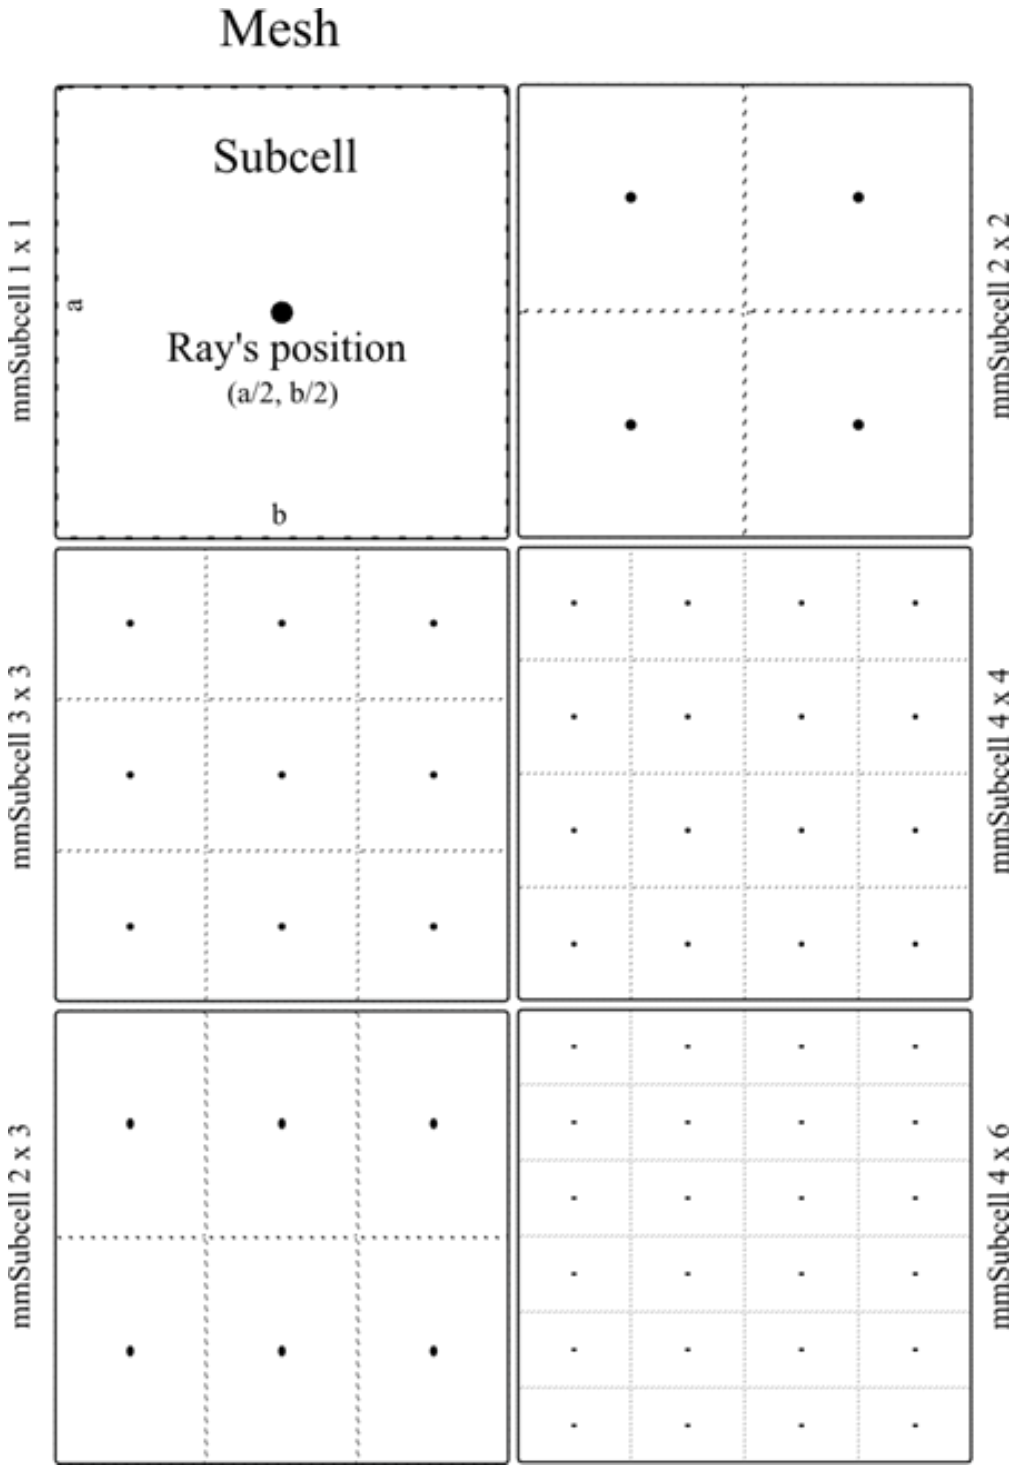

Fig. 4.1.1: Ray positions within a voxel with different mmSubCells parameters.

Ray tracing is a more robust method compared to the simple point testing method used in previous versions of SCALE/MAVRIC; however, it requires more memory than point testing. Ray tracing gives more accurate estimates of volume fractions because track lengths across a voxel give more information than a series of test points. Ray tracing is also much faster than point testing because the particle tracking routines are optimized

to quickly determine lists of materials and distance along a given ray.

Ray tracing operates on the grid geometry supplied by the user and shoots rays in all three directions, starting from the lower bounds of the mesh grid. An example of an arbitrary assembly geometry is shown in Fig. 4.1.2. A ray consists of a number of steps that each correspond to crossing a material boundary along the path of the ray. Ratios of each step's length to the voxel length in the ray's direction determine the material volume fraction of that step in that voxel, and summation of the same material volume fractions gives the material volume fraction of that material in that voxel. Ray tracing through a single voxel that contains a fuel pin is illustrated in Fig. 4.1.3.

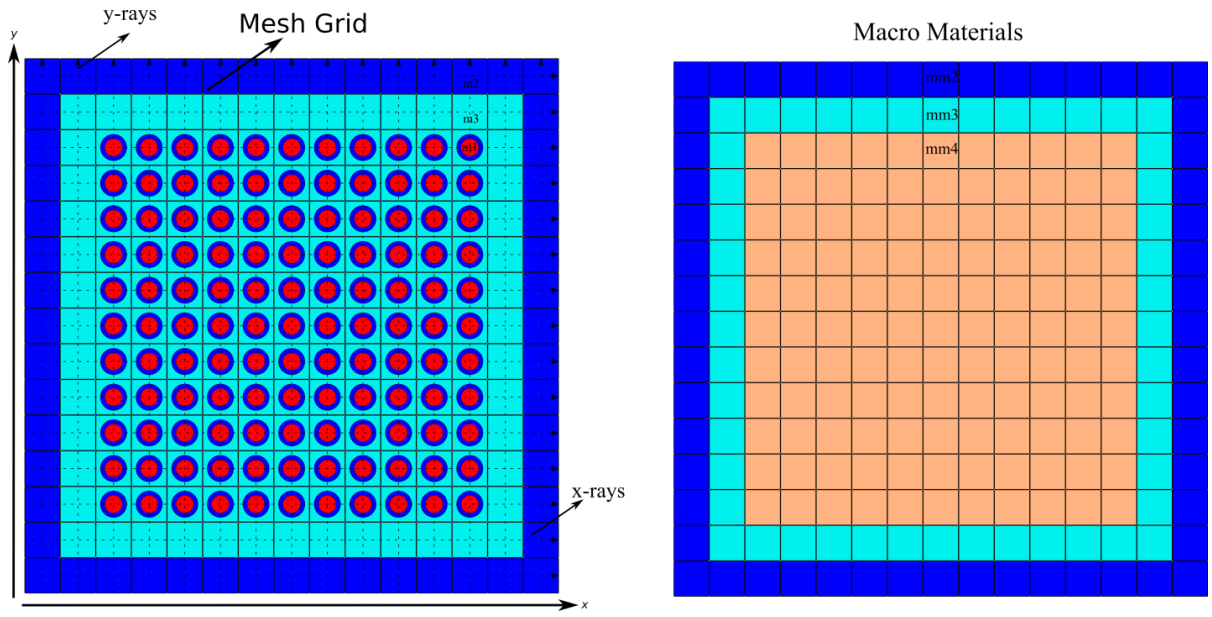

Fig. 4.1.2: Geometry model (left) and the Denovo representation (right) of an assembly using macromaterials determined by ray tracing.

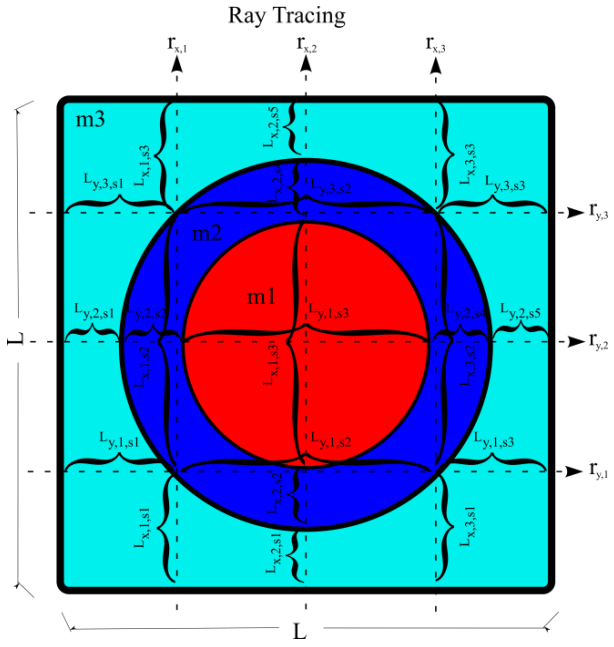

Fig. 4.1.3: Ray tracing (in two dimensions) through a voxel.

The final constructed macromaterials for this model are also shown in Fig. 4.1.2. Voxels that contain only a single material are assigned the original material number in the constructed macromaterials. For the voxels that contain a fuel pin with three different materials, the result is a new macromaterial consisting of the volume weighted fractions of each original material.

After the rays are shot in all three directions, the material volume fractions are updated, and macromaterials are created by using these material volume fractions. Material volume fraction calculations for a single voxel, as shown in Fig. 4.1.3, are given by

$$F_m = \sum_{d=x,y,z} \sum_{r=1}^{N_r} \sum_{s=1}^{N_s} \begin{cases} \frac{L_{d,r,s}}{L_d}, & m_s == m \\ 0, & \text{otherwise} \end{cases} \qquad \textit{and} \qquad V_m = \frac{F_m}{\sum_{n=1}^{N_m} F_n}, \tag{4.1.18}$$

where Fm = sampled fraction of material m in the voxel,

d = direction of the rays (x, y, z),

r = ray number,

N_r = total number of rays in the voxel for direction of d,

s = step number,

N_s = total number of steps for ray r in the voxel for direction of d,

$L_{d,r,s}$ = length of the steps s for ray r in the voxel for direction of d,

L_d = length of the voxel along direction of d,

m_s = material of step s,

m = material number,

N_m = total number of materials in the voxel, and

V_m = volume fraction of material m in the voxel.

Point Testing

The recursive bisection method is utilized in point testing and uses a series of point tests to determine the macromaterial fractions. For a given voxel, the material at the center is compared to the material at the eight corners. If they are all the same, then the entire volume is considered to be made of that material. If they are different, then the volume is divided into two in each dimension. Each subvolume is tested, and the method is then applied to the subvolumes that are not of a single material. When the ratio of the volume of the tested region to the original voxel becomes less than a user-specified tolerance (in the range of 10-1 to 10-4), then further subdivision and testing are stopped. This is illustrated in Fig. 4.1.4.

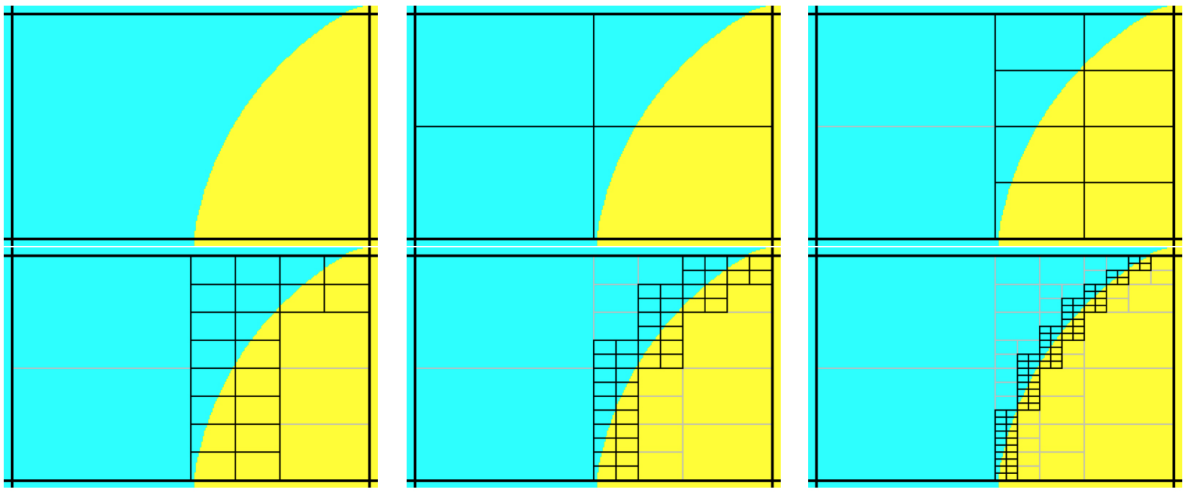

Fig. 4.1.4: Recursive bisection method.

Fig. 4 Successive steps in the recursive macromaterial method

In point testing, the keyword "mmTolerance=f" is interpreted to be where f is the smallest fraction of the voxel volume that can be achieved by bisection method and hence the limiting factor for dividing the voxel. This same tolerance f is also used to limit the number of macromaterials. Before a new macromaterial is created, if one already exists where the fraction of each actual material matches to within the given tolerance, then the existing material will be used. If using only a single point at the center of each voxel, then use "mmTolerance=1". The mmSubCell keyword is not used in point testing.

Example

Fig. 4.1.5 shows an example of a cask geometry with two types of spent fuel (yellows), steel (blue), resin (green), and other metals (gray). When the Denovo geometry is set up by testing only the center of each mesh cell, the curved surfaces are not well represented (upper right). By applying the ray-tracing method and defining a new material made of partial fractions of the original materials, an improved Denovo model can be made. In the lower left of the figure, the Denovo model was constructed using one ray (in each dimension) per voxel and a tolerance of 0.1. This gives 20 new materials that are a mixture of the original 13 actual materials and void. With mmSubCells=3 and an mmTolerance=0.01, 139 macromaterials are created.

A macromaterial table listing the fractions of each macromaterial is saved to a file called "outputName.mmt", where outputName is the name the user chose for his or her output file. This file can be used by the Mesh File Viewer to display the macromaterials as mixtures of the actual materials, as seen in the lower row of

Fig. 4.1.5. See the Mesh File Viewer help pages for more information on how to use colormap files and macromaterial tables.

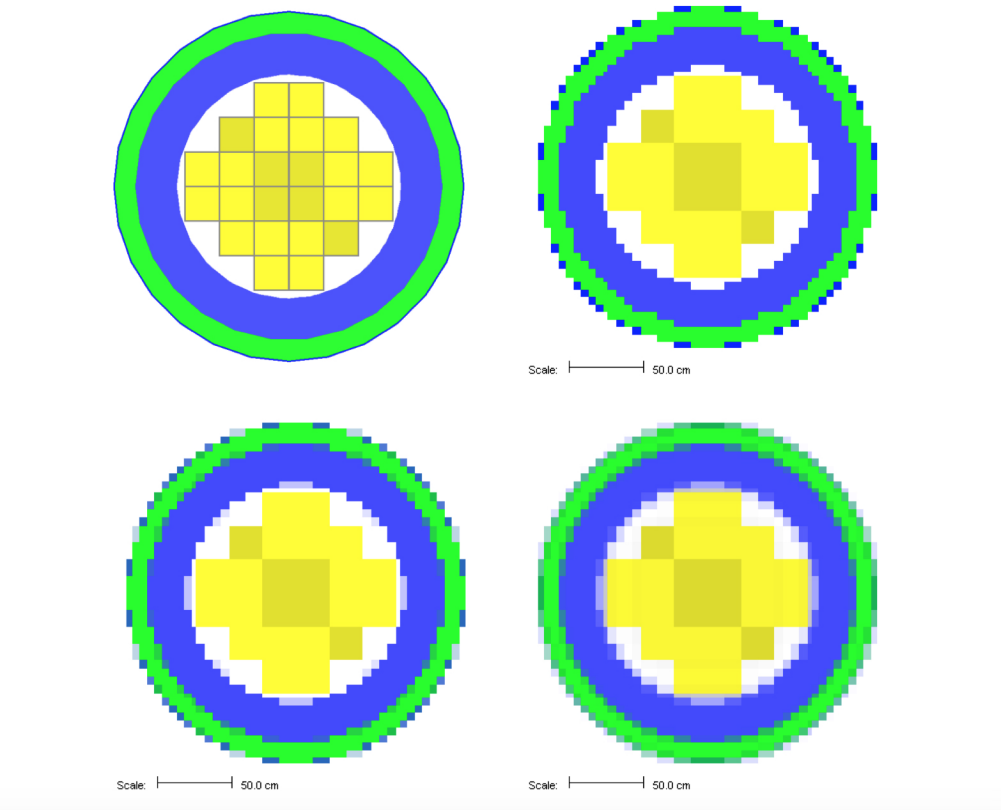

Fig. 4.1.5: Cask geometry model (upper left) and the Denovo representation using cell center testing (upper right). Representations using macromaterials determined by ray tracing are shown for mmSubCell=1/mmTolerance=0.1 (lower left) and mmSubCell=3/mmTolerance=0.01 (lower right).*

Optimizing source/detector problems

For standard source/detector problems in which one tally is to be optimized in the forward Monte Carlo calculation, an adjoint source based on that tally must be constructed. An adjoint source requires a unique and positive identification number, a physical location, and an energy spectrum. The adjoint source location can be specified either by (1) a point location ("locationID=" keyword) or (2) a volume described by a box ("boundingBox" array). A bounding box is specified by maximum and minimum extent in each dimension- x_{max} x_{min} y_{max} y_{min} z_{max} z_{min}-in global coordinates. The boundingBox should not be degenerate (should have volume>0) but can be optionally limited to areas matching a given unit number ("unit="), a given region number ("region="), or a given material mixture number ("mixture="). A mixture and a region cannot both be specified, since that would either be redundant or mutually exclusive. The energy spectrum of an adjoint source is a response function ("responseID=") listing one of the ID numbers of the responses defined in the definitions block. An optional weight can be assigned to each adjoint source using the "weight=" keyword. If not given, the default weight is 1.0.

For example, to optimize a region tally, the user would construct an adjoint source located in the same place as the tally, with an adjoint source spectrum equal to the response function that the tally is computing. Note that the grid geometry 1 and response function 3 must already be defined in the definitions block.

```
read importanceMap
   gridGeometryID=1
   adjointSource 24
       boundingBox 12.0 10.0  5.0 -5.0  10.0 -10.0
       unit=1 region=5
       responseID=3
   end adjointSource
end importanceMap
```

For optimizing a point detector for the calculation of total photon flux, the importance map block would look like the following:

```
read importanceMap
   adjointSource 21
       locationID=4
       responseID=1
   end adjointSource
   gridGeometryID=1
end importanceMap
```

where location 4 is the same location used by the point detector. To calculate total photon flux, response function 1 must be defined in the definitions block similar to this response:

```
read definitions
    response 1
         values 27r0.0 19r1. end
    end response
    ...
end definitions
```

This response is used for computing total photon flux for the 27 neutron/19 photon group coupled cross section library or like this response

```
read definitions
    response 1
         photon
         bounds 1000.0 2.0e7 end
         values  1.0   1.0   end
    end response
    ...
end definitions
```

which is independent of the cross section library.

Multiple adjoint sources

If there are several tallies in very close proximity and/or several different responses being calculated by the tallies, multiple adjoint sources can be used.

```
read importanceMap
   gridGeometryID=1
   adjointSource 1
       locationID=4  responseID=20
   end adjointSource
   adjointSource 2
       locationID=5  responseID=21
       weight=2.0
   end adjointSource
end importanceMap
```

Note that adjoint sources using point locations can be mixed with volumetric adjoint sources (using bounding boxes).

Options for Denovo S_n calculations

While the default values for various calculational parameters and settings used by Denovo for the MAVRIC sequence should cover most applications, they can be changed if desired. The two most basic parameters are the quadrature set used for the discrete ordinates and the order of the Legendre polynomials used in describing the angular scattering. The default quadrature order that MAVRIC uses is a level symmetric S_8 set, and the default scattering order is P_3 (or the maximum number of coefficients contained in the cross-section library if less than 3). S_8/P_3 is an adequate choice for many applications, but the user is free to changes these. For complex ducts or transport over large distances at small angles, S_{12} may be required. S_4/P_1 or even S_2/P_0 would be useful in doing a very cursory run to confirm that the problem was input correctly, but this would likely be inadequate for weight window generation in a problem that is complex enough to require advanced variance reduction.

These and other Denovo options are applied to both the forward and the adjoint calculations that are required from the inputs given in the importance map block.

In problems with small sources or media that are not highly scattering, discrete ordinates can suffer from "ray effects" [MAVRIC-Lat71, MAVRIC-Lat68] where artifacts of the discrete quadrature directions can be seen in the computed fluxes. Denovo has a first-collision capability to help alleviate ray effects. This method computes the uncollided flux in each mesh cell from a point source. The uncollided fluxes are then used as a distributed source in the main discrete-ordinates solution. At the end of the main calculation, the uncollided fluxes are added to the fluxes computed with the first collision source, forming the total flux. While this helps reduce ray effects in many problems, the first-collision capability can take a significant amount of time to compute on a mesh with many cells or for many point sources.

Adjoint sources that use point locations will automatically use the Denovo first-collision capability. Volumetric adjoint sources (that use a boundingBox) will be treated without the first-collision capability. The keywords "firstCollision" and "noFirstCollision" will be ignored by MAVRIC for adjoint calculations. Keywords for Denovo options in the importance map block are summarized at the end of this section, in Table 4.1.5.

Starting with an existing adjoint flux file

An importance map can be made from an existing Denovo flux file by using the keyword "adjointFluxes=" with the appropriate file name in quotes. The file must be a binary file using the *.dff file format, and the number of groups must match the number of groups in the MAVRIC cross section library (i.e., the library entered on the third line of the MAVRIC input file). Instead of performing an adjoint calculation, the fluxes read from the file will be used to create both the mesh-based importance map and the biased mesh source.

```
read importanceMap
    adjointFluxes="c:\mydocu~1\previousRun.adjoint.dff"
    gridGeometry=7
end importanceMap
```

If the "adjointFluxes=" keyword is used and any adjoint sources are defined, an error will result. If a forward flux file is supplied for forward-weighting the adjoint source (see below), then an adjoint flux file cannot be specified.

The grid geometry is not required when using a pre-existing flux file. If grid geometry is not supplied, one will be created from the mesh planes that are contained in the Denovo flux file (which were used to compute the fluxes in that file).

Forward-weighting the adjoint source

To optimize a mesh tally or multiple region tallies/point detector tallies over a large region, instead of a uniform weighting of the adjoint source, a weighting based on the inverse of the forward response can be performed. This requires an extra discrete-ordinates calculation but can help the forward Monte Carlo calculation compute the mesh tally or group of tallies with more uniform statistical uncertainties.

The same grid geometry will be used in both the forward calculation and the adjoint calculation, so the user must ensure that the mesh covers all of the forward sources and all of the adjoint sources, even if they are point sources.

To use forward-weighted CADIS, specify either of the keywords — "respWeighting" or "fluxWeighting". For either, MAVRIC will run Denovo to create an estimate of the forward flux, $\phi\left(\overrightarrow{r}, E\right)$. For response weighting ("respWeighting"), each adjoint source is inversely weighted by the integral of the product of the response function used in that adjoint source and the estimate of the forward flux. For an adjoint source described by the geometric function $g(\overrightarrow{r})$ and the response function $\sigma_d(E)$ (note that $\sigma_d(E) = 1$ for computing total fluxes), the forward-weighted adjoint source becomes

$$q_i^+\left(\overrightarrow{r}, E\right) = \frac{\sigma_d(E)\, g(\overrightarrow{r})}{\int \sigma_d(E)\ \phi\left(\overrightarrow{r}, E\right) \mathrm{dE}} \ . \tag{4.1.19}$$

Response weighting will calculate more uniform relative uncertainties of the integral quantities of the tallies in the final Monte Carlo calculation.

To optimize the calculation of the entire group-wise flux with more uniform relative uncertainties in each group, the adjoint source should be weighted inversely by the forward flux, $\phi\left(\overrightarrow{r}, E\right)$, using the "fluxWeighting" keyword. For an adjoint source described by the geometric function $g(\overrightarrow{r})$ and the response function $\sigma_d(E) = 1$, the forward-weighted adjoint source becomes

$$q_i^+\left(\overrightarrow{r}, E\right) = \frac{\sigma_d(E)\, g(\overrightarrow{r})}{\phi\left(\overrightarrow{r}, E\right)} \ . \tag{4.1.20}$$

For example, consider a problem with a single source and two detectors, one near the source that measures flux and one far from the source that measures some response. In a standard Monte Carlo calculation, it is expected that since more Monte Carlo particles cross the near detector, it will have a much lower relative uncertainty than the far detector. Standard CADIS could be used to optimize the calculation of each in separate simulations:

To optimize the flux in the near detector:

```
read importanceMap
    gridGeometryID=1
    adjointSource 1
        boundingBox x1 x2 y1 y2 z1 z2
        responseID=1
    end adjointSource
end importanceMap
```

To optimize the response in the far detector:

```
read importanceMap
    gridGeometryID=1
    adjointSource 2
        boundingBox u1 u2 v1 v2 w1 w2
        responseID=6
    end adjointSource
end importanceMap
```

where response 1 was defined as $\sigma_1(E) = 1$ and response 6 was defined as $\sigma_6(E) =$ flux-to-response conversion factors. The two options for forward weighting allow the tallies for both detectors to be calculated in the same MAVRIC simulation. Using "fluxWeighting", the importance map and biased source will be made to help distribute Monte Carlo particles evenly through each energy group and every voxel in both detectors, making the relative uncertainties close to uniform. With "respWeighting", the importance map and biased source will optimize the total integrated response of each tally.

To optimize $\phi\left(\vec{r}, E\right)$ in each detector

```
read importanceMap
    gridGeometryID=1
'   near detector
    adjointSource 1
        boundingBox x1 x2 y1 y2 z1 z2
        responseID=1
    end adjointSource
'   far detector
    adjointSource 2
        boundingBox u1 u2 v1 v2 w1 w2
        responseID=6
    end adjointSource
    fluxWeighting
end importanceMap
```

To optimize a total response $\int \sigma_d(E)\,\phi\left(\vec{r}, E\right)dE$ (either total flux or total dose)

```
read importanceMap
    gridGeometryID=1
'   near detector
    adjointSource 1
        boundingBox x1 x2 y1 y2 z1 z2
        responseID=1
    end adjointSource
'   far detector
    adjointSource 2
        boundingBox u1 u2 v1 v2 w1 w2
        responseID=6
    end adjointSource
    respWeighting
end importanceMap
```

Using flux weighting, the adjoint source will be

$$q^{+}\left(\vec{r}, E\right) = \frac{\sigma_1(E)\, g_{\text{near}}(\vec{r})}{\phi\left(\vec{r}, E\right)} + \frac{\sigma_6(E)\, g_{\text{far}}(\vec{r})}{\phi\left(\vec{r}, E\right)}, \tag{4.1.21}$$

or using response weighting, the adjoint source will be

$$q^{+}\left(\vec{r}, E\right) = \frac{\sigma_1(E)\, g_1(\vec{r})}{\int \sigma_1(E)\,\phi\left(\vec{r}, E\right) dE} + \frac{\sigma_6(E)\, g_2(\vec{r})}{\int \sigma_6(E)\,\phi\left(\vec{r}, E\right) dE}. \tag{4.1.22}$$

This implementation is slightly different from the original MAVRIC in SCALE 6. The current approach is simpler for the user and allows the importance parameters to optimize the final Monte Carlo calculation for the calculation of two different responses in two different areas.

If the number of mesh cells containing the true source is less than 10, then MAVRIC will convert these source voxels to point sources and Denovo will automatically use its first-collision capability to help reduce ray effects in the forward calculation. The user can easily override the MAVRIC defaults-to force the calculation of a first-collision source no matter how many voxels contain source; this can be done by using the keyword "firstCollision". To prevent the calculation of a first-collision source, the keyword "noFirstCollision" can be used. If the keywords "firstCollision" or "noFirstCollision" are used, then they will only apply to the forward calculation, not the subsequent adjoint calculation.

The keyword "saveExtraMaps" will save extra files that can be viewed by the Mesh File Viewer. The source used by the forward Denovo calculation is stored in "*outputName*.dofs.3dmap", where *outputName* is the name the user chose for his output file.

Forward weighting with an existing forward flux file

Similar to the capability of using pre-existing adjoint flux files, MAVRIC can use a pre-existing forward flux file to create a forward-weighted adjoint source without performing the forward Denovo calculation. The user may specify the *.dff file containing the forward fluxes using the keyword "forwardFluxes=". The filename should be enclosed in quotes, and the file must be a binary file using the Denovo flux file format. The number of groups must match the number of groups in the MAVRIC cross section library (i.e., the library entered on the third line of the MAVRIC input file).

```
read importanceMap
     forwardFluxes="c:\mydocu~1\previousRun.forward.dff"
     gridGeometry=7
     adjointSource 1
        ...
     end adjointSource
     respWeighting
end importanceMap
```

When using a pre-existing forward flux file, either "respWeighting" or "fluxWeighting" must still be specified.

Using the importance map

An importance map produced by the importance map block consists of the target weight values as a function of position and energy. The upper weight window used for splitting and the lower weight window used for Russian roulette are set by the window ratio. The window ratio is simply the ratio of the weight window's upper bound to the weight window lower bound, with the target weight being the average of the upper and lower bounds.

The keyword "windowRatio=" can be used within the importance map block to specify what window ratio will be used with the importance map that is passed to the Monaco forward Monte Carlo calculation. For a windowRatio of r, the upper weights for splitting, w_{max}, and the lower weights for Russian roulette, w_{min}, are set as

$$w_{\min} = \frac{2}{r+1}\overline{w} \tag{4.1.23}$$

and

$$w_{\max} = \frac{2r}{r+1}\overline{w} \tag{4.1.24}$$

for the target weight $\overline{w}$ in each mesh cell and for each energy of the importance map. The default value for the windowRatio is 5.0.

Other notes on importance map calculations

Since the importance map calculations all take place using mesh geometry, one of the first steps that occurs is to create a mesh representation of the true source (the forward source) on the same grid. This procedure uses the same two methods as the Monaco mesh source saver routine. Mesh cells can be subdivided and tested to see if they are within the defined source, or a set number of points can be sampled from the source. The keywords "subCells=" and "sourceTrials=" are used in the importance map block to change the default settings for constructing the mesh representation of the forward source.

If macromaterials are used ("mmTolerance<1") and the adjoint source is limited to a particular material, then the amount of adjoint source in a mesh voxel will be weighted by the material amount in that voxel.

In SCALE/MAVRIC, Denovo is called as a fixed-source S_N solver and cannot model multiplying media. Neither forward nor adjoint neutron calculations from Denovo will be accurate when neutron multiplication is a major source component. If neutron multiplication is not turned off in the parameters block of the MAVRIC input (using "fissionMult=0"), a warning will be generated to remind the user of this limitation.

By default, MAVRIC instructs Denovo not to perform outer iterations for neutron problems if the cross section library contains upscatter groups. This is because the time required calculating the fluxes using upscatter can be significantly longer than without. For problems in which thermal neutrons are an important part of the transport or tallies, the user should specify the keyword "upScatter=1" in the importance map block. This will instruct Denovo to perform the outer iterations for the upscatter groups, giving more accurate results but taking a much longer time for the discrete-ordinates calculation.

When performing a MAVRIC calculation using a coarse-group energy structure for Denovo (for example with the 27/19 library) but a fine-group energy structure (with the 200/47 library) for the final Monaco calculation, the source biasing parameters are determined on the coarse-group structure. The importance map (*.mim) file and the biased mesh source (*.msm) files all use the coarse-group structure. The source biasing information is then applied to fine-group mesh versions of the sources, resulting in the *.sampling.*.msm files. This way, the biased sources used in the final Monaco calculation retain their fine-group resolution. This can be especially important in representing the high-energy portion of the fission neutron distribution for example. When using CE-Monaco, the source sampling routines first use the *.msm files to determine the source particle's voxel and energy group. From that voxel and energy group, the user-given source distributions are used to sample the specific starting location and specific energy of the source particle. This way, the CE-Monaco calculation samples the true CE distributions.

Table 4.1.4: Keywords for the importance map block

block	keyword	type	length	default	required	restrictions/comments
importanceMap						
	Perform an adjoint S_N calculation using one (or more) adjoint source(s) and a gridGeometry					
	gridGeometryID=	integer			yes	matches one of the id numbers from gridGeometries
	adjointSource id	integer			yes	non-negative integer, unique among adjointSources
	locationID=	integer			a*	matches one of the id numbers from locations
	boundingBox	real	6		b*	parameters: x_{max} x_{min} y_{max} y_{min} z_{max} z_{min}
						*required: either a) locationID= or b) boundingBox
	responseID=	integer			c*	single id number from responses
	responseIDs	integer	any	none	d*	list of id numbers from responses
						*required: either c) responseID= or d) responseIDs
	weight=	real		1.0	no	positive real number
	unit=	integer		-1	no	limit adjoint source in boundingBox to a unit
	region=	integer		-1	no	limit adjoint source in boundingBox to a region of a unit
	mixture=	integer		-1	no	limit adjoint source in boundingBox to a mixture
	end adjointSource					
	Constructing the Denovo geometry using macro materials					
	macromaterial					
	mmSubCell=	integer		1	no	rays per dimension to throw at each voxel
	mmTolerance=	real		0.01	no	smallest volume fraction for macromaterial
	mmSubCells	integer	6		no	rays per dimension to throw (x:ny,nz; y:nx,nz; z: nx,ny)
	mmPointTest				no	use recursive bisection point testing method
	mmRayTest				no	use ray tracing method
	mmRTSpeed				no	optimize ray-tracing method for speed
	mmRTMemory				no	optimize ray-tracing method for memory conservation
	end macromaterial					
	Constructing the mesh version of the true source					
	subCells=	integer		2	no	subcells per cell (each dimension)
	sourceTrials=	integer		1000000	no	how many source particles to sample
	reduce			not present	no	store the smallest cuboid around the voxels with source
	Perform a forward S_N calculation and weight the adjoint source					
	fluxWeighting			not present	no	weight adjoint source with forward flux
	respWeighting			not present	no	weight adjoint source with integrated forward response
	saveExtraMaps			not present	no	save extra 3dmap files associated with forward calculation
	firstCollision			not present	no	forces the use a a first collision source
	noFirstCollision			not present	no	does not allow the use of a first collision source
	Use existing forward flux file for weighting the adjoint source					
	forwardFluxes=	string		not present	no	legal file name for current system, in quotes
	Use existing adjoint flux file to create importance map					
	adjointFluxes=	string		not present	no	legal file name for current system, in quotes
	While using the importance map					
	windowRatio=	real		5.0	no	real number greater than one
	mapMultiplier=	real		1.0	no	multiply targetWeights in imp. Map
end importanceMap						

Table 4.1.5: Denovo options for the importance map block

block	keyword	type	length	default	required	restrictions/comments
importanceMap						
	Optional Denovo S_N code parameters					
	discretization=	integer		4	no	0-diamond-difference, 1-diamond-difference with flux fix-up:lin0, 2-theta-weighted diamond-difference, 3-linear-discontinuous finite element, 4-step characteristics, 5-trilinear discontinuous finite elem
	quadType=	integer		0	no	0-level symmetric, 1-Gauss-Legendre product, 2-QR
	legendre=	integer		3*	no	P_L, L=highest Legendre polynomial, L=0,1,2,3,… *default is to use min(the highest available in the data,3)
	tportcorrection=	integer		1*	no	transport correction: 0-none, 1-diagonal, 2-Cesaro *For P_2 or higher, the default is 2 (Cesaro)
	upScatter=	integer		0	no	upscatter iterations: 0-none, 1-yes, 2-ignore
	xblocks=	integer		1	no	parallel stuff
	yblocks=	integer		1	no	parallel stuff
	zblocks=	integer		1	no	parallel stuff
	numSets=	integer		1	no	?
	partUpscatter=	integer		1	no	partition upscatter (0-no, 1-yes)
	quadrature=	integer		8	no	level symmetric S_N quadrature, N=2, 4, 6, 8, 10, 12, 14, 16
	polarsPerOct=	integer		0	no	Gauss-Legendre product quadrature or QR
	azimuthsPerOct=	integer		0	no	Gauss-Legendre product quadrature or QR
	maxIters=	integer		20	no	maximum number of iterations
	diagnostics=	integer		0	no	0-no diganostics, 1-all diagnostics
	output=	integer		0	no	0-no ouput, 1-all output
	krylovSpaceSize=	integer		10	no	size in memory for Krylov space
	tolerance=	double		1.E-03	no	tolerance used in convergence test
	krylovType=	integer		0	no	0-GMRES, 1-BiCGStab
	eigenSolver=	integer		0	no	0-power iteration, 1-Arnoldi, 2-shifted inverse
	multiGSolover=	integer		0	no	0-Gauss-Seidel, 1-Krylov
	withinGSolver=	integer		0	no	0-Krylov, 1-residual Krylov, 2-source iteration
	mgSettings=	integer		1	no	0-user supplied, 1-automatic
	upGroupSolver=	integer		0	no	0-same as within-group solver, 1-Krylov, 2-residual Krylov, 3-source iteration, 4-single source iteration
	acceleration=	integer		0	no	0-none, 1-two grid
	maxItersMG=	integer		20	no	maximum number of iterations
	toleranceMG=	double		0.001	no	tolerance used in convergence test
end importanceMap						

4.1.4 MAVRIC OUTPUT

4.1.4.1 Main text output file

Similar to other SCALE sequences, MAVRIC returns a text output file containing the output from the SCALE driver, the sequence itself, and all of the functional modules called. The SCALE driver output first displays the problem input file, and then the first reading of the input file by the MAVRIC sequence is shown (which includes some material processing information). If there are any errors or warnings about the input file, they will be shown next. Next in the output file are the different passes through the MAVRIC sequence—up to 10 parts. If any errors or warning messages (such as lack of memory) are generated during processing, they will be displayed here. Finally, the output files from each functional module are concatenated to the above output and shows the files returned to the user.

First, the Monaco section of output first reviews the input it received. First the geometry is reviewed, showing which materials are used in each region and the volume of that region, if input or calculated. Then a detailed list of other Monaco input is reviewed: cross section parameters, data definitions, the source description, the tallies, the Monte Carlo parameters, and the biasing parameters. For MAVRIC calculations, if an importance map is used, then its summary is also given. The "Mesh Importance Map Characterization" shows where the importance map may be changing too rapidly and may require more refinement.

For each Monaco batch, the output file lists the batch time and the starting random number for the next batch, which may be useful in rerunning only a portion of a problem. Once all of the batches are completed, a list of the various tally files that have been created is given. Finally, the tallies are summarized in a section entitled "Final Tally Results Summary." For each point detector, the total neutron and photon fluxes (uncollided and total) are given as well as the final response values for each response function. For each region tally, the total neutron and photon fluxes (both track-length and collision density estimates) are listed, followed by the final response values for each response function. Group-by-group details are saved to separate files for each tally.

4.1.4.2 Additional output files

In addition to the generous amount of data contained in the MAVRIC text output file, many other files are created containing the intermediate data used by the sequence and the final tally data. Many of the files produced can be viewed using the Mesh File Viewer or the Interactive Plotter capabilities of Fulcrum, which is distributed with SCALE. (Note that most of the images in this document were taken from the Mesh File Viewer from SCALE 6.1.) Table 4.1.6 lists the other output files, based on the name of the main output file (here called *outputName)*, that are available to the user. These files will be copied back to the directory where the input file was located. Many of the files come from Monaco and are discussed in the Monaco chapter of the SCALE manual (Sect. 8.2).

Other files that the user may be interested in are listed in Table 4.1.7. These files are kept in the temporary directory where SCALE executes and are not copied back to the directory where the input file was located, unless specifically requested using a SCALE "`shell`" command. Curious users may also be interested in viewing the various input files (i_*) that the MAVRIC sequence writes in order to run the SCALE functional modules.

Table 4.1.6: Output files that are copied back to user's area when the sequence finishes[a]

Filename	Viewer	Description
Output Summary		
outputName.out		main text output file, contains results summary
Diagnostic files		
outputName.respid.chart	P	response input and MG representation for response *id*
outputName.gridid.3dmap	V	mesh version of geometry using grid geometry *id*
outputName.cylid.3dmap	V	mesh version of geometry using cylindrical geometry *id*
outputName.distid.chart	P	distribution input and sampling test for distribution *id*
Mesh Source Saver		
filename.msm	V	mesh representation of a single source or total source
filename.id.msm	V	mesh representation of multiple sources
filename.sampling.msm	V	biased representation of a single source or total source
filename.sampling.id.msm	V	biased representation of multiple sources
Importance Map Generation		
outputName.geometry.3dmap	V	voxelized geometry (cell-center testing only)
outputName.forward.dff	V	scalar forward flux estimate, $\phi(x, y, z, E)$
outputName.adjoint.dff	V	scalar adjoint flux estimate, $\phi^{+}(x, y, z, E)$
outputName.mim	V	Monaco mesh importance map, $\overline{w}(x, y, z, E)$

Table 4.1.7: Other intermediate files-available in the temporary directory (may be useful for testing and debugging)

Filename	**Description**
ft02f001	AMPX formatted cross sections for Denovo
fort.51	text file, listings of the mixing table for Monaco
fort.52	text file, review of MAVRIC sequence input variables
fort.54	energy bin boundaries for the current cross section library
xkba_b.inp	binary input file for Denovo - rename to have a *.dsi extension (Denovo simple input) to be viewed via Mesh

4.1.5 SAMPLE PROBLEMS

4.1.5.1 Graphite shielding measurements with CADIS

As shown in the Monaco sample problem for simulating the Ueki shielding experiments (Monaco chapter Graphite Shielding Measurements) (Sect. 8.2.5.4), as the amount of shielding material between a source and detector increases, the time required to reach a certain level of relative uncertainty increases quickly. This example will use the MAVRIC automated variance reduction capability to optimize the calculation of the dose rate at the detector location by specifying an importance map block with an adjoint source made from the detector response function and the detector location.

Input file

The following is a listing of the file `mavric.graphiteCADIS.inp` located in the SCALE `samples\input` directory. This calculation will use the coarse-group shielding library (27n19g) for all of the importance map calculations and the fine-group library (200n47g) for the final Monaco step. Additions, compared to the file `monaco.graphite.inp`, include a grid geometry for the Denovo computational mesh, a mesh tally to better visualize the particle flow, and the importance map block to optimize the Monte Carlo calculation of the point detector.

This problem took only ~2.5 minutes (0.2 in Denovo and 2.3 minutes in Monaco) on the same processor as the 20 minute analog case. (The figure of merit [FOM] is 15 times higher than the analog.) Note that the point detector dose rate is the same as the Monaco analog sample problem, but the relative uncertainty is smaller with less computation time. CADIS has optimized the calculation by focusing on neutrons that contribute to the dose rate at the detector location at the expense of neutrons in the paraffin block. This is demonstrated by the mesh tally of dose rates where the values for the dose rate are lower in the paraffin block and the relative uncertainties are higher. Since the calculation was optimized for the position of the detector, dose rates in other parts of the problem are underestimated and should not be believed.

The mesh tally shows that the CADIS calculation did not follow as many particles deep into the paraffin block, so the uncertainties are greater there, but that is what this problem was supposed to do-reduce the uncertainty at the point detector at the expense of the other portions of the problem.

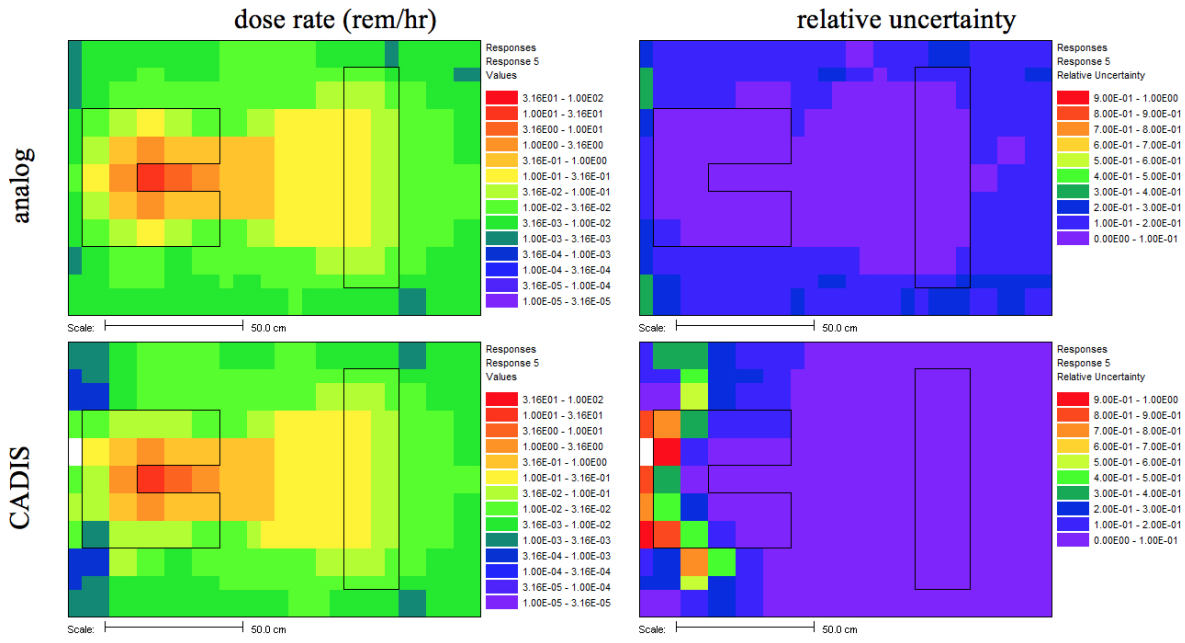

Fig. 4.1.6: Mesh tally showing neutron dose rate (rem/hr) and uncertainties for the analog case and the CADIS case.

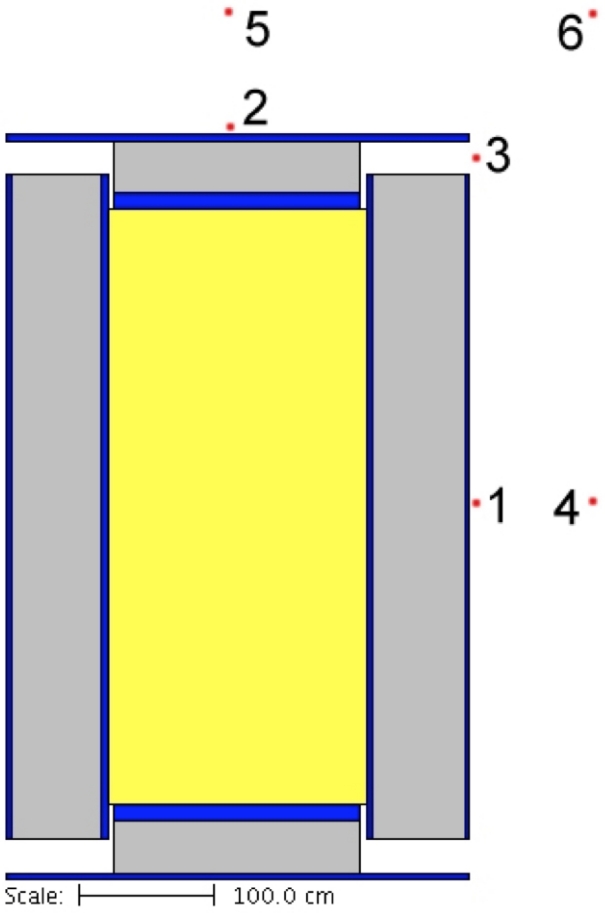
4.1.5.2 Dose rates outside of a simple cask

This example problem is a full-size cylindrical cask model, which consists of an inner steel liner, a thick section of concrete, and an outer steel cover. This problem is intended to be used as a tool to teach users how to build MAVRIC input files. This is not a completely realistic shipping cask; it has been simplified greatly for this purpose. The goal of this example it to show how to quickly calculate neutron and photon does rates at six points outside of the cask, including in front of the vent port.

Geometry and materials

The simple model of a cask is shown in Fig. 4.1.7. Vent ports at the top and bottom of the cask are modeled as void all of the way around the cask. The interior of the cask was modeled using materials from about 20 typical pressurized water reactor (PWR) fuel assemblies (including the UO2, Zr, Fe, Ni, Cr, Sn, and other constituents), homogenized over the interior volume. The total mass of the fuel/assembly hardware in this region is 10.6 metric tonnes. Separate end regions of the assemblies are not modeled in this simple example. Also note that the fuel material is based on fresh fuel, not spent fuel with its hundreds of fission products.



Model Specifics

Materials
fuel: UO_2, Zr, others, ρ=0.9137 g/cm^3
stainless steel :SCALE ss304, ρ=7.94 g/cm^3
concrete :SCALE orconcrete, ρ=2.2994 g/cm^3

Fig. 4.1.7: Cask geometry and detector locations.

Sources and responses

Spent fuel from a typical mid-sized PWR was used to determine the source term. ORIGEN was used to deplete a full core (46.1 metric tonnes of uranium, 4.2% enriched, with O, Zr, Fe, Ni, Cr, Sn, and other constituents) to 55,000 MWdays/MTU. The contents of the modeled fuel represent typical values for PWR fuel. ORIGEN then computed the neutron and photon spectra in 27-group and 19-group energy structures for the fuel following a 10-year cooling period after the last irradiation. The total neutron source strength for the cask (1/6 of a full core, or about 20 assemblies) was 8.577×10^9 neutrons/s. The total photon source strength was 7.155×10^{16} photons/s.

Two cases will be done for this example: one for calculating the neutron dose rates from the spent fuel neutrons and the other for calculating the photon dose rates from the spent fuel photons. The source spectra and response functions are shown in Fig. 4.1.8 through Fig. 4.1.11 and listed in Table 4.1.8. Note that in this example, the neutron source shown in Fig. 4.1.8 and Table 4.1.8 is considered the final neutron source: no further neutron multiplication is considered.

    pointDetector 3  locationID=3  responseID=1  end pointDetector
    pointDetector 4  locationID=4  responseID=1  end pointDetector
    pointDetector 5  locationID=5  responseID=1  end pointDetector
    pointDetector 6  locationID=6  responseID=1  end pointDetector
end tallies
```

The Monte Carlo parameters were tailored for the neutron problem to be 1-minute batches on a 2 GHz Linux computer. For the photon problem, the number per batch would be 91,000 for 1-minute batches.

```
read parameters
    randomSeed=8655745280030001
    perBatch=25400 batches=600
    fissionMult=0    noPhotons
end parameters
```

No biasing is specified, which will use the default weight window target value of 1 for every energy group in every region. To allow the neutrons to penetrate into the cask wall before being rouletted, a larger window ratio is used, making the lower weight window bound 0.01.

```
read biasing
    windowRatio=199.0
end biasing
```

The Monaco input is then ended.

```
end data
end
```

For the photon source/photon dose rate problem, the definitions block would instead contain a photon flux-to-dose-rate response function and the energy distribution for the source.

```

```

Each of the two analog problems in the `samples\input` directory will run for about 10 minutes. In this time, no meaningful results will be generated due to the difficulty of the problem. Analog results for each case running 110 hr are listed in Table 4.1.9 for the neutron source/neutron dose problem, while results for the photon problem are listed in Table 4.1.10. Note that after 110 hr, some of the relative uncertainties in the point detector tallies are still quite high, and only one of the six tallies in each problem passed all of the statistical checks. Fig. 4.1.12 is the convergence plot for the neutron dose rate at point detector 1, showing that the tally is not well converged and that some batches contain rare events that change the tally value a great deal.

Table 4.1.9: Analog Monaco results for the simplified cask model-neutron source/neutron dose rate.

SAS4 calculations

Calculations for these two problems were also done using the SAS4 sequence in SCALE 5.1. SAS4 was specifically designed for cask geometries and used a one-dimensional discrete-ordinates calculation (either radially or axially) to determine weight windows. Results for the neutron problem are shown in Table 4.1.11, and results for the photon problem are shown in Table 4.1.12. Note that SAS4 using radial biasing is only expected to do well for the two radial point detector locations. Similarly, only the two axial point detectors are expected to do well when using axial biasing. SAS4 was not intended to do well for the points near the vent port, but the results using the axial biasing seem reasonable.

Table 4.1.11: SAS4 results using radial biasing (361 minutes) and axial biasing (361 minutes), for the simplified cask model-neutron source/neutron dose rate

	Radial Biasing		Axial Biasing

Calculations using CADIS

In the analog calculations, the dose rates at all six points could be calculated at the same time. With MAVRIC and using CADIS, the importance map will optimize the transport of particles towards only the selected detector. Hence, each detector will have a separate calculation with an importance map tailored to reduce the variance for only that detector. Calculations for close detectors could be performed at the same time. For example, detectors 1 and 4 both need to push particles out of the cask in the positive x direction, towards the z=0 plane. In this example, all six detectors will use separate importance maps.

For the importance map, in the input, the user lists what planes to use for the adjoint discrete-ordinates calculation. These planes define cells, which are treated as homogenous parallelpipeds by Denovo, made of a macro material corresponding to a mixture of materials that are in the cell in the true geometry. Users should try to bound as many materials as possible with their selection of mesh planes. More mesh planes should be used where the importance (adjoint flux) varies quickly, such as near the adjoint sources (the detector positions). It is also important to have planes on the true source bounding box.

In this example problem, different sets of mesh planes will be used for the different detector positions. For detector positions 1 and 4, the mesh planes are shown in Fig. 4.1.13 and Fig. 4.1.14. Note that there are more planes closer to the detectors. Also note that in the z dimension, it is quite easy to place mesh planes at every material boundary, but it is a bit more difficult to do so in the x and y dimensions due to the curved surfaces. Users need not worry about getting things perfect-an approximate importance map can still reduce Monte Carlo variances a great deal. The meshes used for detector positions 2/5 and positions 3/6 are also shown in Fig. 4.1.13 and Fig. 4.1.14. Mesh parameters are listed in Table 4.1.13, and the mesh planes are listed in Table 4.1.14.

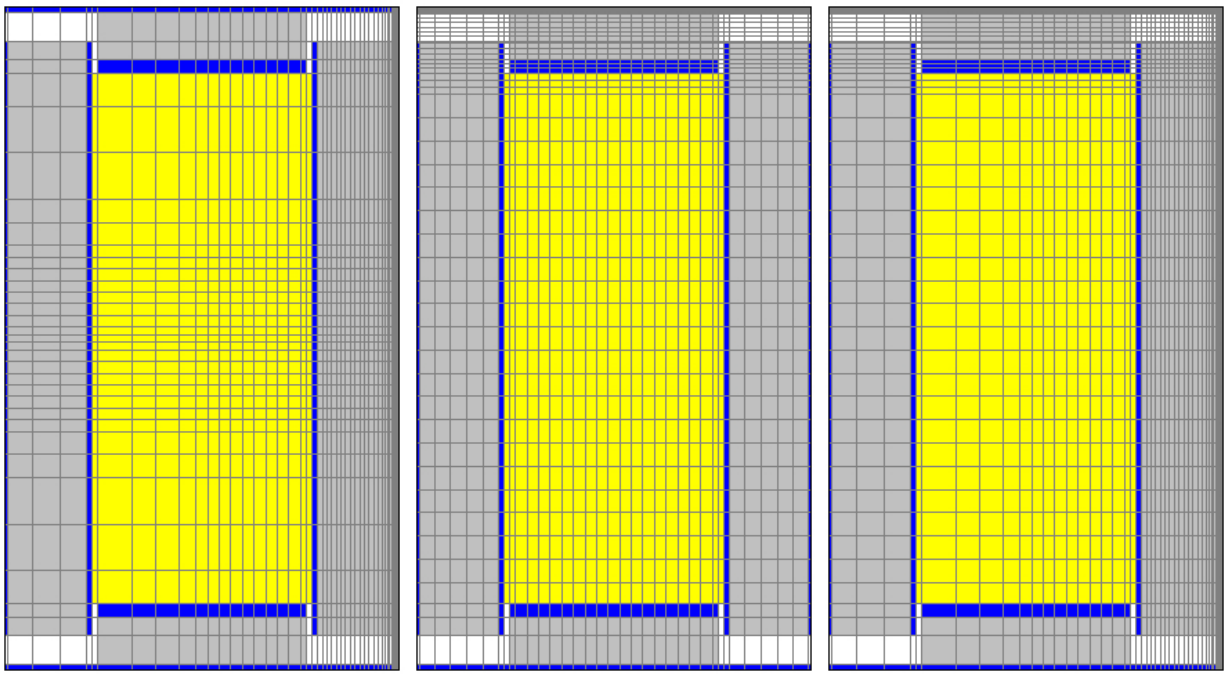

Fig. 4.1.13: Importance map mesh planes in the x and z dimensions for detector positions 1/4, 2/5, and 3/6.

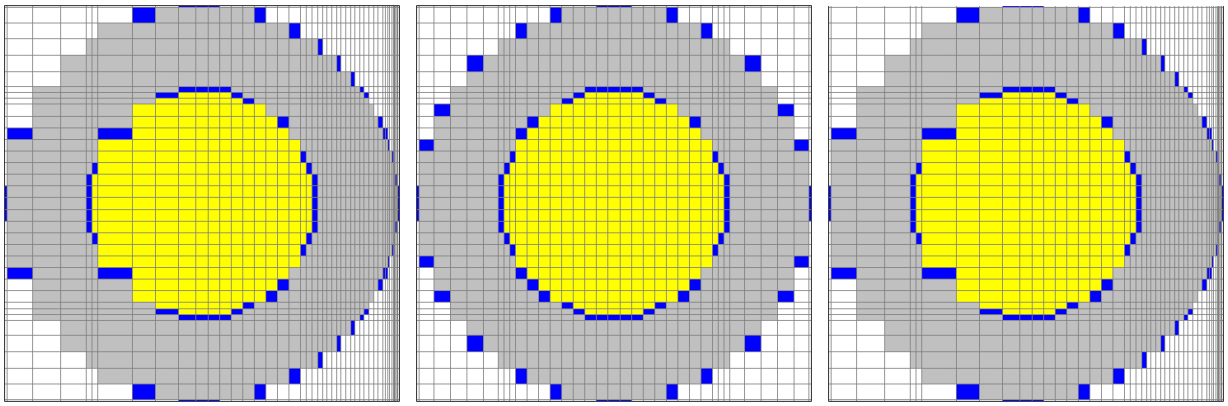

Fig. 4.1.14: Importance map mesh planes in the x and y dimensions for detector positions 1/4, 2/5, and 3/6.

Table 4.1.13: Mesh parameters

Detector position	Number	of	cells	Total cells
	x	y	z	
1/4	46	35	35	56350

MAVRIC input files

With two sources and six detectors, this example problem will require 12 separate input files. Starting with the two input files for the analog calculations, these 12 input files will share most of the same features and will differ only in blocks related to the importance map calculation: the location of the adjoint source and the planes used in the grid geometry.

To change the input for the neutron problem from an analog calculation to one using CADIS, the user first adds the mesh planes for the discrete-ordinates calculation as a grid geometry to the definitions block. This set of planes is tailored for the vent port direction toward detectors 3 and 6.

```
gridGeometry 3
        title="for importance map for detectors 3,6"
        xplanes -170 -168 -146 -122 -100
                -95 -90 -60 -40 -20 -5

                113 127 141 155 168 170  end
        zplanes -285.6 -280.6 -255.2 -240.6 -228.6 -210
                -190 -170 -150 -130 -110 -90 -70 -50 -30 -10
                10 30 50 70 90 110 130 150 170 190
                210    216.2 222.4
                228.6  232.6 236.6
                240.6  245.1 249.7 254.2
                255.2  256.2 260.1 264 267.9 271.8 275.7 279.6
                280.6  281.6 282.6 283.6 284.6 285.6  end
end gridGeometry
```

To help the mesh-based biased source represent the true source, "mixture=1" can be added to the source definition. This will ensure that particles sampled from the mesh source that are not in the fuel are rejected. Then an importance map block replaces the standard biasing block. In this case, the importance map will optimize the flow of particles to location 3 (where point detector 3 is defined).

```
read importanceMap
    adjointSource 1
        locationID=3
        responseID=1
    end adjointSource
    gridGeometryID=3
    macromaterial
        mmTolerance=0.01
    end macromaterial
end importanceMap
```

A mesh tally could be added with the following in the tallies block.

```
meshTally 1
      title="Shows how importance map changes the transport of particles"
      gridGeometryID=3
      responseID=1
end meshTally
```

The above mesh tally uses the same grid geometry as the CADIS calculations, but a different grid (or grids) could be used. The files `mavric.caskCADISn.inp` and `mavric.caskCADISp.inp` are available in the SCALE `samples\input` directory. These are for calculating the dose rates at detector position 3, but they

can be modified for the other five positions (by changing the geometry grid planes and the adjoint source location).

Neutron source/neutron response results

The above MAVRIC input file first performed the discrete-ordinates calculation to determine the adjoint flux from detector position 3. The adjoint Denovo flux file (*.adjoint.dff) produced can be viewed using the Mesh File Viewer and is shown in Fig. 4.1.15 for several of the neutron energy groups.

MAVRIC then combined a mesh representation of the true source (space and energy) with the adjoint fluxes to create the importance map and mesh-based biased source. These are shown in Fig. 4.1.16 for the fifth neutron group, covering the energy range of 0.9 to 1.4 MeV. Notice how the most important region (lowest target weights) is right around the vent port near detector position 3. This is something we know qualitatively, but quantitative values for exactly how the importance changes with space and energy are difficult to guess. Also notice the "consistent" part of CADIS—the source particles—are born with a weight that matches the target weight for the position they are born into. The biased source sampling distribution is depicted in Fig. 4.1.17, showing how the source particles nearest to detector 3 will be sampled more often.

The biased source distribution and the importance map are then used by Monaco to compute the dose equivalent rate response at detector 3.

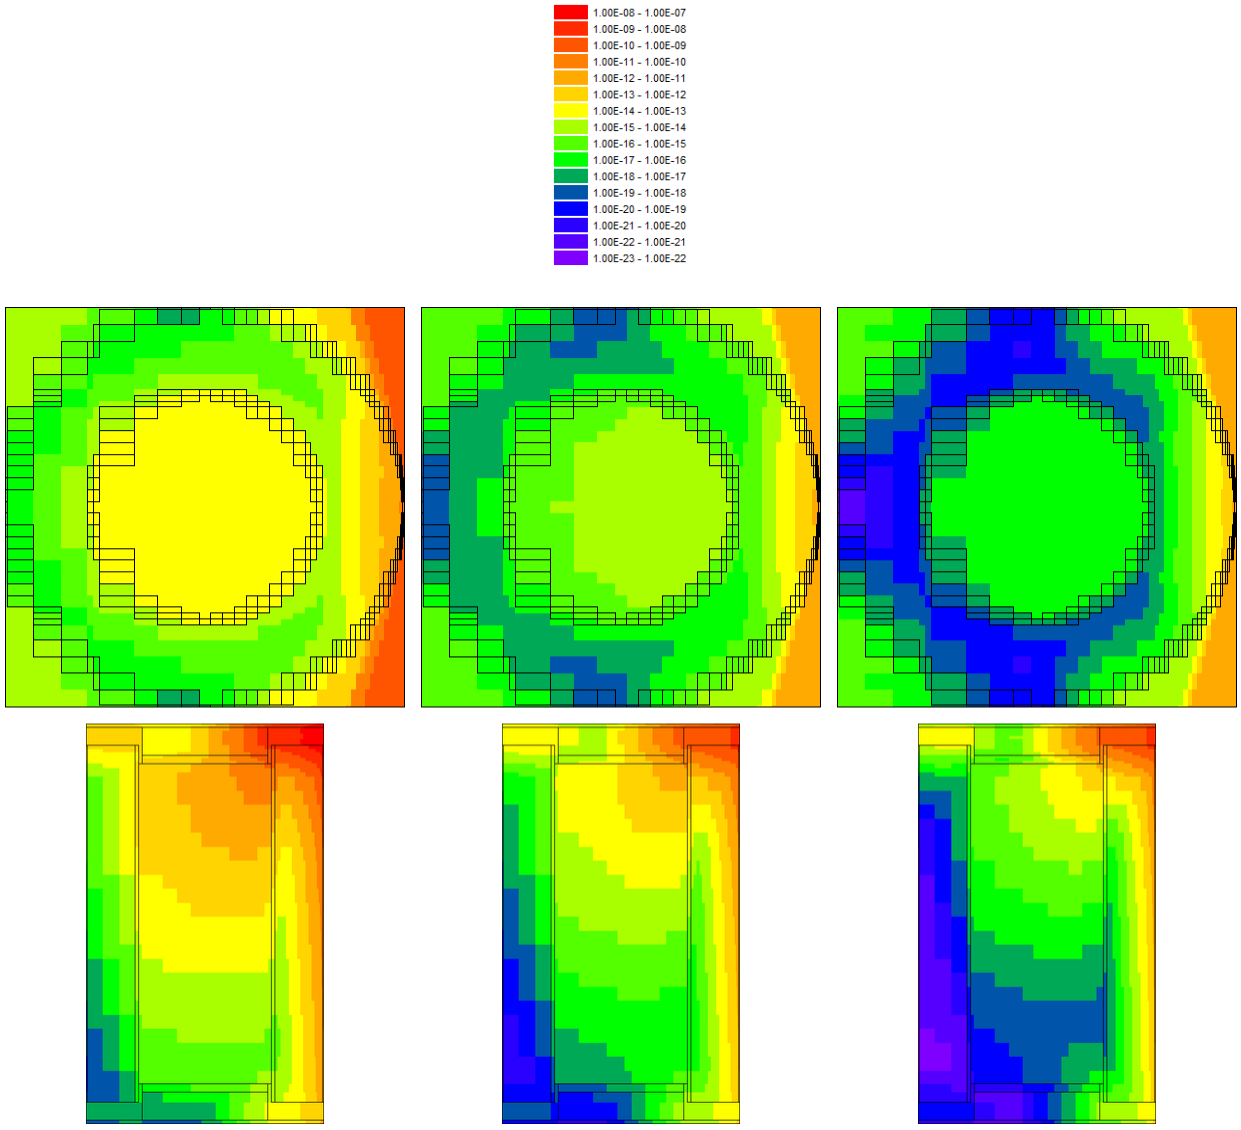

Fig. 4.1.15: Adjoint neutron fluxes (cm^2/s) for groups 5 (0.9-1.4 MeV), 10 (0.58-3.0 keV), and 19 (0.8-1 eV) calculated by Denovo.

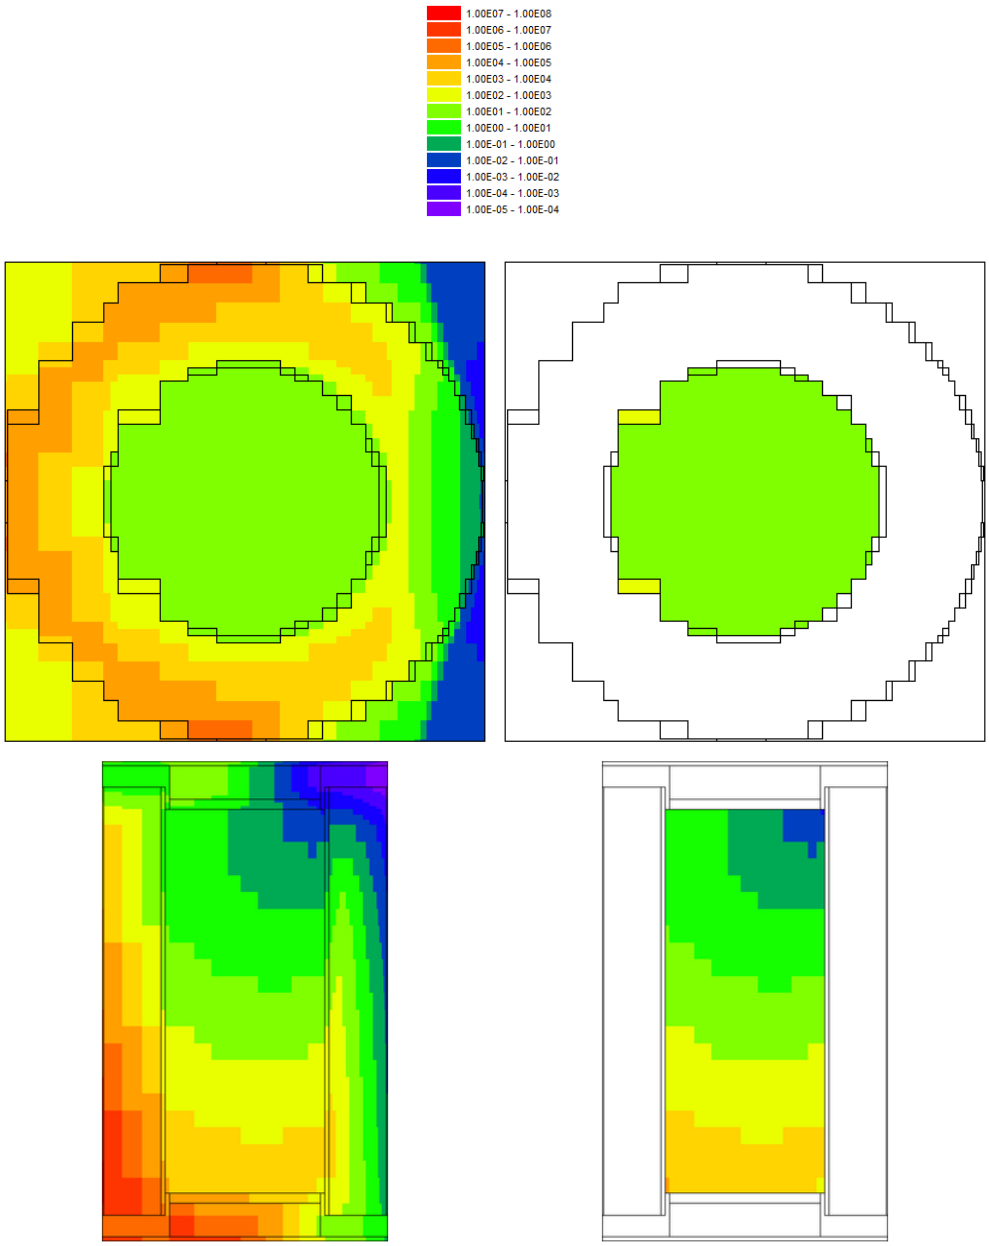

Fig. 4.1.16: Neutron target weights from the importance map and source weights (at birth) for neutron group 5 (0.9 to 1.4 MeV).

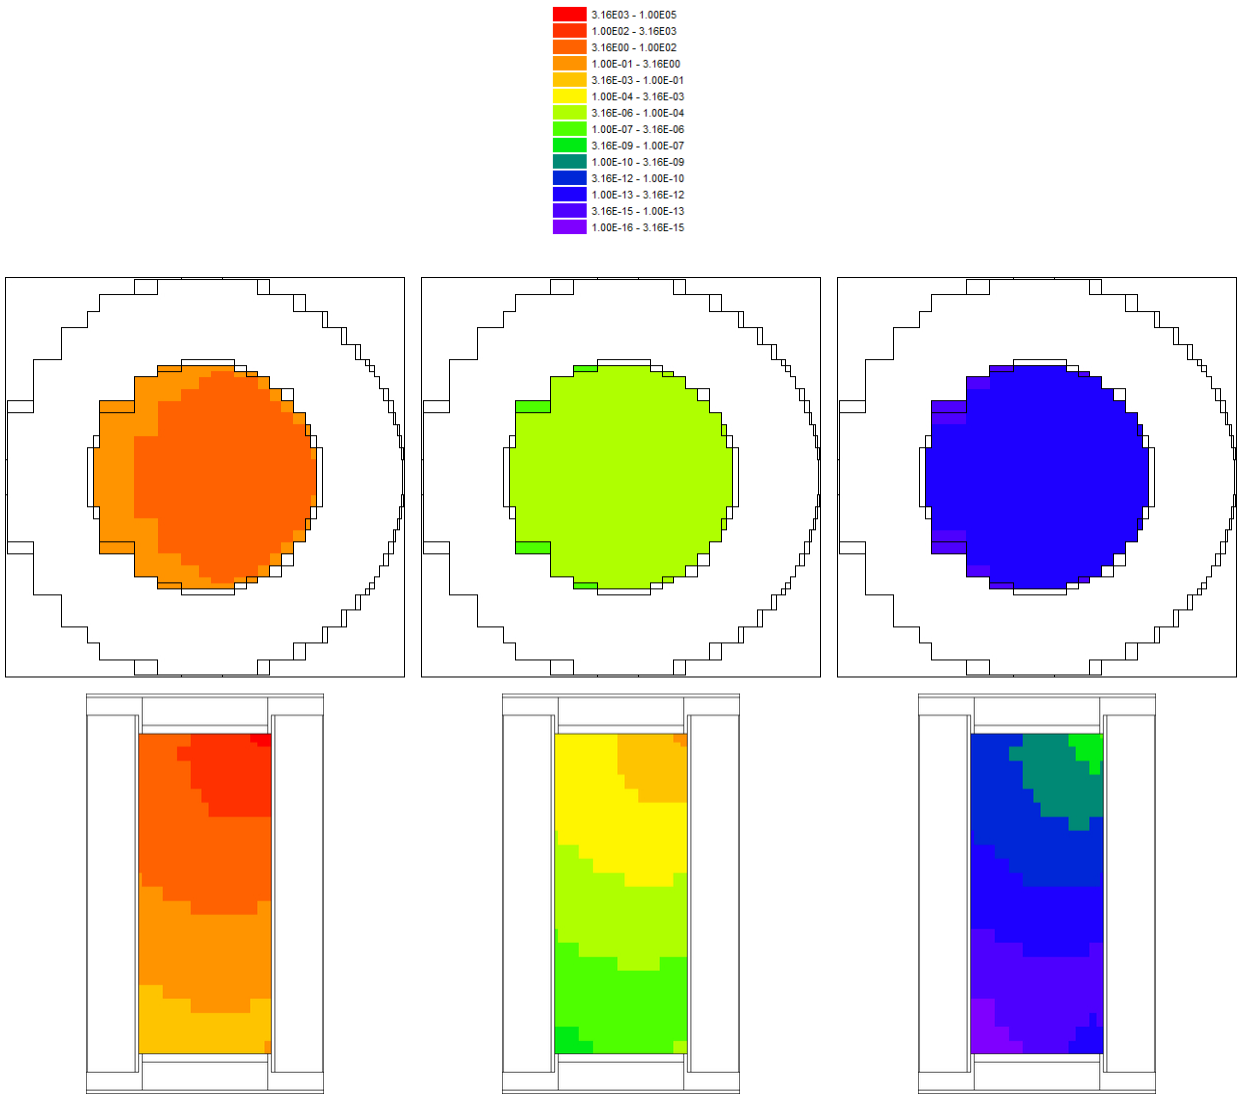

Fig. 4.1.17: Biased source sampling probability (neutrons/cm3) for neutron groups 5 (0.9-1.4 MeV), 10 (0.58-3.0 keV), and 19 (0.8-1 eV).

The results for all six neutron cases, each using their own importance map and biased source, are shown in Table 4.1.15.

This example shows that MAVRIC using CADIS obtains the correct answer much faster than the analog calculations. This is shown with a comparison to the results from the analog Monaco and SAS4 calculations, all of which are listed in Table 4.1.16.

To account for the time it takes to achieve a given level of uncertainties, the calculation figure-of-merit—FOM=1/time/(relative uncertainty)^2—can be calculated for each of the codes. The ratios of each code FOM to the FOM of analog Monaco (speedup) are listed in Table 4.1.17 to show how much faster MAVRIC and SAS4 are compared to analog Monaco. The FOMs for MAVRIC include the Denovo calculation times. The FOMs for analog Monaco and SAS4 were modified to account for calculating all six detectors at once.

Table 4.1.15: Final MAVRIC results (rem/hr) for each point detector in the neutron source/neutron dose rate problem

Photon source/photon response results

The results for the photon source/photon response are similar to the results of the neutron source/neutron response. For the MAVRIC calculation using the photon importance map made from an adjoint source located at detector position 3, Fig. 4.1.18 details the adjoint photon flux. Fig. 4.1.19 compares the target weights from the importance map and the source birth weights. Fig. 4.1.20 shows the distribution of the sampled source positions from the biased source.

Table 4.1.18 shows the results from all six photon MAVRIC runs, each using its own importance map and biased source.

The MAVRIC results of the photon problem compare well against SAS4 and analog Monaco, as shown in Table 4.1.19 and Table 4.1.20.

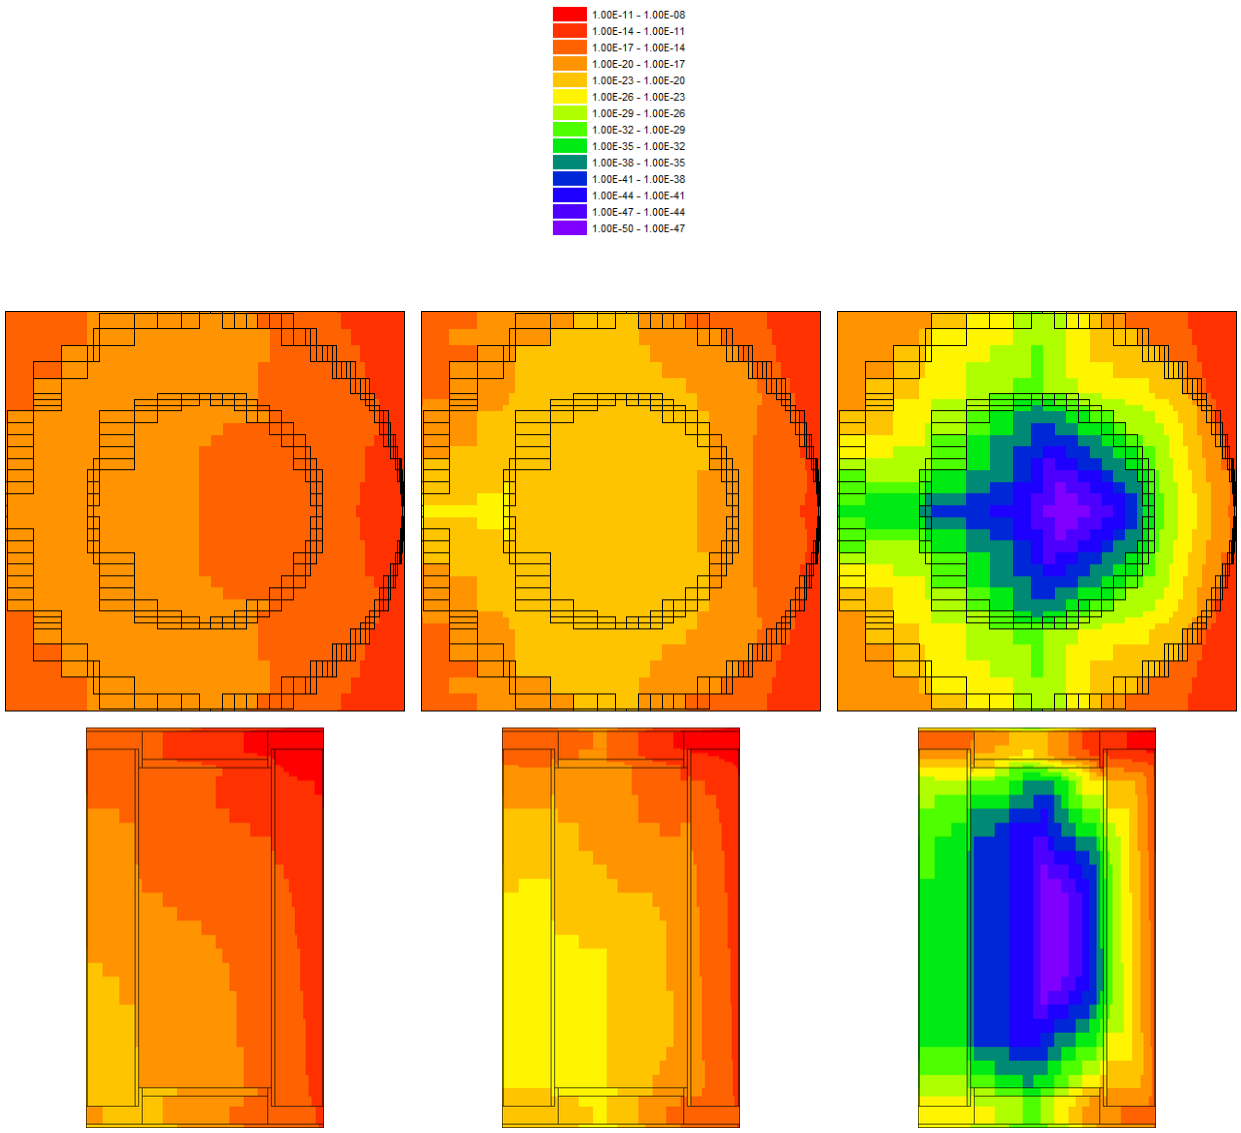

Fig. 4.1.18: Adjoint photon fluxes (/cm: sup:*2*/s) for groups 2 (8-10 MeV), 2 (0.8-1.0 MeV), and 18 (45-00 keV) calculated by Denovo.

Table 4.1.18: Final MAVRIC results (rem/hr) for each point detector in the photon source/photon dose rate problem

4.1.5.3 Gamma-ray litho-density logging tool using FW-CADIS

Consider a simple model of a gamma-ray litho-density tool [MAVRIC-GV91, MAVRIC-WH98] used in well-logging studies, shown in Fig. 4.1.21. This model uses a 10 cm diameter tool made of iron (with a tungsten density) in a 20 cm borehole filled with water. The near detector is a 2 cm diameter cylinder, 2 cm in length, located 20 cm from the source. The far detector is a 4 cm by 4 cm cylinder located 40 cm from the source. Each detector is made of NaI and collimated to look out into the formation. The source is contained in an angled collimator, aiming upward and into the formation. The collimators are filled with oxygen. The extent of the modeled formation is $100 \times 100 \times 140$ cm. The source is an isotropic ^{137}Cs source emitting 10^{11} photons/s (661.7 keV). For these calculations, no response function is used-the goal of this example is to calculate the total photon flux within each detector volume.

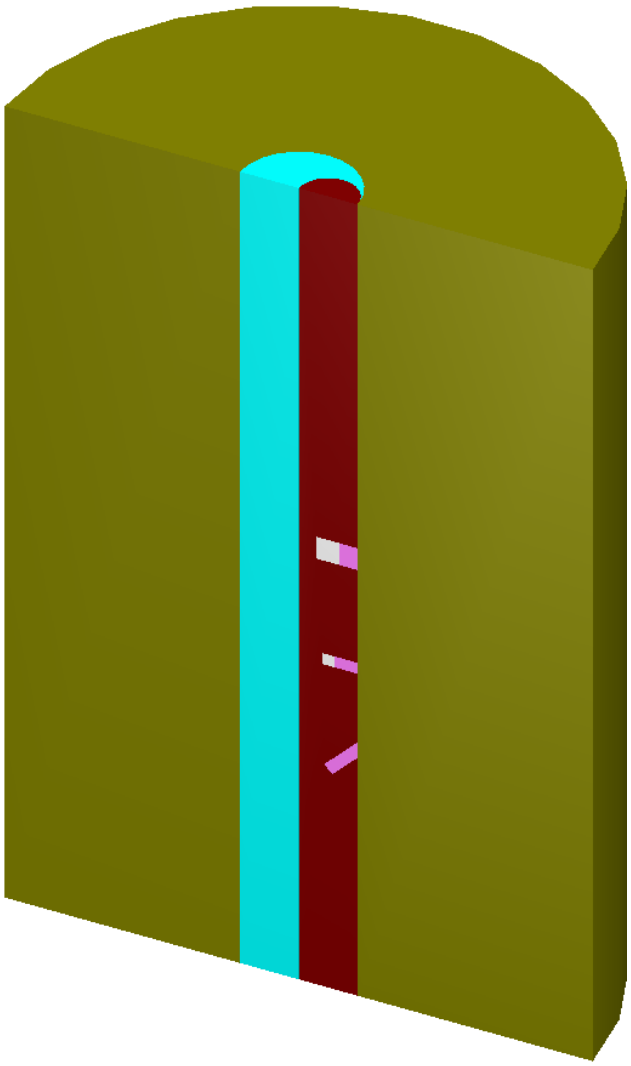

Fig. 4.1.21: Cutaway view of the litho-density tool in a rock formation.

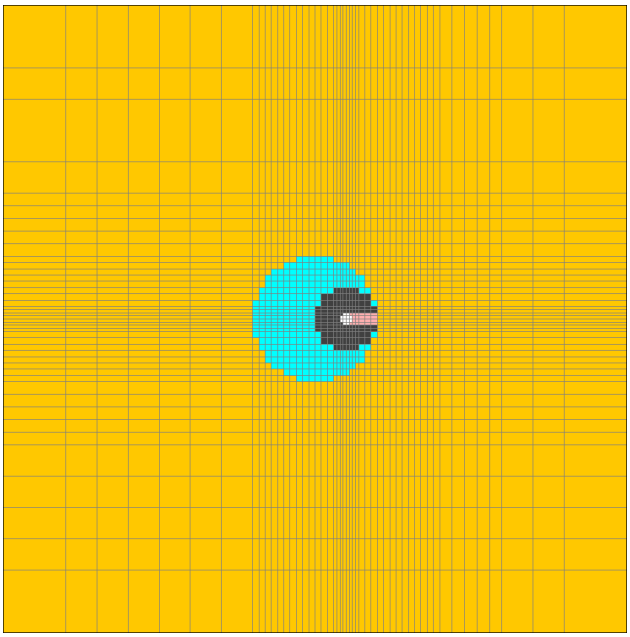

Fig. 4.1.23: Denovo mesh, z=20 plane (through near detector).

Input file

The following input file represents the simple model of the litho-density tool. It lists of the file `mavric.lithoFW.inp` located in the SCALE `samples\input` directory. The 27 neutron group/19 photon group library based on ENDF/B-VII.0 data was used for the discrete-ordinates calculations, whereas the final Monte Carlo calculation used the 200 neutron group / 47 photon group library.

The input file starts with the problem title, the library for the importance calculations, and the materials.

The definitions block lists the response (total photon flux) so that it can be understood by both libraries used in the problem. The mesh grid for the importance calculations used $49 \times 43 \times 59 = 124{,}313$ mesh cells, with particular emphasis on geometric representation of the collimators to ensure accurate importance maps. This mesh grid is shown in Fig. 4.1.22 and Fig. 4.1.23. The source is represented by a distribution in which the most probable bin is located right near the 661.7 keV line, which can be translated into one photon group in either library (from 600 to 800 keV in the 27/19 library or from 600 to 700 keV in the 200/47 library).

The source is a simple point source. For more realistic calculations, the source strength could be modified so that the total energy emitted is preserved, $S' = S\left(\frac{661.7}{0.5}(700+600)\right)$, which uses the ratio of the line energy to the energy at the center of the group in the 200/47 library.

```
read sources
    src 1
        title="Cs-137 Source: 661.7 keV"
        strength=1.0e11

end parameters
```

The importance map defines two adjoint sources that correspond to the two tallies. Forward weighting, based on the response integrated over energy ("respWeighting"), is used. Because the true source is a point source, the subcell method of making a mesh source will fail, so the number of source trials is input. This number is small since the source is a monoenergetic point source. The Denovo calculations used the default S_8 quadrature and the P_3 Legendre order.

```
read importanceMap
    gridGeometryID=1

'   near detector

```

Note that both detectors have similarly low relative uncertainties (about 1%) even though the tally values differ by a factor of 30. These results should be compared to analog results (no biasing at all) and optimizations of each detector in separate input files, as shown in Table 4.1.21. The CADIS calculations for each detector

(near or far) do exactly what they were supposed to do—optimize the Monte Carlo calculation for one tally or the other. The FOMs for the FW-CADIS calculation were about half of the FOMs for the single-detector CADIS calculations. Hence, for this two-detector problem, two CADIS calculations are just as efficient as one FW-CADIS calculation. For modern well-logging tools with up to a dozen detectors, a single FW-CADIS would be much more efficient and manageable. Note that the near detector still needs more time to pass the second (uncertainty fit) and the fourth (VOV fit) statistical checks. Neither of the single-detector CADIS calculations passed the fourth statistical check within an hour.

Fig. 4.1.24 shows a mesh tally of total photon flux in the y=0 plane for all four of the simulations: analog, CADIS for the near detector, CADIS for the far detector, and the FW-CADIS calculation for both.

Table 4.1.21: Comparison of different CADIS techniques for the litho-density problem

	Time (min)			Near Detector			Far Detector

4.1.5.4 AOS-100 using FW-CADIS and continuous-energy transport

The advanced variance reduction in MAVRIC can also be used when the final Monaco Monte Carlo transport calculation is performed using a CE cross section library. Simulations involving discrete-energy photon sources are best handled with CE. Consider the AOS-100, one of several radioactive material transport packaging systems developed by Alpha Omega Services, Inc., and a ^{60}Co source. (International Isotopes Inc. of Idaho Falls, Idaho, distributes the AOS Radioactive Material Transport Packaging Systems.)

A simple model of the AOS-100 package, which is constructed primarily of steel and tungsten, is shown in Fig. 4.1.25. The diameter is 71.12 cm, and the height is 91.44 cm. The innermost cylinder (16.51 cm diameter and 50.8 cm height) typically contains the material to be transported, but in this study, this region is simply modeled as an air region containing a uniform source of 1 Ci of ^{60}Co. This is conservative-it assumes the radioactive material containing the cobalt provides no self-shielding.

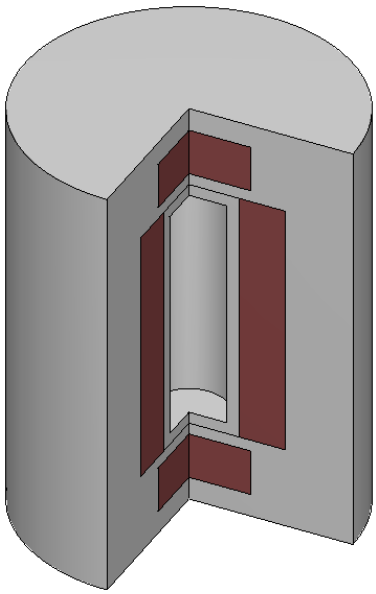

Fig. 4.1.25: Simple AOS-100 cask geometry showing tungsten (brown) and steel (gray).

The objective in this study is to compute the dose rates around the cask. This can be done using a mesh tally. Note that the dose rates inside the package are not of concern-only the dose rates outside the package are.

The results of a 15-hour analog calculation (using only implicit capture with a lower weight limit of 10^{-7}) are shown in Fig. 4.1.26. This calculation does not show many photons that have escaped the package into the air, which is similar to reality for this heavily shielded cask. To compute dose rates outside the package, variance reduction is needed.

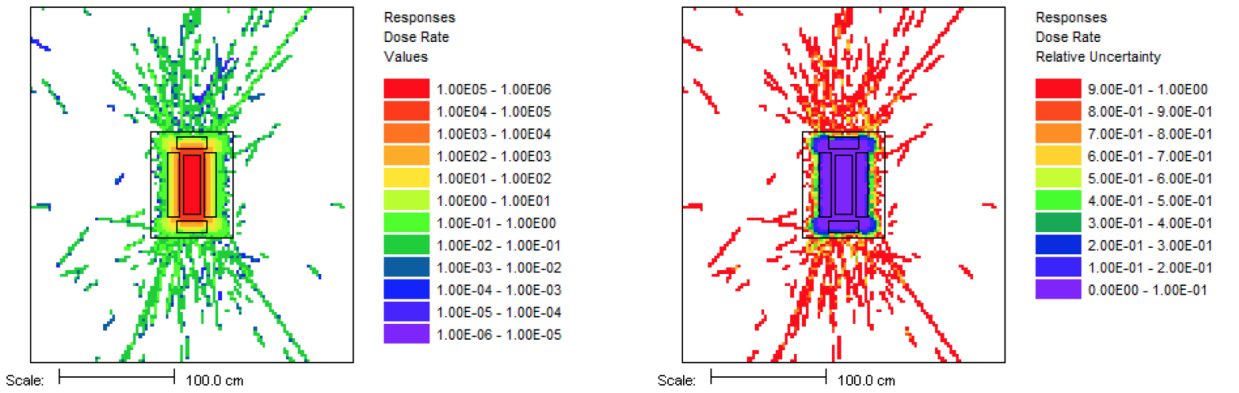

Fig. 4.1.26: Dose rates (mrem/hr/Ci) and relative uncertainties along the $y = 0$ midplane of the cask as calculated by an analog calculation.

Input file

The sample problem file `mavric.aos100.inp` is located in the `samples\input` directory. For this demonstration, a very simplified geometry is used, with a few tungsten regions inside a steel cylinder. The library given at the beginning of the input is the MG library for the importance calculations. The final Monaco Monte Carlo calculation will use the CE library, which is specified in the parameters block. About 1 meter of air is modeled around the cask.

In the definitions block, the photon dose response function, the cobalt-60 line spectrum, two grid geometries, and an energy boundaries structure are all defined. The first grid geometry is used for the deterministic

calculation, the importance map, and the biased source. The second grid geometry is for the high-resolution (1 in.) mesh tally. The energyBounds defined here has a base structure of 30 bins that are 50 keV wide, with three bins that are 2 keV wide at the dominant cobalt line energies and the 511-keV annihilation gamma energy.

The source is modeled as a uniform volumetric source in the center region of the cask. Because the distribution of cobalt gamma rays was entered as gammas per decay, the keyword “useNormConst” will set the source strength to be the total of the energy distribution-about 2 photons/decay. The “multiplier” keyword is used to multiply that strength by 37e9 decays/sec to get 1 Ci.

```
read sources
    src 1
        title="one Ci of cobalt-60"
        useNormConst
        multiplier=37e9
        cylinder  8.255   25.40 -25.40
        photons
        eDistributionID=1
    end src
end sources
```

A single mesh tally is defined and is limited to the air region outside of the cask. A multiplier of 1,000 is used to convert the response values from rem/hr to mrem/hr.

```
read tallies
    meshTally 1
        photon
        gridGeometryID=8
        responseID=5
        unit=1 region=7

    end meshTally

    multiplier=1000.0
end tallies
```

In this problem, the importance calculations will use the 200/47 MG library, which will transport all particles contained in the library by default. The keyword "noNeutrons" is used to turn off neutron transport during the Denovo calculations, thereby saving time. The final Monaco calculation will use the CE library ("ceLibrary="), which only transports the particles specifically requested by the user (to avoid loading large amounts of cross section from disk to memory). Thus, the keyword "photons" is included to specifically tell the CE Monaco to transport photons.

```
read parameters
    randomSeed=00003ecd7b4e3e8b
    ceLibrary="ce_v7np_endf.xml"
    perBatch=2000000 batches=233
    photons   noNeutrons
end parameters
```

The importance map uses FW-CADIS to construct a map and biased source that will optimize the photon dose rate in the air outside the cask. Since photon scatter is typically forward peaked, an S_{12} quadrature and P_5 Legendre scattering expansion are used.

```

Output file

Results for the mesh tally after 958 minutes (27 forward Denovo, 31 adjoint Denovo, and 900 CE-Monaco) are shown in Fig. 4.1.27. Since dose rates inside the package are not of concern, that region was excluded from the mesh tally. Due to the optimization that focused the Monte Carlo calculation on dose rates outside the cask, values of the dose rate inside the cask are underestimated and should not be used. Also note that voxels along the outer cylindrical edge of the package could show low dose rates, since the voxel value is an average and only part of the voxel is actually outside the package. The resolution of the mesh tally is 2.54 cm.

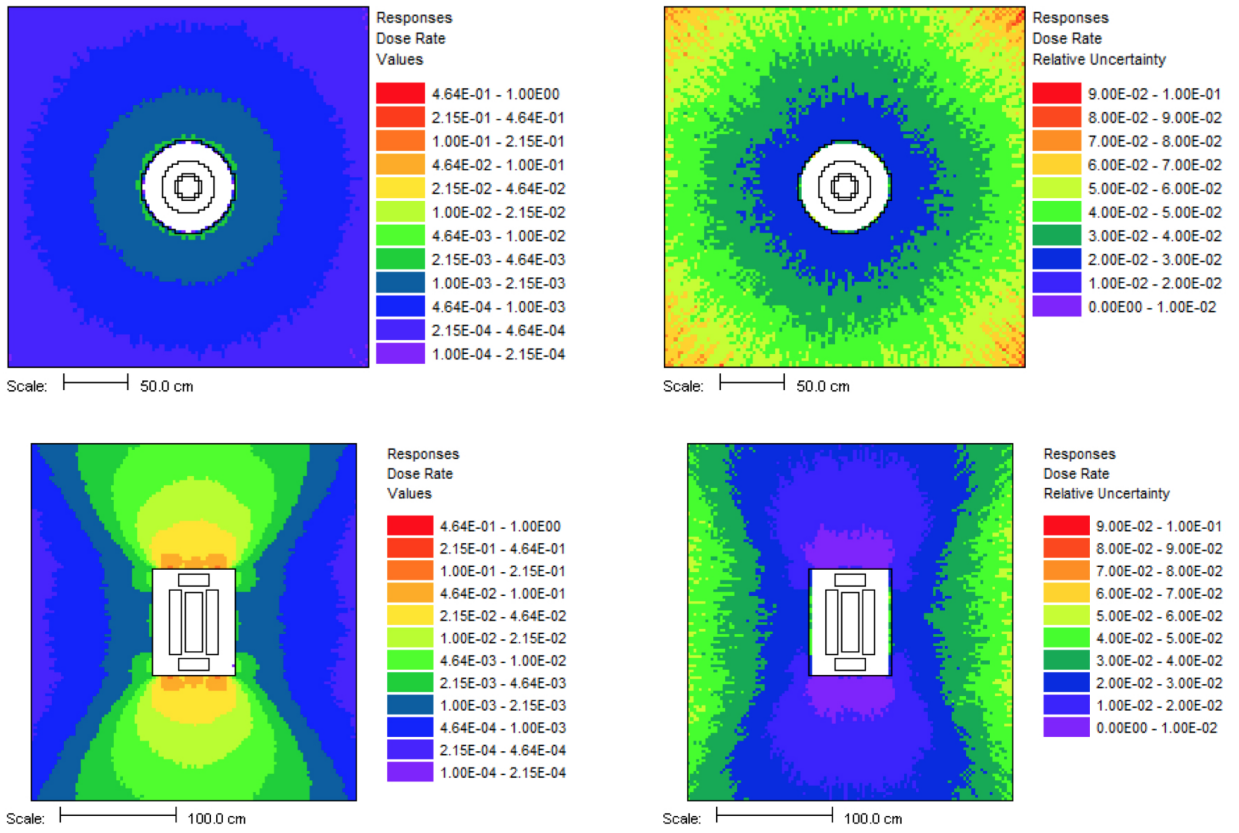

Fig. 4.1.27: Dose rates (mrem/hr/Ci) and relative uncertainties from the CE FW-CADIS calculation showing the midplane views of the cask ($z = 0$ above and $y = 0$ below).

The flux using the user-defined energy bin boundaries for a point 10 cm above the top of the package (along the axis) is shown in Fig. 4.1.28. Note that since the importance map was made to optimize the photon dose rate, some of the low-energy bins that do not contribute much to dose may have larger uncertainties.

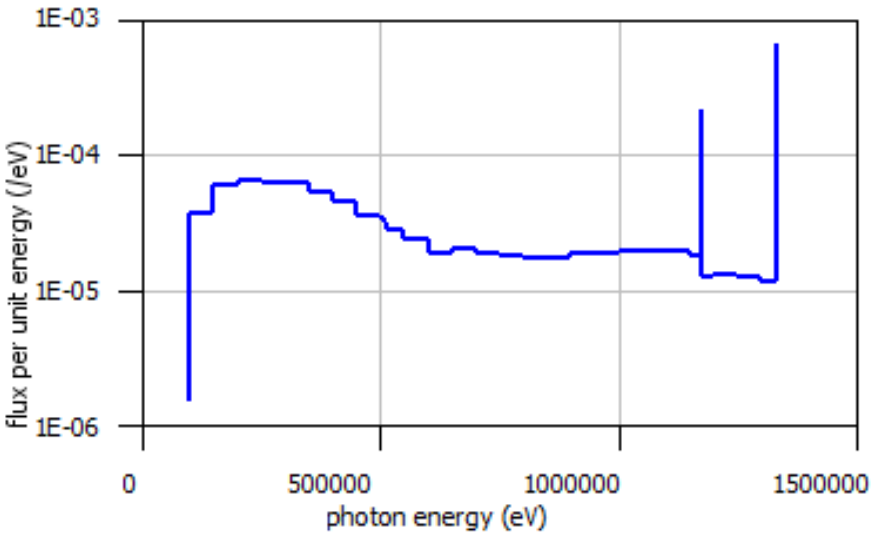

Fig. 4.1.28: Flux 10 cm above the cask.

Fig. 4.1.29 and Fig. 4.1.30 show the ratios of the dose rates computed using a MG calculation to the CE calculation. Dose rates inside the cask should not be compared because the importance map is focused on dose outside the cask, so low-energy photons are not simulated inside. The 47-group MG calculation is fairly close to the CE-calculation in dose rate (10% high axially, 20% high radially), but the 19-group MG dose rates are much higher than the CE. Neither of the MG calculations shows the 1.17 and 1.33 MeV lines in the energy spectra.

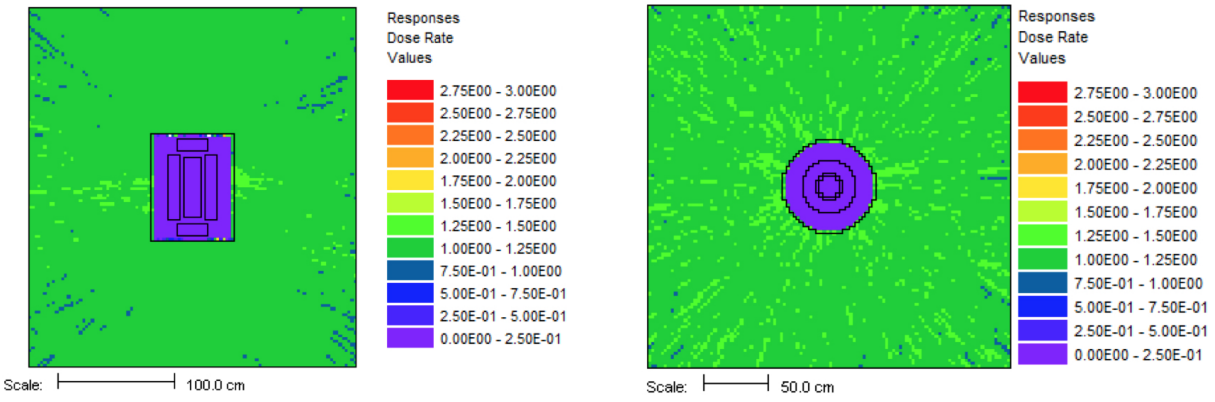

Fig. 4.1.29: Ratio of the 47-group MG computed dose rates to the CE dose rates ($y = 0$ left and $z = 0$ right).

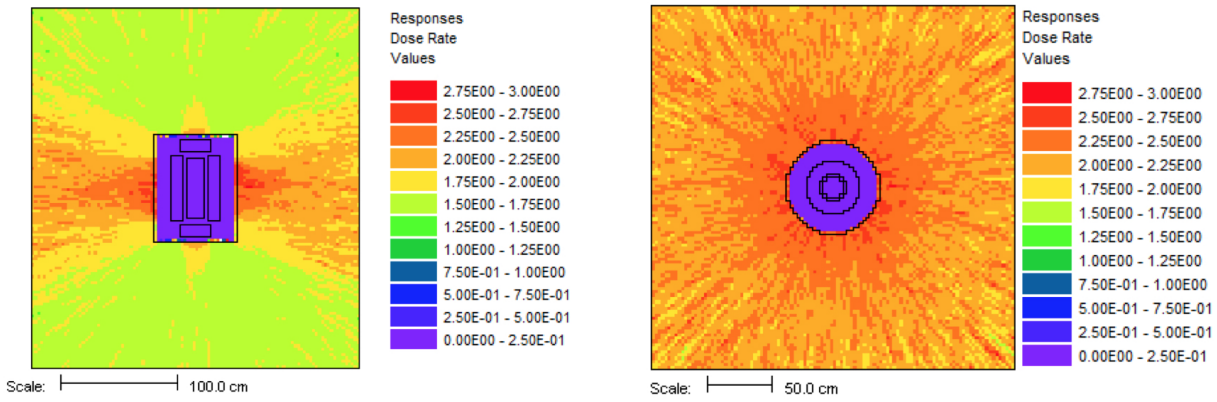

Fig. 4.1.30: Ratio of the 19-group MG computed dose rates to the CE dose rates ($y = 0$ left and $z = 0$ right).

4.1.5.5 Independent spent fuel storage installation

A good example of a problem in which the dose rate needs to be known well everywhere—in low dose areas and high dose areas—is an independent spent fuel storage installation. The dose rates around these arrays of spent fuel casks need to be evaluated over a large area of ground to determine the boundary of the controlled area. This sample problem uses a simplified model of a cask array, shown in Fig. 4.1.31 and Fig. 4.1.32, to demonstrate the FW-CADIS method for obtaining the dose rates with reasonably low relative uncertainties over a mesh tally which covers a very large area.

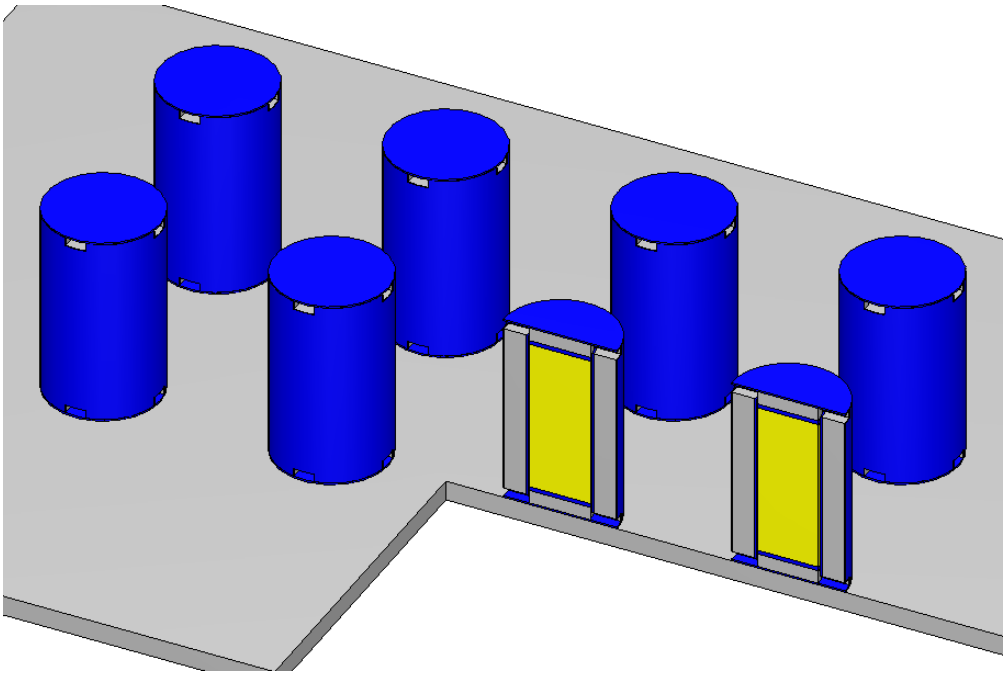

Fig. 4.1.31: Array of eight casks.

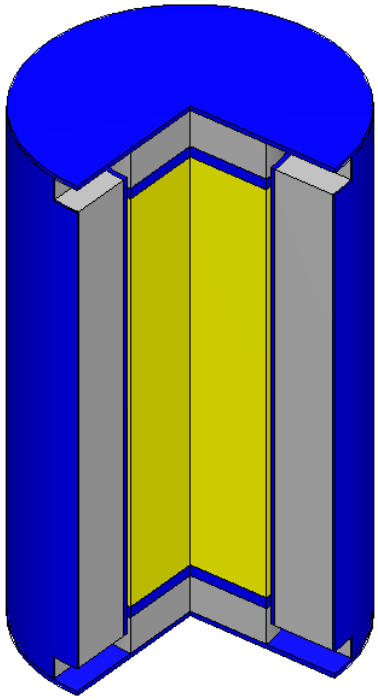

Fig. 4.1.32: Cask detail.

Source term

The calculation of the spent fuel source term using data from the Kewaunee nuclear power plant is described in the cask example problem and is modeled in the first part of `mavric.isfsi.inp` with ORIGEN. The result of this calculation is a binary concentration (ft71f001) file. This file also contains a list of the group-wise neutron source term ("total neutron spectra, neutrons/sec/basis") and photon source term ("gamma spectra, photons/sec/basis") for each time step. In this example problem, the source term for the MAVRIC calculation will be read directly from the binary concentration file. The file contains the concentration and source-term data at each of 64 time steps. For this analysis, the photon source at the last time step will be used.

Input file

The following is a listing of the second part (the MAVRIC input) of the file `mavric.isfsi.inp` located in the SCALE `samples\input` directory. Note that soil and air are included in the model to properly account for dose near the ground. The mesh tally does not extend into the air above 2 meters since this problem is only concerned with the area near the ground where people could be. For MAVRIC to read the ORIGEN binary concentration file, it must be named as a Fortran unit file with a number matching the distribution input. In this example, unit 71 is used in both the ORIGEN input and MAVRIC input.

```
=mavric
ISFSI - forward-weighted adjoint using photon dose response
v7-27n19g
```

The materials include the fresh fuel (with a density representing homogenization), concrete, steel, air, and ordinary soil.

The source can be defined in two ways. Since there are eight casks, eight sources could be defined, each over a cylinder with a strength of 7.155×10^{16} photon/s. In this example of eight identical sources, one source region can be defined and then limited to only exist in the spent fuel material (the first material) but with a strength for all the casks of 5.724×10^{17} photon/s.

Output

The MAVRIC calculational times were 3 minutes for the forward Denovo, 3.5 minutes for the adjoint Denovo, and 60 minutes for the Monaco forward Monte Carlo. Results for the mesh tally of dose rates are shown in Fig. 4.1.33. For a longer Monaco calculation (64 hr), the mesh tally results are shown in Fig. 4.1.34. Note that the scale for the dose rate has been adjusted to only show the values outside of the cask array.

Using the Mesh File Viewer, the distribution of relative uncertainty in a mesh tally can be plotted. For this 1 hr calculation, 50% of the voxels in the mesh tally had less than 20% relative uncertainty. Fig. 4.1.35 shows how the distribution of relative errors changes with longer run times. For the 64 hr run, 90% of the voxels had less than 10% relative uncertainty.

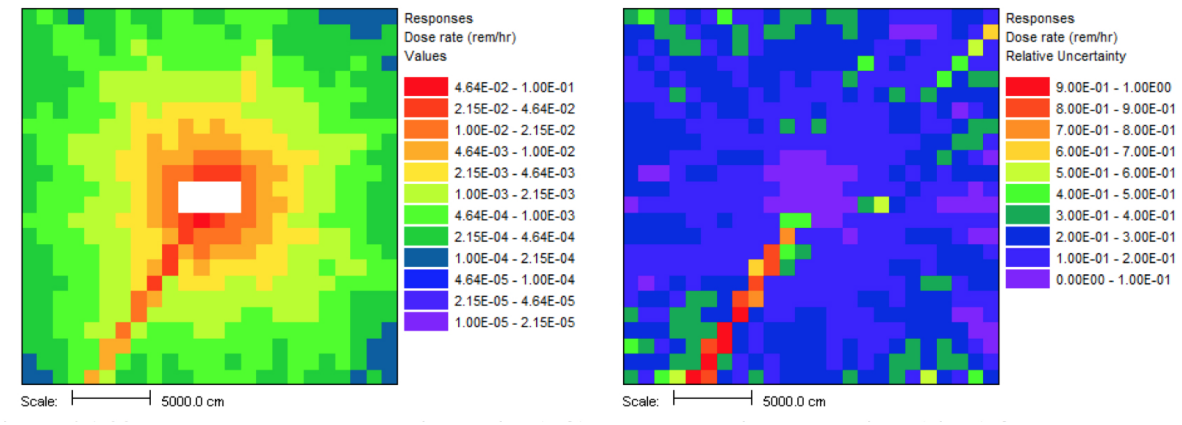

Fig. 4.1.33: Photon dose rate values in rem/hr (left) and the relative uncertainty (right) for the area around the cask array (1 hr Monaco).

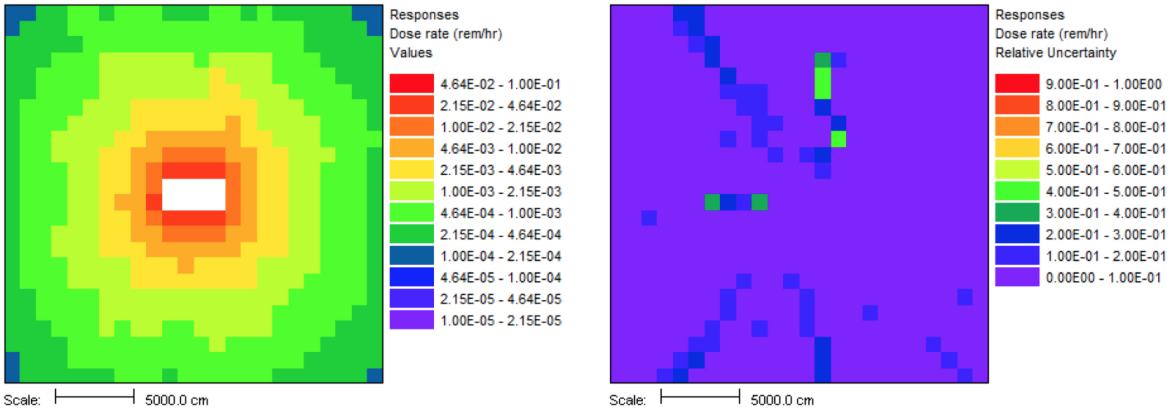

Fig. 4.1.34: Photon dose rate values in rem/hr (left) and the relative uncertainty (right) for the area around the cask array (64 hr Monaco). For the uncertainty plot, purple represents <=5%.

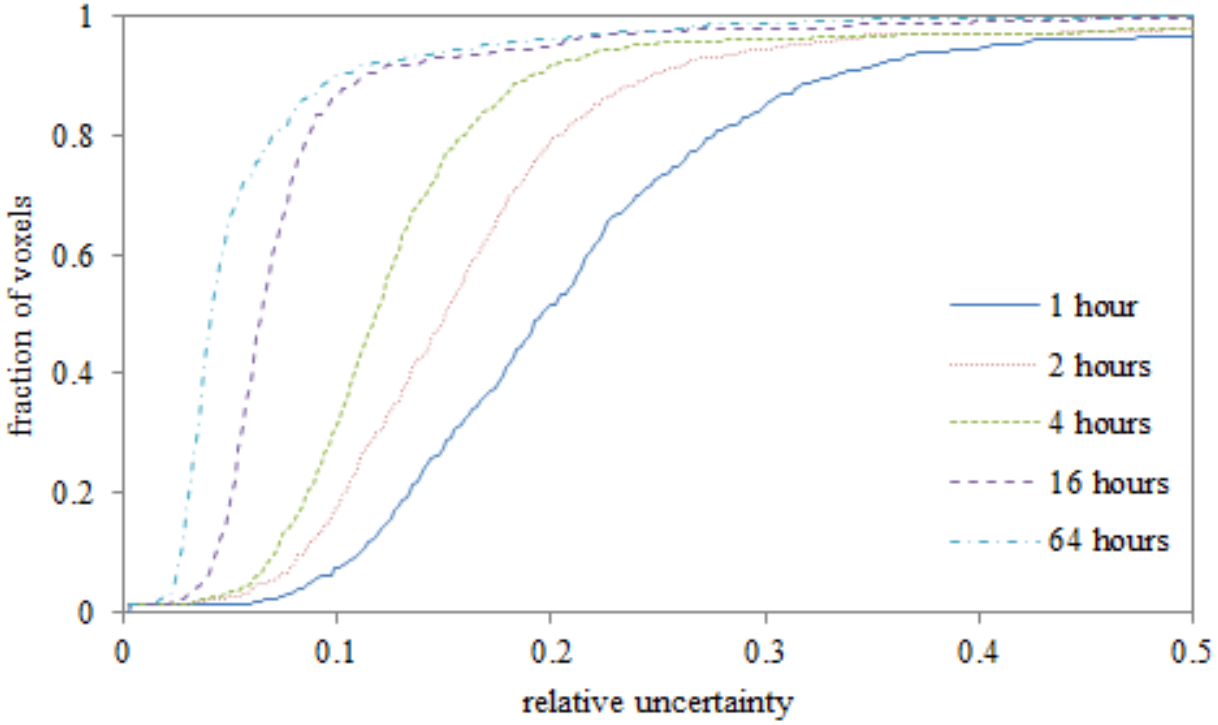

Fig. 4.1.35: Distribution of relative uncertainties for different run times of `mavric.isfsi.inp` showing the fraction of the mesh tally voxels that had less than a given amount of relative uncertainty.

4.1.5.6 TN24-P spent fuel cask

For an example that uses multiple sources, user-defined distributions in those sources, macromaterials for improved S_N calculations, and the automated variance reduction capabilities in MAVRIC, consider the model for the TN-24P cask, as used in previous SCALE shielding reports [MAVRIC-WDP+09] and shown in Fig. 4.1.36. This model contains two types of PWR spent fuel assemblies (Types V and W, both Westinghouse 15×15 assemblies of different starting enrichments and burnups), each with specified neutron and photon sources, in an aluminum/boron fuel basket. The cask is made of forged steel for photon shielding with a resin layer for neutron shielding. The model also includes three activated hardware regions (bottom nozzle, top nozzle, and top plenum), which consist of specified amounts of ^{60}Co (a photon source). The task for this example is to calculate the total dose rate within 2 meters of the cask surface.

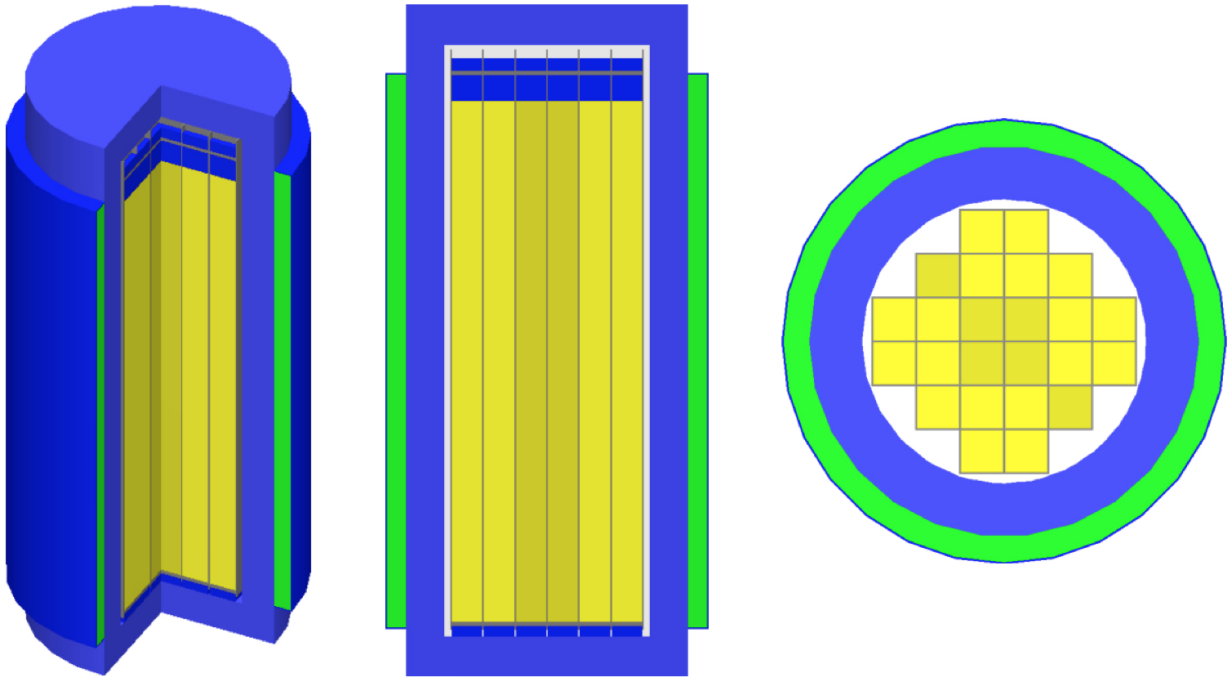

Fig. 4.1.36: MAVRIC model of the TN24-P cask. Materials: spent fuel (light and dark yellow), steels (blues), resin (green), and other metals (gray).

For MAVRIC, this means that the calculation of a dose rate mesh tally is calculated using FW-CADIS to ensure that each voxel has low relative uncertainty, independent of the dose rate. Without MAVRIC, the calculation of dose rate everywhere in three dimensions would be too challenging. Most likely, the dose rate would be evaluated with reasonable uncertainty at only a few locations. In fact, with analog calculations, this example would be a very difficult problem since most source particles never leave the cask, just as in the real-life situation. This type of problem really benefits from the CADIS-biased source distribution, in which source particles deep inside the cask are sampled very rarely since they do not contribute significantly to the response.

Input file

The following is a partial list of the file `mavric.tn24p.inp` located in the SCALE `samples\input` directory. This calculation will use the coarse-group shielding library for all of the importance map calculations but then will use the fine-group library for the final Monaco step. The full geometry and source distributions are not printed here due to their length.

The goal of this example is to calculate the total dose outside the cask. Therefore, the adjoint source uses the total dose rate response function for its energy component, whereas for the spatial component, it uses a large block around the cask. Note the "mixture=" keyword, which restricts the adjoint source to only exist where the material is air (13). There is no need to put adjoint source deep in the cask since the dose rates inside the cask are not of interest. Response weighting is used to put more adjoint source in the low dose areas outside the cask. Note that since this area is air, not many interactions/scatter take place, so a great balance in relative uncertainties near and far from the cask should not be expected. Macromaterials are used to improve the results from the discrete-ordinates calculations, which should improve the FOM of the final Monaco calculation. The geometry images in Sect. 4.1.3.4.2 are taken from this problem.

Output

The distributions used by the source descriptions of the TN24-P model are shown in Fig. 4.1.38, and the responses used in this problem are shown in Fig. 4.1.37. Fig. 4.1.39 and Fig. 4.1.40 show the total (neutron + photon) dose rate outside the TN24-P cask, up to 2 meters from each surface using rectilinear and cylindrical mesh tallies with 10 cm voxels. Uncertainties in the computed dose rates were 3-4% after this 16 hr calculation. The scale of the figure was adjusted to only show the dose rate outside the cask; dose rates inside the cask went as high as 6×10^5 rem/hr. Likewise, the scale of the uncertainties ranged from 0 to 10% to highlight the uncertainties outside the cask. Relative uncertainties inside the cask were much higher (white areas) since those areas were deemed unimportant by the chosen adjoint source. Obtaining dose rates on a 10 cm mesh would not be achievable without the variance reduction capabilities of MAVRIC.

4.2 MAVRIC CAAS CAPABILITY

4.2.1 INTRODUCTION

Modeling criticality accident alarm systems (CAAS) presents challenges since the analysis consists of both a criticality problem and a deep-penetration shielding problem [CAASPLMP10, CAASPPJ09]. Modern codes are typically optimized to handle one of those types of problems but usually not both. The two problems also differ in scale-the criticality problem depends on materials relatively close to the fissionable materials while the shielding problem can cover a much larger range. SCALE now contains fully three-dimensional tools to perform both parts of a CAAS analysis.

CAAS analysis can be performed with SCALE using the KENO-VI criticality code and the MAVRIC shielding sequence. First, the fission distribution (in space and energy) is determined by KENO-VI. This distribution is saved to a file using a user-specified three-dimensional mesh grid and an energy structure from the cross section library (or a user-defined energy structure). MAVRIC then uses the fission distribution as the source for a shielding calculation. MAVRIC is designed to implement advanced variance reduction methods to calculate dose rates or detector responses for difficult shielding problems.

For different types of shielding and different combinations of sources and detector locations, different strategies can be used within SCALE [CAASPW12, CAASWODonnellN12]. Due to the way that cross sections for neutron reactions that create photons are stored in ENDF, some of the parameters used in the CAAS capability have changed since SCALE 6.1. Please be sure to understand and follow the new guidance for the correct accounting of secondary photons from neutron reactions [CAASMP13a, CAASMP13b, CAASMP13c].

4.2.2 METHODS

The CAAS capability in SCALE is a two-step approach using KENO-VI and MAVRIC. The first step is the determination of the source distribution, done with the CSAS6 sequence which uses the KENO-VI functional module. Along with calculating the system k_{eff}, KENO-VI has been modified to now accumulate the fission distribution over the non-skip generations. This information is collected on a three-dimensional Cartesian mesh that overlays the physical geometry model and is saved as a Monaco mesh tally file. A utility program is used to convert the mesh tally into a Monaco mesh source.

The mesh source is then used in the second step as the source term in MAVRIC. The absolute source strength is set by the user based on the total number of fissions (based on the total power released) during the criticality excursion. Further neutron multiplication should be prevented in the MAVRIC transport calculation. Because the fission neutrons have already been accounted for in the KENO-VI calculation, failure to suppress neutron multiplication in the MARVIC sequence would lead to incorrect flux estimates. In addition, if further fissions were allowed, Monaco would add neutrons to its particle bank faster than they could be removed (since the system is at or above critical) and the simulation may never finish.

For the transport part of a CAAS analysis, MAVRIC can be optimized to calculate one specific detector response at one location using CADIS or can be optimized to calculate multiple responses/locations with roughly the same relative uncertainty using FW-CADIS. For calculating mesh tallies of fluxes or dose rates, MAVRIC also uses FW-CADIS to help balance the Monaco Monte Carlo calculation such that low flux voxels are computed with about the same relative uncertainty as high flux voxels.

With this two-step approach, users will have a great deal of flexibility in modeling CAAS problems. The CSAS6 step and the MAVRIC step could both use the same geometry and materials definitions or could have different levels of detail included in each. The fission source distribution from one CSAS6 calculation could be used in a number of different MAVRIC building/detector models, with each MAVRIC calculation being optimized for a given type of detector.

4.2.3 USER INPUT

The user can create either one input file containing both the CSAS6 and MAVRIC calculations or can create two input files-one for each sequence. The materials and geometry for these two models could be the same but do not have to be. For example, the CSAS6 sequence might only contain the materials and geometry important to the criticality calculation. Note, however, that the critical source geometry and materials should be modeled identically in both problems. This allows users greater flexibility in modeling their specific problems.

4.2.3.1 KENO-VI input

For the criticality problem, the only extra input a user needs to supply is the keyword *cds=yes* in the parameter block and a spatial mesh around all of the fissionable materials of the problem in its own gridGeometry block. Standard input for KENO-VI is described in the KENO-VI chapter and CSAS6 chapter. The mesh used for the fission source distribution is input using the *read gridGeometry *id** block, where *id* is an identification number for that grid. Note that only one grid can be specified, but that may change in the future. The cells of the mesh are specified in each dimension separately by either (1) listing all of the planes bounding the cells (keyword "xplanes" followed by an "end"), (2) using keyword *xLinear *n* *a* *b** to specify *n* cells between *a* and *b*, or by (3) specifying the minimum plane, the maximum plane, and how many cells to make in that dimension (*xmin=*, *xmax=*, *numXCells=*). The keywords *xplanes* and *xLinear* can be used together and multiple times. Similar keywords are used for the *y*- and *z*-dimensions. An example CSAS6 input file that collects the fission distribution information would be as follows:

```
=csas6
CAAS Example
v7-238n
read composition
    ...
end composition
read parameters
    ...
    cds=yes
end parameters
read geometry
    ...
end geometry
read gridGeometry 1
    title="Mesh for Collecting Fission Source"
    xLinear 13 0.0 78.0
    yplanes 0 8 16 24 32 34 36 38 40 48 56 64 72 end
    zLinear 10 -2.54 77.46
end gridGeometry
end data
end
```

The fission source distribution collected by KENO-VI is saved to a Monaco mesh tally file and copied back to the home area with the name **problemName*.fissionSource.3dmap*. This file can be viewed with the Mesh File Viewer capability of Fulcrum that comes with SCALE. Note that the finer the mesh spacing is the more generations/histories will have to be simulated by the criticality calculation in order to reduce the stochastic uncertainty in each mesh voxel of the distribution. Regardless of the mesh size, creation of a fission mesh source file will take more iterations than the number required to find k_{eff}. KENO-VI also saves the value of the system the average number of neutrons per fission, in a file called **problemName*.kenoNuBar.txt*. This value is needed to properly determine the source strength.

4.2.3.2 Mesh tally to mesh source conversion

A utility program is used to convert the Monaco mesh tally file into a Monaco mesh source file. It can be part of the CSAS6 input file. The user then needs to copy the resulting *.msm file back to his home area.

```
=csas6
...
end

=mt2msm
'fissionSource.3dmap'    ! existing Keno fission source mesh tally
1                         ! which family (for Keno files, there is only 1)
-1                        ! use the whole family (keep all energy groups)
1                         ! particle type for *.msm file (1-neutron, 2-photon)
'fissionSource.msm'      ! name of newly created mesh source map file
end

=shell
  copy fissionSource.msm "C:\mydocu~1\caasExample"
end
```

Details on the conversion utility program are contained in Sect. 4.3 of the MAVRIC manual.

In SCALE 6.1, the fission source distribution mesh tally produced by KENO contained data representing the number of fissions in each mesh cell in each energy group. In SCALE 6.2, the data stored was changed to be the fissions per unit volume - the fission density. This is more consistent with other mesh tallies from Monaco which store flux or dose rates that represent averages over the mesh cells. This change also allows the Mesh File Viewer to display the KENO fission source distribution better. The mt2msm utility program also changed from SCALE 6.1 to SCALE 6.2 to account for the change in what is stored in the Keno mesh tally file. Therefore, **KENO-produced fission source mesh tallies and the mt2msm utility should not be mixed-and-matched across versions of SCALE**. Doing so would result in the final Monaco mesh source file being improperly normalized, which would not represent the KENO fission source distribution and would give incorrect results in subsequent MAVRIC calculations. Because there is not a specific 'version flag' in a mesh tally file or mesh source map file, the user must ensure that they have used the same version of SCALE for both the CSAS6 and MAVRIC sequences any time the CAAS capability is used.

4.2.3.3 MAVRIC input

The input for the MAVRIC portion of the CAAS problem should include the materials and geometry of the criticality model, use the fission distribution as a source, set the source strength, and set any optional modifiers to the source to change its location or add fission photons. The cross section library used by the MAVRIC calculation does not need to have the same group structure as the fission distribution. MAVRIC will automatically convert the fission source group structure to match the group structure of its cross section library.

The shielding calculation needs to specify that the source is the fission distribution file, which is typically *fissionSource.msm*. The total source strength can be specified by either the number of fissions in the criticality accident (fission rate or total number) or by the number of released neutrons (the fission rate multiplied by $\bar{\nu}$ per fission). The value of $\bar{\nu}$ will be read from the file *kenoNuBar.txt* in the SCALE temporary directory if it is not given in the source input with the keyword *nu-bar=*. The mesh source can also be placed at different coordinates in the geometry using the *origin x= *x* y= *y* z=*z** keywords, if a different reference frame was used with the criticality geometry model that created the mesh source. Rotations of mesh sources are not available at this time. It is also recommended to use filters in the source block to define the source, such as the *mixture=* filter to only allow source sampling from a specific mixture since the mesh source can be transformed from its original origin or meshes can cover non-fissionable materials.

For example, using a KENO-VI fission distribution, placing it somewhere in the MAVRIC model and setting the source strength (in neutrons/s) to correspond to 10^{17} fission/s would look like

```
=shell
    copy "C:\mydocu~1\caasExample\kenoInput.kenoNuBar.txt"  kenoNuBar.txt
end

=mavric
...
read sources
    src 1
        meshSourceFile "C:\mydocu~1\caasExample\fissionSource.msm"
            origin x=600 y=650 z=400
        fissions=1.0e17
    end src
end sources
...
end data
end
```

The source strength in neutrons/s will be calculated by MAVRIC to be the fission rate multiplied by the value of read from the "kenoNuBar.txt" file. The neutron strength could have alternatively been specified using the standard source strength keyword "strength=2.5e17" (for an example with the average number of neutrons per fission of 2.5).

The Monte Carlo functional module used by MAVRIC, Monaco, is a fixed-source code. Unless told otherwise, neutrons will multiply in fissionable materials. Since all of the neutrons were part of the source, neutron multiplication should not be allowed and MAVRIC should be run with the keyword "fissionMult=0" in the parameters block. For systems at or near critical without the "fissionMult=0" keyword, Monaco simulations may not end since neutrons will be added to the particle bank at the same rate they leave the system or get killed.

The shielding calculation can be run using standard variance reduction methods (such as path length stretching, user-defined weight windows based on geometry regions, and user-defined source biasing) or using the automated tools which employ approximate discrete-ordinates calculations to determine the space/energy weight windows as well as a biased source distribution in space and energy. The automated tools can be used to optimize the shielding calculation to determine one specific tally using CADIS or several separate tallies or a mesh tally over a large volume of the problem space using FW-CADIS. When using these advanced variance reduction methods, remember to include planes in the discrete-ordinates mesh definition that correspond to the planes in the fission distribution that the source is based on. If they are not included, MAVRIC will resample the fission source on the discrete-ordinates mesh it is using for the importance map, possibly smearing or reducing the original resolution of the fission distribution.

4.2.4 EXAMPLE PROBLEM

Consider the Jezebel critical plutonium sphere experiment, shown in Fig. 4.2.1, taking place inside a simple fictitious building, shown in Fig. 4.2.2. The building has two rooms: an experiment room and a control room. In the control room there is a criticality alarm detector, and it is positioned furthest from the entry to the experiment room. For this example, assume that a criticality excursion results in a total of 10^{18} fissions. This example will calculate the neutron and photon doses seen by a detector in the control room, as well as calculate a dose map for the entire building.

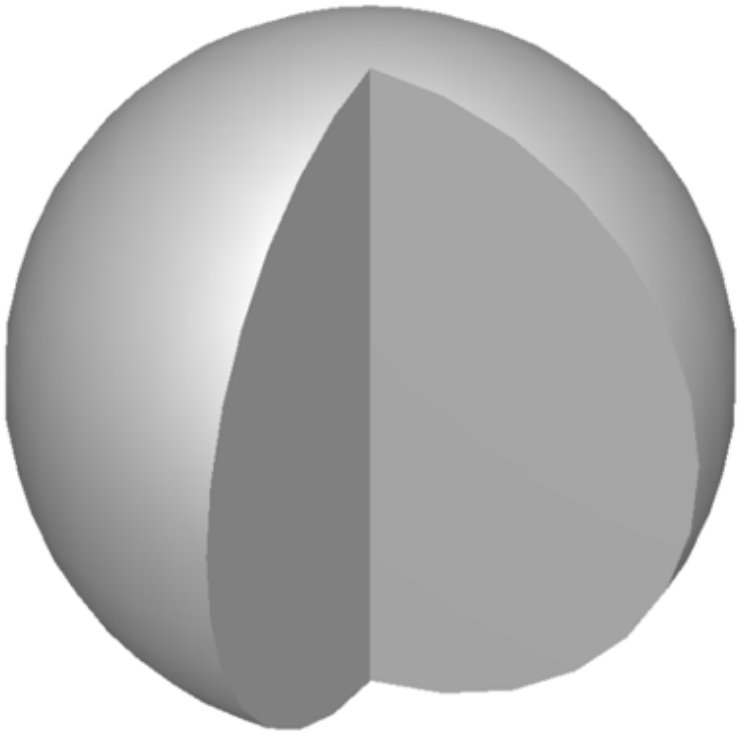

Fig. 4.2.1: Cutaway view of Jezebel.

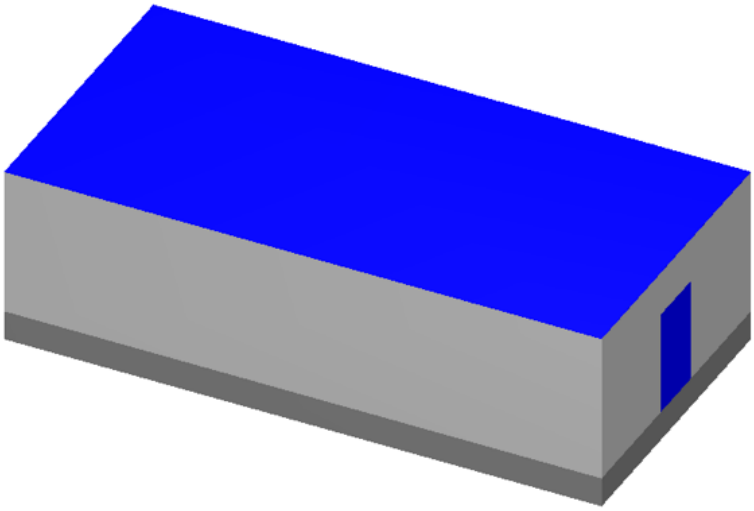

Fig. 4.2.2: Simple two-room building.

4.2.4.1 KENO-VI criticality and fission source distribution

For the criticality calculation, consider just a bare sphere of plutonium, with a radius of 6.38493 cm. Atom densities (atoms/b·Pu 0.037047; ^{240}Pu 0.0017512; ^{241}Pu 0.00011674; and Cu 0.0013752. This can be easily modeled as a sphere at the origin. For collecting the fission distribution, a uniform mesh grid can be constructed around the sphere, extending 7 cm in each direction, with a $1 \times 1 \times 1$ cm voxel size. The first portion of the input files `mavric.caasA.inp` and `mavric.caasB.inp` looks like the following:

```
=csas6

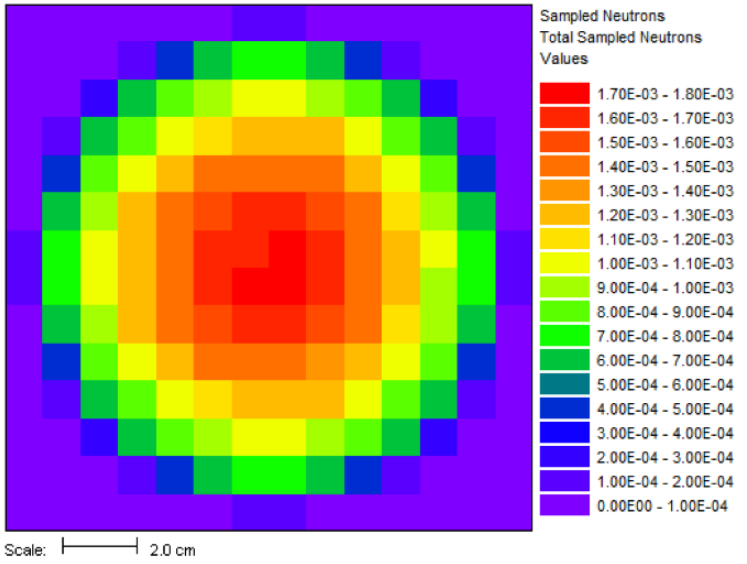

Fig. 4.2.3: Fission source spatial distribution for the center horizontal slice.

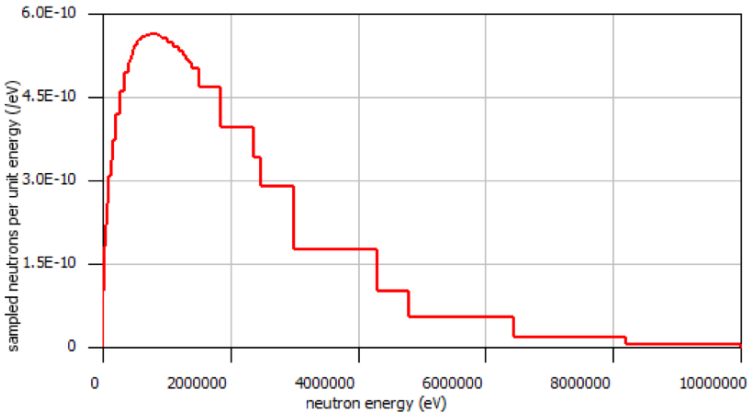

Fig. 4.2.4: Fission source energy distribution for the center voxel.

4.2.4.2 MAVRIC transport calculations

Two MAVRIC calculations will be done-one that calculates the doses seen at the detector and one that computes mesh tallies of doses over the entire building. They will share the same materials, geometry, and source but will have different tally and variance reduction options.

The two-room building will be a simple model using concrete-block walls, a concrete floor, and a steel roof, with dimensions shown in Fig. 4.2.5. The building exterior dimensions are 1200 cm long, 600 cm wide, and 300 cm high above the ground. The exterior and interior walls are all made of a double layer of typical concrete blocks (total of 40 cm thick.) Concrete blocks are typically 39 × 19 × 19 cm and weigh ~13.5 kg, since they have a volume fraction of 33.2%. The floor is made of poured concrete, extending 60 cm into the ground. The roof and the exterior door (120 cm wide and 210 cm tall) are made of 1/8 in. (0.3175 cm) thick steel. The experiment room on the left connects to the control room on the right through a maze that prevents radiation streaming. Assume that the critical experiment was in the center of the experiment room, 100 cm above the floor. Assume the detector in the control room is a 30 cm diameter sphere located at position (1145, 55, 285).

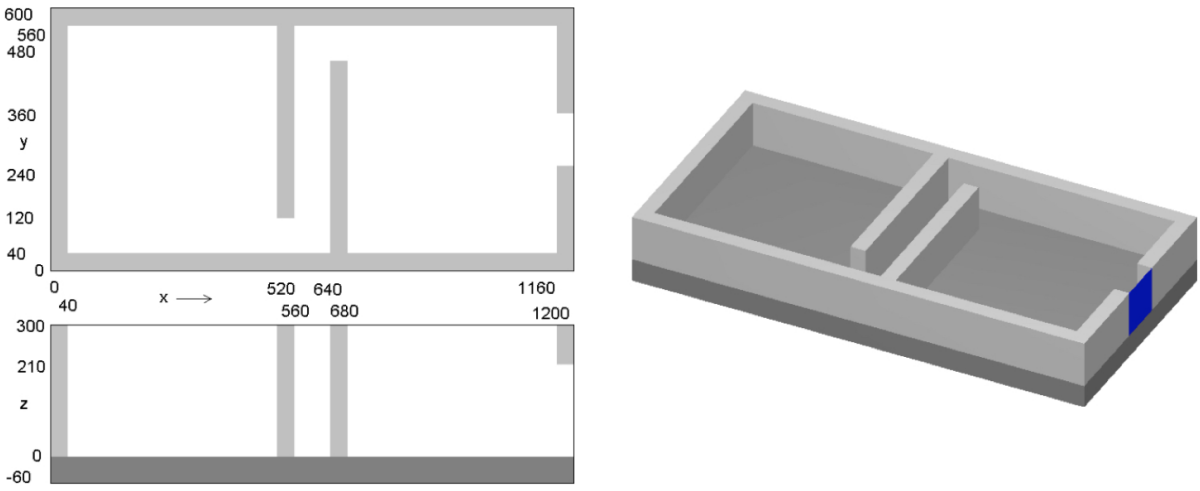

Fig. 4.2.5: Coordinates of the floor, walls, ceiling, and door of the simple block building model (in cm).

If the MAVRIC transport calculation is not in the same file as the CSAS6 calculation, the MAVRIC input would start by moving the KENO-VI results into the SCALE temporary area:

```
=shell
    copy %RTNDIR%\caas.kenovi.fissionSource.msm  fissionSource.msm
    copy %RTNDIR%\caas.kenovi.kenoNuBar.txt      kenoNuBar.txt
end
```

The materials and geometry blocks of the two MAVRIC input files for each of the two calculations, `smplprbs/caas.mavricA.inp` and `smplprbs/caas.mavricB.inp`, look like the following:

```
'------------------------------------------------------------------------------
' Composition Block
'------------------------------------------------------------------------------
read composition

```

The source used by each MAVRIC simulation will be based on the fission distribution mesh source determined by KENO-VI. The strength of the source can be specified by the total number of fissions that occurred in the criticality event. Fission photons will be added for ^{239}Pu. MAVRIC will determine the total source strength, including the fission photons, from the value of saved by KENO-VI and the multiplicity data from the fission photon data file.

```
'--------------------------------------------------------------------------------
' Sources Block
'--------------------------------------------------------------------------------
read sources
    src 1
        meshSourceFile="fissionSource.msm"
        origin x=280  y=300  z=100
        fissions=1.0e18
        mixture=1
    end src
end sources
```

Note that further multiplication needs to be turned off in MAVRIC using the *fissionMult=0* keyword in the parameter block as shown below.

For the responses from the tallies, MAVRIC usually calculates dose rates (rem/hr) using a source strength in particles/s. For this example problem, instead of a source rate, we used a total number of particles (by specifying the number of fissions). Hence, the computed fluxes will have units of particles/cm^2 and the computed responses using the standard dose responses from the cross section libraries will have units of rem s/hr. To get a dose in rem, the responses need to be multiplied by (3600 s/hr)$^{-1}$. This can be done using the MAVRIC tally multiplier keyword.

Each MAVRIC simulation will need a discrete-ordinates mesh. The planes in each dimension where there are material changes are listed in Table 4.2.2. In addition to these planes, the discrete-ordinates mesh should also subdivide the thick shields in the direction of particle travel. For example, the walls of the maze should be divided to better model the radiation attenuation through the walls in the Denovo calculation. The interior walls of the building will reflect particles, so the first few centimeters are the most important to capture in the importance map. Mesh planes should also be added that correspond to the mesh source after it is placed into the geometry model.

Table 4.2.2: Main planes in the building

             300.3175   end
 end gridGeometry
```

The tallies are region tallies over the detector region (the 10th media card in unit 1) using the appropriate response function for the particle type of the tally. The volume of the detector sphere needs to be listed in the geometry block so that the fluxes and tallies will be correctly computed. The importance map uses standard CADIS to bias the particles towards the detectors, optimizing the calculation of the total dose (by listing both response functions together, the total response will be used in the adjoint source).

```

```

The results of this example problem are shown in Table 4.2.3. Calculation times were 12 minutes for Denovo and 135 minutes for Monaco. Note that the uncertainty for the photon dose is much higher than the neutron dose uncertainty. This is because the simulation was optimized for the calculation of total dose, and the photon component of the total dose is less than 2%. Had a separate calculation been done that used an adjoint source of just the photon response, the photon dose rate uncertainty would have been much smaller but at the expense of the neutron dose rate uncertainty. A single calculation could have also been performed using two adjoint sources, one using the neutron dose response and one using the photon dose response, and forward weighting to help calculate each component of dose with more uniform relative uncertainties.

Table 4.2.3: Doses seen by the detector

	Value	**Rel.**
Dose	**(rem)**	**Unc.**
neutron	1539	0.78%
photon	30.0	8.00%

Dose map using FW-CADIS

The grid geometry for this calculation does not need extra planes around the detector. The grid geometry in `smplprbs/caas.mavricB.inp` looks like the following:

```
gridGeometry 1
        title="mesh for discrete ordinates 46x36x23 = 38088"
        xplanes 0     10 20 30 35
                40    120 160 240
                      270 272 274 276 278 280 282 284 286 288 290
                      360 440
                520   525 530 550 555
                560   600
                640   645 650 670 675
                680   760 840 920 1000 1080
                1160  1165 1170 1180 1190
                1199.6825
                1200  end
        yplanes 0     10 20 30 35
                40
                120   125 130 140 200
                240   280 290 292 294 296 298 300 302 304 306 308 310
                      320
                360   440 460 470 475
                480
                560   565 570 580 590
                600   end
        zplanes -60   -30 -20 -10 -5
                0     45
                      90 92 94 96 98 100 102 104 106 108 110
                      140 175
                210   255
                300   300.3175   end
end gridGeometry
```

A second grid geometry also needs to be added to the definitions block for the mesh tally to use.

```
gridGeometry 2
    title="mesh for uniform mesh tally - 40x40x30 cm voxels"
    xLinear 30 0.0 1200.0
    yLinear 15 0.0  600.0
    zLinear 10 0.0  300.0
end gridGeometry
```

The mesh tallies for each particle type are listed, along with the appropriate response function. The importance map uses FW-CADIS to better spread the particles out over the entire geometry, optimized for the calculation of total dose in the void regions.

```
'------------------------------------------------------------------------------

        responseIDs 5 6 end
        mixture=0
    end adjointSource
    respWeighting
end importanceMap
```

This calculation used 5 minutes for the forward Denovo S_N calculation, 6 minutes for the adjoint Denovo, and 120 minutes for the Monaco Monte Carlo. The resulting mesh tally is shown in Fig. 4.2.6. The uncertainties for each voxel are shown in Fig. 4.2.7. Note that the dose in the voxel containing the detector (not shown in the figures) is 1.552×10^3 rem with a relative uncertainty of 3.8%, closely matching the value calculated with the first MAVRIC simulation.

Similar to the detector doses above, a single calculation could have also been performed for the dose maps using two adjoint sources, one using the neutron dose response and one using the photon dose response, and forward weighting to help calculate each component of dose with more uniform relative uncertainties.

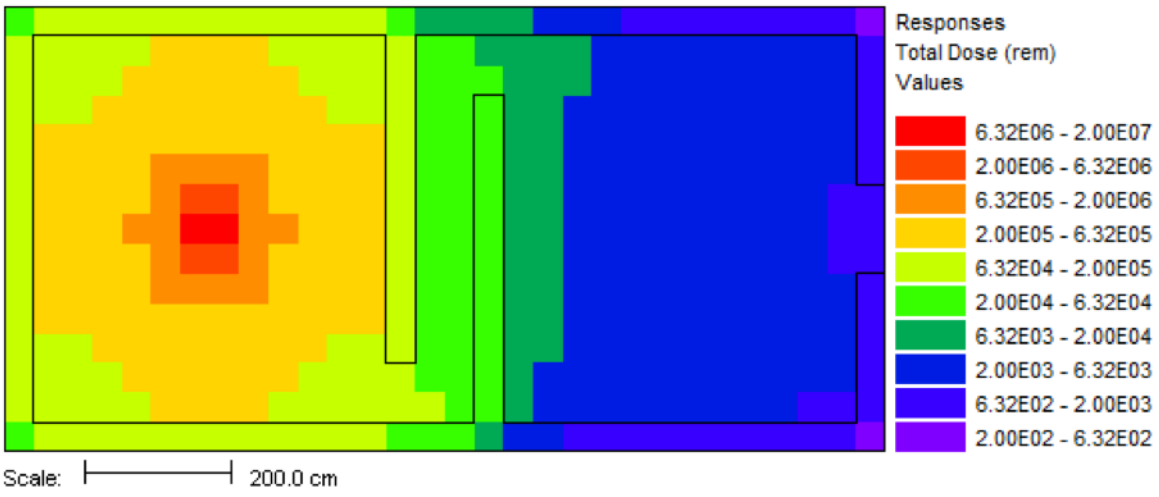

Fig. 4.2.6: Dose (rem) results for the z=100 cm plane (containing the source).

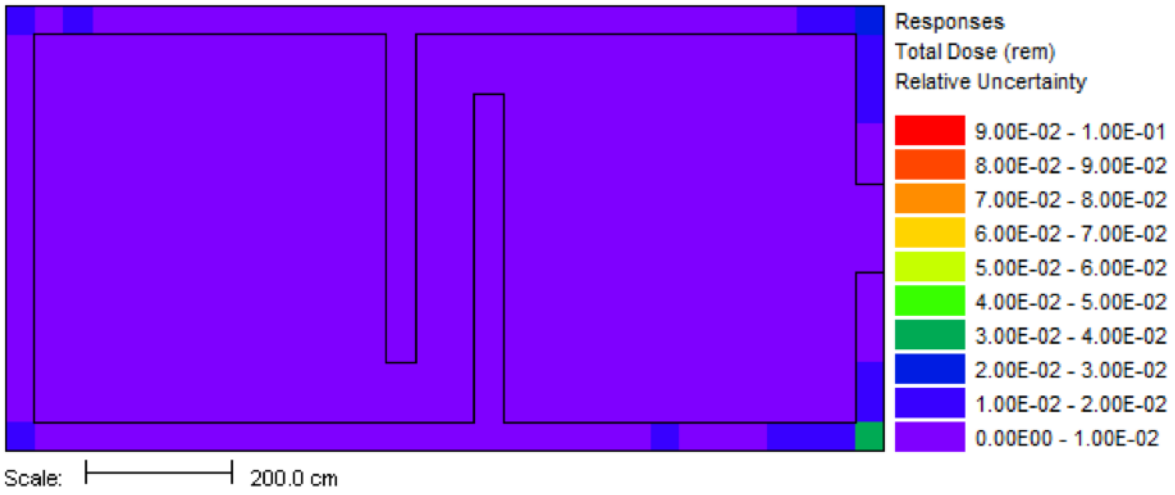

Fig. 4.2.7: Relative uncertainties in the dose, most less than 1%, for the z=100 cm plane.

4.2.5 SUMMARY

SCALE now has the capability to do detailed simulations of criticality accident alarm systems. The advanced variance reduction capabilities of the MAVRIC radiation transport sequence allow for the full three-dimensional analysis of CAAS problems in reasonable amounts of computer time. This enables the use of more realistic source definitions, such as a detailed spatial/energy dependent fission source distribution determined by the KENO-VI criticality code, and the critical assembly itself can be included in the transport model.

4.3 MAVRIC UTILITIES

4.3.1 INTRODUCTION

Several utilities are provided to aid users in dealing with some of the output files produced by Monaco and MAVRIC. These utilities were developed at ORNL for specific projects and have been added to SCALE so that all users can benefit. More utilities have been added that deal with Denovo, including the older *.varscl files for flux output used in SCALE 6.1 and the current binary *.dff file for flux output used in SCALE 6.2. These tools do not have the modern block/keyword input structure but instead have a fixed format, which is fairly simple since each utility is made for a very specific function.

Each is described in the following sections. Five sample problems, `mavricUtilities1.inp`, `mavricUtilities2.inp`, `mavricUtilities3.inp`, `mavricUtilities4.inp` and `mavricUtilities5.inp` demonstrate the use of some of these. For all of these utilities, filenames should be enclosed in quotes.

4.3.2 UTILITIES WORKING WITH MONACO MESH TALLY (3DMAP) FILES

mt2ascii	Convert a mesh tally into an ASCII text file.
mt2msl	Convert a mesh tally into a mesh source lite.
mt2msm mt2silo	Convert a mesh tally into a mesh source. Convert a mesh tally file into a Silo file for VisIt.
mt2vtk	Convert one dataset of one family in a mesh tally to VTK format.

continues on next page

Table 4.3.1 – continued from previous page

mtAdder	Add several Monaco mesh tally files together into one mesh tally.
mtAverager	Average several Monaco mesh tally files into one mesh tally.
mtBinOp	Binary operation of mesh tally files: sum, difference, product, and ratio.
mtDisp	Display the basics of a mesh tally file.
mtExpand	Expand a space-only mesh from a mesh tally with an energy function.
mtFilter	Perform various filters on a mesh tally file.
mtInv	Invert all of the values in a mesh tally.
mtMask	Keep only or remove specified voxels of a mesh tally based on geometry.
mtMinMax	Find the location/value of the min or max of each real mesh in a mesh tally.
mtMultiply	Multiply a mesh tally by a constant factor.
mtPull	Pull values from certain voxels out of a mesh tally file.
mtRefine	Subdivide the mesh into smaller meshes for better visualization.
mtResp	Apply a response function to one family of a mesh tally file.
mtSplit	Split off part of a mesh tally file into a separate mesh tally file.

mt2ascii - Convert a mesh tally into an ASCII text file.

Intended use: Since mesh tally files are in binary, the viewer can be used to list mesh values. To get the values from the entire file, this utility can be used to create an ASCII text version.

Input: The mesh tally file name and the filename for the resulting ASCII file

Output: An ASCII formatted file

Example:

```
=mt2ascii
"/optional/path/meshTallyFilename.3dmap"  ! the mesh tally
"/optional/path/outputFilename.txt"       ! output file name
end
```

mt2msl - Convert a mesh tally into a mesh source lite.

Intended use: Convert a fissionSource.3dmap mesh tally computed by KENO into a meshSoureLite (*.msl) file that can be used by a subsequent KENO run using starting source type nst=9.

Input: Name of mesh tally (*.3dmap) file

Output: A mesh source lite (*.msl) file

Example:

```
=mt2msl
"input.3dmap"    ! mesh file (*.3dmap) name
1                ! family
14               ! group, or 0 for family total
"result.msl"     ! mesh source lite (*.msl) file name
end
```

mt2msm - Convert a mesh tally into a mesh source.

Intended use: Turn a tally of fission rate data into a mesh source file. Mesh tallies are stored in a generic *.3dmap format, which consist of several families, each with one or more datasets. A typical mesh tally (without the “noGroupFluxes” keyword) contains three families: the neutron fluxes with each energy group

as a dataset, the photon fluxes with each energy group as a data set, and the responses with each response as a dataset. This program uses the spatial information of the mesh tally and combines a user-given energy distribution for all voxels. A second way to use this program is to use a whole family (all the energy groups) without a user-given energy distribution.

Input:

Line 1: filename of mesh tally
Line 2: which family of tally
Line 3: which dataset of that family (or 0 for sum of family)
Line 4: source type: 1-neutron, 2-photon
Line 5: number of bins for mesh source
Lines : energy (eV) and pdf values
Lines : energy (eV) and pdf values

... ...

Lines : energy (eV) and pdf values
Line : energy (eV)
Line last: desired output name

Input:

Line 1: filename of mesh tally
Line 2: which family of tally
Line 3: -1 (meaning use the whole family)
Line 4: source type: 1-neutron, 2-photon
Line 5: desired output name

Output: The resulting mesh source stored with the desired filename

---

Note: Statistics of mesh tally are discarded.

Example:

```
=shell
   cp ${RTNDIR}/barrel1.mt1.3dmap .
end

=mt2msm
"barrel1.mt1.3dmap"    ! mesh tally
```

(continues on next page)

(continued from previous page)

```
3                     ! mesh tally family (1-n, 2-p, 3-responses)
1                     ! real mesh in that family (0 means total of family)
1                     ! mesh source particle type  1-neutron, 2-photon
143                   ! number of bins in binned histogram distribution
1.9640E+07 1.29403E-08 ! E_1  pdf_1
1.7332E+07 4.60970E-07 ! E_2  pdf_2
1.6905E+07 2.56619E-06 ! E_3  pdf_3
   ...        ...
1.2341E+03 5.28408E-06 ! E_142  pdf_142
9.6112E+02 1.77756E-06 ! E_143  pdf_143
7.4852E+02             ! E_144
"barrel.fission.msm"   ! output filename
end

=shell
   cp barrel.fission.msm ${RTNDIR}
end
```

Example:

```
=mt2msm
"fissionSource.3dmap"
1                      ! neutron flux (for KENO 3dmap files there is only one family)
-1                     ! use the whole family (keep all the energy groups)
1                      ! particle type (neutron)
"caas.kenovi.fissionSource.msm"
end
```

In SCALE 6.1, the fission source distribution mesh tally produced by KENO contained data representing the number of fissions in each mesh cell in each energy group.

In SCALE 6.2, the data stored was changed to be the fissions per unit volume–the fission density. This is more consistent with other mesh tallies from Monaco which store flux or dose rates that represent averages over the mesh cells. This change also allows the MeshFileViewer to display the KENO fission source distribution better. The mt2msm utility program also changed from SCALE 6.1 to SCALE 6.2 to account for the change in what is stored in the KENO mesh tally file. Therefore, **KENO-produced fission source mesh tallies and the mt2msm utility should not be mixed-and-matched across versions of SCALE.** Doing so would result in the final Monaco mesh source file being improperly normalized, which would not properly represent the KENO fission source distribution and would give incorrect results in subsequent MAVRIC calculations. Because there is not a specific 'version flag' in a mesh tally file or mesh source map file, the user must ensure that they have used the same version of SCALE for both the CSAS6 and MAVRIC sequences any time the CAAS capability is used.

mt2silo - Convert a mesh tally file into a Silo file for VisIt.

Input: Name of mesh file (*.3dmap), name of a Silo file, and a format

Output: A new Silo file

Note: For format, use either 2 (PDB) or 7 (HDF5).

Example:

```
=mt2silo
"perfect.3dmap"        ! the existing mesh tally
"perfect.silo"         ! the new silo file
7                      ! format - HDF5
end
```

mt2vtk - Convert one dataset of one family in a mesh tally to VTK format.

Intended use: This is a way to transfer Monaco mesh tally data into a common format that can be used by many data visualization packages, including VisIt. Mesh tallies are stored in a generic *.3dmap format, which consist of several families, each with one or more datasets. A typical mesh tally contains three families: the neutron fluxes with each energy group as a dataset, the photon fluxes with each energy group as a data set, and the responses with each response as a dataset. This program selects one dataset of one family and saves the data (and optionally the absolute uncertainties) in an ASCII file using a VTK file format.

Input: The mesh file name, which family, which dataset of that family, whether or not to include absolute uncertainties and the filename for the resulting VTK file

Output: An ASCII VTK-formatted file

Example:

```
=mt2vtk
"/optional/path/meshTallyFilename.3dmap"  ! the mesh tally
1                                         ! neutron flux family
5                                         ! energy group 5
true                                      ! include uncertainties
"/optional/path/outputFilename.vtk"       ! output file name
end
```

Example:

```
=mt2vtk
"/optional/path/meshTallyFilename.3dmap"  ! the mesh tally
3                                         ! the response family
1                                         ! first response
false                                     ! do not include uncertainties
"/optional/path/outputFilename.vtk"       ! output file name
end
```

mtAdder - Add several Monaco mesh tally files together into one mesh tally.

Intended use: Add mesh tally results from different sources into one tally. The resulting mesh tally is the sum of all the components in the several mesh tallies-fluxes are added and responses are added. For example, two runs of MAVRIC from two different sources can be made. The mesh tally results can then be added together, getting the total fluxes and total responses from each.

Input: The number of files, followed by the list of mesh tally filenames to add, then the name of the total mesh tally

```
  =mtAdder
  n
  "filename_1"
  "filename_2"
  ...
  "filename_n"
  "resultFilename"
end
```

Output: A new mesh tally file

Note: All of the mesh tally files must be the same size and shape (number of families, x cells, y cells, z cells, and energy groups in each family) and have the same number of responses. Responses (if any) must be consistent to calculate meaningful results.

Example:

```
=mtAdder
3
"meshFilename_1.3dmap"
"meshFilename_2.3dmap"
"meshFilename_3.3dmap"
"meshFilenameTotal.3dmap"
end
```

mtAverager - Average several Monaco mesh tally files into one mesh tally.

Intended use: Combine (average) separate runs of the same problem with different random number seeds into one tally. For example, if a user does 10 separate runs of the same problem (poor man's parallel) and wants to combine the results as if they were from one run, an average is needed. The average and uncertainties are weighted by the number of histories in each run, to maintain proper statistics.

Input: The number of files, each filename and how many histories, then the name of the total mesh tally

```
=mtAverager
n
"filename_1"   histories_1
"filename_2"   histories_2
...           ...
"filename_n"   histories_n
"resultFilename"
end
```

Output: A new mesh tally file

Note: All of the mesh tally files must be the same size and shape (number of families, x cells, y cells, z cells, and energy groups in each family) and have the same number of responses. Responses (if any) must be consistent to calculate meaningful results.

Example:

```
=mtAverager
3
"meshFilename_1.3dmap"   800000
"meshFilename_2.3dmap"   900000
"meshFilename_3.3dmap"   800000
"/home/area/meshFilename.ave.3dmap"
end
```

mtBinOp - Binary operation of mesh tally files: sum, difference, product, and ratio.

Intended use: Apply simple math to the results stored in mesh tally files

Input: The first mesh tally, the operator: add (or sum, +), subtract (or difference, -), multiply (or product, x, *) and divide (or ratio, ÷," /"), the second mesh tally name and then name of the resulting mesh tally file.

Output: A new mesh tally file

Note: Uncertainties are propagated assuming the two mesh tallies are uncorrelated, which may not always be a good assumption. Mesh tallies must have the same grid structure and number of families and groups. Dataset names in the results are inherited from the first mesh tally and may not make sense after the operation. When using the / (slash) for division, enclose it in quotes ("/").

```
=mtBinOp
"neutron.3dmap"     ! first operand
divide              ! operation
"total.3dmap"       ! second operand
"ratio.3dmap"       ! output file name
end
```

mtDisp - Display the basics of a mesh tally file.

Input: A mesh tally (*.3dmap) file

Output: Some of the basic details of mesh file

Example:

```
=mtDisp
"simulation.mt2.dff"    ! existing mesh file
end
```

mtExpand - Expand a space-only mesh from a mesh tally with an energy function

Input: A mesh tally (*.3dmap) file and some parameters

Output: A mesh file similar to a mesh source but with uncertainty

Example:

```
=mtExpand
'activate.mt1.3dmap'
2 1  ! response family, first response - cobalt activate rate
true ! multiply by voxel volumes
2    ! make photon source
19   ! groups
2.00E+07 0
1.00E+07 0
8.00E+06 0
6.50E+06 0
5.00E+06 0
4.00E+06 0
3.00E+06 0
2.50E+06 0
2.00E+06 0
1.66E+06 0.5
1.33E+06 1.5
1.00E+06 0
8.00E+05 0
6.00E+05 0
4.00E+05 0
3.00E+05 0
2.00E+05 0
1.00E+05 0
4.50E+04 0
1.00E+04
'photonSource.3dmap'
end
```

mtFilter - Perform various filters on a mesh tally file.

Input: A *.3dmap mesh tally file and a group-wise response function

Output: A *.3dmap mesh tally file

Note: Three basics types of filters: (0) flattening filter, (1) high-pass filter, (2) low-pass filter. For types 1 and 2, the values plus a given number of standard deviations will be compared to the criteria. The input

list depends on filter type. Types 1 and 2 require a value and a number of standard deviations (n_sigma). A flattening filter turns any positive value into the value of "1.0".

Filtering performed based on following comparisons;

value + n_sigmas*abs_unc > minValue (high-pass)

or

value + n_sigmas*abs_unc < maxValue (low-pass)

The number of sigmas can be positive or negative.

Examples:

```
=mtFilter
"doseRates.3dmap"     ! existing mesh tally file
1                     ! high-pass filter:
0.150                 !    keep dose rates above 0.150
-3.0                  ! add -3.0 standard deviations to values before comparing
"above.3dmap"         ! new mesh tally file
end

=mtFilter
"above.3dmap"         ! existing mesh tally file
0                     ! flattening filter
"boolean.3dmap"       ! new mesh tally file
end
```

mtInv - Invert all of the values in a mesh tally.

Intended use: Invert non-zero values in a mesh tally to be used in further processing.

Input: The original mesh tally, the name of the resulting mesh tally file

Output: A new mesh tally file

Note: Uncertainties are propagated (the relative uncertainty of the reciprocal of a value is the same as the relative uncertainty of the value).

Example:

```
=mtInv
'someTally.3dmap'     ! existing mesh tally file
'inverted.3dmap'      ! new mesh tally file
end
```

mtMask - Keep only or remove specified voxels of a mesh tally based on geometry.

Intended use: Only keep or remove certain portions of a mesh tally based on the unit, media, or mixture at the center of the voxel.

Input: A mesh tally file, an action (keeponly or remove), an operation (intersection or union) of the unit=u, media=r and mixture=m, a replacement value for voxels not kept and the file name of the resulting mesh tally file. User can specify things such as 1) keep only the voxels that have unit=2 and mixture=5, 2) keep only the voxels that have media=3 or mixture=4, 3) remove voxels that have unit=2 and mixture=5, 4) remove voxels that have media=3 or mixture=4. To not include the unit, media, or mixture in the specification, use a value of -1.

Output: A new mesh tally file.

Note: When processing a file before finding the maximum, make the replacement value something very low. If `mtMask` is being used before finding the minimum, then set the replacement value high. Media is the SGGP media number within the unit.

```
=mtMask
"theTally.3dmap"       ! existing mesh tally file
keeponly               ! use 'keeponly' or 'remove'
intersection           ! use 'intersection' or 'union'
2 -1 5                 ! unit=2 AND mixture=5
0.0                    ! replacement value for voxels not kept
'new.3dmap'           ! new mesh tally file
end

=mtMask
"theTally.3dmap"       ! existing mesh tally file
remove                 ! use 'keeponly' or 'remove'
union                  ! use 'intersection' or 'union'
-1 3 4                 ! media=3 OR mixture=4
0.0                    ! replacement value for voxels removed
'new.3dmap'           ! new mesh tally file
end
```

mtMinMax - Find the location/value of the min or max of each real mesh in a mesh tally.

Intended use: Determine the minimum or maximum values in a mesh tally.

Input: The mesh tally, what to find (minimums or maximums), how many mins/maxs for each real mesh in the mesh tally, and the name of the text output file to store the results

Output: A text output containing the values and locations of the minimums or maximums of each real mesh in a tally file

---

Note: The same information is also in the main SCALE output file.

Example:

```
=mtMinMax
'bigOleMeshTally.3dmap'   ! existing mesh tally file
maximum                    ! find either minimums or maximums
5                          ! list top 5 maximum values in each real mesh
'theList.txt'             ! file name to store all of the results
end
```

mtMultiply - Multiply a mesh tally by a constant factor.

Intended use: Multiply every group of every family in a mesh tally for either a change in source strength or a change in units.

Input: The original mesh tally, the multiplier, and the name of the resulting mesh tally file

Output: A new mesh tally file

Example:

```
=mtMultiply
"simulation.mt1.3dmap"       ! the mesh tally
25.0                         ! source strength increase of 25
"simulation.bigger.3dmap"    ! output file name
end
```

mtPull - Pull values from certain voxels out of a mesh tally file.

Intended use: Get energy-dependent fluxes for certain locations from a mesh file.

Input: A mesh file (*.3dmap) file and a list of positions and/or voxels

Output: Listing of energy-dependent fluxes from each desired location to an ASCII text file

---

Note: Can pull fluxes either by a physical coordinate position or by voxel indices. Positions should be entered as a set of x, y, z for a Cartesian coordinate system and r, θ, z for a cylindrical coordinate system.

Example:

```
=mtPull
"duh.mt2.3dmap"    ! existing mesh file
n                  ! number of x,y,z points to pull
x_1 y_1 z_1        ! coordinates of point 1
x_1 y_2 z_2        ! coordinates of point 2
...
x_n y_n z_n        ! coordinates of point n
m                  ! number of i,j,k voxels to pull
i_1 j_1 k_1        ! indices of voxel 1
i_2 j_2 k_2        ! indices of voxel 2
...
i_m j_m k_m        ! indices of voxel m
"outputName.txt"   ! name of output text file
=end
```

mtRefine - Subdivide the mesh into smaller meshes.

Input: A *.3dmap mesh tally file with geometry mesh size (I,J,K) and three integers describing how many subdivisions of each voxel to create in each dimension

Output: A *.3dmap mesh tally file with geometry mesh size (I*nx,J*ny,K*nz)

Example:

```
=mtRefine
"fluxes.3dmap"        ! existing *.3dmap mesh tally file (I,J,K)
nx ny nz              ! how to subdivide each
"refined.3dmap"       ! new (largerer) *.3dmap mesh tally file (I*nx,J*ny,K*nz)
end
```

mtResp - Apply a response function to one family of a mesh tally file.

Intended use: Compute group-wise dose or reaction rates by combining a response function with the scalar fluxes.

Input: A *.3dmap mesh tally file and a group-wise response function

Output: A *.3dmap mesh tally file containing one family

Example:

```
=mtResp
"fluxes.3dmap"          ! existing *.3dmap mesh tally file
200                     ! number of bins in response
1                       ! which family
2.2675480E-04           ! response group 1
2.2283355E-04           ! response group 2
2.1878259E-04           ! response group 3
...
3.6748440E-06           ! response group nbins-2
3.6748443E-06           ! response group nbins-1
3.6748436E-06           ! response group nbins
"doseByGroup.3dmap"     ! new (smaller) *.3dmap mesh tally file
end
```

mtSplit - Split off part of a mesh tally file into a separate mesh tally file.

Intended use: Some mesh tallies may become so large that the MeshFileViewer cannot load the entire file to view. This utility allows users to split off one family or just one group of one family into a separate mesh tally file.

Input: The original mesh tally, which family (neutron, photon, or responses), and which dataset (usually a group). Instead of a dataset, users may specify 0 to get the total of a family or -1 to get all datasets for that family. The name of the resulting mesh tally also needs to be given.

Output: A new, smaller, mesh tally file

Example:

```
=mtSplit
"mavricUtilities3.mt1.3dmap"        ! the mesh tally
1                                   ! the family of neutron fluxes
5                                   ! fifth neutron flux group
"mavricUtilities3.nfluxg5.3dmap"    ! output file name
end
```

4.3.3 UTILITIES FOR WORKING WITH DENOVO BINARY FLUX (*.DFF) FILES

These utilities include the following:

dff2dso	Convert a Denovo flux file into a Denovo spatial output file.
dff2mai	Convert a Denovo flux file into a mesh angular information file.
dff2mim	Invert a Denovo flux file and store as a mesh importance map.
dff2msl	Convert a Denovo flux file into a mesh source lite.
dffBinOp	Binary operation of Denovo flux files: sum, difference, product, and ratio.
dffDisp	Display the basics of a Denovo flux file.
dffExpand	Expand a space-only Denovo flux file by an energy function.
dffFilter	Perform various filters on a Denovo flux file.
dffFix	Fix the zero and negative values in a Denovo flux file.
dffInt	Integrate a single particle type from a Denovo flux file.
dffInv	Invert the values in a Denovo flux file.
dffMult	Multiply a Denovo flux file by a constant factor.
dffPull	Pull fluxes from certain voxels out of a Denovo flux file.
dffResp	Apply a response function to scalar fluxes in a Denovo flux file.
dffSplit	Split off a single particle type from a Denovo flux file.

dff2dso - Convert a Denovo flux file into a Denovo spatial output file.

Input: A binary (stream) Denovo flux file and which particle types to convert

Output: A binary (stream) Denovo Spatial Output file

Note: For particle type, use 1 for neutron, 2 for photon, and 0 for all types.

Example:

```
=dff2dso
"neatStuff.dff"       ! existing Denovo flux file
1                     ! keep only neutron information
"neatStuff.dso"       ! new Denovo spatial output file
end
```

dff2mai - Convert a Denovo flux file into a mesh angular information file.

Intended use: Take the optional net current information from a Denovo flux file and create the adjoint current unit vectors and lambda parameters required for directional CADIS. This is stored in a mesh angular information (*.mai) file.

Input: A binary (stream) denovoFluxFile

Output: A binary (stream) meshAngularInfoFile, a mesh angular information file

Example:

```
=dff2mai
"mavricUtilities3.adjoint.dff"          ! new denovoFluxFile
"mavricUtilities3.mai"                  ! mesh angular info file
end
```

dff2mim - Invert a Denovo flux file and store as a mesh importance map.

Intended use: Make weight targets without a consistent biased mesh source.

Input: A Denovo flux (*.dff) file, a scalar constant, and the name of Monaco mesh importance map (*.mim) file.

Output: A Monaco mesh importance map (*.mim) file.

Example:

```
=dff2mim
"adjoint.dff"    ! existing adjoint denovoFluxFile
3.0e-10          ! constant  targetWeight = constant/adjFlux
"test.mim"       ! new Monaco mesh importance map
end
```

dff2msl - Convert a Denovo flux file into a mesh source lite.

Intended use: Take Denovo fission source information stored in a *.dff file and convert it to a mesh source lite file (*.msl) to be used as a KENO starting source, nst=9.

Input: A Denovo flux (*.dff) file

Output: A mesh source lite (*.msl) file

Example:

```
=dff2msl
"wishfulThinking.dff"    ! existing Denovo flux file
"startingSource.msl"     ! mesh source lite file
end
```

dffBinOp - Binary operation of Denovo flux files: sum, difference, product and ratio.

Intended use: Apply simple math to the results stored in Denovo flux files.

Input: The first flux file, the operator: add (or sum, +), subtract (or difference, -), multiply (or product, x, *), or divide (or ratio, ÷, "/"), the second flux file name, and the name of the resulting flux file

Output: A Denovo flux file

Note: Flux files need to have the same grid structure and number of groups. When using the / (slash) for division, enclose it in quotes ("/").

Example:

```
=dffBinOp
"neutron.dff"     ! first operand
divide            ! operation
"total.dff"       ! second operand
"ratio.dff"       ! output file name
end
```

dffDisp - Display the basics of a Denovo flux file.

Input: A Denovo flux (*.dff) file

Output: Some of the basic details of the Denovo flux file

Example:

```
=dffDisp
"fluxes.dff"          ! existing Denovo flux file
end
```

dffExpand - Expand a space-only Denovo flux file by an energy function.

Input: A Denovo flux (*.dff) file (with a single group - a space-only function), one or more particle types, and an energy function for each

Output: A full space/energy Denovo flux file

Example:

```
=dffExpand
"spatialFluxes.dff"       ! existing Denovo flux file (single group)
2                         ! number of particles
1                         ! particle type (1-neutron, 2-photon)
27                        ! number of bins in binned histogram distribution
2.00000E+07 3.0658021E-09 ! E_1  amount_1
6.37630E+06 6.9767163E-09 ! E_2  amount_2
3.01190E+06 1.1495182E-08 ! E_3  amount_3
   ...         ...
3.00000E-02 1.7127996E-04 ! E_26  amount_26
1.00000E-02 3.0910611E-04 ! E_27  amount_27
```

(continues on next page)

(continued from previous page)

```
1.00000E-05               ! E_28
2                         ! particle type (1-neutron, 2-photon)
19                        ! number of bins in binned histogram distribution
2.00E+07 0.0              ! E_1  amount_1
1.00E+07 0.0              ! E_2  amount_2
8.00E+06 0.0              ! E_3  amount_3
   ...       ...
1.00E+05 0.0              ! E_17  amount_17
4.50E+04 0.0              ! E_18  amount_18
1.00E+04                  ! E_19
"expanded.dff"            ! new Denovo flux file
end
```

dffFilter - Perform various filters on a Denovo flux file.

Intended use: Keep fluxes in a *.dff file where the flux or response meets a specified criterion.

Input: A Denovo flux file name, filter type, filter options, the output file name

Output: A Denovo flux file

Note: There are three basics types of filters: (0) flattening filter, (1) high-pass filter, (2) low-pass filter. For types 1 and 2, the criteria could be a computed response. The input list changes depending on the filter type and whether a response function is included. For no response function, use 0 for the number of groups. A flattening filter turns any positive value into a value of "1.0".

Examples:

```
=dffFilter
"some.dff"                ! input Denovo flux filename
0                         ! filter type
"flattened.dff"           ! output Denovo flux filename
end

=dffFilter
"some.dff"                ! input Denovo flux filename
2                         ! filter type
10.0                      ! maximum value
0                         ! number of groups for response function
"simpleFiltered.dff"      ! output Denovo flux filename
end

=dffFilter
"some.dff"                ! input Denovo flux filename
1                         ! filter type
10.0                      ! minimum value
19                        ! number of groups for response function
1.1620022E-05             !   should match total groups in file
8.7445696E-06
7.4596655E-06
6.3505804E-06
5.3994922E-06
4.6016462E-06
3.9522688E-06
3.4588520E-06
3.0130868E-06
2.6200121E-06
2.1944491E-06
1.8269592E-06
1.5149031E-06
```

(continues on next page)

(continued from previous page)

```
1.1595382E-06
8.7044964E-07
6.2187445E-07
3.7080767E-07
2.6877788E-07
5.9327226E-07
"respFiltered.dff"       ! output Denovo flux filename
end
```

dffFix - Fix the zero and negative values in a Denovo flux file.

Intended use: Replace zero or negative values with nearest good neighboring value. Checks previous group, previous x voxel, previous y voxel, then previous z voxel.

Input: A Denovo flux file

Output: A new Denovo flux file

Example:

```
=dffFix
"original.dff"    ! existing Denovo flux file
"repaired.dff"    ! new Denovo flux file
end
```

dffInt - Integrate a single particle type from a Denovo flux file.

Input: A Denovo flux file, which particle type to integrate (1-neutron, 2-photon), and the filename of the resulting integrated file

Output: A single-group Denovo flux file

Example:

```
=dffInt
"coupled.dff"       ! existing Denovo flux file
2                   ! particle type
"photonTotal.dff"   ! new Denovo flux file (single group)
end
```

dffInv - Invert the values in a Denovo flux file.

Input: A Denovo flux file

Output: A Denovo flux file

Note: Only non-zero values are inverted.

Example:

```
=dffInv
"fluxes.dff"        ! existing Denovo flux file
"inverted.dff"      ! new Denovo flux file
end
```

dffMult - Multiply a Denovo flux file by a constant factor.

Intended use: source strength change, change in units, etc.

Input: A Denovo flux file and a constant factor

Output: A Denovo flux file

Example:

```
=dffMult
"fluxes.dff"        ! existing Denovo flux file
10000.0             ! change units from (/cm^2/s) to (/m^2/s)
"multiplied.dff"    ! new Denovo flux file
end
```

dffPull - Pull fluxes from certain voxels out of a Denovo flux file.

Intended use: Get energy-dependent fluxes for certain locations from a flux file.

Input: A Denovo flux file and a list of positions and/or voxels

Output: Listing of energy-dependent fluxes from each desired location to an ASCII text file

---

Note: Can pull fluxes either by a physical coordinate position or by voxel indices.

Example:

```
=dffPull
"fluxes.dff"        ! file with the scalar fluxes you want
n                   ! number of x,y,z points to pull
x_1 y_1 z_1         ! coordinates of point 1
x_1 y_2 z_2         ! coordinates of point 2
...
x_n y_n z_n         ! coordinates of point n
m                   ! number of i,j,k voxels to pull
i_1 j_1 k_1         ! indices of voxel 1
i_2 j_2 k_2         ! indices of voxel 2
...
i_m j_m k_m         ! indices of voxel m
"outputName.txt"    ! name of output text file
=end
```

dffResp - Apply a response function to scalar fluxes in a Denovo flux file.

Intended use: Compute group-wise dose or reaction rates by combining a response function with the scalar fluxes. This can be done for every particle type in the flux file or a single specific particle type.

Input: A Denovo flux file, particle indicator and a group-wise response function

Output: A Denovo flux file

Note: 0-all particles, 1-neutron, 2-photon.

Example:

```
=dffResp
"fluxes.dff"          ! existing coupled Denovo flux file
1                     ! keep only neutron information
200                   ! number of bins in response
2.2675480E-04         ! response group 1
2.2283355E-04         ! response group 2
2.1878259E-04         ! response group 3
...
3.6748440E-06         ! response group nbins-2
3.6748443E-06         ! response group nbins-1
3.6748436E-06         ! response group nbins
"doses.dff"           ! new (smaller) Denovo flux fle
end
```

or

```
=dffResp
"fluxes.dff"          ! existing Denovo flux file
0                     ! keep all particles information
46                    ! number of bins in response
1.6151395E-04         ! response group 1, first neutron
1.4451494E-04         ! response group 2
1.2703618E-04         ! response group 3
...
3.6748447E-06         ! response group 27, last neutron
1.1620022E-05         ! response group 28, first photon
8.7445696E-06         ! response group 29
7.4596655E-06         ! response group 30
...
5.9327226E-07         ! response group 46, last photon
"doses.dff"           ! new Denovo flux file
end
```

dffSplit - Split off a single particle type from a Denovo flux file.

Intended use: Make a flux file containing a single particle type from another Denovo flux file.

Input: A Denovo flux file and a particle type

Output: A (smaller) Denovo flux file

Note: 1-neutron, 2-photon.

Example:

```
=dffSplit
"coupled.dff"     ! existing Denovo flux file
2                 ! particle type
"photons.dff"     ! new (smaller) Denovo flux file
end
```

4.3.4 UTILITIES FOR WORKING WITH DENOVO *.VARSCL (A TORT FORMAT) FILES

These utilities include the following:

vs2dff	Convert a varscl file into a Denovo flux file.
vsAdder	Add two TORT *.varscl files together into one *.varscl file.
vsBinOp	Binary operation of TORT *.varscl files: sum, difference, product and ratio.

continues on next page

Table 4.3.3 – continued from previous page

vsDisp	Display the basic contents of a TORT *.varscl file.
vsFilter	Perform various filters on a TORT *.varscl file.
vsInt	Integrate a single particle type from a TORT *.varscl file.
vsInv	Invert the values in a TORT *.varscl file.
vsMult	Multiply a TORT *.varscl file by a constant factor.
vsPull	Pull fluxes from certain voxels out of a TORT *.varscl file.
vsReGrp	Regroup a TORT *.varscl file.
vsResp	Apply a response function to scalar fluxes in a TORT *.varscl file.
vsSplit	Split off part of a TORT *.varscl file into a separate *.varscl file.

These utilities work with the *.varscl files produced with SCALE 6 and SCALE 6.1. The *.varscl format (a TORT format) is a single precision, binary format that has been replaced with the double precision, binary *.dff file (Denovo flux file) in SCALE 6.2. SCALE 6 and SCALE 6.1 users can request the executable binaries for these utilities by sending an email to scaleHelp@ornl.gov.

vs2dff - Convert a varscl file into a Denovo flux file.

Intended use: Convert a varscl file (used in previous versions of MAVRIC) into a Denovo flux file (introduced in SCALE 6.2).

Input: The *varscl file name, whether or not it is an adjoint flux, and the filename for the resulting denovoFluxfile

Output: A binary (stream) denovoFluxFile

Example:

```
=vs2dff
"mavricUtilities3.adjoint.varscl"        ! the TORT varscl file
true                                     ! it is an adjoint flux
"mavricUtilities3.adjoint.dff"           ! new denovoFluxFile
end
```

vsAdder - Add two TORT *.varscl files together into one *.varscl file.

Intended use: Beta versions of MAVRIC used TORT and GRTUNC-3D and could add the *.varscl files from each together before using them to create importance maps. MAVRIC now uses Denovo and no longer needs to add separate GRTUNC/TORT files. This utility is designed for people wishing to use the older files with the latest MAVRIC.

Input: Two *.varscl file names, typically one from GRTUNC-3D and the other from TORT, the filename of the added file, whether you want lots of output displayed ("true" or "false") and whether or not there is a minimum value of flux to use. If so, it is then listed.

Output: A single *.varscl with the specified name

Note: Addition is commutative, but not all varscl files are created equal. Do not mix up the GRTUNCL and the TORT files. GRTUNCL3D does not fill in the header info quite right, so the added varscl file takes header info only from the TORT varscl file.

Example:

```
=vsAdder
"/some/path/problem.gtunc.adjoint.varscl"
"/some/path/problem.tort.adjoint.varscl"
"total.varscl"
f
t
1.0e-25
end

=shell
  cp total.varscl ${RTNDIR}/total.varscl
end
```

vsBinOp - Binary operation of TORT *.varscl files: sum, difference, product and ratio.

Intended use: Apply simple math to the results stored in TORT *.varscl files.

Input: The first flux file, the operator: add (or sum, +), subtract (or difference, -), multiply (or product, x, *), and divide (or ratio, ÷, "/"), the second flux file name, and the name of the resulting flux file

Output: A TORT *.varscl file

Note: Flux files must have the same grid structure and number of groups. When using the / (slash) for division, enclose it in quotes ("/").

Example:

```
=vsBinOp
"neutron.varscl"     ! first operand
false                ! are these adjoint files?
divide               ! operation
"total.varscl"       ! second operand
"ratio.varscl"       ! output file name
end
```

vsDisp - Display the basic contents of a TORT *.varscl file.

Input: A TORT *.varscl file name and adjoint flag

Output: Text display

Examples:

```
=vsDisp
"some.varscl"            ! input TORT *.varscl filename
false                    ! is this an adjoint varscl?
end

=vsDisp
"some.varscl"            ! input TORT *.varscl filename
adjoint                  ! is this an adjoint varscl?
end
```

vsFilter - Perform various filters on a TORT *.varscl file.

Intended use: Keep fluxes in a *.varscl file where the flux or response meets a specified criterion.

Input: A TORT *.varscl file name, filter type, filter options, the output file name

Output: A TORT *.varscl file

Note: There are three basics types of filters: (0) flattening filter, (1) high-pass filter, (2) low-pass filter. For types 1 and 2, the criteria could be a computed response. The input list changes depending on the filter type and whether a response function is included. For no response function, use 0 for the number of groups.

Examples:

```
=vsFilter
"some.varscl"            ! input TORT *.varscl filename
false                    ! is this an adjoint varscl?
0                        ! filter type
"flattened.varscl"       ! output TORT *.varscl filename
end

=vsFilter
"some.varscl"            ! input TORT *.varscl filename
false                    ! is this an adjoint varscl?
2                        ! filter type
10.0                     ! maximum value
0                        ! number of groups for response function
"simpleFiltered.varscl"  ! output TORT *.varscl filename
end

=vsFilter
"some.varscl"            ! input TORT *.varscl filename
false                    ! is this an adjoint varscl?
1                        ! filter type
10.0                     ! minimum value
19                       ! number of groups for response function
1.1620022E-05            !   should match total groups in file
8.7445696E-06
7.4596655E-06
6.3505804E-06
5.3994922E-06
4.6016462E-06
3.9522688E-06
3.4588520E-06
3.0130868E-06
2.6200121E-06
2.1944491E-06
1.8269592E-06
1.5149031E-06
1.1595382E-06
8.7044964E-07
6.2187445E-07
3.7080767E-07
2.6877788E-07
5.9327226E-07
"respFiltered.varscl"    ! output TORT *.varscl filename
```

vsInt - Integrate a single particle type from a TORT *.varscl file.

Input: A TORT *.varscl file

Output: A single-group TORT *.varscl file

Example:

```
=vsInt
"coupled.varscl"       ! existing TORT *.varscl file
false                  ! is this an adjoint file?
2                      ! particle type (0-all, 1-neutron, 2-photon)
"photonTotal.varscl"   ! new TORT *.varscl file (single group)
end
```

vsInv - Invert the values in a TORT *.varscl file.

Input: A TORT *.varscl file

Output: A TORT *.varscl file

Note: Only non-zero values are inverted.

Example:

```
=vsInv
"fluxes.varscl"        ! existing TORT *.varscl file
false                  ! is this an adjoint file?
"inverted.varscl"      ! new TORT *.varscl file
end
```

vsMult - Multiply a TORT *.varscl file by a constant factor.

Intended use: source strength change, change in units, etc.

Input: A TORT *.varscl file and a constant factor

Output: A TORT *.varscl file

Example:

```
=vsMult
"fluxes.varscl"        ! existing TORT *.varscl file
false                  ! is this an adjoint file?
10000.0                ! change units from (/cm^2/s) to (/m^2/s)
"multiplied.varscl"    ! new TORT *.varscl file
end
```

vsPull - Pull fluxes from certain voxels out of a TORT *.varscl file.

Intended use: Get energy-dependent fluxes for certain locations from a flux file.

Input: A TORT *.varscl file and a list of positions and/or voxels

Output: Listing of energy-dependent fluxes from each desired location to an ASCII text file

---

Note: Can pull fluxes either by a physical coordinate position or by voxel indices.

Example:

```
=vsPull
"fluxes.varscl"    ! file with the scalar fluxes you want
false              ! is this an adjoint file?
n                  ! number of x,y,z points to pull
x_1 y_1 z_1        ! coordinates of point 1
x_1 y_2 z_2        ! coordinates of point 2
...
x_n y_n z_n        ! coordinates of point n
m                  ! number of i,j,k voxels to pull
i_1 j_1 k_1        ! indices of voxel 1
i_2 j_2 k_2        ! indices of voxel 2
...
i_m j_m k_m        ! indices of voxel m
"outputName.txt"   ! name of output text file
end
```

vsReGrp - Regroup a TORT *.varscl file.

Input: A TORT *.varscl file and adjoint flag, then a list of how the new groups should be formed from the old groups

Output: A smaller TORT *.varscl file

Example:

```
=vsReGrp
"coupled.varscl"       ! existing TORT *.varscl file
false                  ! is this an adjoint file?
27                     ! number of neutron groups in file
1                      ! new group assignment for each
1                      !     existing neutron group
1                      !   must start with one
2                      !   each entry is same as last or
...                    !     increases by 1
8                      ! new group assignment for neutron group 27
19                     ! number of photon groups in file
1                      ! new group assignment for each
1                      !     existing photon group
1                      !   must start with one
2                      !   each entry is same as last or
...                    !     increases by 1
4                      ! new group assignment for photon group 19
"smaller.varscl"       ! new TORT *.varscl file name
end
```

vsResp - Apply a response function to scalar fluxes in a TORT *.varscl file.

Intended use: Compute group-wise dose or reaction rates by combining a response function with the scalar fluxes.

Input: A TORT *.varscl file and a group-wise response function

Output: A TORT *.varscl file

Example:

```
=vsResp
"fluxes.varscl"       ! existing coupled TORT *.varscl file
false                 ! is this an adjoint file?
200                   ! number of bins in response
2.2675480E-04         ! response group 1
2.2283355E-04         ! response group 2
2.1878259E-04         ! response group 3
...
3.6748440E-06         ! response group 198
3.6748443E-06         ! response group 199
3.6748436E-06         ! response group 200
"doses.varscl"        ! new (smaller) Denovo flux fle
end
```

vsSplit - Split off part of a TORT *.varscl file into a separate *.varscl file.

Intended use: Make a flux file containing a single particle type from another TORT *.varscl file.

Input: A TORT *.varscl file and a particle type

Output: A (smaller) TORT *.varscl file

Example:

```
=vsSplit
"coupled.varscl"     ! existing TORT *.varscl file
false                ! is this an adjoint file?
2                    ! particle type (1-neutron, 2-photon)
"photons.varscl"     ! new (smaller) TORT *.varscl file
end
```

4.3.5 MISCELLANEOUS UTILITIES

These utilities include the following:

dsi2asc	Convert a Denovo simple input (*.dsi) from binary to ASCII.
dsiDisp	Display the basics of a Denovo simple input file.
dso2msl	Use a Denovo spatial output to create a mesh source lite.
dsoDisp	Display the basics of a Denovo spatial output file.
mim2wwinp	Convert a mesh importance map into an MCNP weight window file.
mimDisp	Display the basics of a mesh importance map (*.mim) file.
mimNorm	Normalize a mesh importance map to a given location/energy.
msmDisp	Display the basics of a mesh source map (*.msm) file.

dsi2asc - Convert a Denovo simple input (*.dsi) from binary to ASCII.

Intended use: Check a Denovo input file for correctness.

Input: Names of original binary Denovo simple input (*.dsi) file and the desired ASCII text file

Output: Human-readable form of the Denovo input file

Example:

```
=dsi2asc
"input.dsi"    ! Denovo simple input file (binary)
"ascii.txt"    ! new ascii text file
end
```

dsiDisp - Display the basics of a Denovo simple input file.

Input: A Denovo simple input (*.dsi) file

Output: Some of the basic details of the Denovo simple input file

Example:

```
=dsiDisp
"godiva.dsi"          ! existing Denovo simple input file
end
```

dso2msl - Use a Denovo spatial output to create a mesh source lite.

Input: A *.dso file is made of three-dimensional data sets called fields. Which field to convert? 1-n: convert that field 0: convert sum of all fields

Output: A mesh source lite (*.msl) file for KENO-VI.

Example:

```
=dso2msl
"fisSource.dso"  ! Denovo spatial output file with many fields
1                ! which field to use
"test.msl"       ! new Monaco mesh source lite
end
```

dsoDisp - Display the basics of a Denovo spatial output file.

Input: A Denovo spatial output (*.dsi) file

Output: Some of the basic details of the Denovo spatial output file

Example:

```
=dsoDisp
"godiva.dso"          ! existing Denovo spatial output file
end
```

mim2wwinp - Convert a mesh importance map into an MCNP weight window file.

Intended Use: To create an MCNP weight window file from a Monaco mesh importance map file outside of a MAVRIC calculation. Monaco mesh importance map files store target weights, but MCNP wwinp files store lower weight bounds. To convert, the user needs to supply the windowRatio, r (the ratio of the upper weight bound for splitting to the lower weight bound for roulette). Target weights, t, are the average of the upper, u, and lower, l, weight window bounds, so l=2t/(r+1). For example, for a Monaco target weight of 1.0 and a windowRatio of 10.0, the MCNP lower weight bound will be l=2(1.0)/(10.0+1)=0.1818. To reduce the size of the map, the user can specify which neutron and photon groups to store in the new file. If the last group is less than the first group, no groups of that particle will be stored.

Input:

Line 1: filename of the Monaco mesh importance map file
Line 2: windowRatio (>1.0)
Line 3: first_neutron_group last_neutron_group
Line 4: first_photon_group last_photon_group
Line 5: filename of the MCNP weight window input file

Output: The resulting weight window input file stored with the desired filename

---

Note: Geometry information in the Monaco mesh importance map file is lost since the MCNP wwinp format does not support it.

Example:

```
=mim2wwinp
"/scale/smplprbs/mavric.graphiteCADIS.mim"  ! importance map
19.0                                        ! window ratio
5 22                                        ! save n groups 5-22
19 1                                        ! save no p groups
"/scale/test9/testmimww.wwinp"              ! new file
end
```

mimDisp - Display the basics of a mesh importance map file.

Input: A mesh importance map (*.mim) file

Output: Some of the basic details of mesh importance map file

Example:

```
=mimDisp
"the.mim"    ! existing mesh importance map file
end
```

mimNorm - Normalize a mesh importance map to a given location/energy.

Input: A mesh importance map (*.mim) file, a location (x, y, z), a particle type and energy, and a filename for the normalized map file. Use 1 for neutron and 2 for photon. Energy should be in eV. The new importance map file will be normalized such that the given location/energy has a target weight of 1. If a particle type or energy is 0, then the energy group with the minimum non-zero target value at the given location will be the group that is set to 1.0 in the new file. (This option is similar to the MCNP weight window generator.)

Output: A mesh importance map file

Example:

```
=mimNorm
"the.mim"       ! existing mesh importance map file
27.5 -16.5 32.0 ! location
1 1.0e6         ! neutron, 1 MeV
"normed.mim"    ! new file that is normalized
end
```

msmDisp - Display the basics of a mesh source map file.

Input: A mesh source map (*.msm) file

Output: Some of the basic details of mesh source map file

Example:

```
=msmDisp
"the.msm"    ! existing mesh source map file
```

4.4 MAVRIC ADVANCED FEATURES

This appendix contains information on several advanced features that are still under development or are non-standard use of the MAVRIC sequence.

4.4.1 ALTERNATE NORMALIZATION OF THE IMPORTANCE MAP AND BIASED SOURCE

The importance map and biased source implemented in MAVRIC are only functions of space and energy. The importance for a specific location and energy represents the average over all directions. For applications involving a collimated beam source, a space/energy importance map may not be representative of the true importance of the particles as they stream away from the source.

As an example, consider a 14.1 MeV active interrogation beam source 1 meter from a small spherical boat containing illicit nuclear material. The objective is to compute the fission rate in the nuclear material. To create the biasing parameters, an adjoint source is located within the nuclear material and the resulting importance map is shown in Fig. 4.4.1. Note that in both the air and water, the importances change with

distance from the ship, but for the beam source, the importance (to causing a fission in the nuclear material) anywhere along the beam should be the same, since there is little chance a 14.1 MeV neutron will interact with the air before striking the ship.

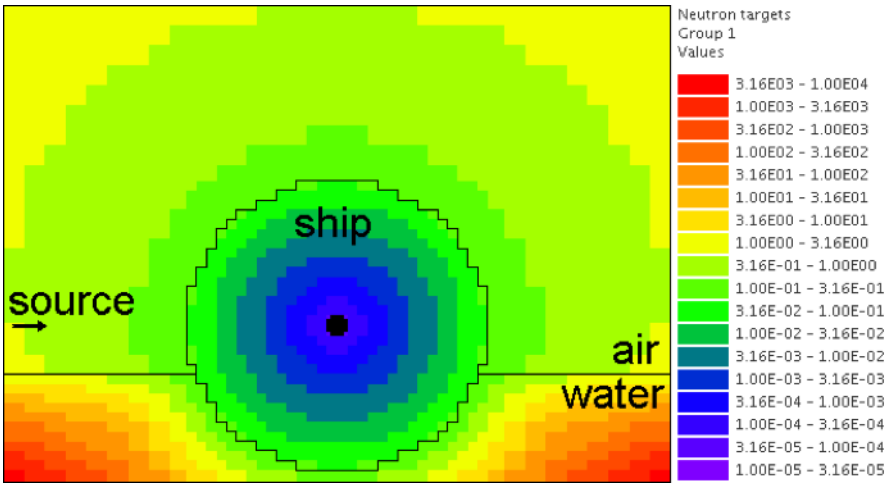

Fig. 4.4.1: Importance map computed using standard CADIS.

The CADIS algorithm has done exactly what it was supposed to: it made a space/energy importance map and normalized it such that the target weight where the 14.1 MeV source particles are born is 1. The problem with this is that the source particles will stream towards the ship and strike the hull where the target weight is 0.092. Since source particles have little chance of interacting in the air, the weight windows are not used to split the particle as they travel towards the ship. When source particles cross into the ship, they are split by a factor of 11 to match the target weight. For this example, splitting each particle by a factor of 11 once they strike the ship is not so bad, but for longer distances, this will result in much larger splits. For a polyenergetic source, this could lead to undersampling of the source and could result in higher variances.

To remedy this problem when using beam sources, the normalization of the importance map and biased source should not be done at the source location but instead at the point where the source particles first interact with the ship. The keyword “shiftNormPos ΔDelta`y ΔDelta`x, ΔDelta`z when the biased source and importance map are developed. For the Monaco Monte Carlo calculation, the source is returned to its normal position. The source input for the above problem would then be

```
read sources
    src 1
        title="14.1 DT neutrons - collimated"
        strength=1e30
'       (true source position)
        sphere 0 origin x=-195 y=0 z=0
'       (a mono-energetic 14.1 MeV distribution)
        eDistributionID=1
        direction 1.0 0.0 0.0
'       (a 2° beam )
        dDistributionID=2
'       (just inside the hull)
        shiftNormPos 107.7 0.0 0.0
    end src
end sources
```

where the shift moves the source position from x = -195 to x = -87.3, just inside the hull. The resulting target weights are shown in Fig. 4.4.2 The source particles are born with weight 1 in a location with a target weight

10.9. The particle weight is not checked until the particle crosses into the hull, where the target weight is 1.0.

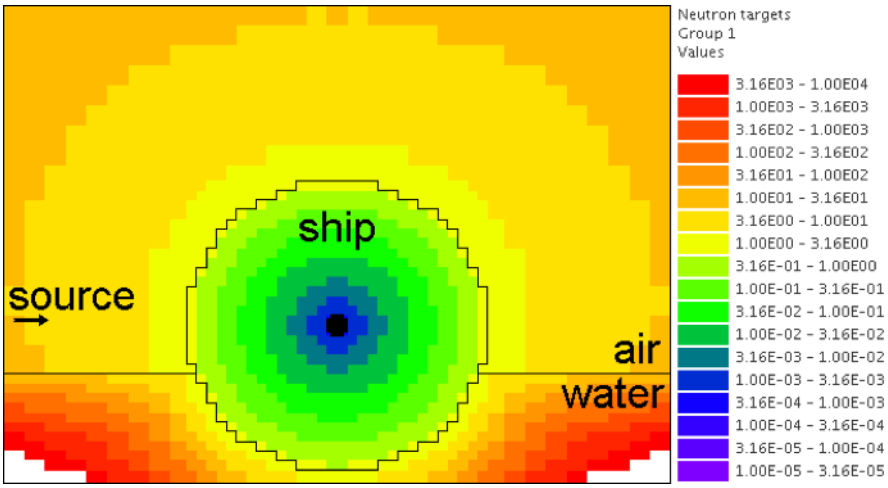

Fig. 4.4.2: Targets weights using the "shiftNormPos" keyword.

Other options to manipulate the importance map for special situations include the "mapMultiplier=*f*" keyword (in the importanceMap block or the biasing block), which will multiply every target weight by the factor *f*, and the keyword "noCheckAtBirth" in the parameters block will prevent the weight windows from being applied to source particles when they are started. When used in the MAVRIC sequence, the "shiftNormPos" capability automatically adds "noCheckAtBirth" to the Monaco input that is created.

4.4.2 IMPORTANCE MAPS WITH DIRECTIONAL INFORMATION

In MAVRIC, the CADIS method is implemented in space and energy, but in general, it could also include particle direction as well. This formulation would be the following:

True source:

$$q\left(\vec{r}, E, \widehat{\Omega}\right) \tag{4.4.1}$$

Desired response:

$$\sigma\left(\vec{r}, E, \widehat{\Omega}\right) \tag{4.4.2}$$

Adjoint flux using $q^{+}\left(\vec{r}, E, \widehat{\Omega}\right) = \sigma\left(\vec{r}, E, \widehat{\Omega}\right)$:

$$\psi^{+}\left(\vec{r}, E, \widehat{\Omega}\right) \tag{4.4.3}$$

Estimate of detector response

$$R = \iiint q(\vec{r}, E, \widehat{\Omega})\psi^{+}(\vec{r}, E, \widehat{\Omega}) d\Omega dE dV \tag{4.4.4}$$

Biased source:

$$\widehat{q}\left(\vec{r}, E, \widehat{\Omega}\right) = \frac{1}{R} q\left(\vec{r}, E, \widehat{\Omega}\right) \psi^{+}\left(\vec{r}, E, \widehat{\Omega}\right) \tag{4.4.5}$$

Target weight windows:

$$\overline{w}\left(\vec{r}, E, \widehat{\Omega}\right) = \frac{R}{\psi^{+}\left(\vec{r}, E, \widehat{\Omega}\right)} \tag{4.4.6}$$

For a system using a deterministic method to compute the adjoint fluxes, this completely general, space/energy/angle, approach presents many difficulties in implementation, namely,

a. dealing with the amount of memory required for a $\left(\vec{r}, E, \widehat{\Omega}\right)$ importance map in memory,

b. interpolating the importance for particle directions in between quadrature angles, and

c. expressing the biased source in a form suitable for a general MC code since the above biased source is, in general, not separable.

4.4.2.1 Approaches incorporating directional information

Completely general space/energy/angle CADIS is most likely too difficult to implement and may not be necessary for most applications. In most real problems that involve directionally dependent source distributions, the directional dependence is azimuthally symmetric about some reference direction, $\widehat{d}$. The angular distribution, $q_i\left(\widehat{\Omega}\right)$, can be expressed as the product of the uniform azimuthal distribution and a polar distribution about reference direction $\widehat{d_i}$ giving $\frac{1}{2\pi} q_i\left(\widehat{\Omega} \bullet \widehat{d_i}\right)$. The geometric size of these sources tends to be small, allowing each source distribution to be expressed as the product of two separable distributions: $q_i\left(\vec{r}, E, \widehat{\Omega}\right) \cong q_i\left(\vec{r}, E\right)\ q_i\left(\widehat{\Omega}\right)$.

What is needed is a CADIS method that (1) can account for the importance of a particle traveling in a certain direction; (2) can be cast as a simple modification of the space/energy CADIS method using $\overline{w}\left(\vec{r}, E\right)$ and $\widehat{q}\left(\vec{r}, E\right)$; and (3) is simpler than the full space/angle/energy approach. This can be done starting with the approximation that the angular component of the adjoint flux $\psi^{+}\left(\vec{r}, E, \widehat{\Omega}\right)$ is separable and symmetric about the average adjoint current direction $\widehat{n}\left(\vec{r}, E\right)$, such that

$$\psi^{+}\left(\vec{r}, E, \widehat{\Omega}\right) \cong \phi^{+}\left(\vec{r}, E\right)\ \frac{1}{2\pi} f\left(\widehat{\Omega} \bullet \widehat{n}\right)\ . \tag{4.4.7}$$

This is similar to the AVATAR approach [MAV-AppC-VRUS97] but with explicitly including the azimuthal distribution so that the standard definition $\int \phi^{+}\left(\vec{r}, E\right)\ \frac{1}{2\pi} f\left(\widehat{\Omega} \bullet \widehat{n}\right)\ d\widehat{\Omega} = \phi^{+}\left(\vec{r}, E\right)$ applies. The probability distribution function $f(\mu)$ describing the shape of the azimuthally symmetric current at $\left(\vec{r}, E\right)$ has the form of

$$f(\mu) = \frac{\lambda e^{\lambda\mu}}{2\sinh(\lambda)}, \tag{4.4.8}$$

with the single parameter $\lambda\left(\vec{r}, E\right)$ determined from $\overline{\mu}\left(\vec{r}, E\right)$, the average cosine of scatter.

From this, we can propose that weight window targets be developed that are inversely proportional to the approximation of the adjoint angular flux:

$$\overline{w}\left(\vec{r}, E, \widehat{\Omega}\right) = \frac{2\pi\ k}{\phi^{+}\left(\vec{r}, E\right)\ \ f\left(\widehat{\Omega} \bullet \widehat{n}\right)}\ , \tag{4.4.9}$$

where k is the constant of proportionality that will be adjusted to make the importance map consistent with the biased source(s). Two methods will be examined here, one without and one with biasing of the source directional dependence.

For both of the methods, the S_N code Denovo was modified to report not only the adjoint scalar fluxes, $\phi^+\left(\vec{r},E\right)$, but also the adjoint net currents in x, y, and z directions: $J_x\left(\vec{r},E\right)$, $J_y\left(\vec{r},E\right)$, and $J_z\left(\vec{r},E\right)$. These currents are used to find $\widehat{n}\left(\vec{r},E\right)$ and $\lambda\left(\vec{r},E\right)$. The following methods have been developed so that the standard CADIS routines can be used to compute space/energy quantities of the response per unit source R, the weight window target values $\overline{w}\left(\vec{r},E\right)$, and biased source $\widehat{q}\left(\vec{r},E\right)$ with just the adjoint scalar fluxes. These quantities are then modified by the directional information.

4.4.2.2 Directionally dependent weight windows without directional source biasing

It is proposed that the biased source $\widehat{q}\left(\vec{r},E,\widehat{\Omega}\right)$ should be proportional to both the true source distribution and the space/energy component of the adjoint flux:

$$\widehat{q}\left(\vec{r},E,\widehat{\Omega}\right)=\frac{1}{R}\left[q\left(\vec{r},E\right)\ \frac{1}{2\pi}q\left(\widehat{\Omega}\bullet\widehat{d}\right)\right]\ \phi^+\left(\vec{r},E\right)\ , \tag{4.4.10}$$

where the constant of proportionality, R, is determined by forcing $\widehat{q}\left(\vec{r},E,\widehat{\Omega}\right)$ to be a pdf. Since the angular component of the adjoint flux is not included, the directional distribution of the biased source will be exactly the same as the true source. Note that this approach would be exact for cases where no directional biasing could be applied — beam sources.

For multiple sources (each with a probability distribution function $q_i\left(\vec{r},E\right)$ and a strength S_i, giving a total source strength of $S=\sum S_i$), the user is required to provide one point in phase space $\left(\vec{r}_i,E_i,\widehat{\Omega}_i\right)$ for each source i that is representative of that entire source where the biased source will match the target weight windows. For each source, a vector $\widehat{n}_i=\widehat{n}\left(\vec{r}_i,E_i\right)$ is computed using that point. For the general case of multiple sources, the biased source sampling distribution, the biased source distributions, and the weight windows are computed using

$R_i=\iint q_i\left(\vec{r},E\right)\ \phi^+\left(\vec{r},E\right)dE\ dr$ (estimated response from source i)

$\widehat{p}\left(i\right)=\frac{S_iR_i\ f\left(\widehat{\Omega}_i\bullet\widehat{n}_i\right)}{\sum S_iR_i\ f\left(\widehat{\Omega}_i\bullet\widehat{n}_i\right)}$ (biased sampling of source i)

$$\widehat{q}_i\left(\vec{r},E,\widehat{\Omega}\right)\ =\ \tfrac{1}{R_i}q_i\left(\vec{r},E\right)\ \phi^+\left(\vec{r},E\right)\ \tfrac{1}{2\pi}q_i\left(\widehat{\Omega}\bullet\widehat{d}_i\right)\ =\ \widehat{q}_i\left(\vec{r},E\right)\ \tfrac{1}{2\pi}q_i\left(\widehat{\Omega}\bullet\widehat{d}_i\right)$$

$$\overline{w}\left(\vec{r},E,\widehat{\Omega}\right)\ \ =\ \ \frac{\sum S_iR_i\ f\left(\widehat{\Omega}_i\bullet\widehat{n}_i\right)}{S\phi^+\left(\vec{r},E\right)}\frac{1}{f\left(\widehat{\Omega}\bullet\widehat{n}\right)}\ \ =\ \ \frac{\sum S_iR_i\ f\left(\widehat{\Omega}_i\bullet\widehat{n}_i\right)}{\sum S_iR_i}\overline{w}\left(\vec{r},E\right)\frac{1}{f\left(\widehat{\Omega}\bullet\widehat{n}\right)}$$

4.4.2.3 Directionally dependent weight windows with directional source biasing

Here it is proposed that the biased source be proportional to both the true source distribution and the approximation of the adjoint angular flux. With a small geometric source, it is also assumed that there is one vector, $\widehat{n}_0=\widehat{n}\left(\vec{r}_0,E_0\right)$, evaluated at a specific location and energy, which represents the adjoint current direction over that source. The biased source then looks like

$$\begin{aligned}\widehat{q}\left(\vec{r},E,\widehat{\Omega}\right)&=\frac{1}{\mathrm{Rc}}q\left(\vec{r},E,\widehat{\Omega}\right)\ \psi^+\left(\vec{r},E,\widehat{\Omega}\right)\\&=\frac{1}{\mathrm{Rc}}\left[q\left(\vec{r},E\right)\ \frac{1}{2\pi}q\left(\widehat{\Omega}\bullet\widehat{d}_i\right)\right]\left[\phi^+\left(\vec{r},E\right)\ \frac{1}{2\pi}\ f\left(\widehat{\Omega}\bullet\widehat{n}_0\right)\right]\ ,\end{aligned} \tag{4.4.11}$$

where the constant Rc is used to make $\widehat{q}$ a pdf. Note that if either the original source directional distribution $q\left(\widehat{\Omega}\right)$ or the adjoint angular flux distribution at the source is isotropic, then $c=\frac{1}{4\pi}$.

For the general case of multiple sources, the biased source sampling distribution, the biased source distributions and the weight windows are

$$R_i = \iint q_i\left(\vec{r}, E\right)\ \phi^+\left(\vec{r}, E\right)\mathrm{dE\ dr} \tag{4.4.12}$$

$$c_i = \int \frac{1}{2\pi} q_i\left(\widehat{\Omega} \bullet \widehat{d_i}\right)\ \frac{1}{2\pi} f\left(\widehat{\Omega} \bullet \widehat{n_i}\right) d\widehat{\Omega} \tag{4.4.13}$$

$$\widehat{p}\,(i) = \frac{S_i R_i c_i}{\sum S_i R_i c_i} \tag{4.4.14}$$

$$\begin{aligned} \widehat{q_i}\left(\vec{r}, E, \widehat{\Omega}\right) &= \left[\frac{1}{R_i}\ q_i\left(\vec{r}, E\right)\ \phi^+\left(\vec{r}, E\right)\right]\left[\frac{1}{c_i}\ q_i\left(\widehat{\Omega}\right)\ f\left(\widehat{\Omega}\right)\right] \\ &= \widehat{q_i}\left(\vec{r}, E\right)\ \frac{1}{c_i}\ \frac{1}{2\pi} q_i\left(\widehat{\Omega} \bullet \widehat{d_i}\right)\ \frac{1}{2\pi} f\left(\widehat{\Omega} \bullet \widehat{n_i}\right) \end{aligned} \tag{4.4.15}$$

$$\begin{aligned} \overline{w}\left(\vec{r}, E, \widehat{\Omega}\right) &= \frac{\sum S_i R_i c_i}{S\,\phi^+\left(\vec{r}, E\right)}\ \frac{2\pi}{f\left(\widehat{\Omega} \bullet \widehat{n}\right)} \\ &= \frac{\sum S_i R_i c_i}{\sum S_i R_i}\ \overline{w}\left(\vec{r}, E\right)\ \frac{2\pi}{f\left(\widehat{\Omega} \bullet \widehat{n}\right)}\,. \end{aligned} \tag{4.4.16}$$

More details on the development of these methods and their application for several problems have been presented [MAV-AppC-PME12, MAV-AppC-PMEW10].

4.4.2.4 Using space/energy/angle CADIS in MAVRIC

The two angular CADIS methods that use the AVATAR-type approximation of adjoint flux are specified in MAVRIC with the "angularBiasing=" keyword in the importanceMap block. Values for this keyword are 1 or 2.

Space/Energy/Angle CADIS without directional biasing (for beam sources) — This method uses one specific location, $\vec{r}_0$, energy, E_0, and direction, $\widehat{\Omega}_0$, which is the reference direction of the source $\widehat{d}$, where the weight of the biased source matches the weight window.

Space/Energy/Angle CADIS with directional biasing (for general sources) — This method uses one specific energy, E_0, to determine the adjoint current vector $\widehat{n}_0$ and the λ_0 parameter for the biased angular distribution for each source.

With each method, the user must specify at what energy the importance map and the biased sources should be made consistent. The particle type must also be specified. This is done with the keywords "angBiasParType=" (1 for neutron or 2 for photon) and "angBiasEnergy=" (with a value in eV), also in the importanceMap block.

Note that all sources should have a direction $\widehat{d}$ set, using "direction *u v w*" within each source, even if the angular distribution for a given source is isotropic. The direction is used for source biasing and for aligning the weight windows and biased sources. Also note that for either angular biasing method, the Denovo S_N calculation must use a Legendre order greater than 0.

With angular biasing, a mesh angular information (*.mai) file is produced which can be visualized with the MeshFileViewer. This file contains the space/energy-dependent $\lambda\left(\vec{r}, E\right)$ values and components of the average adjoint current direction $\widehat{n}\left(\vec{r}, E\right) = \left\langle n_x, n_y, n_z\right\rangle$. An existing mesh angular information (*.mai) file can be used in a separate MAVRIC problem by using the "meshAngInfoFile=" keyword in the biasing block.

4.4.2.5 Example problem

Consider the Ueki shielding problem used as sample problems in the Monaco and MAVRIC manuals. The goal is to calculate the neutron dose on one side of a shield from a partially collimated ^{252}Cf source on the other side of the shield. Both of the angular approaches discussed above can be compared to analog and standard space/energy CADIS calculations. For the analog calculations, no importanceMap block is used. For the other cases, the importance map blocks are shown below.

CADIS

```
read importanceMap
    adjointSource 1
        locationID=1
        responseID=5
    end adjointSource
    gridGeometryID=7
    macromaterial
      mmTolerance=0.01
    end macromaterial

end importanceMap
```

Angular CADIS 1 - without a biased source angular dist.

```
read importanceMap
    adjointSource 1
        locationID=1
        responseID=5
    end adjointSource
    gridGeometryID=7
    macromaterial
      mmTolerance=0.01
    end macromaterial

    angularbiasing=1
    angBiasParType=1
    angBiasEnergy=2.0e6
end importanceMap
```

Angular CADIS 2 - with a biased source angular dist.

```
read importanceMap
    adjointSource 1
        locationID=1
        responseID=5
    end adjointSource
    gridGeometryID=7
    macromaterial
      mmTolerance=0.01
    end macromaterial

    angularbiasing=2
    angBiasParType=1
    angBiasEnergy=2.0e6
end importanceMap
```

Note that the energy at which to tie the importance map to the biased source, 2 MeV, is about the average energy of the source energy distribution. The figure-of-merit (FOM) of the calculation could change as this parameter is varied.

Results, shown in Table 4.4.1, demonstrate that the two directional approaches improved the FOM for this problem by more than a factor of 2. A larger boost is seen in method 2 where biasing is applied to the source directional distribution. In this case, the biased source distribution was an exponential distribution with a power of 2.45, significantly sampling more source neutrons in the direction of the shield than into the paraffin collimator block.

Note that the space/energy/angle CADIS methods require more memory to hold the importance information. Improvements to the CADIS calculation can also be made with a judicious choice of standard source direction biasing, without an increase in memory requirements. A simple distribution (where $\mu = 0.924$ represents the edge of the cone cutout and $\mu = 0.974$ is the center half of the shield dimension) added that to the source

```
distribution 2
    abscissa -1.0     0.924    .974   1.0 end
    truepdf      0.962     0.025   .013   end
    biasedpdf    0.500     0.250  0.250   end
end distribution

src 1
    neutrons  strength=4.05E+07
    cuboid  0.01 0.01  0 0  0 0
    eDistributionID=1
    direction 1.0 0.0 0.0
    dDistributionID=2
end src
```

results in an FOM improvement of nearly 3 over the standard CADIS without the overhead of the angular CADIS methods.

Table 4.4.1: Results of the Ueki Shielding Problem (35 cm graphite shield)

Calculation Method	Adj. S_N (min)	MC (min)	dose rate (rem/hr)	relative uncert	MC FOM (/min)
Analog	0.0	152.7	3.998E-03	0.0101	64.7
CADIS	0.2	9.9	3.998E-03	0.0081	1550
Directional CADIS 1, no src bias	0.2	10.3	4.035E-03	0.0054	3390
Directional CADIS 2, with src bias	0.2	10.0	4.012E-03	0.0049	4190
CADIS, standard src dir. bias	0.2	10.0	3.998E-03	0.0047	4550

A series of problems was used to compare the space/energy/angle CADIS to the standard space/energy CADIS. Most of the problems saw an improvement of a factor of about 2 or 3. Some problems did not improve at all, and some photon problems actually performed worse. In that case (a photon litho-density gauge), it could be that the angular approximation for importance, an exponential function in μ, cannot adequately describe the true importance.

Since the space/energy/angle CADIS methods are more difficult to explain (more theory, adjustable parameters set by the user), require more memory than standard CADIS, and may not offer any improvement over standard space/energy CADIS, they have not been made part of the main MAVRIC manual and have been left as an advanced/developing feature. These methods were not removed from the MAVRIC code since they may be helpful to future problems.

4.4.3 UNIVERSITY OF MICHIGAN METHODS FOR GLOBAL VARIANCE REDUCTION

The use of hybrid deterministic/Monte Carlo methods, particularly for global variance reduction, has been an active area of research by the transport team at the University of Michigan for a long time. One of the first approaches studied was a way to develop Monte Carlo weight window target values that were proportional to deterministically estimated values of the forward flux [MAV-AppC-CL01]. For global problems using isotropic weight windows, this reference argues that in order to get uniform relative uncertainties in the Monte Carlo calculation, the weight windows should be set such that the number density of Monte Carlo particles, $m\left(\overrightarrow{r}\right)$, is constant. The physical particle density, $n\left(\overrightarrow{r}\right)$, is related by the average weight, $\overline{w}\left(\overrightarrow{r}\right)$, to the Monte Carlo particle density by

$$n\left(\overrightarrow{r}\right) = \overline{w}\left(\overrightarrow{r}\right)\, m\left(\overrightarrow{r}\right) \ . \tag{4.4.17}$$

To make $m\left(\overrightarrow{r}\right)$ constant over the geometry, the weight window targets $\overline{w}\left(\overrightarrow{r}\right)$ need to be proportional to the physical particle density. Cooper and Larsen calculate the weight window targets from an estimate of the forward scalar flux $\phi\left(\overrightarrow{r}\right)$ to be

$$\overline{w}\left(\overrightarrow{r}\right) = \frac{\phi\left(\overrightarrow{r}\right)}{\max\left(\phi\left(\overrightarrow{r}\right)\right)} \ . \tag{4.4.18}$$

Two approaches have since been developed [MAV-AppC-BL09], based on what global information the user desires from the simulation: global flux weight windows, for obtaining every energy group at every location, and global response weight windows, for obtaining an energy-integrated response at every spatial location. Both of these methods are designed for calculating the "global solution" — everywhere in the geometry of the problem — with nearly uniform statistics.

Note that none of the University of Michigan methods discussed here included the development of biased sources. These methods have all been extended to include a consistent biased source by ORNL during their implementation in the MAVRIC sequence of SCALE. The methods have also been extended by ORNL for multiple sources.

4.4.3.1 Weight windows using only forward estimates of flux

Global flux weight windows

This method keeps the Monte Carlo particle distribution uniform in space and energy. Note that this is a space/energy version of the original space-only Cooper's Method. The target weight windows, $\overline{w}\left(\overrightarrow{r}, E\right)$, should be proportional to the estimate of the forward scalar flux, $\phi\left(\overrightarrow{r}, E\right)$.

$$\overline{w}\left(\overrightarrow{r}, E\right) = c\, \phi\left(\overrightarrow{r}, E\right) \ . \tag{4.4.19}$$

A biased source distribution, $\widehat{q}\left(\overrightarrow{r}, E\right)$, that is consistent with the target weight windows can be found from the true source distribution, $q\left(\overrightarrow{r}, E\right)$, and the forward flux to be

$$\widehat{q}\left(\overrightarrow{r}, E\right) = \frac{1}{c}\, \frac{q\left(\overrightarrow{r}, E\right)}{\phi\left(\overrightarrow{r}, E\right)} \ , \tag{4.4.20}$$

where the constant c can be determined so that the biased source distribution is a probability distribution function,

$$c = \int_V \int_E \frac{q\left(\overrightarrow{r}, E\right)}{\phi\left(\overrightarrow{r}, E\right)} \, \mathrm{dE}\, d\overrightarrow{r} \ . \tag{4.4.21}$$

Thus, using the estimate of forward flux, we can first compute c and then form a consistent set of weight window target values and a biased source distribution.

Global response weight windows

For an energy-integrated response (such as dose) desired at all spatial locations, this method keeps the Monte Carlo particle distribution proportional to the integral of the product of the response function, $\sigma_d\left(\overrightarrow{r},E\right)$, and the estimate of the forward flux, $\phi\left(\overrightarrow{r},E\right)$. The energy-integrated response, $D\left(\overrightarrow{r}\right)$, is found from the estimate of the forward flux as

$$D\left(\overrightarrow{r}\right)=\int_E \sigma_d\left(\overrightarrow{r},E\right)\ \phi\left(\overrightarrow{r},E\right)DE. \tag{4.4.22}$$

The target weight windows, $\overline{w}\left(\overrightarrow{r},E\right)$, should be

$$\overline{w}\left(\overrightarrow{r},E\right)=c\ \frac{D\left(\overrightarrow{r}\right)}{\sigma_d\left(\overrightarrow{r},E\right)}\ . \tag{4.4.23}$$

A biased source distribution, $\widehat{q}\left(\overrightarrow{r},E\right)$, that is consistent with the target weight windows can be found from the true source distribution, $q\left(\overrightarrow{r},E\right)$, and the forward dose estimate to be

$$\widehat{q}\left(\overrightarrow{r},E\right)=\ \frac{1}{c}\ \frac{q\left(\overrightarrow{r},E\right)\ \sigma_d\left(\overrightarrow{r},E\right)}{D\left(\overrightarrow{r}\right)} \tag{4.4.24}$$

using a proportionality constant of

$$c=\int_V \frac{1}{D\left(\overrightarrow{r}\right)}\int_E q\left(\overrightarrow{r},E\right)\ \sigma_d\left(\overrightarrow{r},E\right)\ \mathrm{dE}\ d\overrightarrow{r}\ . \tag{4.4.25}$$

Implementation in MAVRIC

The global flux weight windows (GFWW) approach and the global response weight windows (GRWW) are both triggered by specifying an importance map block without any adjoint sources. For the GRWW approach, the response of interest is listed in the importance map block. If none is listed, GFWW is used.

For problems with multiple sources (each with probability distribution function $q_i\left(\overrightarrow{r},E\right)$ and strength S_i, giving a total source strength of $S=\sum S_i$), the GWW methods require a biased mesh source for each. This was implemented in MAVRIC in a manner similar to the multiple source CADIS routines. Each biased source, $\widehat{q_i}\left(\overrightarrow{r},E\right)$, is developed as

$$\widehat{q_i}\left(\vec{r},E\right)=\begin{cases}\frac{1}{c_i}\frac{q_i\left(\vec{r},E\right)}{\phi\left(\vec{r},E\right)} & \text{global flux weight windows}\\ \frac{1}{c_i}\frac{q_i\left(\vec{r},E\right)\sigma_d\left(\vec{r},E\right)}{D\left(\vec{r}\right)} & \text{global response weight windows}\end{cases} \tag{4.4.26}$$

where c_i is a normalization constant. The weight windows are then set to

$$\overline{w}\left(\overrightarrow{r},E\right)=\begin{cases}\frac{\sum c_i}{\sum S_i}\ \phi\left(\overrightarrow{r},E\right) & \text{global flux weight windows}\\ \frac{\sum c_i}{\sum S_i}\ \frac{D\left(\overrightarrow{r}\right)}{\sigma_d\left(\overrightarrow{r},E\right)} & \text{global response weight windows}\end{cases}\ . \tag{4.4.27}$$

In the final Monte Carlo, the specific source i is sampled with probability $p(i) = S_i/S$, and then the particle is sampled from the biased mesh source $\widehat{q_i}\left(\overrightarrow{r}, E\right)$. Unlike the CADIS method for multiple sources, there is no way to develop a biased probability distribution for which source to sample without knowing the contribution to the global estimate from each source separately.

For multiple source problems where the expected contribution from each source is very different from the true strengths of those sources, it may be more efficient to run a series of problems with one source each for different amounts of time. The resulting mesh tallies can then be added together using the mesh tally adder (part of the MAVRIC utilities).

4.4.3.2 Methods using forward and adjoint estimates

Becker [MAV-AppC-Bec09] proposed three methods for developing weight windows based on both forward and adjoint deterministic solutions. These three methods correspond to the portion of the phase space over which uniform relative uncertainties are desired: a small "detector" region, a region comprising a significant portion of the entire problem, and the global problem. In this discussion, only a brief outline of each method, focusing on its implementation into MAVRIC, will be given.

Source/detector problems

For a small detector of volume $V_D$where we want to optimize the MC calculation of the detector response

$$R = \int_{V_D} \int_0^\infty \sigma\left(\overrightarrow{r}, E\right)\ \phi\left(\overrightarrow{r}, E\right)\text{dE dV} \tag{4.4.28}$$

or optimize for the energy dependent flux at the detector, the following is used:

forward flux estimate

$$\phi\left(\overrightarrow{r}, E\right) \tag{4.4.29}$$

adjoint source for flux

$$q^+\left(\overrightarrow{r}, E\right) = \frac{1}{\phi\left(\overrightarrow{r}, E\right)} \tag{4.4.30}$$

or for response

$$q^+\left(\overrightarrow{r}, E\right) = \sigma\left(\overrightarrow{r}, E\right) \tag{4.4.31}$$

adjoint flux

$$\phi^+\left(\overrightarrow{r}, E\right) \tag{4.4.32}$$

contributon flux

$$\phi^c\left(\overrightarrow{r}, E\right) = \phi\left(\overrightarrow{r}, E\right)\ \phi^+\left(\overrightarrow{r}, E\right) \tag{4.4.33}$$

normalization constant

$$C_{\text{norm}} = \frac{V_D}{\int_{V_D} \int_0^\infty \phi^c\left(\overrightarrow{r}, E\right) dE\ dV} \tag{4.4.34}$$

space-only contributon flux

$$\widetilde{\phi}^c\left(\overrightarrow{r}\right) = C_{\text{norm}} \int_0^\infty \phi^c\left(\overrightarrow{r}, E\right) dE \tag{4.4.35}$$

spatial parameter

$$\alpha\left(\overrightarrow{r}\right) = \left[1 + exp\left(\frac{\widetilde{\phi}^c_{\max \in V_D}}{\widetilde{\phi}^c\left(\overrightarrow{r}\right)} - \frac{\widetilde{\phi}^c\left(\overrightarrow{r}\right)}{\widetilde{\phi}^c_{\max \in V_D}}\right)\right]^{-1} \tag{4.4.36}$$

spatial parameter

$$B\left(\overrightarrow{r}\right) = \alpha\left(\overrightarrow{r}\right)\widetilde{\phi}^c\left(\overrightarrow{r}\right) + 1 - \alpha\left(\overrightarrow{r}\right) \tag{4.4.37}$$

weight windows

$$\overline{w}\left(\overrightarrow{r}, E\right) = \frac{B\left(\overrightarrow{r}\right)}{\phi^+\left(\overrightarrow{r}, E\right)} \tag{4.4.38}$$

Source-region problems

For a detector of volume V_D and surface area A_D (smaller than the entire problem) where we want to optimize the MC calculation of the detector response

$$R\left(\overrightarrow{r}\right) = \int_0^\infty \sigma\left(\overrightarrow{r}, E\right)\ \phi\left(\overrightarrow{r}, E\right) dE \qquad \overrightarrow{r} \in V_D \tag{4.4.39}$$

or optimize for the energy dependent flux in the region, the following is used:

forward flux estimate

$$\phi\left(\overrightarrow{r}, E\right) \tag{4.4.40}$$

adjoint source for flux

$$q^+\left(\overrightarrow{r}, E\right) = \frac{1}{\phi\left(\overrightarrow{r}, E\right)} \tag{4.4.41}$$

adjoint source for response

$$q^+\left(\overrightarrow{r}, E\right) = \frac{\sigma\left(\overrightarrow{r}, E\right)}{\int_0^\infty \sigma\left(\overrightarrow{r}, E\right)\ \phi\left(\overrightarrow{r}, E\right) dE} \tag{4.4.42}$$

adjoint flux estimate

$$\phi^+\left(\overrightarrow{r}, E\right) \tag{4.4.43}$$

contributon flux

$$\phi^c\left(\overrightarrow{r},E\right)=\phi\left(\overrightarrow{r},E\right)\ \phi^+\left(\overrightarrow{r},E\right) \tag{4.4.44}$$

normalization constant

$$C_{\text{norm}}=\frac{A_D}{\int_{A_D}\int_0^\infty \phi^c\left(\overrightarrow{r},E\right)dE\ dA} \tag{4.4.45}$$

space-only contributon flux

$$\widetilde{\phi}^c\left(\overrightarrow{r}\right)=\ C_{\text{norm}}\int_0^\infty \phi^c\left(\overrightarrow{r},E\right)dE \tag{4.4.46}$$

spatial parameter

$$\alpha\left(\overrightarrow{r}\right)=\left[1+exp\left(\frac{\widetilde{\phi}^c_{\max\in V_D}}{\widetilde{\phi}^c\left(\overrightarrow{r}\right)}-\frac{\widetilde{\phi}^c\left(\overrightarrow{r}\right)}{\widetilde{\phi}^c_{\max\in V_D}}\right)\right]^{-1} \tag{4.4.47}$$

spatial parameter

$$B\left(\vec{r}\right)=\begin{cases}\tilde{\phi}^c\left(\vec{r}\right) & \vec{r}\in V_D\\ \alpha\left(\vec{r}\right)\tilde{\phi}^c\left(\vec{r}\right)+1-\alpha\left(\vec{r}\right) & \text{otherwise}\end{cases} \tag{4.4.48}$$

weight windows

$$\overline{w}\left(\overrightarrow{r},E\right)=\frac{B\left(\overrightarrow{r}\right)}{\phi^+\left(\overrightarrow{r},E\right)} \tag{4.4.49}$$

Note that A_D does not include surfaces of V_D which are on the boundary of the problem.

Global response problem

For optimizing the Monte Carlo calculation of a detector response everywhere in phase space

$$R(\overrightarrow{r})=\int_0^\infty \sigma\left(\overrightarrow{r},E\right)\ \phi\left(\overrightarrow{r},E\right)\text{dE} \tag{4.4.50}$$

or optimizing for the energy-dependent flux everywhere, the following is used:

forward flux estimate

$$\phi\left(\overrightarrow{r},E\right) \tag{4.4.51}$$

adjoint source for flux

$$q^+\left(\overrightarrow{r},E\right)=\frac{1}{\phi\left(\overrightarrow{r},E\right)} \tag{4.4.52}$$

adjoint source for response

$$q^{+}\left(\overrightarrow{r},E\right)=\frac{\sigma\left(\overrightarrow{r},E\right)}{\int_{0}^{\infty}\sigma\left(\overrightarrow{r},E\right)\ \phi\left(\overrightarrow{r},E\right)dE} \tag{4.4.53}$$

adjoint flux estimate

$$\phi^{+}\left(\overrightarrow{r},E\right) \tag{4.4.54}$$

contributon flux

$$\phi^{c}\left(\overrightarrow{r},E\right)=\phi\left(\overrightarrow{r},E\right)\ \phi^{+}\left(\overrightarrow{r},E\right) \tag{4.4.55}$$

space-only contributon flux

$$\phi^{c}\left(\overrightarrow{r}\right)=\int_{0}^{\infty}\phi^{c}\left(\overrightarrow{r},E\right)dE \tag{4.4.56}$$

spatial parameter

$$B\left(\overrightarrow{r}\right)=\phi^{c}\left(\overrightarrow{r}\right) \tag{4.4.57}$$

weight windows

$$\overline{w}\left(\overrightarrow{r},E\right)=\frac{B\left(\overrightarrow{r}\right)}{\phi^{+}\left(\overrightarrow{r},E\right)} \tag{4.4.58}$$

4.4.3.3 Implementation in MAVRIC

Like CADIS and FW-CADIS, the Denovo S_N code is used to calculate the forward flux estimate, $\phi\left(\overrightarrow{r},E\right)$, and the estimate of the adjoint flux, $\phi^{+}\left(\overrightarrow{r},E\right)$, for all of the Michigan weight window methods.

None of the above discussions of the University of Michigan methods include information on how the weight window target values were adjusted to match the source sampling. When implemented into MAVRIC, each of the above problem types will compute a biased source, $\widehat{q}\left(\overrightarrow{r},E\right)$, along with the target weight, $\overline{w}\left(\overrightarrow{r},E\right)$, that are produced. For a problem with a single source of strength S and distribution $q\left(\overrightarrow{r},E\right)$, the biased source distribution $\widehat{q}\left(\overrightarrow{r},E\right)$ is found by using

$$\widehat{q}\left(\overrightarrow{r},E\right)=\frac{q\left(\overrightarrow{r},E\right)}{\overline{w}\left(\overrightarrow{r},E\right)}\ . \tag{4.4.59}$$

The weight windows are multiplied by a factor of R/S, where R is defined as

$$R=\iint\widehat{q}\left(\overrightarrow{r},E\right)\phi^{+}\left(\overrightarrow{r},E\right)\ dE\ dV. \tag{4.4.60}$$

Sampled source particles will then be born with a weight that matches the weight window of the phase space where they are born.

For multiple sources, each with strength S_i and distribution $q_i\left(\overrightarrow{r}, E\right)$, each biased source distribution $\widehat{q_i}\left(\overrightarrow{r}, E\right)$ is found by using

$$\widehat{q_i}\left(\overrightarrow{r}, E\right) = \frac{q_i\left(\overrightarrow{r}, E\right)}{\overline{w}\left(\overrightarrow{r}, E\right)} \tag{4.4.61}$$

and the response from each source being

$$R_i = \iint \widehat{q_i}\left(\overrightarrow{r}, E\right) dE\, dV\ . \tag{4.4.62}$$

The individual sources are sampled with a biased probability of $\widehat{p}(i) = R_i / \sum R_i$. The weight windows are then multiplied by a factor of

$$\frac{\sum_i R_i}{\sum_i S_i} \tag{4.4.63}$$

to match the source birth weights.

To use one of the Becker methods in MAVRIC, the keyword "beckerMethod=" is used with values of 1, 2, or 3 for the source/detector, source/region, or global method. Adjoint sources are described just like standard MAVRIC CADIS and FW-CADIS problems. To switch between optimizing flux in every group or optimizing a response, the keywords "fluxWeighting" and "respWeighting" are used. Just like FW-CADIS, the response listed in each adjoint source is the response that is optimized. Note that even when starting a calculation with known forward and adjoint flux files, the adjoint source(s) still need to be listed since they are used in the final normalization of the weight windows.

Example problems

The first Becker method (source/detector) is demonstrated using the Ueki shielding problem (used as sample problems in the Monaco and MAVRIC manuals and above in the space/energy/angle CADIS example). The goal is to calculate the neutron dose on one side of a shield from a partially collimated ^{252}Cf source on the other side of the shield. For the analog calculations, no importanceMap block is used. For the other cases, the importance map blocks are shown below.

CADIS

```
read importanceMap
    adjointSource 1
        locationID=1
        responseID=5
    end adjointSource
    gridGeometryID=7
    macromaterial
      mmTolerance=0.01
    end macromaterial

end importanceMap
```

Becker 1 - flux optimization

```
read importanceMap
    adjointSource 1
        locationID=1
        responseID=5
    end adjointSource
    gridGeometryID=7
    macromaterial
      mmTolerance=0.01
    end macromaterial

    beckerMethod=1
    fluxWeighting
end importanceMap
```

Becker 2 - response optimization

```
read importanceMap
    adjointSource 1
        locationID=1
        responseID=5
    end adjointSource
    gridGeometryID=7
    macromaterial
      mmTolerance=0.01
    end macromaterial

    beckerMethod=1
    respWeighting
end importanceMap
```

The results are shown in Table 4.4.2. The Becker response-optimized source/detector method, which requires two deterministic estimates, does slightly better for this problem than standard CADIS, which only requires one deterministic estimate.

Table 4.4.2: Results of the Ueki Shielding Problem (35 cm graphite shield)

Calculation method	For. S_N	Adj. S_N	MC	dose rate (rem/hr)	relative uncert	MC FOM (/min)
Analog	0.0	0.0	152.7	3.998E-03	0.0101	6.47
CADIS	0.0	0.2	9.9	3.988E-03	0.0081	1550
Becker, source/detector flux	0.2	0.2	9.9	4.027E-03	0.099	1040
Becker, source/detector resp	0.2	0.2	10.1	4.025E-03	0.0075	1760

A global problem

For an example of a global problem, consider a two-room block building with a criticality accident in one room. The objective is to find the photon dose everywhere in order to see the locations where criticality alarms would trigger. The building is 12 meters long, 6 meters wide, and 3 meters tall. A comparison will be made between an analog calculation, an FW-CADIS calculation (using response weighting), GRWW, Becker's source/region method (response optimization), and Becker's global method (response optimization). The MAVRIC importance map block of each calculation is as follows.

FW-CADIS

```
read importanceMap
    gridGeometryID=1
    adjointSource 1
        boundingBox
            1200 0
            600 0
            300 -60.0
        responseID=6
    end adjointSource

    respWeighting
end importanceMap
```

GRWW

```
read importanceMap
    gridGeometryID=1
    responseID=6
end importanceMap
```

Becker source/region

```
read importanceMap
    gridGeometryID=1
    adjointSource 1
        boundingBox
            1190 10
            590 10
            290 -560.0
        responseID=6
    end adjointSource
    beckerMethod=2
    respWeighting
end importanceMap
```

Becker - global

```
read importanceMap
    gridGeometryID=1
    adjointSource 1
        boundingBox
            1200 0
            600 0
            300 -60.0
        responseID=6
    end adjointSource
    beckerMethod=3
    respWeighting
end importanceMap
```

Note that Becker's source/region method is designed for regions smaller than the entire problem, so this is not a fair comparison, just a demonstration on how to use it in MAVRIC. The bounding box of the adjoint source in this case is set slightly smaller than the extent of the entire problem.

Results for the photon dose and its relative uncertainty using the five different methods of calculation are shown in Fig. 4.4.3. Information on the distribution of relative uncertainties is shown in Fig. 4.4.4 and listed in Table 4.4.3.

A more detailed comparison of the different hybrid methods for representative shielding problems can be found in [MAV-AppC-Pep13].

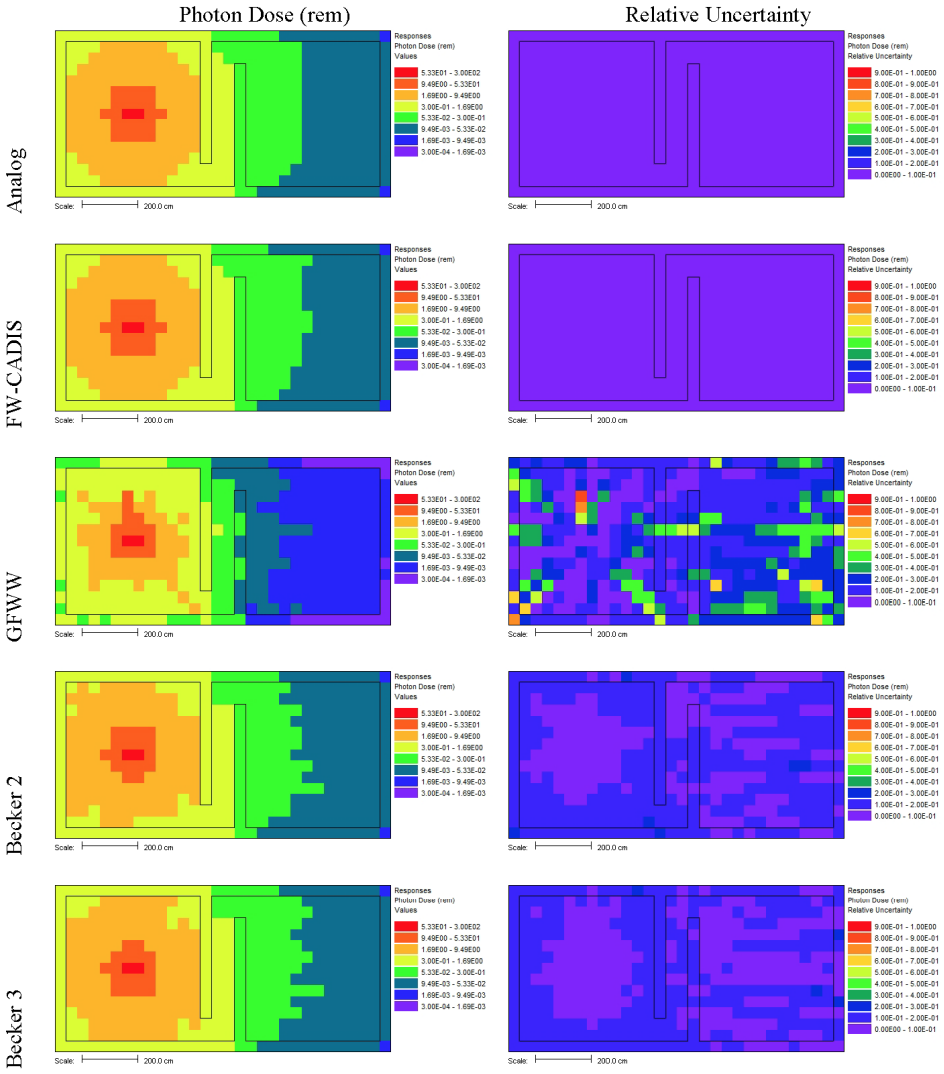

Fig. 4.4.3: Mesh tally results for the photon dose over the entire building use five different methods.

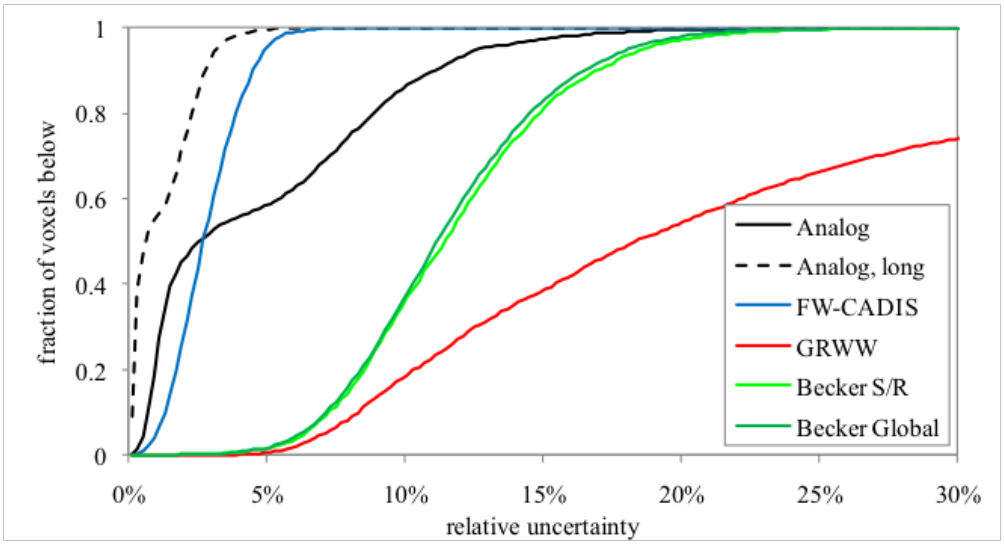

Fig. 4.4.4: The fraction of mesh tally voxels with less than a given amount of relative uncertainty for the five different methods.

Table 4.4.3: Comparison of the five different methods

Calculation method	Forward S_N (min)	Adjoint S_N (min)	Monte Carlo (min)	fraction of voxels with relative uncertainties less than 5%	fraction of voxels with relative uncertainties less than 10%	fraction of voxels with relative uncertainties less than 15%
Analog			20.1	0.583	0.857	0.973
Analog, long			308.1	0.996	1.000	1.000
FW-CADIS, response weighting	3.5	3.4	20.3	0.946	1.000	1.000
GRWW	4.0		20.2	0.005	0.180	0.387
Becker, source/region	4.0	3.6	19.0	0.016	0.350	0.800
Becker, global response	4.2	4.4	20.4	0.016	0.358	0.832

4.4.3.4 Other special options for the importance map block input

In MAVRIC, the above methods have been extended to use biased sources. To turn off the use of a biased source, use the keyword "selfNormalize". For forward flux-based methods, this will scale the target weights in the importance map so that the largest value is 1, which typically is at the source location. To use the forward-based Michigan methods (Cooper, GFWW, GRWW) or the van Wijk [MAV-AppC-VWVdEH11] methods as they were presented (without the MAVRIC biased source), use this keyword.

Use the keyword "spaceOnly=n" to create an importance map that contains one energy group over the entire range of energy. Use a value of 1 for neutron problems or a value of 2 for photon problems. This option is not designed for coupled problems. Both of the methods that van Wijk presents use importance maps that are space only.

Use the keyword "forwardParam=p" to allow the target weights to be proportional to the forward estimate (using Denovo) of flux raised to any power p.

$$\overline{w}\left(\overrightarrow{r}\right) = \frac{\phi^p\left(\overrightarrow{r}\right)}{\max\left(\phi^p\left(\overrightarrow{r}\right)\right)} \; . \tag{4.4.64}$$

For Cooper's method or van Wijk's first method, $p = 1$, which is the default if "forwardParam" is not specified. For van Wijk's second method, based on the relative error estimate $\mathrm{Re}\left(\overrightarrow{r}\right) \propto \frac{1}{\sqrt{\phi\left(\overrightarrow{r}\right)}}$, set this parameter to $p = 0.5$. Note that with a power less than 1, the weight window targets will span a smaller range than the expected Monte Carlo flux values. Particles may be rouletted before they reach the lowest flux areas of the problem.

When applying FW-CADIS for a semi-global problem, the adjoint source should cover the area where the lowest uncertainties are desired. Sometimes the area where this is desired is not a fixed geometric area but instead an area that has a final answer of a certain range. For example, when finding dose rate maps, the user may only be interested in getting low uncertainties for areas below the dose limit — areas above the dose limit may not matter as much since people will not be allowed in those areas. Another example may be that the dose map should be optimized in those areas above the background dose rate, since dose rates below that are of no concern. To allow the adjoint source area to be tailored in this way, the keywords "minForwardValue=" and/or "maxForwardValue="can be used. Default values are 0 and 10^{100}, respectively. For flux weighting, only the voxels within the adjoint source bounding box and containing a forward flux estimate between the min and max are included as adjoint sources.

A comparison [MAV-AppC-Pep13] of FW-CADIS to the University of Michigan methods and the Van Wijk methods showed that FW-CADIS performs better and is more straightforward to use than the other methods. These other methods were added to SCALE so that a fair comparison could be made and have been left in the code base for academic use in case some types of problems could benefit from them.

4.4.4 USING MAVRIC TO RUN FIXED-SOURCE DENOVO CALCULATIONS

The MAVRIC sequence of SCALE can be used to run the new discrete-ordinates code Denovo [MAV-AppC-ESSC10] The sequence is designed to use Denovo to compute an importance map for the Monte Carlo code Monaco but can be stopped without starting the final Monaco calculation. The full version of Denovo has a python-based user interface where the user must construct the geometry, source, and cross sections on their own. MAVRIC provides an easy interface to run the serial-only version of Denovo within SCALE (called 'xkba'). Denovo inputs made using MAVRIC can also be imported into the python interface for the HPC version of Denovo.

To create Denovo inputs or run Denovo using MAVRIC, input the composition, geometry (including arrays if needed), definitions (grid geometry and response information), and sources block as if an actual full MAVRIC case were being run. The sequence should then be started with a `parm=xxx` flag to indicate to MAVRIC to stop after making Denovo inputs or running Denovo.

parm=	MAVRIC stops after
Forward Calculations	
forinp	Making cross sections and Denovo input
forward	Running Denovo

Adjoint Calculations	
adjinp	Making cross sections and Denovo input
adjoint	Running Denovo

For forward Denovo simulations, the importance map block should contain which grid geometry to use and any of the optional Denovo parameters:

For forward Denovo simulations, the importance map block should contain which grid geometry to use and any of the optional Denovo parameters:

```
read importanceMap
    gridGeometryID=7
end importanceMap
```

For adjoint Denovo calculations, the importance map block should contain which grid geometry to use, one or more adjoint sources, and any of the optional Denovo parameters:

```
read importanceMap
    gridGeometryID=7
    adjointSource 1
        locationID=1
        responseID=5
    end adjointSource
end importanceMap
```

For either forward or adjoint, the following files will be produced and should be copied out of the SCALE temporary directory back to your home area:

ft02f001	the AMPX mixed working library cross section file
xkba_b.inp	binary input file for Denovo
*.dff	Denovo flux file (binary) - scalar fluxes

The scalar flux file is automatically copied back to the home area when SCALE completes. The others can be copied back if desired using a shell command at the end of the MAVRIC input file:

```
=shell
    cp ft02f001   ${OUTDIR}/mixed.ft02f001
    cp xkba_b.inp ${OUTDIR}/denovo.dsi
end
```

The xkba_b.inp file and the *.dff file can both be viewed with the Java utility, Mesh File Viewer, that is shipped with SCALE. The xkba_b.inp file shows the Denovo source distribution (space and energy), and the *.dff shows the final computed scalar fluxes. The binary Denovo input file should be renamed with an extension of *.dsi (Denovo simple input) so that the viewer can properly interpret the data.

4.4.4.1 Optional Denovo parameters

The default values for various calculational parameters and settings used by Denovo for the MAVRIC sequence should cover most applications. These settings can be changed by the interested user in the importance map block. The two most basic parameters are the quadrature set used for the discrete ordinates and the order of the Legendre polynomials used in describing the angular scattering. The default quadrature order that MAVRIC uses is S_8, and for the order of Legendre polynomials, the default is P_3 (or the maximum number of coefficients contained in the cross section library, if less than 3). S_8/P_3 should be a good choice for many applications, but the user is free to changes these. For complex ducts or transport over large distance at small angles, S_{12} may be required. S_4/P_1 would be useful in doing a very cursory run just to check if the problem was input correctly. Other parameters that can be set by the user in the importance map block for Denovo calculations are listed in Table 4.4.4.

Table 4.4.4: Optional Denovo parameters for the MAVRIC Importance Map Block

block keyword	type	length	default	required	restrictions/comments
importanceMap					
Optional Denovo S_N code parameters					
discretization=	integer		4	no	0-diamond-difference, 1-diamond-difference with flux fix-up:lin0, 2-theta-weighted diamond-difference, 3-linear-discontinuous finite element, 4-step characteristics, 5-trilinear discontinuous finite elem
quadType=	integer		0	no	0-level symmetric, 1-Gauss-Legendre product, 2-QR
legendre=	integer		3*	no	P_L, L=highest Legendre polynomial, L=0,1,2,3,… *default is to use min(the highest available in the data,3)
tportcorrection=	integer		1*	no	transport correction: 0-none, 1-diagonal, 2-Cesaro *For P_2 or higher, the default is 2 (Cesaro)
upScatter=	integer		0	no	upscatter iterations: 0-none, 1-yes, 2-ignore
xblocks=	integer		1	no	parallel stuff
yblocks=	integer		1	no	parallel stuff
zblocks=	integer		1	no	parallel stuff
numSets=	integer		1	no	?
partUpscatter=	integer		1	no	partition upscatter (0-no, 1-yes)
quadrature=	integer		8	no	level symmetric S_N quadrature, N=2, 4, 6, 8, 10, 12, 14, 16
polarsPerOct=	integer		0	no	Gauss-Legendre product quadrature or QR
azimuthsPerOct=	integer		0	no	Gauss-Legendre product quadrature or QR
maxIters=	integer		20	no	maximum number of iterations
diagnostics=	integer		0	no	0-no diganostics, 1-all diagnostics
output=	integer		0	no	0-no ouput, 1-all output
krylovSpaceSize=	integer		10	no	size in memory for Krylov space
tolerance=	double		1.E-03	no	tolerance used in convergence test
krylovType=	integer		0	no	0-GMRES, 1-BiCGStab
eigenSolver=	integer		0	no	0-power iteration, 1-Arnoldi, 2-shifted inverse
multiGSolover=	integer		0	no	0-Gauss-Seidel, 1-Krylov
withinGSolver=	integer		0	no	0-Krylov, 1-residual Krylov, 2-source iteration
mgSettings=	integer		1	no	0-user supplied, 1-automatic
upGroupSolver=	integer		0	no	0-same as within-group solver, 1-Krylov, 2-residual Krylov, 3-source iteration, 4-single source iteration
acceleration=	integer		0	no	0-none, 1-two grid
maxItersMG=	integer		20	no	maximum number of iterations
toleranceMG=	double		0.001	no	tolerance used in convergence test
end importanceMap					

In problems with small sources or media that are not highly scattering, discrete ordinates can suffer from "ray effects"-where artifacts of the quadrature directions can be seen in the computed fluxes. To help alleviate the ray effects problem, Denovo has a first-collision capability. This computes the amount of uncollided flux in each mesh cell from a point source. These uncollided fluxes are then used as a distributed source in the

main discrete-ordinates solution. At the end of the main calculation, the uncollided fluxes are added to the fluxes computed with the first-collision source, forming the total flux. While this helps reduce ray effects in many problems, the first-collision capability can take a long time to compute on a mesh with many cells or for many point sources.

The macromaterials option ("mmTolerance=") can be used to better represent the geometry in Denovo. Refer to the main MAVRIC manual for details on macromaterials.

4.4.4.2 Forward source preparations

The user-entered source description is converted to a mesh-based source for Denovo. To create the mesh source, MAVRIC determines if the defined source exists within each cell. This is done by dividing each mesh cell into $n \times n \times n$ subcells (from the keyword "subCells=n" in the importance map block with a default of n=2) and testing each subcell center. For every subcell center that is a valid source position (within the spatial solid and meets optional unit, region, or mixture requirements), an amount of source proportional to the subcell volume is assigned to the mesh cell. The keyword "subCells=" can be used to better refine how much source is computed for the mesh cells at the boundary of a curved source region. Of course, more subcell testing takes more time.

The above process may miss small sources or degenerate sources (surfaces, lines, points) that do not lie on the tested subcell centers. If none of the mesh cells contain any source after the subcell method, then random sampling of the source is used. A number of source positions are sampled from the source (set by the "sourceTrials=" keyword, default of 1000000) and then placed into the proper mesh cell. If this method is used, the resulting Denovo input file should be visualized to ensure that the statistical nature of the source trials method does not unduly influence the overall mesh source.

For forward calculations, if the number of mesh cells containing the true source is less than 10, then MAVRIC will convert these source voxels to point sources, to allow Denovo to use its first-collision capability to help reduce ray effects. The user can easily override the MAVRIC defaults-to force the calculation of a first-collision source no matter how many voxels contain source-by using the keyword "firstCollision." To prevent the calculation of a first-collision source, the keyword "noFirstCollision" can be used.

For coupled problems, there are two ways to make Denovo compute photon fluxes from a neutron source: 1) include a tally using a photon response or 2) manually specify the "startGroup=" and the "endGroup=" to cover the particles/energy groups that are desired in the final Denovo output.

4.4.4.3 Adjoint source preparation

For adjoint calculations, adjoint sources that use point locations will use the Denovo first-collision capability. Volumetric adjoint sources (that use a boundingBox) will be treated without the first-collision capability. The keywords "firstCollision" and "noFirstCollision" will be ignored by MAVRIC for adjoint calculations.

Note that for an adjoint Denovo calculation, the MAVRIC input must still list a forward source. Otherwise, the sequence will report an error and stop. The forward source is not used for an adjoint Denovo calculation, but it must be present to make a legal MAVRIC input. For a coupled problem using an adjoint photon source, using a neutron forward source will make Denovo compute both photon and neutron adjoint fluxes. If the forward source(s) and adjoint source(s) are all photon, then only photon adjoint fluxes will be computed. The keywords "startGroup=" and "endGroup=" can also be used to manually set the particles/energy groups that are desired in the final Denovo output.

4.4.4.4 Other notes

Denovo (in SCALE 6) is a fixed-source S_N solver and cannot model multiplying media. Neither forward nor adjoint neutron calculations from Denovo will be accurate when neutron multiplication is a major source component. If neutron multiplication is not turned off in the parameters block of the MAVRIC input (using keyword "noFissions"), a warning will be generated to remind the user of this limitation.

By default, MAVRIC instructs Denovo not to perform outer iterations for neutron problems if the cross-section library contains upscatter groups. This is because the time required to calculate the fluxes using upscatter can be significantly longer than without. For problems where thermal neutrons are an important part of the transport or tallies, the user should specify the keyword "upScatter=1" in the importance map block. This will instruct Denovo to perform the outer iterations for the upscatter groups, giving more accurate results but taking a longer time.

4.4.4.5 MAVRIC utilities for Denovo

Denovo simply calculates scalar fluxes for every mesh cell and energy group — it does not compute responses based on those fluxes. Several utilities have been added to the collection of MAVRIC utilities in order to allow the user to further process Denovo scalar flux results. The full details and input descriptions for these utilities can be found in the MAVRIC Utilities description in Sect. 4.3.

dff2dso	Convert a Denovo flux file into a Denovo spatial output file.
dff2mai	Convert a Denovo flux file into a mesh angular information file.
dff2mim	Invert a Denovo flux file and store as a mesh importance map.
dff2msl	Convert a Denovo flux file into a mesh source lite.
dffBinOp	Binary operation of Denovo flux files: sum, difference, product, and ratio.
dffDisp	Display the basics of a Denovo flux file.
dffFilter	Perform various filters on a Denovo flux file.
dffFix	Fix the zero and negative values in a Denovo flux file.
dffInt	Integrate a single particle type from a Denovo flux file.
dffInv	Invert the values in a Denovo flux file.
dffMult	Multiply a Denovo flux file by a constant factor.
dffPull	Pull fluxes from certain voxels out of a Denovo flux file.
dffResp	Apply a response function to scalar fluxes in a Denovo flux file.
dffSplit	Split off a single particle type from a Denovo flux file.

There are also two utility programs that look at the Denovo simple input file (binary) that MAVRIC creates. In the SCALE temporary directory, the file is called xkba_b.inp. In order to display in the MeshFileViewer, Denovo simple input files need to be renamed with a *.dsi extension. The utilities are as follows.

dsi2asc	Convert a Denovo simple input (*.dsi) from binary to ASCII (so the user can see every detail).
dsiDisp	Display the basics of a Denovo simple input file.

4.4.4.6 Example problem

Forward

As an example, consider a simulation based on the Ueki shielding experiments (see Monaco manual). A ^{252}Cf neutron source was placed in the center of a 50 cm cube of paraffin which had a 45° cone cut-out. The goal is to calculate the neutron dose at a detector 110 cm from the source.

The input file (`denovo1.inp`) needs the compositions of the paraffin and graphite

```
read composition
    para(h2o)    3         1.0 293.0 end
    carbon       4 den=1.7 1.0 293.0 end
end composition
```

then the geometry

```
read geometry
    global unit 1
        cuboid  1   25.0 -25.0  25.0 -25.0   25.0 -25.0
        cone    2  10.35948  25.01   0.0 0.0   rotate  a1=-90 a2=-90 a3=0
        cuboid  3   90.0  70.0  40.0 -40.0   40.0 -40.0
        cuboid 99  120.0 -30.0  50.0 -50.0   50.0 -50.0
        media 3 1  1 -2
        media 0 1  2
        media 4 1  3
        media 0 1  99 -1  -2 -3
    boundary 99
end geometry
```

then the position of the detector, the response of the detector and the mesh to use for Denovo

```
read definitions
    location 1
        position 110 0 0
    end location
    response 5
        title="ANSI standard (1977) neutron flux-to-dose-rate factors"
        specialDose=9029
    end response
    distribution 1
        title="Cf-252 neutrons, Watt spectrum a=1.025 MeV and b=2.926/MeV"
        special="wattSpectrum"
        parameters 1.025 2.926 end
    end distribution

        zLinear  5  15 40
    end gridGeometry
end definitions
```

the description of the true source

```
read sources
    src 1
        neutrons  strength=4.05E+07
        cuboid  0.01 0.01  0 0  0 0
        eDistributionID=1
    end src
end sources
```

and finally the importance map block to trigger the Denovo calculation

```
read importanceMap
    gridGeometryID=7
    mmTolerance=0.001
end importanceMap
```

An optional shell command can be used to retrieve the cross section file and the Denovo input file.

```
=shell
  cp ft02f001       ${OUTDIR}/denovo1.ft02f001
  cp xkba_b.inp     ${OUTDIR}/denovo1.xkba.dsi
end
```

The `denovo1.xkba.dsi` file (the Denovo simple input) contains both the source and mesh geometry that MAVRIC prepared for Denovo, as shown in Fig. 4.4.5.

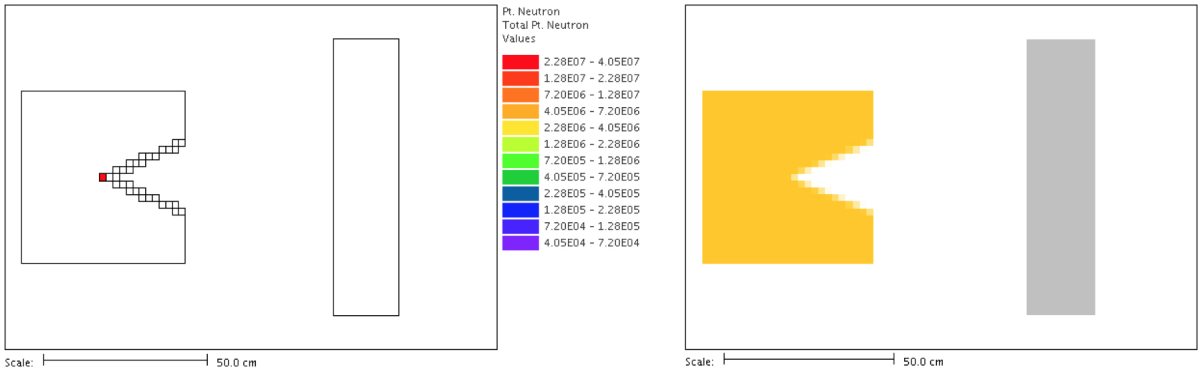

Fig. 4.4.5: Forward Denovo source (left) and mesh geometry (right).

The result of the Denovo-only MAVRIC calculation is a file, `denovo1.forward.dff`, containing the scalar fluxes for each energy group. The Mesh File Viewer can be used to display each group or the total scalar flux, which is shown in Fig. 4.4.6.

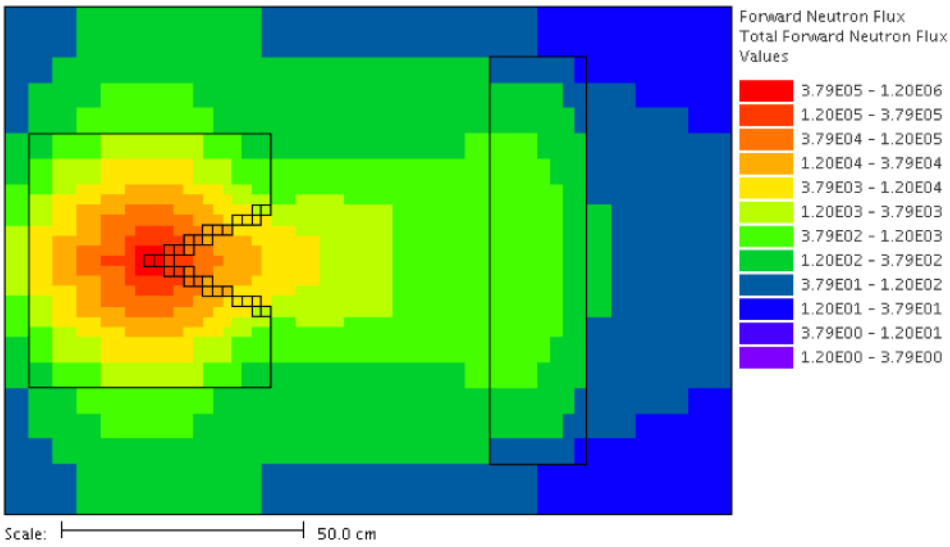

Fig. 4.4.6: Total forward fluxes.

The MAVRIC utilities can be used to further process the Denovo flux into a detector response. The fluxes at the location of the detector need to be multiplied by the photon flux-to-dose conversion factors (the response function) and then summed. This is can be done in the same input file using

```
=dffResp
"denovo1.forward.dff"

and results in a neutron dose rate of 5.426×10^{-3} rem/hr, calculated in about 2 minutes. Other combinations of the MAVRIC utilities can be used to simply "pull" out the fluxes from the detector location and then use a spreadsheet to compute the dose rate. With upscatter on, the result is 5.424×10^{-3} rem/hr, showing that upscatter does not contribute to dose rate at the detector. Note that with upscatter on, the Denovo calculation required 81 minutes.

Adjoint

For the same calculation of neutron dose as above, a Denovo adjoint calculation can be performed. The input file (`denovo2.inp`) has the same composition, geometry, definitions, and source blocks as the forward example. The adjoint input importance map block contains a description of the adjoint source:

```
read importanceMap
    adjointSource 1
        locationID=1
        responseID=5
    end adjointSource
    gridGeometryID=7
    mmTolerance=0.001
end importanceMap
```

The result of this Denovo-only MAVRIC calculation is a file, `denovo2.adjoint.dff`, containing the scalar adjoint fluxes for each energy group, as shown in Fig. 4.4.7.

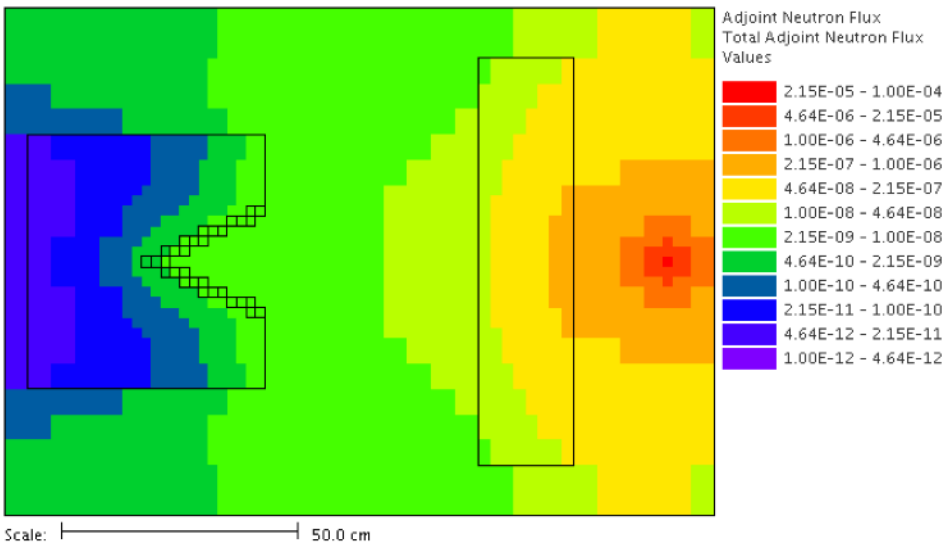

Fig. 4.4.7: Total adjoint fluxes.

As with the forward fluxes, the MAVRIC utilities can be used to further process the Denovo adjoint fluxes into a detector response. The adjoint fluxes at the location of the forward source need to be multiplied by the source distribution and strength and then summed. This is can be done using

and results in a neutron dose rate of $5.463 \cdot 10^{-3}$ rem/hr.

The results of the example problems above used a fairly coarse mesh ($44 \times 27 \times 27$) and the default values of S_8 and P_3. Run times were 2 minutes for the forward case and 2.5 minutes for the adjoint. With a finer mesh, larger quadrature order and larger numbers of Legendre moments for the scattering representation, the values calculated using Denovo should converge towards the Monte Carlo solution of $1.494 \cdot 10^{-2}$ rem/hr $\pm$ 1.2%.

5. DEPLETION, ACTIVATION, AND SPENT FUEL SOURCE TERMS

Introduction by W. A. Wieselquist

SCALE's general depletion, activation, and spent fuel source terms analysis capabilities are enabled through a family of modules related to the main ORIGEN depletion/irradiation/decay solver. The nuclide tracking in ORIGEN is based on the principle of explicitly modeling all available nuclides and transitions in the current fundamental nuclear data for decay and neutron-induced transmutation and relies on fundamental cross section and decay data in ENDF/B VII. Cross section data for materials and reaction processes not available in ENDF/B-VII are obtained from the JEFF-3.0/A special purpose European activation library containing 774 materials and 23 reaction channels with 12,617 neutron-induced reactions below 20 MeV. Resonance cross section corrections in the resolved and unresolved range are performed using a continuous-energy treatment by data modules in SCALE. All nuclear decay data, fission product yields, and gamma-ray emission data are developed from ENDF/B-VII.1 evaluations. Decay data include all ground and metastable state nuclides with half-lives greater than 1 millisecond. Using these data sources, ORIGEN currently tracks 174 actinides, 1149 fission products, and 974 activation products.

The purpose of this chapter is to describe the stand-alone capabilities and underlying methodology of ORIGEN-as opposed to the integrated depletion capability it provides in all coupled neutron transport/depletion sequences in SCALE, as described in other chapters. Through the stand-alone capabilities, there is generality to handle arbitrary systems (e.g., fast reactor fuel depletion or structural activation) by providing arbitrary flux spectra and arbitrary one-group cross sections to the module COUPLE, which in turn creates ORIGEN library (.f33) files containing the problem-dependent, one-group reaction coefficients required to solve the actual equations governing depletion/decay. These libraries are required input for the ORIGEN module, along with the initial isotopics and irradiation history, in terms of either a time-dependent power or flux level. Two high-performance equation solvers are available: the hybrid linear chains and matrix exponential method and a new Chebyshev Rational Approximation Method (CRAM). Typical execution times are on the order of a few seconds for a multi-step solution, with each individual solution (step) taking approximately 10 milliseconds. ORIGEN also includes capabilities for continuous feed and removal by element. Output capabilities include isotopics (moles or grams), source spectra (alpha, beta, gamma, and neutron), activity (becquerels or curies), decay heat (total watts or gamma only), and radiological hazard factors (maximum permissible concentrations in air or water). These results can be displayed in the output file (.out extension) and/or archived in an ORIGEN binary results file (.f71 extension).

The use of current, fundamental data resources is a key feature of ORIGEN, including nuclear decay data, multigroup neutron reaction cross sections, neutron-induced fission product yields, and decay emission data for photons, neutrons, alpha particles, and beta particles. The nuclear decay data are based primarily on ENDF/B-VII.1 evaluations. The multigroup nuclear reaction cross section libraries now include evaluations from the JEFF-3.0/A neutron activation file containing data for 774 target nuclides, more than 12,000 neutron-induced reactions, and more than 20 different reaction types below 20 MeV, provided in various energy group structures. Energy-dependent ENDF/B-VII.0-based fission product yields are available for 30 fissionable actinides. Gamma-ray and x-ray emission data libraries are based on ENDF/B-VII.1. The photon libraries contain discrete photon line energy and intensity data for decay gamma-ray and x-rays emission for 1,132 radionuclides, prompt and delayed continuum spectra for spontaneous fission, (α, n) reactions in oxide fuel, and bremsstrahlung from decay beta (electron and positron) particles slowing down in either a UO_2 fuel or water matrix. Methods and data libraries used to calculate the neutron yields and energy spectra for spontaneous fission, (α, n) reactions, and delayed neutron emission are adopted from the SOURCES4C code. Capabilities to calculate the beta and alpha particle emission source and spectra have also been added.

The ORIGEN reactor libraries distributed with SCALE include a set of pre-calculated ORIGEN libraries (with TRITON) for a variety of fuel assembly designs:

- BWR 7 × 7, 8 × 8-1, 8 × 8-2, 9 × 9-2, 9 × 9-9, 10 × 10-9, 10 × 10-8, SVEA-64, SVEA-96, and SVEA-100;
- PWR 14 × 14, 15 ×times` 16, 17 × 17, 18 × 18;
- CANDU reactor (19-, 28-, and 37-element bundle designs);
- Magnox graphite reactor;
- Advanced Gas-Cooled Reactor (AGR);
- VVER 440 and VVER 1000;
- RBMK;
- IRT;
- MOX BWR 7 × 7, 8 × 8-1, 8 × 8-2, 9 × 9-2, 9 × 9-9, 10 × 10-9, 10 × 10-8, SVEA-64, SVEA-96, and SVEA-100;
- MOX PWR 14 × 14, 15 × 15, 16 × 16, 17 × 17, 18 × 18.

These libraries may be used to rapidly assess spent fuel isotopics and source terms in these systems for arbitrary burnups and decay times. For UO_2-based assembly isotopics, the new ORIGAMI sequence provides a very convenient, easy-to-use interface. The most general capability, and requiring more user input, is available using the ARP interpolator module in conjunction with the ORIGEN solver module.

Finally, with regards to user interfaces, ORIGEN has a new keyword-based input in SCALE 6.2 but also maintains the ability to read SCALE 6.1 input. Both ORIGEN and ORIGAMI are tightly integrated with the SCALE graphical user interface, Fulcrum, which includes syntax highlighting, input checking with immediate feedback, and (.f71) output viewing. Additionally, Fulcrum provides an ORIGAMI Automator project interface to characterize the fuel inventory for an entire reactor site and generate data needed for severe accident analysis. ORIGAMI Automator is not documented in this chapter, but a primer is available with step by step instructions on its use.

5.1 ORIGEN: NEUTRON ACTIVATION, TRANSMUTATION, FISSION PRODUCT GENERATION, & RADIATION SOURCE TERM CALCULATION

ORIGEN (Oak Ridge Isotope Generation code) calculates time-dependent concentrations, activities, and radiation source terms for a large number of isotopes simultaneously generated or depleted by neutron transmutation, fission, and radioactive decay. ORIGEN is used internally within SCALE's TRITON and Polaris sequences to perform depletion and decay. As a stand-alone SCALE module, ORIGEN provides additional unique capabilities to (1) simulate continuous nuclide feed and chemical removal, which can be used to model reprocessing or liquid fuel systems, and (2) generate alpha, beta, neutron and gamma decay emission spectra. A standard decay library is provided to perform decay calculations. For neutron activation and fuel depletion problems, neutron spectrum-dependent ORIGEN libraries are required and may be created from (1) user-defined spectrum and self-shielded cross sections using the COUPLE module or (2) interpolation of existing ORIGEN reactor libraries (precalculated by TRITON) using the Automated Rapid Processing (ARP) module. Post-processing using the OPUS module allows calculated isotopics and spectra to be sorted, ranked, and converted to other units.

5.1.1 ACKNOWLEDGEMENTS

Development and maintenance of ORIGEN and related codes and methods have been sponsored by many organizations including the US Nuclear Regulatory Commission (NRC), the US Department of Energy (DOE), and nuclear power and research institutions.

5.1.2 VERSION INFORMATION

The ORIGEN (Oak Ridge Isotope Generation) code [ORIGEN-Bel73] was developed at Oak Ridge National Laboratory (ORNL) to calculate nuclide compositions and radioactivity of fission products, activation products, and products of heavy metal transmutation. Since 1991, ORIGEN has been developed as the depletion/decay module in SCALE with support from the NRC. ORIGEN in SCALE is the only version supported at ORNL, and it supersedes all earlier versions. The following is a brief description of the major enhancements in each version. Data are described in the ORIGEN Data Resources chapter.

5.1.2.1 Version 6.3 (2021)

Code Responsible(s): W. A. Wieselquist

Contributors: W. Wieselquist, S. Hart, K. Bledsoe, S. Skutnik, K. Bekar

Continued modernization focused on incorporating the capabilities of COUPLE into the ORIGEN sequence, improved data formats, and interoperation with ENDF-formatted data. The main new feature is a nuclear data sensitivity capability.

5.1.2.2 Version 6.2 (2016)

Code Responsible(s): W. A. Wieselquist

Contributors: W. Wieselquist, S. Hart, A. Isotalo[1], F. Havlůj[2], S. Skutnik, R. Lefebvre, I. Gauld, D. Wiarda, J. Lefebvre, G. Hu[4], N. Sly[3], and D. Lago[5]

A major modernization effort for ORIGEN was initiated by I. Gauld in 2011 and has resulted in approximately 5 person-years of effort refactoring the ORIGEN and related codes to be more efficient and easily testable. The major enhancements and responsible parties are listed below.

- Extensive refactor and modernization of Fortran 77 to Fortran 90+ performed by F. Havlůj, including substantial extension of the output capability
- Implementation of an alpha and beta spectrum calculation by F. Havlůj and I. Gauld
- Introduction of C++ core data structures with Fortran bindings, implemented by S. Skutnik using R. Lefebvre's C++/C/Fortran binding generator created for this purpose
- Testing suite developed by S. Skutnik, W. Wieselquist, D. Lago, and N. Sly
- Standardization of codebase while developing application programming interface (API) for high-performance depletion in the Consortium for Advanced Simulation of Light Water Reactors (CASL) and Nuclear Energy Advanced Modeling and Simulation (NEAMS) projects performed by W. Wieselquist
- Unification of readers/writers for ORIGEN data files developed by W. Wieselquist

[1] Aalto University, Finland
[2] ÚJV Řež, a. s., Czech Republic
[4] University of Illinois, Urbana-Champaign
[3] University of Tennessee, Knoxville
[5] Georgia Tech

- Improvement of binary formats for the ORIGEN library (f33) and ORIGEN concentration file (f71) by J. Lefebvre, R. Lefebvre, and W. Wieselquist
- Implementation of Chebyshev Rational Approximation Method (CRAM) solver by A. Isotalo
- Development of new input format (ORIGEN sequence only) by S. Hart and W. Wieselquist using the SCALE Object Notation (SON) syntax developed by R. Lefebvre
- Improvement of cubic spline interpolation scheme for ARP by S. Skutnik and W. Wieselquist with monotonicity fix-up determined by G. Hu
- Major revision of manuals by W. Wieselquist, combining ORIGEN, ARP, COUPLE, and OPUS into a single manual

Additional guidance provided by D. Wiarda and I. Gauld with testing by J. W. Hu.

5.1.2.3 Version 6.1 (2011)

The following section acknowledgements appeared in the SCALE 6.1 manual.

ORIGEN

Code Responsible(s): I. C. Gauld

The ORIGEN code was first developed by M. J. Bell with contributions from J. P. Nichols and other members of the Chemical Technology Division at ORNL. Development of the ORIGEN code as a depletion module of the SCALE code system was performed by O. W. Hermann with contributions from R. M. Westfall, supported by the NRC.

COUPLE

Code Responsible(s): D. Wiarda and I. C. Gauld

The COUPLE code was originally developed by O. W. Hermann with guidance from staff members including L. M. Petrie, N. M. Greene, W. E. Ford III, and R. M. Westfall, who contributed greatly to formulation of the methods, design of the data library interface with other modules, and testing. Many valuable suggestions concerning code applications were received from J. C. Ryman, J. R. Knight, and E. J. Allen.

ARP

Code Responsible(s): I. C. Gauld, S. M. Bowman, and J. E. Horwedel

The authors thank S. B. Ludwig for his support in earlier stages of this work. The authors are grateful for the technical advice received from B. L. Broadhead, M. D. DeHart, N. M. Greene, O. W. Hermann, C. V. Parks, L. M. Petrie, and J. C. Ryman. The authors thank Germina Ilas and Georgeta Radulescu for reviewing the manual and Willena Carter for preparation of the manuscript.

OPUS

Code Responsible(s): I. C. Gauld and J. E. Horwedel

The work of O. W. Hermann in developing the PLORIGEN program, from which OPUS was later developed, and the work of D. L. Barnett in developing the original version of PlotOPUS, are acknowledged. Appreciation is extended to J. C. Ryman for his review and testing of the program. Finally the authors thank S. J. Poarch for formatting the manuscript.

5.1.3 METHOD OF SOLUTION

ORIGEN solves the system of ordinary differential equations (ODEs) that describe nuclide generation, depletion, and decay,

$$\frac{dN_i}{\mathrm{dt}} = \sum_{j \neq i} (l_{\mathrm{ij}} \lambda_j + f_{\mathrm{ij}} \sigma_j \Phi) N_j(t) - (\lambda_i + \sigma_i \Phi) N_i(t) + S_i(t) \tag{5.1.1}$$

where

- N_i = amount of nuclide i (atoms),
- λ_i = decay constant of nuclide i (1/s),
- l_{ij} = fractional yield of nuclide i from decay of nuclide j,
- σ_i = spectrum-averaged removal cross section for nuclide i (barn),
- f_{ij} = fractional yield of nuclide i from neutron-induced removal of nuclide j,
- Φ = angle- and energy-integrated time-dependent neutron flux (neutrons/cm^2-s), and
- S_i = time-dependent source/feed term (atoms/s).

Note that Eq. (5.1.1) has no spatial dependence and can be interpreted as either a solution at a point in space or the spatial average over some volume. The latter interpretation is preferred here, such that Φ is the spatially averaged neutron flux magnitude, and all energy-dependence is embedded in the one-group flux-weighted average cross sections σ_i and reaction yields f_{ij}. Eq. (5.1.1) is conveniently written in matrix form as

$$\frac{d\vec{N}}{dt} = \mathbf{A}\vec{N}(t) + \vec{S}(t) \tag{5.1.2}$$

with a $\mathbf{A}$ commonly referred to as the "transition matrix." The representation of the transition matrix as $\mathbf{A} = \mathbf{A}_\sigma \Phi + \mathbf{A}_\lambda$, where $\mathbf{A}_\sigma$ is the part of the transition matrix containing reaction terms and $\mathbf{A}_\lambda$ is the part containing decay terms, is convenient, as the numerical solution of this system of ODEs holds the reaction, flux, and feed terms constant over step n,

$$\frac{d\vec{N}}{\mathrm{dt}} = (\mathbf{A}_{\sigma,n} \Phi_n + \mathbf{A}_\lambda) \vec{N}(t) + \vec{S}_n \tag{5.1.3}$$

over time step $t_{n-1} \leq t \leq t_n$.

Adding a continuous removal process described with rate constant $\lambda_{i,rem}$ simply modifies the decay constant, $\lambda_i \rightarrow \lambda_i + \lambda_{i,rem}$, whereas a continuous feed process defines a nonzero component of the $\vec{S}$ vector.

ORIGEN can also compute the alpha, beta, neutron, and gamma emission spectra during decay. For the "stand-alone" ORIGEN calculations described here, the transition matrix is loaded from an ORIGEN binary library file (f33), which uses sparse-matrix storage to store one or more transition matrices. The f33s may be created using COUPLE, saved from TRITON depletion calculations, or interpolated using ARP from a set of precompiled f33s distributed with SCALE.

Results from ORIGEN calculations may be stored on a binary concentration file (f71), which facilitates transfer of isotopics to other codes in SCALE. The f71 file can also store calculated emission spectra. Within ORIGEN, the f71 can be used to restart calculations from an existing set of compositions.

5.1.3.1 Methodology

This section describes the methodology used in performing the following main functions:

- generation of problem-dependent transition matrices,
- solution of the system of depletion/decay equations,
- conversion from power to flux (important for reactor applications),
- calculation of emission spectra, and
- interpolation of pregenerated sets of transition matrices.

Generation of Problem-dependent Transition Matrix

In the transition matrix **A** from Eq. (5.1.2), each matrix element a_{ij} is the first-order rate constant for the formation of nuclide i from nuclide j given below.

$$a_{ij} = \begin{cases} l_{ij}\lambda_j + f_{ij}\sigma_j\Phi & i \neq j \\ \lambda_i - \sigma_i\phi & \text{otherwise} \end{cases} \tag{5.1.4}$$

The transition matrix coefficients for decay and reaction transitions are stored separately and reaction transitions are always stored with $\Phi = 1$ and later during solution of the system, depending on the step-average flux level the actual transition matrix $\mathbf{A}_n = \mathbf{A}_{\sigma,n}\Phi_n + \mathbf{A}_\lambda$ is reconstructed using step-average flux, Φ_n.

The decay coefficients $l_{\mathrm{ij}}\lambda_j$ and λ_i are generated directly from ORIGEN decay resource data. The reaction coefficients $f_{\mathrm{ij}}\sigma_j$ and σ_i are generated using the following two-stage procedure.

1. Calculate all removal cross sections σ_i and yields f_{ij}, including isomeric branching ratios and fission yields, by folding provided flux spectrum ϕ^g with multigroup cross sections from the ORIGEN reaction resource and energy-dependent fission yield data from the ORIGEN yield resource.
2. Overwrite specific removal cross sections and yields based on a provided multigroup cross section library (see the SCALE Nuclear Data Libraries chapter) and/or user-provided one-group cross sections and yields.

The second stage is optional, but it is important for cases which there is significant self-shielding because ORIGEN's reaction resource assumes infinite dilution for its multigroup data. The decay, reaction, and yeld resources mentioned here are described in the ORIGEN Data Resources chapter. The collapse to a one-group cross section in either stage is given by

$$\sigma_{\mathrm{ri}} = \frac{\sum_g \sigma_{\mathrm{ri}}^g \phi^g}{\sum_g \phi^g} \tag{5.1.5}$$

for reaction type r, nuclide i, and provided multigroup flux ϕ^g. Different reaction types are recognized by their ENDF MT numbers [SCALE Cross Section Libraries chapter] on the appropriate data resource For example, MT=16 is $(n, 2n)$, and MT=107 is (n, α). The removal cross section σ_i is simply calculated as the sum over all relevant reactions for a particular nuclide, $\sigma_i = \sum_r \sigma_{\mathrm{ri}}$. This type of reaction-dependent multigroup data may be contained in either the data sources available in stage 1 or 2 above. However, only two types of data are expected to be available in stage 1 reaction resource data: (1) isomeric branching and (2) fission yields.

The energy-dependent isomeric branching that describes the yield of each excited level (metastable state) of a daughter nucleus is calculated in a similar way,

$$f_{\text{rim}} = \frac{\sum_g f_{\text{rim}}^g \sigma_{\text{ri}}^g \phi^g}{\sum_g \sigma_{\text{ri}}^g \phi^g} \tag{5.1.6}$$

where m indicates the possible metastable states and the fractions always satisfy $\sum_m f_{\text{rim}} = 1$.

Fission product yields are typically tabulated at discrete neutron energies such as thermal (0.0253 eV), fission (500 keV), and high energy (14 MeV). The yield for each fissionable nuclide is calculated in stage 1 by linearly interpolating the tabulated data using the computed average energy of fission,

$$\overline{E}_{\text{fi}} = \frac{\sum_g \overline{E}^g \sigma_{\text{fi}}^g \phi^g}{\sum_g \sigma_{\text{fi}}^g \phi^g} \tag{5.1.7}$$

where σ_{fi}^g is the multigroup fission cross section, and $\overline{E}^g$ is the average energy in the group (simple midpoint energy used). In addition to generating transition data for daughter/residual nuclides, the coefficients for byproducts such as He-4/α byproducts from (n, α) reactions are also retained in the transition matrix and associated to an appropriate nuclide in the system: hydrogen, deuterium, tritium, ^{3}He, or ^{4}He.

Solution of the Depletion/Decay Equations

ORIGEN includes two solver kernels that can solve the depletion/decay equations of Eq. (5.1.3):

1. a hybrid matrix exponential/linear chains method (MATREX) and
2. a Chebyshev Rational Approximation Method (CRAM).

They are described in the following sections.

MATREX

Referring to the system of ODEs shown in Eq. (5.1.2) and setting the external feed/source $S\ (t) = 0$, there is a formal solution by matrix exponential (an analog to the solution of a single ODE of this type by exponential),

$$\overrightarrow{N}(t) = \exp(\mathbf{A}t)\,\overrightarrow{N}(0) \tag{5.1.8}$$

where $\overrightarrow{N}(0)$ is a vector of initial nuclide concentrations, by defining the series expansion of $exp(\mathbf{A}t)$ to be

$$\exp(\mathbf{A}t) = \mathbf{I} + \mathbf{A}t + \frac{(\mathbf{A}t)^2}{2} + \ldots = \sum_{k=0}^{\infty} \frac{(\mathbf{A}t)^k}{k!} \tag{5.1.9}$$

with $\mathbf{I}$ the identity matrix. Eq. (5.1.8) and Eq. (5.1.9) describe the matrix exponential method, which yields a complete solution to the problem. However, in certain instances related to limitation in computer precision, difficulties occur in generating accurate values of the matrix exponential function. Under these circumstances, alternative procedures using either the generalized Bateman equations [ORIGEN-Bat10] or Gauss-Seidel iterative techniques are applied. These alternative procedures will be discussed in further sections.

A straightforward solution of Eq. (5.1.8) and Eq. (5.1.9) would require storage of the complete transition matrix. To avoid excessive memory requirements, a recursion relation has been developed. Substituting Eq. (5.1.9) into Eq. (5.1.8),

$$\overrightarrow{N}(t) = \left[\mathbf{I} + \mathbf{A}t + \frac{(\mathbf{A}t)^2}{2} + \ldots\right]\overrightarrow{N}(0) \tag{5.1.10}$$

one may recognize a recursion relation for a particular nuclide, $N_i(t)$.

$$N_i(t) = N_i(0) + t\sum_j a_{ij}N_j(0) + \frac{t}{2}\sum_k\left[a_{ik}t\sum_j a_{kj}N_j(0)\right] + \frac{t}{3}\sum_m\left\{a_{im}\frac{t}{2}\sum_k\left[a_{mk}t\sum_j a_{kj}N_j(0)\right]\right\} + \ldots \tag{5.1.11}$$

where the range of indices, j, k, m, is 1 to M for matrix $\mathbf{A}$ of size $M \times M$. The result is a series of terms that arise from the successive post-multiplication of the transition matrix by the vector of nuclide concentration increments produced from the computation of the previous terms. Within the accuracy of the series expansion approximation, physical values of the nuclide concentrations are obtained by summing a converged series of these vector terms. By defining the terms $C_i^n(t)$ as

$$\begin{aligned} C_i^0 &= N_i(0) \\ C_i^{n+1} &= \frac{t}{n+1}\sum_j a_{\mathrm{ij}}C_j^n \end{aligned} \tag{5.1.12}$$

the solution for $N_i(t)$ is given as

$$N_i(t) = \sum_{n=0}^{\infty} C_i^n \tag{5.1.13}$$

The use of Eq. (5.1.12) and Eq. (5.1.13) requires storage of only two vectors–$\overrightarrow{C}^n$ and $\overrightarrow{C}^{n+1}$ —-in addition to the current value of the solution. However, the series summation solution in Eq. (5.1.13) is not valid until a finite limit is identified which can achieve a reasonable accuracy, i.e.,

$$N_i(t) = \sum_{n=0}^{n_{\mathrm{term}}} C_i^n + \epsilon_{\mathrm{trunc}} \tag{5.1.14}$$

where n_{term} is the number of terms and $\epsilon_{\mathrm{trunc}}$ is the truncation error. The key is to split the nuclides into two sets: those that are long-lived and permit a rapid, accurate solution via Eq. (5.1.14), and those that are short-lived and require an alternate solution.

Solution for Long-Lived Nuclides

This section describes the various tests used to ensure that the summations indicated in Eq. (5.1.14) do not lose accuracy due to large changes in magnitudes or small differences between positive and negative rate constants. Nuclides with large rate constants (short-lived) are removed from the transition matrix and treated separately. For example, in the decay chain A → B → C, if the decay constant for B is large, a new rate constant is inserted in the matrix for A → C. This technique was originally employed by Ball and Adams [ORIGEN-BA67]. The key to determining which transitions should be removed involves calculation of the matrix norm. The norm of matrix $\mathbf{A}$ is defined by Lapidus and Luus [ORIGEN-LL67] as being the smaller of the maximum-row absolute sum and the maximum-column absolute sum,

$$[\mathbf{A}] = \min\left\{\max_j \sum_i \left|a_{\mathrm{ij}}\right|, \max_i \sum_j \left|a_{\mathrm{ij}}\right|\right\} \tag{5.1.15}$$

To maintain precision in performing the summations of Eq. (5.1.14), the matrix norm is used to balance the user-specified time step, t, with the precision associated with the word len>h employed in the machine calculation. The constraint on the matrix norm has been chosen as

$$[\mathbf{A}]\, t \leq \; -2 \; \ln(0.001) = 13.8155 \tag{5.1.16}$$

The remainder of this section shows that this constraint serves two purposes.

- It allows reasonable accuracy for a reasonable number (20–60) of matrix exponential terms.
- It defines what "short-lived" means over a particular time step, dictating which concentrations must be solved by alternate means.

A relationship between m digits of machine precision and p significant digits required in all results can be stated by the following inequality:

$$(\text{Largest term in series}) \times 10^{-m} \leq (\text{Series result}) \times 10^{-p} \tag{5.1.17}$$

In this particular series, the relationship may be represented as

$$\max_n \frac{|[\mathbf{A}]\, t|^n}{n!} 10^{-m} \leq \; e^{-[\mathbf{A}]t} 10^{-p} \text{`}, \tag{5.1.18}$$

or alternatively,

$$\max_n \frac{|[\mathbf{A}]\, t|^n}{n!} e^{[\mathbf{A}]t} \leq \; 10^{m-p}. \tag{5.1.19}$$

Lapidus and Luus have shown that the maximum term in the summation for any element in the matrix exponential function cannot exceed $\frac{([\mathbf{A}]t)^n}{n!}$, where n is the largest integer not larger than $[\mathbf{A}]\, t$. For the constraint in Eq. (5.1.16), this yields n=13 and yields limit $\frac{([\mathbf{A}]t)^n}{n!} \approx 10^5$. With $e^{[\mathbf{A}]t} \approx 10^6$ and standard double precision with *m=16*, Eq. (5.1.19) evaluates to $10^{11} \leq 10^{16-j}$, which indicates that five significant figures will be maintained in values as small as 10^{-6}. The number of terms required to converge the matrix exponential series can be investigated by a plot of the $\frac{|[\mathbf{A}]t|^n}{n!} e^{[\mathbf{A}]t}$ as a function of term index n in Eq. (5.1.19), as shown in Fig. 5.1.1

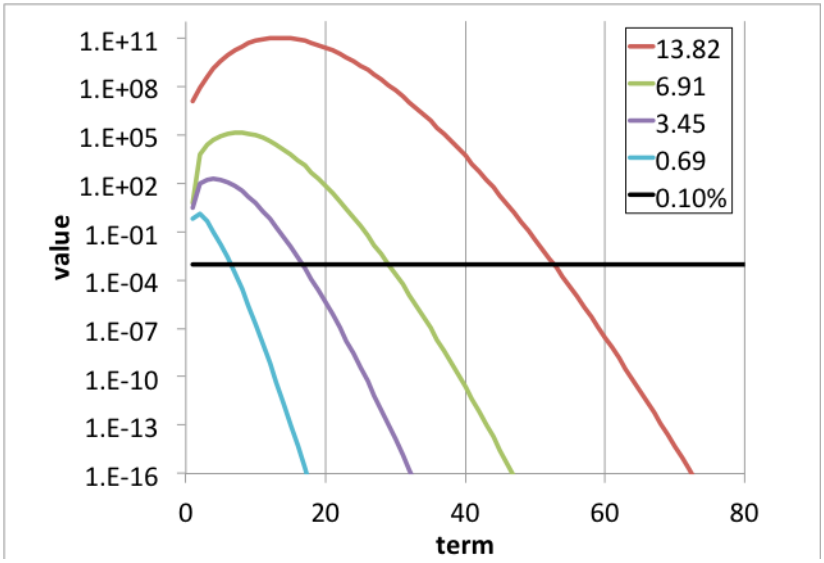

Fig. 5.1.1: Values of terms in series for various values of the matrix norm.

The intersection between the black line in Fig. 5.1.1 and the various curves indicates the number of terms needed to achieve $\epsilon_{\text{trunc}} \leq 0.1\%$. For example, with $[\mathbf{A}]\,t = 13.8155$, $n_{\text{term}} = 54$ is required, and with $[\mathbf{A}]\,t = 13.8155/2$, approximately $n_{\text{term}} = 29$ is required. This behavior has been used to develop the heuristic

$$n_{\text{term}} = 7\ [\mathbf{A}]t/2 + 6. \tag{5.1.20}$$

Thus it has been shown that the limit imposed in Eq. (5.1.16) leads to a maximum of $n_{\text{term}} = 54$ terms with $\epsilon_{\text{trunc}} \leq 0.1\%$.

It remains to be shown that any arbitrary system can be modified so that it does not violate Eq. (5.1.16). Because the time step t is provided and fixed, $[\mathbf{A}]\,t \leq -2\ \ln(0.001)$ cannot be satisfied unless the system is modified. The physical nature of the system leads to $\max_j \sum_i \left|a_{\text{ij}}\right| \leq \max_j 2|a_{\text{jj}}|$ based on production rates equal to loss rates when both parent and daughter nuclide are included in the system. The maximum column sum in Eq. (5.1.15) can then be bounded by twice the maximum diagonal term, $\max_j 2|a_{\text{jj}}|$. Using this upper limit as the matrix norm and substituting into Eq. (5.1.16) yields

$$[\mathbf{A}]\,t \leq 2 \max_j \left|a_{\text{jj}}\right| \leq -2 \ln(0.001) \tag{5.1.21}$$

Rearranging Eq. (5.1.21) leads to the condition

$$e^{-\|a_{jj}\|t} < 0.001 \tag{5.1.22}$$

which is used to mark nuclide j as a short-lived nuclide for this time step, to be solved with linear chains instead of the series-based matrix exponential. An alternative interpretation of the short-lived condition can be made by rewriting Eq. (5.1.22) in terms of an effective half-life, $t_{1/2} = \frac{\ln(2)}{|a_{\text{jj}}|}$, which results in $t_{1/2} < \frac{-ln(2)}{\ln(0.001)} t \approx 0.1t$. In other words, when a nuclide's effective half-life (including destruction by both decay and reaction mechanisms) is less than 10% of the time step, it can be considered short-lived.

Finally, as a note for applications where the nuclides of interest are in long transmutation chains, it has been found that the above algorithm may not yield accurate concentrations for those nuclides near the end of the chain that are significantly affected by those near the beginning of the chain. In these applications, specifying the minimum n_{term} as

$$n_{\text{term}} \geq |\Delta Z| + |\Delta A| + 5 \tag{5.1.23}$$

where ΔZ is the atomic number difference and ΔA is the mass number difference, has been found to ameliorate the issue.

Solution for Short-Lived Nuclides

The condition in Eq. (5.1.22) forms the basis for declaring a nuclide short-lived, and its solution is found via solution of the nuclide chain equations. In conjunction with maintaining the transition matrix norm below the prescribed level, a queue is formed of the short-lived precursors of each long-lived isotope. These queues extend back up the several chains to the last preceding long-lived precursor. According to Eq. (5.1.22), the queues will include all nuclides whose effective half-lives are less than 10% of the time interval. A generalized form of the Bateman equations developed by Vondy [ORIGEN-Von62] is used to solve for the concentrations of the short-lived nuclides at the end of the time step. For an arbitrary forward-branching chain, Vondy's form of the Bateman solution is given by,

$$N_i(t) = N_i(0)\, e^{-d_i t} + \sum_{k=1}^{i-1} N_k(0) \left[\sum_{j=k}^{i-1} \frac{e^{-d_j t} - e^{-d_i t}}{d_i - d_j} a_{j+1,j} \prod_{\substack{n=k \\ n \neq j}}^{i-1} \frac{a_{n+1,n}}{d_n - d_j} \right] \tag{5.1.24}$$

where $N_1\,(0)$ is the initial concentration of the first precursor, $N_2\,(0)$ is that of the second precursor, etc.

As in Eq. (5.1.4), a_{ij} is the first-order rate constant, and $d_i = -a_{\mathrm{ii}}$ which is the magnitude of the diagonal element. Bell recast Vondy's form of the solution through multiplication and division by $\prod_{n=k}^{i-1} d_n$ and rearranged to obtain

$$N_i\,(t) = N_i\,(0)\,e^{-d_i t} + \sum_{k=1}^{i-1} N_k(0) \prod_{n=k}^{i-1} \frac{a_{n+1,n}}{d_n} \left[\sum_{j=k}^{i-1} d_j \frac{e^{-d_j t} - e^{-d_i t}}{d_i - d_j} \prod_{\substack{n=k \\ n \neq j}}^{i-1} \frac{d_n}{d_n - d_j} \right] \tag{5.1.25}$$

The first product over isotopes n is the fraction of atoms that remains after the *kth* particular sequence of decays and captures. If this product becomes less than 10^{-6}, the contribution of this sequence to the concentration of nuclide i is neglected. Indeterminate forms that arise when *di=dj* or *dn=dj* are evaluated using L'Hôpital's rule. These forms occur when two isotopes in a chain have the same diagonal element.

Eq. (5.1.25) is applied to calculate all contributions to the "queue end-of-interval concentrations" of each short-lived nuclide from the initial concentrations of all others in the queue described above. It is also applied to calculate contributions from the initial concentrations of all short-lived nuclides in the queue to the long-lived nuclide that follows the queue, in addition to the total contribution to its daughter products. These values are appropriately applied either before or after the matrix expansion calculation is performed to correctly compute concentrations of long-lived nuclides and the long-lived or short-lived daughters. Eq. (5.1.25) is also used to adjust to certain elements of the final transition matrix, which now excludes the short-lived nuclides. The value of the element must be determined for the new transition between the long-lived precursor and the long-lived daughter of a short-lived queue. The element is adjusted so that the end-of-interval concentration of the long-lived daughter calculated from the single link between the two long-lived nuclides (using the new element) is the same as what would be determined from the chain including all short-lived nuclides. The method assumes zero concentrations for precursors to the long-lived precursor. The computed values asymptotically approach the correct value with successive steps through time. For this reason, at least five to ten time intervals during the decay of discharged fuel is reasonable, because long-lived nuclides have built up by that time.

If a short-lived nuclide has a long-lived precursor, an additional solution is required. First, the amount of short-lived nuclide i due to the decay of the initial concentration of long-lived precursor j is calculated as

$$N_{j\to i}\,(t) = N_j\,(0)\,a_{ij} \frac{e^{-d_j t}}{d_i - d_j} \tag{5.1.26}$$

from Eq. (5.1.24), assuming $e^{-d_i t} \ll e^{-d_j t}$. However, the total amount of nuclide i produced depends on the contribution from the precursors of precursor j, in addition to that given by Eq. (5.1.26). The quantity of nuclide j not accounted for in Eq. (5.1.26) is denoted by $N'_j\,(t)$, the end-of-interval concentration, minus the amount that would have remained had there been no precursors to nuclide j:

$$N_j^{'(t)} = N_j\,(t) - N_j(0) e^{-d_j t} \tag{5.1.27}$$

Then the short-lived daughter and subsequent short-lived progeny are assumed to be in secular equilibrium with their parents, which implies that the time derivative is zero,

$$\frac{dN_i}{\mathrm{dt}} = \sum_j a_{\mathrm{ij}} N_j(t) = 0. \tag{5.1.28}$$

The queue end-of-interval concentrations of all the short-lived nuclides following the long-lived precursor are augmented by amounts calculated with Eq. (5.1.25). The concentration of the long-lived precursor used in Eq. (5.1.27) is that given by Eq. (5.1.26). The set of linear algebraic equations given by Eq. (5.1.28) is solved by the Gauss-Seidel iterative technique. This algorithm involves an inversion of the diagonal terms and an iterated improvement of an estimate for $N_i(t)$ through the expression

$$N_i^{k+1} = -\frac{1}{a_{\text{ii}}} \sum_j a_{\text{ij}} N_j^k \tag{5.1.29}$$

Since short-lived isotopes are usually not their own precursors, this iteration often reduces to a direct solution.

Solution of the Nonhomogeneous Equation

The previous sections have presented the solution of the homogeneous equation in Eq. (5.1.8), applicable to fuel burnup, activation, and decay calculations. However, the solution of a nonhomogeneous equation is required to simulate reprocessing or other systems that require an external feed term, $S\,(t) \neq 0$. The nonhomogeneous equation is given in matrix form (assumed constant over a step n) as

$$\frac{d\overrightarrow{N}}{\text{dt}} = \mathbf{A}\overrightarrow{N}\,(t) + \overrightarrow{S} \tag{5.1.30}$$

for a fixed feed or removal rate, $\overrightarrow{S}$. A particular solution of Eq. (5.1.30) will be determined and added to the solution of the homogeneous equation given by Eq. (5.1.10). As before, the matrix exponential method is used for the long-lived nuclides, and solution by linear chains is used for the short-lived nuclides. Assume $\overrightarrow{C}$ an arbitrary vector with which to test a particular solution of the form

$$\overrightarrow{N}\,(t) = \sum_{k=0}^{\infty} \frac{(\mathbf{A}t)^k}{(k+1)!} \overrightarrow{C}\,t \tag{5.1.31}$$

Substituting Eq. (5.1.31) into Eq. (5.1.30) yields

$$\sum_{k=0}^{\infty} \frac{A^k t^k}{k!} \overrightarrow{C} = \sum_{k=0}^{\infty} \frac{A^{k+1} t^{k+1}}{(k+1)!} \overrightarrow{C} + \overrightarrow{S} \tag{5.1.32}$$

in which the *k=0* term may be extracted from the LHS,

$$\overrightarrow{C} + \sum_{k=1}^{\infty} \frac{A^k t^k}{k!} \overrightarrow{C} = \sum_{k=0}^{\infty} \frac{A^{k+1} t^{k+1}}{(k+1)!} \overrightarrow{C} + \overrightarrow{S} \tag{5.1.33}$$

which allows the summations on the left and right to be easily shown equal. This proves the particular solution is indeed valid if the arbitrary vector is in fact the feed term $\overrightarrow{C} = \overrightarrow{S}$. The solution to the nonhomogeneous problem is therefore (as a series),

$$\overrightarrow{N}\,(t) = \sum_{k=0}^{\infty} \frac{(\mathbf{A}t)^k}{k!} \overrightarrow{N}\,(0) + \sum_{k=0}^{\infty} \frac{(\mathbf{A}t)^k}{(k+1)!} \overrightarrow{S}\,t \tag{5.1.34}$$

For the second term in Eq. (5.1.34), a new recursion relation is developed for the particular solution in the same manner as was done for the homogeneous solution,

$$N_i^P\,(t) = \sum_{n=1}^{\infty} D_i^n \tag{5.1.35}$$

where

$$D_i^1 = S_i t;\ D_i^{n+1} = \frac{1}{n+1} \sum_j a_{ij} D_j^n \tag{5.1.36}$$

For the short-lived nuclides, the secular equilibrium equations are modified to become

$$\frac{dN_i}{\mathrm{dt}} = \sum_j a_{\mathrm{ij}} N_j(t) + S_i = 0. \tag{5.1.37}$$

The Gauss-Seidel iterative method is applied to determine the solution. The complete solution to the nonhomogeneous equation in Eq. (5.1.31) is given by the sum of the homogeneous solutions described in previous sections and the particular solutions described here.

CRAM

The solver kernel based on the Chebyshev Rational Approximation Method (CRAM) is described in detail in references [ORIGEN-IA11, ORIGEN-Pus11, ORIGEN-Pus13, ORIGEN-PL10]. Compared to the MATREX solver, CRAM generally has similar runtimes but is more accurate and robust on a larger range of problems. CRAM relies on the lower upper (LU) decomposition, so the SuperLU library has been used. The accuracy of CRAM is related to the order, with an order 16 solution having a truncation error less than 0.01% for all nuclides in most problems.

Unlike many methods for solving this type of system of ODEs, the len>h of a step does not significantly affect the accuracy of CRAM. However, any significant errors from CRAM will shrink rapidly over multiple steps as long as there are no large changes in reaction rates. The CRAM solver has an efficient internal substepping algorithm that can perform multiple same-sized substeps (with the same transition matrix) very efficiently by reusing the LU decomposition. When using internal substepping, 2–4 substeps are typical, with a large gain in accuracy for marginal increase in runtime.

Power Calculation

The following is formula is used to calculate power during irradiation ($\Phi > 0$),

$$P(t) = \sum_i \left(\kappa_{fi}\sigma_{fi} + \kappa_{ci}\sigma_{ci}\right)\phi N_i(t) \tag{5.1.38}$$

where κ_{fi} and κ_{ci} are nuclide-dependent energy released per fission and "capture," with *capture* defined as removal minus fission: $\sigma_{\mathrm{ci}} = \sigma_i - \sigma_{\mathrm{fi}}$. The σ_{fi} and σ_{ci} terms are extracted from the transition matrix itself, whereas the κ_{fi} and κ_{ci} are available from a separate ORIGEN energy resource (see ORIGEN Data Resources chapter). If the flux ϕ is specified, then the power can be calculated at any time according to Eq. (5.1.38). However in reactor fuel systems, it is convenient to be able to specify the power produced by the system and internally to the depletion code, to convert the power to an equivalent flux. Solving Eq. (5.1.38) for the flux, however,

$$\Phi(t) = \frac{P}{\sum_i \left(\kappa_{\mathrm{fi}}\sigma_{\mathrm{fi}} + \kappa_{\mathrm{ci}}\sigma_{\mathrm{ci}}\right) N_i(t)} \tag{5.1.39}$$

it is apparent that a fixed power over a time step n does not lead to a fixed flux, due to changing isotopics that produce different amounts of power per fission and capture. ORIGEN performs a flux-correction calculation to obtain an estimate of the average flux over the step. The beginning-of-step flux is first calculated for the initial compositions: Eq. (5.1.39) is evaluated as $\Phi(t_{n-1})$, and then Eq. (5.1.38) is solved with that flux. The

flux is then recalculated at the end of step $\Phi(t_n)$ using the estimated end-of-step isotopics, and the step-average flux Φ_n is estimated as the simple average of the beginning and end-of-step fluxes, i.e. Eq. (5.1.40),

$$\Phi_n = 0.5[\Phi(t_n) + \Phi^{\text{pred}}(t_{n+1})] \tag{5.1.40}$$

noting that the "predicted" flux at end-of-step $\Phi^{\text{pred}}(t_{n+1})$ is based on "predicted" end-of-step isotopics, based on a beginning-of-step flux level.

Decay Emission Sources Calculation

ORIGEN can calculate the emission sources (and spectra) during decay for alpha, beta, neutron, and photon particles according to

$$R_x^g(t) = \sum_i \lambda_i N_i(t) \int_{E^g}^{E^{g-1}} w_{i,x}(E)\,\mathrm{dE} \tag{5.1.41}$$

where $w_{i,x}(E)$ is the number of particles of type x emitted per disintegration of nuclide i at energy E, using provided energy bins defined by energy bounds E^g to E^{g-1}, where g is an energy index. The fundamental data resources for performing emission source calculations are described in the ORIGEN Data Resources chapter.

Neutron Sources

Computed neutron sources include neutrons spontaneous fission, (α, n) reactions, and delayed (β^-, n) neutron emission,

$$w_{i,n}(E) = w_{i,SFn}(E) + w_{i,(\alpha,n)}(E) + w_{i,Dn}(E) \tag{5.1.42}$$

with components that will be described below. The method of computing the spontaneous fission and delayed neutron source is independent of the medium containing the fuel. However, (α, n) production varies significantly with the composition of the medium. The homogeneous medium (α, n) calculation methodology has been adopted from the Los Alamos code SOURCES 4B [ORIGEN-Sho00, ORIGEN-WPC+99, ORIGEN-WPS+83].

The total yield of spontaneous fission neutrons from decay of nuclide i is

$$Y_{i,SFn} = \frac{\lambda_{i,SFn}}{\lambda_i}, \tag{5.1.43}$$

where $\frac{\lambda_{i,SFn}}{\lambda_i}$ is the fraction of decays which undergo spontaneous fission. The distribution of spontaneous fission neutrons, $w_{i,SFn}(E)$ is given by a Watt fission spectrum,

$$w_{i,SFn}(E) = Y_{i,SFn}\, C_i\, e^{-E/A_i} \sinh \sqrt{B_i E} \tag{5.1.44}$$

where Ai, Bi, and Ci are model parameters.

The (α, n) neutron source is strongly dependent on the low-Z content of the medium containing the alpha-emitting nuclides and requires modeling the slowing down of the alpha particles and the probability of neutron production as the α particle slows down. The calculation assumes (1) a homogeneous mixture in which the alpha-emitting nuclides are uniformly intermixed with the target nuclides and (2) that the dimensions of the

target are much larger than the range of the alpha particles. Thus, all alpha particles are stopped within the mixture. The yield of a particular α is given by

$$Y_{i,\alpha}^{\ell} = f_{i,\,\alpha}^{\ell} \frac{\lambda_{i,\alpha}}{\lambda_i} \tag{5.1.45}$$

where $\frac{\lambda_{i,\alpha}}{\lambda_i}$ is the relative probability of α–decay, and $f_{i,\,\alpha}^{\ell}$ is the fraction of those α–decays producing an α particle with initial energy $E_{i,\alpha}^{\ell}$, and is considered fundamental data. The *total* neutron yield from an alpha particle ℓ emitted by nuclide i and interacting with target k is given by the following,

$$Y_{i,k,(\alpha,n)}^{\ell} = Y_{i,\alpha}^{\ell} \frac{N_k}{N} \int_0^{E_{i,\alpha}^{\ell}} \frac{\sigma_{k,(\alpha,n)}(E_\alpha)}{S(E_\alpha)} dE_\alpha \tag{5.1.46}$$

where $S\,(E_\alpha)$ is the total stopping power of the medium, $\sigma_{k,(\alpha,n)}(E_\alpha)$ is the (α, n) reaction cross section for target nuclide k, and $\frac{N_k}{N}$ is the fraction of atoms in the medium composed of nuclide k. This expression is used to calculate the neutron yield for each target nuclide and from each discrete-energy alpha particle emitted by all alpha-emitting nuclides in the material. The stopping power for compounds, rather than pure elements, is approximated using the Bragg-Kleeman additivity rule. The energy-dependent elemental stopping cross sections are determined as parametric fits to evaluated data. Eq. (5.1.46) is solved for the total neutron yields from the alpha particle, as it slows down in the medium by subdividing the maximum energy $E_{i,\alpha}^{\ell}$ into a number of discrete energy bins and evaluating stopping power and (α, n) reaction cross section at the midpoint energy of the bin. The distribution of (α, n) neutrons as required by Eq. (5.1.41) is

$$w_{i,(\alpha,n)}\,(E) = \sum_k \sum_{\ell \in i} Y_{i,k}^{\ell}\,(\alpha, n)\, X_{i,k}^{\ell}\,(\alpha, n)\,(E) \tag{5.1.47}$$

with the distribution of (α, n) neutrons in energy, $X_{i,k,(\alpha,n)}^{\ell}\,(E)$, calculated using nuclear reaction kinematics, assuming that the (α, n) reaction emits neutrons with an isotropic angular distribution in the center-of-mass system. The maximum and minimum permissible energies of the emitted neutron are determined by applying mass, momentum, and energy balance for each product's nuclide energy level. The product nuclide levels, the product level branching data, the (α, n) reaction Q values, the excitation energy of each product nuclide level, and the branching fraction of (α, n) reactions result in the production of product levels. A more detailed discussion of the theory and derivation of the kinematic equations can be found in [ORIGEN-WPC+99].

Delayed neutrons are emitted by decay of short-lived fission products. The observed delay is due to the decay of the precursor nuclide. The total yield of delayed neutrons from decay of nuclide i is

$$Y_{i,Dn} = \frac{\lambda_{i,Dn}}{\lambda_i} \tag{5.1.48}$$

where $\frac{\lambda_{i,Dn}}{\lambda_i}$ is the fraction of decays which emit delayed neutrons. The delayed neutrons emitted per decay of nuclide i at energy E is given by

$$w_{i,Dn}\,(E) = Y_{i,Dn} X_{i,Dn}\,(E) \tag{5.1.49}$$

where the spectrum $X_{i,Dn}\,(E)$ is fundamental library data. Delayed neutrons are not important in typical spent fuel applications due to the very short half-lives of the parent nuclides, dropping off significantly after ~10 seconds, but they may be of value in specialized applications where calculating time-dependent delayed neutron source spectra is important.

Alpha Sources

An α slowing down calculation is performed as part of the (α, n) neutron calculation. However, the alpha source (i.e. without considering slowing down in the media) is also available, simply as the sum of delta functions at the discrete initial alpha particle energies $w_{i,\alpha}(E) = \sum_{\ell \in i} Y^{\ell}_{i,\alpha} \delta\left(E - E^{\ell}_{i,\alpha}\right)$ with yields $Y^{\ell}_{i,\alpha}$, as required by Eq. (5.1.41).

Beta Sources

The beta source (i.e. without considering slowing down in the media) is available as the sum of the continuous emission spectra for each β^- decay in nuclide i. The total yield of beta particles from decay of nuclide i is

$$Y_{i,\beta} = \frac{\lambda_{i,\beta}}{\lambda_i} \tag{5.1.50}$$

where $\frac{\lambda_{i,\beta}}{\lambda_i}$ is the fraction of decays which emit betas. The betas emitted by nuclide i at energy E is given by

$$w_{i,\beta}(E) = Y_{i,\beta} X_{i,\beta}(E) \tag{5.1.51}$$

where the spectrum $X_{i,\beta}(E)$ is fundamental data, independent of the media. The spectrum includes betas from allowed transitions and first, second, and third forbidden transitions.

Photon Sources

The total yield of photons from decay of nuclide i is

$$Y_{i,\gamma} = \frac{\lambda_{i,\gamma}}{\lambda_i} \tag{5.1.52}$$

where $\frac{\lambda_{i,\gamma}}{\lambda_i}$ is the fraction of decays which emit photons. The photons emitted by nuclide i at energy E is given by

$$w_{i,\gamma}(E) = Y_{i,\gamma} X_{i,\gamma}(E) \tag{5.1.53}$$

where the spectrum $X_{i,\gamma}(E)$ is fundamental data and includes both line data from x-rays, gamma-rays and continuum data from Bremsstrahlung, spontaneous fission gamma rays, and gamma rays accompanying (α, n) reactions. The Bremsstrahlung component of the photon source has been tabulated for various media and no on-the-fly slowing down calculation is performed.

Library Interpolation

Accurate solution of fuel depletion with Eq. (5.1.1) requires coupling to self-shielding and neutron transport to accurately capture the time-dependent change in space and energy flux distribution and 1-group cross sections with isotopic change. This is in generally a fairly computationally intensive problem compared to stand-alone depletion. In typical assembly design and analysis, the same basic assembly problem must be solved repeatedly with variations in power history, different periods of decay/burnup, different moderator density, etc. A question naturally arises: could the isotopics from numerous well-constructed cases be saved and interpolated to the actual system? Interpolating the isotopics themselves is fraught with difficulty. For example, consider two cases with the same burnup but different periods of decay between cycles. A better approach—the ORIGEN Automated Rapid Processing (ARP)—was developed with the key realization that one can reconstruct very accurate isotopics from stand-alone depletion calculations by interpolating *transition matrices* rather than *isotopics*.

The accuracy of the interpolation methodology compared to the coupled transport/depletion solution (e.g., with TRITON) depends on the suitability of the interpolation parameters and the deviation of the desired system from the systems used to create the library. For example, for thermal systems with uranium-based fuels, it was found that enrichment, water density, and burnup were the dominant independent variables and thus were best suited for interpolation. An example of the variation of removal cross sections for key actinides is shown in Fig. 5.1.2 for a Westinghouse 17 × 17 pressurized water reactor (PWR) assembly type with 5% initial enrichment in ^{235}U. Each cross section has been divided by its initial value at zero burnup to show the variation more clearly. ^{240}Pu has been observed to have the most variation with spectral changes, with ~60% reduction in cross section from beginning to end of life. The variations in ^{240}Pu with respect to enrichment and moderator density are shown in Fig. 5.1.3, Fig. 5.1.4, Fig. 5.1.5, and Fig. 5.1.6.

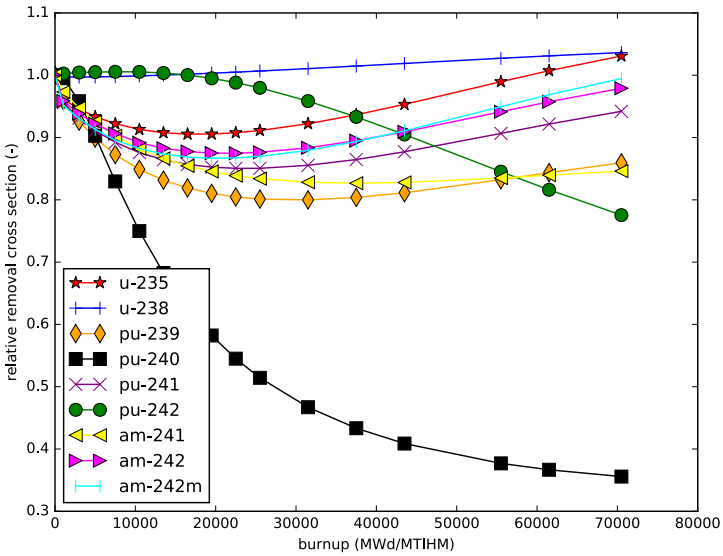

Fig. 5.1.2: Relative removal cross section as a function of burnup for key actinides (Westinghouse 17 × 17 assembly with 5\% enrichment).

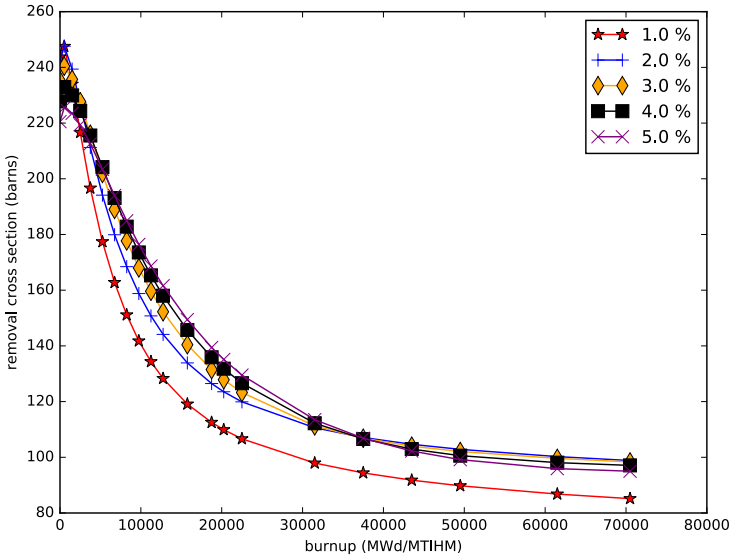

Fig. 5.1.3: ^{240}Pu-240 removal cross section as a function of burnup for various enrichments (GE 10 × 10 assembly).

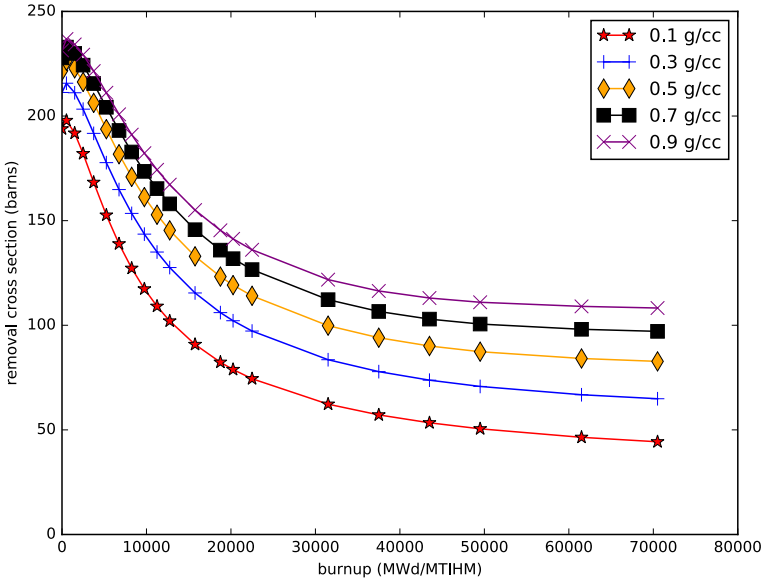

Fig. 5.1.4: ^{240}Pu removal cross section as a function of burnup for various moderator densities (GE 10 × 10 assembly).

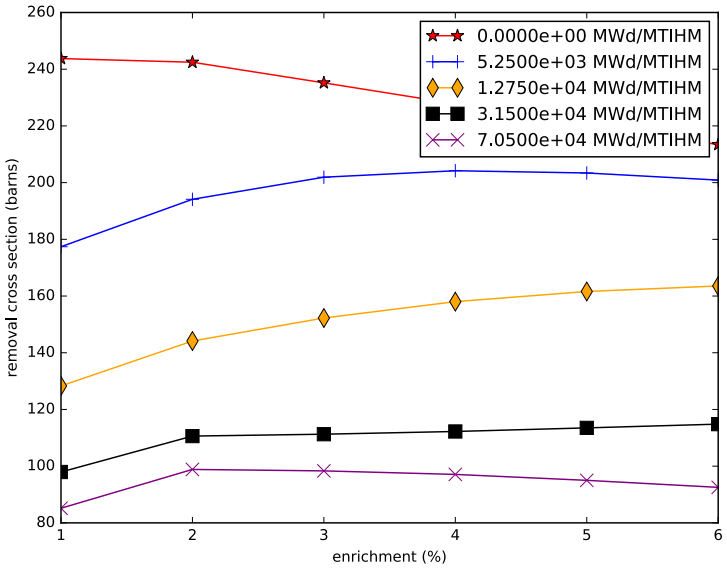

Fig. 5.1.5: ^{240}Pu removal cross section as a function of initial enrichment for various burnups (GE 10 × 10 assembly).

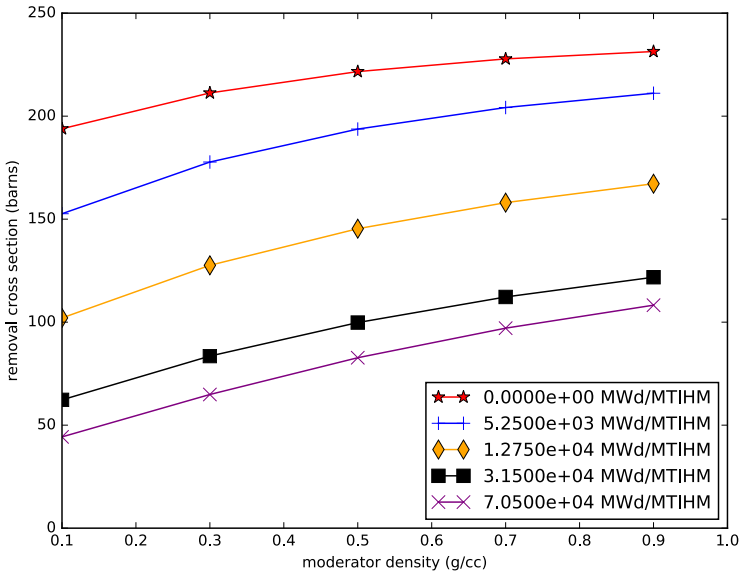

Fig. 5.1.6: ^{240}Pu removal cross section as a function of moderator density for various burnups (GE 10 × 10 assembly).

Currently there are two interpolation methods: a Lagrangian based on low-order polynomials and a cubic spline with an optional monotonicity fix-up.

Lagrangian Interpolation

Lagrangian interpolation [ORIGEN-REFed68] seeks the unique *n-1* order polynomial that will pass through *n*-points of the function and then interpolating to the desired point by evaluating the polynomial,

$$y(x) = \prod_{i=1}^{n} (x - x_i) \sum_{k=1}^{n} \frac{y_k}{(x - x_k) \prod_{\substack{i=1 \\ i \neq k}}^{n} (x_k - x_i)} \tag{5.1.54}$$

where x_i and y_i are the known x- and y-values in the neighborhood of the desired x-value x, with n the number of data points/order of Lagrangian interpolation. Note that Lagrangian interpolation is by definition *local*, involving only points in the neighborhood of the desired value. Global alternatives such as Hermite cubic splines use the entire data set to construct the interpolants. Common interpolation methods based on polynomials can have difficulty with data that vary quickly and have uneven x-spacing, as is expected with transition data. Polynomials tend to produce unphysical oscillations in these cases. In cases with very small y-values (~10^{-10}), oscillations of the interpolant can produce negative interpolated values.

Cubic Spline Interpolation

Cubic spline interpolation has been observed to produce fewer, lower frequency oscillations. Oscillations can be effectively eliminated by enforcing monotonicity on the interpolation: that is, additional max maxima or minima are not introduced by the interpolant between known values of the function. Monotonic cubic splines [ORIGEN-WA02] have shown particularly stable behavior and have been implemented as an interpolation option.

5.1.4 ORIGEN FAMILY OF MODULES

This section describes how to perform the calculations and evaluations described in Sect. 5.1.3 using the ORIGEN family of modules in SCALE. These modules are summarized briefly below.

1. The ARP module creates a new ORIGEN library by interpolating a set of existing libraries. ORIGEN libraries organized for this purpose are called ORIGEN Reactor libraries. Those distributed with SCALE are described in Sect. 5.3.
2. The ORIGEN module is used to solve depletion, decay, activation, and feed problems described by Eq. (5.1.1), as well as the decay emission calculations described by Eq. (5.1.41). For spent fuel calculations using the ARP interpolation methodology, it may be more convenient to use ORIGAMI, as described in the ORIGAMI chapter.
3. The OPUS module is used to perform post processing and analysis on ORIGEN results contained in ORIGEN concentrations files, including sorting, ranking, and unit conversion.

Two types of files are an integral part of the ORIGEN family of modules: the library file and the concentrations files.

- The library file is a binary file, usually either with the complete filename "ft33f001" or with extension ".f33," and it contains a collection of transition matrices **A**, usually corresponding to different burnups. It is typically called an "ORIGEN library," "ft33," or "f33" file.
- The concentrations file is also a binary file, usually either with the complete filename "ft71f001" or with extension ".f71." The f71 is a solution archive containing isotopics vectors $\vec{N}$ corresponding to different materials or different points in time.

Note: A fundamental cability to create ORIGEN libraries within the ORIGEN sequence has been added to SCALE 6.3, effectively deprecating the stand-alone COUPLE module.

5.1.5 ORIGEN MODULE

The ORIGEN module drives depletion, decay, and activation calculations as described in Sect. 5.1.3.1, including the conversion of generated powers to fluxes described in Sect. 5.1.3.1.8, as well as alpha, beta, gamma, and neutron source calculations described in Sect. 5.1.3.1.9.

5.1.5.1 Key Features

This section briefly highlights some key features in ORIGEN and describes how they are used.

Nuclide Specification and ORIGEN Sub-libraries

The nuclide identifiers in ORIGEN are more flexible than those in other modules of SCALE and even within the ORIGEN family. Table 5.1.1 shows the possible ways to specify nuclides (and elements).

Table 5.1.1: Nuclide / element specification in ORIGEN

Identifier Form	**Comments**	**Examples**	
		nuclide	*input id*
IZZZAAA I - *isomeric state* ZZZ - *atomic nummber* AAA - *mass number*	Standard numeric identifier with one optional digit of isomeric state, three digits of atomic number, three digit of mass number; elements have mass number of 000.	^{235}U	92235
		^{235m}U	1092235
		^{135}Xe	54135
		^{1}H	1001
		^{10}B	5010
		Fe	54000
EAm E - *element symbol* A - *mass number* m - *metastable indicator*	Standard symbolic identifier with element symbol followed by mass number, followed by optional metastable indicator; can include a dash between E and A (E-Am); case insensitive.	^{235}U	u235
		^{235m}U	u235m
		^{135}Xe	xe135
		^{1}H	h1
		^{10}B	b10
		Fe	fe

One important aspect ORIGEN users must be aware of is that the ORIGEN library (f33) being used dictates the set of nuclides available in a calculation and that there may be more than one *version* of a nuclide in a library. The duplicates arise in large part from the need to analyze fission products separately. For example, a gadolinia-doped uranium oxide fuel with burnup will have some ^{155}Gd from the initial gadolinia loading and some ^{155}Gd generated as a fission product. Although these fuels physically behave the same way, it is sometimes important to be able to analyze them separately. These groups, versions, or categories are referred to as sublibraries because in an ORIGEN library, they appear almost like three separate, smaller ORIGEN libraries. The three libraries are for

1. naturally occurring, light nuclides, sometimes called “light elements” or “activation products,”
2. actinides and their reaction and decay products, and
3. fission products.

Called “sublibs” for short, they are identified by a number or 2-character specifier:

1. light nuclides with “LT” or 1,
2. actinides with “AC” or 2, and
3. fission products with “FP” or 3.

The production of fission products from actinides (2/AC3/FP) is the only type of transition in a typical ORIGEN library that spans sublibs. The sublib is optional in a nuclide specification and is indicated in parentheses after the identifier-IZZZAAA(S), EAm(S). If the sublib for a nuclide/element is not provided, it is guessed in the following manner:

1. If the nuclide is in fact an element, then it is placed in sublib=1/LT.
2. If the atomic number Ztextlt 26, an *attempt* is made to place it in sublib=1/LT.
3. Otherwise (Ztextgeq 26 or attempt fails), sublibs are searched in reverse order, from 3/FP, 2/AC, and then 1/LT.

The third rule, which is to search sublibs in reverse order, correctly handles spent reactor fuel, a common and important scenario. The other two conditions can be interpreted as exceptions. The first exception correctly handles activation scenarios where it is most convenient to specify the initial elemental constituents. The second exception handles light nuclides that could not be real fission products, as fission products have Ztextgeq 26 by definition. The byproducts ^{1}H, ^{2}H, ^{3}H, ^{3}He, and ^{4}He actually exist in all sublibs, but FP and AC byproducts have a reduced set of transitions compared to the LT version, which has full decay and activation chains. Thus when a user specifies one of the byproduct nuclides as input, it is best to associate it to the LT version.

Physical Units in Calculations

A variety of units can be used in the input and specified for the output of an ORIGEN calculation. The input allows for initial concentrations in

1. grams,
2. moles (or gram-atoms),
3. number density in atoms/barn-cm, and
4. curies.

Time may be expressed in seconds, minutes, hours, days, years, or a user-defined unit. Irradiation may be expressed in terms of neutron flux (n/cm^2-s) or power (W). The allowed units for output include those for input, as well as the following decay quantities:

1. total decay heat power (W),
2. gamma decay heat power (W),
3. airborne toxicity (m^3) required to dilute activities to the Radiation Concentration Guide (RCG) limit for air,
4. ingestion toxicity (m^3) required to dilute activities to the RCG limit for water, and
5. alpha, beta, neutron, photon sources (particles/s or MeV/s).

Table 5.1.2 summarizes the available units in ORIGEN. During irradiation cases, the following can also be returned:

1. absorption rates (absorptions/s),
2. fission rates (fissions/s), and
3. infinite neutron multiplication constant, k_∞.

Table 5.1.2: Availalble physical units in ORIGEN

Unit name	Description	Input	Output	
			(irrad.)	(decay)
GRAMS	Mass in grams	*	*	*
MOLES or GRAM-ATOMS	Number in moles (or legcy equivalent of gram-atoms)	*	*	*
ATOMS-PER-BARN-CM	Density in atoms/barn-cm (10^{-24} cm/barn $\times$ density in atoms/ cm^3); requires volume input	*	*	*
CURIES	Activity in curies	*	*	*
BECQUERELS	Activity in becquerels	*	*	*
ATOMS_PPM	Atom fractions x 10^6		*	*
WEIGHT_PPM	Weight fractions x 10^6		*	*
WATTS	Total decay heat in watts			*
G-WATTS	Total decay heat from photons in watts			*
M3_AIR	Radiotoxicity m^3 for for inhalation			*
M3_WATER	Radiotoxicity in m^3 for ingestion			*

Saving Results

ORIGEN can save any results (isotopics and source spectra) in a special ORIGEN binary concentrations file (f71). The file is a simple sequence of solutions, and new results are simply appended on to the end of an existing file. Note that no matter how initial isotopics are entered or what units are asked for in the output file, the ORIGEN f71 contains **moles** (gram-atoms) of each isotope and an optional **volume** to permit unit conversions to number density (atoms/barn-cm). Isotopics for an ORIGEN calculation can be initialized from any position on this file in an ORIGEN calculation. The f71 can also be read by OPUS to perform various post-processing tasks.

5.1.5.2 Input Description

ORIGEN uses the SCALE Object Notation (SON) language for its input, although it can also read FIDO-based input for backwards compatibility with SCALE 6.1 [ORIGEN-ORN11]. The basic structure of an ORIGEN input is shown in Example 5.1.1.

Example 5.1.1: ORIGEN input file overview

```
'SCALE comment
=origen

% ORIGEN comment %

bounds{ ... }
solver{ ... }
options{ ... }

case(A){
    time=[31 365] % days
    ...
}

case(B){
   ...
}
```

(continues on next page)

(continued from previous page)

```
...
% more cases?

end
```

The ORIGEN input is hierarchical, containing four levels, where level 0 is the "root" level, allowed between "=origen" and "end." The complete set of keywords is shown in Table 5.1.3, with arrays denoted with "=[]" and blocks with "{}". Referring to the overview in Example 5.1.1, at the root level, there is a "solver" block for changing solver options, a "bounds" block for entering the energy boundaries for various particle emissions, and an "options" block for altering the miscellaneous global options. These blocks may only appear once. The remainder of the input is a sequence of "case" blocks (in the above examples there are two cases with identifiers "A" and "B"), which each case is executed in order, with each case possibly depending on one or more of the previous cases.

The percent sign (%) is the comment character *inside the ORIGEN sequence,* between "=origen" and "end." The % is a very flexible comment that may be placed almost anywhere in the input and continues until the end of the line. Outside the ORIGEN sequence, the SCALE comment character of a single quote ‘ at the beginning of a line must be used. Arrays in SON begin with "[" and end with "]" and support the following special shortcuts inherited from FIDO. Note that the interpolation shortcuts (I and L) *insert* values between two specified values so that there will be N+2 values in the final expanded array section.

Table 5.1.4: Array entry shortcuts

Shortcut	**Format**	**Examples** *shortcutexpansion*
Repeat (**R**)	*N***R***X*	3r1e141e14 1e14 1e14 6r3 3 3 3 3 3 3
Linear interpolation (**I**)	*N***I** *X Y*	3i 5 1 5 4 3 2 1 9i 0.0 1.0 0.0 0.1 0.2 0.3 0.4 0.5 0.6 0.7 0.8 0.9 1.0
Log interpolation (**L**)	*N***L** *X Y*	3l 1 5 5l 1e-9 1e-3 1e-9 1e-8 1e-7 1e-6 1e-5 1e-4 1e-3

As an alternative to manually creating an ORIGEN input file via a text editor, the user may use the SCALE graphical user interface (GUI) Fulcrum to create ORIGEN input files. Advantages to using Fulcrum include syntax highlighting, autocomplete, immediate feedback when input is incorrect, and one-click running of calculations.

Calculation Case (case)

A single ORIGEN sequence may contain an unlimited number of case blocks. Each case block is processed in order and can represent either an independent calculation or continuation of a previous case. The complete contents of a single case block are shown in Table 5.1.1.

Example 5.1.2: ORIGEN "case" overview

```
case(ID){
   title="my title"

    lib{ ... }
    mat{ ... }
    time{ ... }
    flux{ ... } % or power{ ... }

    print{ ... }
    save{ ... }

    alpha{ ... }
    beta{ ... }
    gamma{ ... }
    neutron{ ... }
}
```

The most important three components are the lib, mat, and time/power/flux inputs:

1. an ORIGEN library and the transition matrix data set on it to use (lib),
2. initial amounts of nuclides (mat), and
3. a power or flux history (time/power or time/flux).

The case identifier and case title string (shown as ID and title="my title" in Example 5.1.2) are echoed in the output file and can be a convenient way to differential cases. Both are optional, with the ID defaulting to the case index, with "1" for the first case, "2" for the second, etc. The "print" and "save" blocks represent two ways to analyze the output from a calculation. The "print" block prints tables directly to the output file, and the "save" block saves the solution in a special ORIGEN binary concentration file (f71), e.g., for later post-processing. Finally, the "alpha," "beta," "gamma," and "neutron" blocks control the emission source calculations for alpha, beta, gamma, and neutron particles, respectively. The remaining subsections will describe the input for each of these blocks.

Transition Matrix Specification (lib)

The transition matrix to use in a case is controlled by the "lib" shown in Example 5.1.3.

Example 5.1.3: ORIGEN "lib" overview

```
lib{
    file="origen.f33"  % ORIGEN library filename
    pos=1              % data set position on library
}
```

A "lib" **must** be present in the first case with a defined ORIGEN library file. The default position is "pos=1". The "lib" may be omitted in subsequent cases, and if so, the previous case's "lib" is used. The position refers to the set of transition coefficients (transition matrix **A**) to load. To load another position on the same library file, the "lib" block with "pos=X" can be used to load position X. When ARP generates an ORIGEN

library, it will contain a set of transition coefficients for each requested burnup. When COUPLE generates an ORIGEN library, it will contain a single position. **For decay calculations, file="end7dec" can be used to load a decay-only library.**

Material Specification (mat)

The initial isotopics for a case a controlled by the "mat" shown in Example 5.1.4. Note that the material specification has a few different variants, with only one allowed to specify the material in a given case.

Example 5.1.4: ORIGEN "mat" block overview

```
% from iso
mat{
    iso=[ u235=1.0 u238=9.0 ] %id(sublib)=amount
    units=GRAMS               %units in iso array
}

% from iso with number density input
mat{
    iso=[ u235=1e-2 u238=1e-1 ] %id(sublib)=amount
    units=ATOMS-PER-BARN-CM     %units in iso array
    volume=200                  %cm^3
}

% from position on f71 file
mat{
    load{ file="origen.f71" pos=11 }
}

% from previous case (previous=LAST is default)
mat{
    previous=4 %step index from previous case
}
```

In the first variant in Example 5.1.4, the isotopic distribution "iso" is used with "units." The "iso" array contains a sequence of "id=amount" pairs, where "id" is a nuclide identifier in the format described in Sect. 5.1.5.1.1, and the units of the amount are given by the "units" keyword, one of the unit names listed in the third column of Table 5.1.2. Default units are MOLES.

In the second variant, the number density (ATOMS-PER-BARN-CM) is specified which requires an additional specification of the "volume" in cm^3. Internally, the number density will be converted to MOLES using that volume. For any type of units specified internally for calculations, isotopics are always converted to MOLES and then reconverted to the output units required.

In the third variant, the isotopics are loaded from a specific position on the f71 file. Note that the position index starts at one (not zero) and because the f71 is always appended to, it may contain multiple materials, cases, timelines, etc. In the fourth and final variant, the isotopics are loaded from *end* of step 4 from the previous case ("previous=4"). The index zero (e.g., "previous=0") corresponds to the initial isotopics of the previous case. The keyword "LAST" may be used to load the isotopics from the end of the last step, "previous=LAST". This is the default behavior, used when a "mat" block is not present.

There are two additional special material specifications shown in Example 5.1.5: (1) with a feed rate term, $\vec{S}(t)$ in Eq. (5.1.4), or (2) the blend array. The feed specified is in the units specified *per second* and constant for the entire case. It is possible to perform a calculation with feed but with zero initial isotopics by specifying "iso=0". Feed can be negative, however, the calculation becomes undefined and will abort when the number of atoms of any nuclide becomes negative.

The blend array allows a fraction of each result from the previous cases to be loaded. The identifier is the case name, or the *index* of the case if a case name is not provided and the fraction is the atom fraction. The step index for the isotopics can be specified in parentheses. For example, B(2)=0.9 indicates that 90% of the case(B) isotopics should be taken at the end of step 2. The default step index is the final step for the case. **Only one blend is allowed in an ORIGEN input (between "=origen" and "end").** Multiple blends currently requires saving isotopics to an f71 file and reloading in a subsequent calculation.

Example 5.1.5: ORIGEN "feed" and "blend" arrays

```
% with feed array
mat{
    % units for iso and feed
    units=GRAMS

    % material is natural sodium
    iso=[na=1.0e6]
    % with feed array, set initial isotopics of zero
    %iso=0

    % continuous feed of U-235 at 1 kg/day
    % converted to grams/second
    feed=[u235=0.01157]
}

% with blend array (only one allowed in an input)
case(A){ ... }
case(B){ ... }
case{
    ...
    mat{
        % case ID(step index)=fraction of atoms
        blend[ A=0.1 B(2)=0.9 ]
    }
}
```

Operating History (power, flux, time)

The operating history is specified using "time," "power," and "flux," with examples shown in Example 5.1.6. For decay cases, only the "time" array in units of days is required. For irradiation cases, either "power" or "flux" may be provided. When flux is used, it is the step-wise flux Φ_n $\left(\frac{n}{cm^2 s}\right)$ appearing directly in the depletion equations of Eq. (5.1.4). When power is used, it is the total step-average power– P_n (MW) –converted to step-wise average flux using Eq. (5.1.40). With irradiation cases using flux or power, the same number of entries must be specified on the time and flux/power array. The start time corresponding to the initial conditions is not included in the array of time values. Additionally, the time specification allows time units (including a custom unit) and a start time in which the block form of "time" must be used "time{...}."

Example 5.1.6: ORIGEN operating history blocks ("time," "flux," and "power").

```
% simple decay case (two steps 0 unicode::U+2192 1 and 31 unicode::U+2192 65 days)
time = [ 31 365 ]

% flux irradiation (decay if flux=0)
time = [ 31   365  396 ]
flux = [ 2e14 1e14 0 ]

% power irradiation (decay if power=0)
time = [ 31 365 396 ]
power= [ 50 45  0 ] %50 MW, 45 MW, then decay
```

(continues on next page)

(continued from previous page)

```
% changing units using time block
time{
    t = [ 5 15 300 ]
    units = HOURS
    % available units:
    % SECONDS, MINUTES, HOURS, DAYS, YEARS, CUSTOM
}

% custom units
time{
    t = [ 1 2 3 ]
    units = CUSTOM
    custom_name = "MONTH"
    custom_length = 2678400 %seconds per "MONTH"
}

% 10-step detailed power history
time=[   5  10 20 100 300 400 405 500 800 1000]
power=[ 20  41 43  42  37  33  16 14.5 28.5 26]
```

To illustrate some aspects of specifying a power history, refer to Fig. 5.1.7, where the black line ("actual power") shows a piecewise linear power history that is translated to a possible step-wise constant power history shown by the red line ("step-wise constant power"), with input shown in Example 5.1.6 labeled "10-step detailed power history". The secondary (right) y-axis shows the step-wise flux, calculated from the step-wise power via the predictor-corrector approach of Eq. (5.1.40). The dependence of the power-to-flux conversion on the actual material composition is shown in the comparison of flux results for an initial composition with 6% fissile ^{235}U (blue dotted line) versus 2% fissile ^{235}U (purple dashed line). The flux at the beginning of the irradiation is a factor of 3 higher with the 2% fissile case, due to approximately a factor of 3 lower fissile content. With time, fissile plutonium build-up closes the gap to a factor of 1.5.

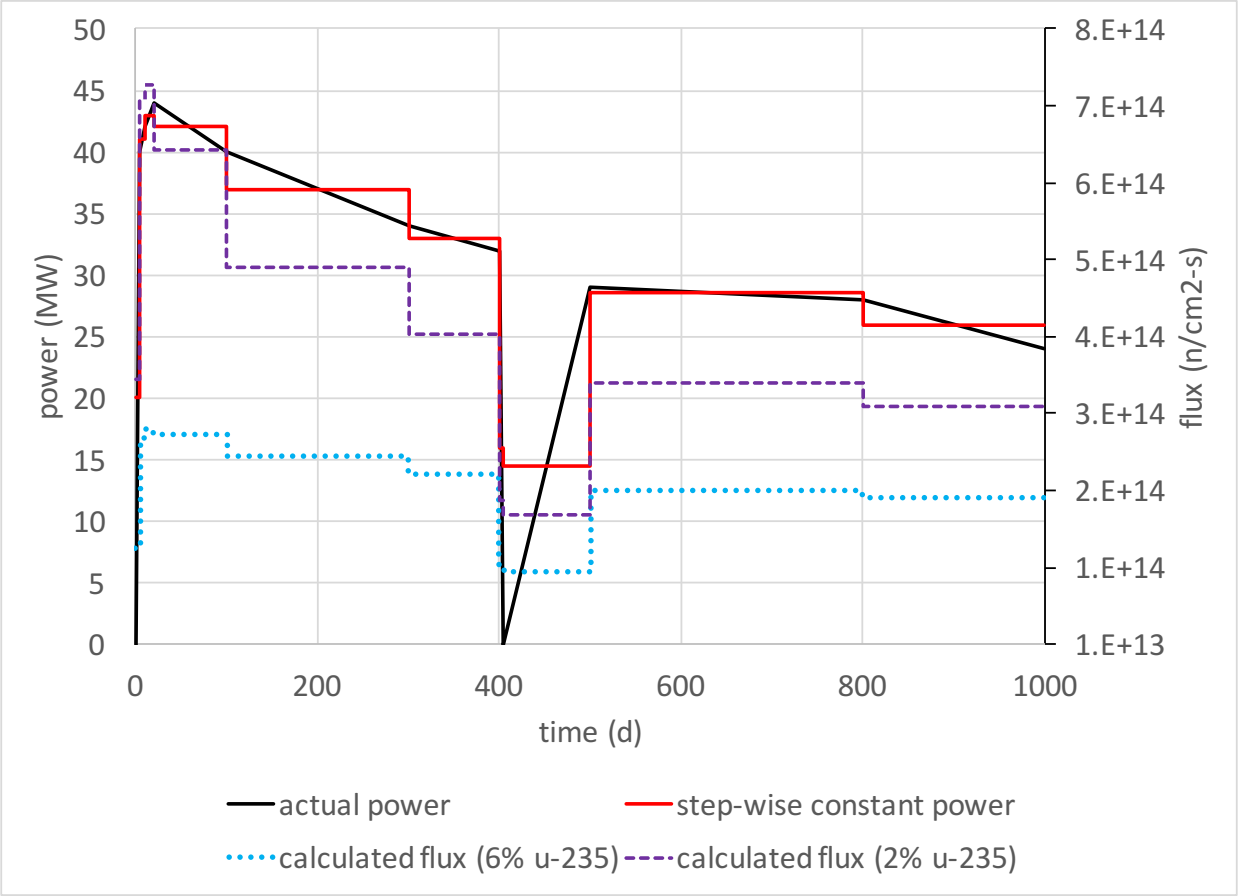

Fig. 5.1.7: Example of ORIGEN operating history and power-to-flux conversion.

Example 5.1.7: ORIGEN "start" time usage.

```
% first case
case{
    mat{ ... }
    time=[ 1 10 25 50]
    flux=[ 4r1e14 ]
}
% continuation case (time zero is 50 days)
case{
    time{
        units=YEARS
        %without start, times must continue > 50 days
        %t=[50/365.+0.1 50/365.+0.3 ... ]
        %with start=0, times given assume start at zero
        start=0
        t=[0.1 0.3 0.9 2.7]
    }
}
```

By default, subsequent cases that continue operations on a material, continue the timeline of that material. Using "start=0" is convenient when switching time unitsfrom irradiation in days to decay time in years, for example. Otherwise, the final time must be converted to years.

Printing Options (print)

The "print" command is one of the most complex inputs, with options to set printing cutoffs and control the concentrations returned, broken down by nuclides and elements and emission sources for gamma, neutron, alpha, and beta particles. Additionally, there are options to print fission rates, absorption rates, and the ratio of fission rate to absorption rate. Each case is allowed a print block.

Inventories by nuclide and element

The options for printing nuclides and elements are shown in Example 5.1.8. The print block allows the "nuc" block and "ele" block for printing nuclide and element results, respectively.

Example 5.1.8: ORIGEN nuclide and element "print" blocks

```
% print each nuclide (total across all sublibs) in grams
print{
    nuc{ total=yes units=GRAMS }
}

% print each element (total across all sublibs)
% in moles, grams, and curies with cutoffs of 1%
print{
    ele{ total=yes units=[MOLES GRAMS CURIES] }
    cutoffs[ ALL=1.0 ]
}

% print decay heat and mass (by element)
% of fission products and actinides only
print{
    ele{ sublibs=[AC FP] units=[GRAMS WATTS] }
}

% change cutoff to absolute curies by element,
% in step of interest (7), but print GRAMS
print{
    cutoff_step = 7 % default -1 for average
    rel_cutoff = no % default is yes for cutoff in percent
    % only print above 1e-3 curies
    cutoffs[ CURIES=1e-3 ]   % default is 1e-6 percent
    nuc{
     total=yes
     units=GRAMS
    }
}
```

Inside the "nuc" or "ele" blocks, there are three possible entries:

- a "sublibs" array (a list from LT, AC, FP, ALL),
- a "total" (yes or no), and
- a "units" array (see column 1 of Table 5.1.2 for possible units).

The "total" is whether to sum over all "sublibs," i.e., if Gd-155 occurs in both LT and FP sublibs, then the total will be the sum of the two. It is possible to have "sublibs=[LT AC FP] total=yes," which results in four output tables, one for each of the sublibs and one for the total. The specification of "sublibs=ALL" is the same as "sublibs=[LT AC FP]."

Three parameters set the cutoff for printing a nuclide or element:

- "cutoff_step" sets the index on which to base the cutoff (default -1 means use an average over all steps),

- "rel_cutoff" determines whether to treat the cutoff as a percent of the total (default/yes) or an absolute amount (no), and
- the "cutoffs" array allows one to specify the cutoff for each unit in Table 5.1.2 as a sequence of "unit=cutoff" pairs.

Radiological Emissions (alpha, beta, gamma, neutron)

The emission printing options are controlled by the "alpha," "beta," "gamma," and "neutron" emission blocks inside a "print" block (examples shown in Example 5.1.9).

Example 5.1.9: ORIGEN emission "print" blocks.

```
print{
    % default neutron options
    neutron{
     summary=yes
     spectra=no
     detailed=no
    }

    % default gamma options
    gamma{
     summary=yes
     spectra=no
     principal_step=NONE  %step index to calculate
                          %(NONE to suppress)
     principal_cutoff=2   %principal emitter cutoff
                          %in percent
     unbinned_warning=no  %print warning
                          %when line not binned
    }

    % default alpha options
    alpha{
     summary=yes
     spectra=no
    }

    % default beta options
    beta{
     summary=yes
     spectra=no
     principal_step=NONE  %step index to calculate
                          %principal (NONE to suppress)
     principal_cutoff=2   %principal emitter cutoff
                          %in percent
    }
} %end print
```

Neutron print options

The "neutron" print options are

- "summary" (yes/no) controls the printing of a source strength summary,
- "spectra" (yes/no) controls the printing of the spectra (energy group-wise), and
- "detailed" (yes/no) controls the printing of extra details about the neutron calculation.

The "gamma" print options are

- "summary" (yes/no) controls the printing of a source strength summary and
- "spectra" (yes/no) controls the printing of the spectra (energy group-wise).

Gamma print options

The gamma print allows a special output of the principal emitters in each energy group, controlled by setting the "principal_step" keyword to a specific step index in the case, with the "principal_cutoff" keyword used to set the minimum percent of the total a nuclide must have to be considered a principal emitter. For the gamma print there is a warning that can be enabled with "unbinned_warning=yes" if some gamma lines fall outside the user group structure and thus are not included.

Alpha print options

The "alpha" print options are

- "summary" (yes/no) controls the printing of a source strength summary and
- "spectra" (yes/no) controls the printing of the spectra (energy group-wise).

Beta print options

The "beta" print options are

- "summary" (yes/no) controls the printing of a source strength summary and
- "spectra" (yes/no) controls the printing of the spectra (energy group-wise).

The beta print also allows a special output of the principal emitters by setting the "principal_step" keyword to a specific step index in the case, with the "principal_cutoff" keyword used to set the minimum percent of the total a nuclide must have to be considered a principal emitter.

The special printing options are shown in Example 5.1.10.

Example 5.1.10: ORIGEN special "print" options

```
% defaults special printing options
print{
    absfrac_sublib = ALL %print absorption fractions for
                         %a specific sublib (LT,AC,FP)
                         %or ALL sublibs (DEFAULT)

    absfrac_step = 7  %if absfrac active, step to print
                      % default is last step

    fisrate = NONE    %print fission rates (default NONE)
                      %absolute (ABS) or relative (REL)

    kinf = no         %print fission/absorption (yes/no)
}
```

Saving Results (save)

Saving the results to an ORIGEN binary file (f71) is requested with the "save" block, which specifies both the name of the file and the step indices to save, as shown in Example 5.1.11. The default for the filename is "file=ft71f001" and default for the steps is the special "steps=ALL" which saves all isotopics and spectra as a shortcut to having to specify "steps=[0 1 2 3 . . . LAST]". The step index "0" corresponds to the initial isotopics and the step index "LAST" may be used as a shortcut for the last case index. There is a special rule for copying f71 files from SCALE's temporary/working directory. If the file name "ft71f001" exists in the directory when SCALE finishes, it is copied to the user's "${OUTDIR}" as "${BASENAME}.f71", e.g. if my.inp produces "ft71f001" in the temporary/working directory then it will be copied to the same location as the main output file ("my.out") as "my.f71". Note that f71 files are always appended to by ORIGEN. To save with the defaults, the shortcut "save=yes" is provided. The default is "save=no".

Example 5.1.11: ORIGEN "save" block.

```
case{
    mat{ ... }
    time=[ 1 10 100 1000 ] % 4 steps to 1000 days
    save{
          file="short.f71"   % file name
          steps=[0 2 4]      % save initial (0) and isotopics
                                 % end-of-step 2 (10 days)
                                 % end-of-step 4 (1000 days)
    }

    save{
          file="ft71f001"    % file name (DEFAULT)
          steps=ALL          % save ALL steps (DEFAULT)
    }
    save=yes               % equivalent to the above

    save{
          file="last.f71"    % file name
          steps=[LAST]       % save only last (LAST=4 here)
          time_offset=1000   % write time - time_offset
          time_units=DAYS    % units of time_offset
    }
}
```

In order to change the time values written to the f71 file, use "time_offset=T_0" which will write the current cumulative time minus T_0 to the file. The "time_offset" is convenient, for example, when time *since discharge* is desired instead of the absolute, cumulative time. The "time_units" entry specifies the units of the "time_offset", with the same units available in the "time" block. The default is "time_units=DAYS".

Decay Emission Calculations (alpha, beta, gamma, neutron)

A decay emission calculation is initiated with the appropriate block inside the calculation "case." The group structure for any emission spectra result is determined by the energy bounds provided as described in Sect. 5.1.3.1.9. Each type of emission calculation is activated by the existence of a calculation block named "alpha", "beta", "gamma", or "neutron" for those respective types of calculations. Alternatively, to turn on an emission calculation with defaults, use "alpha=yes", "beta=yes", "gamma=yes", or "neutron=yes" in a "case" block.

Neutron source calculation

The neutron calculation (Sect. 5.1.3.1.10) is activated by the "neutron" calculation block. All neutron calculation options are to control the (α, n) calculation.

Three (α, n) options can be indicated with the "alphan_medium": a UO_2 fuel matrix (alphan_medium=UO2), a borosilicate glass matrix (alphan_medium=BOROSILICATE), and the problem-dependent matrix defined by the user input compositions (alphan_medium=CASE). The numeric options 0, 1, and 2 are also valid for the UO2, BOROSILICATE, and CASE options, respectively. Note that the UO_2 and borosilicate glass matrix options assume that the neutron source nuclides reside in these respective matrices, *regardless of the actual composition of the material in the problem.*

For oxide fuels, a significant neutron source can be produced from ^{17}O (α, n) and ^{18}O (α, n) reactions in the oxygen compounds of the fuel. For this reason, the UO_2 matrix option (enabled by alphan_medium=UO2) is provided with natural isotopic distribution of ^{17}O and ^{18}O. This includes the impact of oxygen isotopes on the neutron source without having to include oxygen in the initial composition.

Another common use case is fuel storage in a borosilicate glass matrix (enabled by `alphan_medium=BOROSILICATE`), listed in Table 5.1.5 from [ORIGEN-DJPB86]. Elements with atomic number less than 17 have (α, n) yields.

Table 5.1.5: Elemental composition used in the borosilicate glass option.

Atomic number	**Element symbol**	**Wt %**	**Atom %**
3	Li	2.18	6.296
5	B	2.11	3.913
8	O	46.4	58.138
9	F	0.061	0.0644
11	Na	7.65	6.671
12	Mg	0.49	0.404
13	Al	2.18	1.620
14	Si	25.4	18.130
17	Cl	0.049	0.0277
20	Ca	1.08	0.540
25	Mn	1.83	0.668
26	Fe	8.61	3.091
28	Ni	0.70	0.239
40	Zr	0.88	0.193
82	Pb	0.049	0.0047
Total		99.669	100.000

In the last most rigorous option, the (α, n) neutron source and spectra are calculated using the source, target, and constituents determined using the material compositions in the problem *at a particular time,* dictated by "alphan_step" in the "neutron" print options. For spent fuel neutron source calculations, there are a large number of potential source, target, and constituent nuclides in the (α, n) calculation and in order to remove low-importance nuclides from the calculation, the "alphan_step" and "alphan_cutoff" parameters are used. Only those nuclides with an α-decay activity exceeding the product of "alphan_cutoff" times the total α activity are included as source nuclides in the (α, n) neutron calculation. Additionally, only those nuclides with a constituent or target atom fraction less than "alphan_cutoff" are included unless the concentration is greater than 1 ppm, in which case it will be retained regardless of the cutoff. The "blend" array is particularly useful for creating a problem-dependent medium composed of fuel and another material.

Example 5.1.12: ORIGEN "neutron" calculation block

```
case{
    ...
    neutron{
          alphan_medium=CASE %0/UO2 for UO2
                             %1/BOROSILICATE
                             %  for Borosilicate glass
                             %2/CASE for case-specific (DEFAULT)
          alphan_bins=200    %use 200 bins for
                             %alpha slowing down calculation
          alphan_cutoff=0.0  %cutoff for alpha,n calculation
          alphan_step=LAST   %step index in this case
    }
    %alternatively, to enable neutron calculation with defaults
    %neutron=yes
}
```

Gamma source calculation

The gamma (photon) calculation described in Sect. 5.1.3.1.13 is activated with the "gamma" block, as shown in Example 5.1.13. The gamma block includes a host of options where the default should be appropriate in most cases.

- The "sublib" option (default "ALL") affects the sublibraries included in the gamma emission calculation. The "immediate" option (default "yes") includes immediate gamma and x-rays.
- The "spont" option (default "yes") includes photons emitted during spontaneous fission and (α, n).
- The "continuum" option (default "yes") enables mapping of continuum data stored artificially as lines to a continuum across the user-defined energy bins.

The following options may need to be modified in some scenarios.

- The "brem_medium" option (default "UO2") includes the photons emitted by beta particles as they slow down in a medium (Bremsstrahlung) in the gamma calculation. A problem-dependent medium is not available for "brem." The only options are "NONE," "H2O" (for Bremsstrahlung in water) and "UO2" (for uranium dioxide).
- The "conserve_line_energy" option (default "no") modifies the intensity of each gamma line within a group to conserve energy according to *Ig = Ia Ea/Eg*, where *Ia* is the original line intensity, *Ea* the original line energy and *Eg* is the group energy (simple midpoint energy). Note that this option modifies intensities and thus results in number of particles not being conserved.
- The "adjust_for_missing" option (default "no") accounts for the scenario where a nuclide has a known gamma decay mode with known recoverable energy release, but the spectral data do not exist in the available emission resource. If "adjust_for_missing=yes," the *entire spectrum* is scaled up to include the missing energy. If the missing energy is more than 1% of the total, a warning is printed.
- The "split_near_boundary" option (default "no") enables a splitting of a line when it appears very close to a bin boundary. If "split=yes" and a photon line is within 3% of an interior energy boundary, then the intensity is split equally between the adjacent groups.

Example 5.1.13: ORIGEN "gamma" calculation block

```
case{
    ...
    gamma{
         sublib=ALL      %LT, FP, or AC - single sublib
                         %ALL - all sub-libraries
         brem_medium=UO2 %assume Bremsstrahlung in UO2
         continuum=yes   %expand continuum data stored as
                         %lines into proper continuua
         immediate=yes   %load lines for immediate gamma/x-rays
         spont=yes       %include photons from
                         %spontaneous fission
                         %and alpha,n reactions

         conserve_line_energy=no %conserve line energy instead
                                 %of line intensity
         adjust_for_missing=no   %adjust photon intensity
                                 %for energy of missing spectra
         split_near_boundary=no  %lines within 3% of a
                                 %group boundary are split
                                 %into two bins
    }
    %alternatively, to enable gamma calculation with defaults
    %gamma=yes
}
```

Alpha and beta source calculation

The alpha calculation (Sect. 5.1.3.1.11) has no options and the beta calculation (Sect. 5.1.3.1.12) only has a single option to choose the nuclide sublibraries included (see Example 5.1.14). Note that the alpha and beta calculations determine *sources* and do not include any slowing down physics for charged particles.

Example 5.1.14: ORIGEN "alpha" and "beta" calculation blocks.

```
case{
    ...
    alpha{
        %no options
    }
    %alternatively, to enable alpha calculation with defaults
    %alpha=yes

    beta{
       sublib=ALL  %LT, FP, or AC - single sublib
                   %ALL - all sub-libraries
    }
    %alternatively, to enable beta calculation with defaults
    %beta=yes
}
```

Processing Options (processing)

The processing options are contained inside the "processing" block (inside a "case") and have two ways to modify the isotopics vector: the "removal" block and the "retained" array (see ::numref::*fig-origen-processing-block*). Both operate on *elements* instead of nuclides.

- Each "removal" block specifies a list of elements and a rate of continuous removal in units *(1/s)*. This removal is an artificial increase of the decay constant, from Eq. (5.1.4), and it can be used to model any continuous system of removal, such as filtration. Note that more than one removal block may be specified.
- The "retained" array specifies a list of elements and the mole/atom fraction to be retained at the start of this case. **Note that all unspecified elements become zero.**

Example 5.1.15: ORIGEN "processing" block

```
case{
    ...
    processing{
        %rate is in 1/s
        removal{ rate=1e-2 ele=[H Xe Ar] }
        removal{ rate=1e-7 ele=[U Pu] }
        %id=frac
        retained=[ u=1.0 pu=0.5 ]
    }
}
```

Bounds Block

The "bounds" block appears outside all cases and is valid for the entire input, dictating the energy bins (i.e., groups) for emission spectra and source calculations (see Example 5.1.16). The array shortcuts-"L" for logarithmically spaced intervals and "I" for linearly-spaced intervals-can be particularly useful for specifying the bounds (see Table 5.1.4). The energy bounds are in units *(eV)* and can be given in increasing or decreasing order with the output convention of decreasing order. Additionally, neutron and gamma energy bounds can be read from a standard SCALE cross section library file by specifying the path to the file instead of the array bounds.

Example 5.1.16: ORIGEN "bounds" block.

```
=origen
bounds{
    neutron=[1e6 1e3 1] %2-group with 1MeV, 1keV, 1eV
    gamma=[100L 1.0e7 1.0e-5] %101 logarithmically spaced bins
    alpha=[1e6 2e7] %high-energy bin between 1 and 20 MeV
    beta=[22I 1 100] %23 linear bins between 1 and 100 eV
    %read neutron bounds from SCALE multi-group library file
    %neutron="scale.rev04.xn252v7.1"
}
case{ ... }
end
```

Solver Block

The solver block controls high-level solver options, the most important of which is the actual solver kernel used, either the default MATREX (Sect. 5.1.3.1.3, Example 5.1.17) or CRAM (Sect. 5.1.3.1.7, Example 5.1.18).

Example 5.1.17: ORIGEN "solver" block for MATREX

```
=origen
solver{
    type=MATREX    %(DEFAULT)
    opt{
        terms=21   %number of expansion terms (DEFAULT)
        maxp=100   %maximum number of short-lived precursors
                   % for a long-lived nuclide (DEFAULT)
        substeps=1 %number of time step divisions (DEFAULT)
    }
}
case{ ... }
end
```

Example 5.1.18: ORIGEN "solver" block for CRAM

```
=origen
solver{
    type=CRAM
    opt{
        order=16   %order of the method (DEFAULT)
        substeps=1 %number time step divisions (DEFAULT)
    }
}
case{ ... }
end
```

The MATREX kernel contains two parameters that are generally sufficient with the default values. The minimum number of "terms" is $n_{terms} = 21$, which overrides the heuristic in Eq. (5.1.20). Experience indicates that high flux levels (e.g., greater than 10^{16} n/cm^2-s) may require more terms. The second parameter, "maxp," is generally sufficient, describing the amount of storage available for the short-lived precursors of a long-lived isotope.

The CRAM kernel has a single parameter that impacts the numerical error: the "order." Both the CRAM and MATREX solver include the "substeps" parameter that adds substeps to each user-defined time step. Testing the same input with a different number of substeps (e.g., "substeps=1," "substeps=2," "substeps=4") can be a simple way to check that the time grid is sufficient.

Options Block

The "options" block contains miscellaneous global options that apply to all cases, as shown in Example 5.1.19. The "print_xs" option enables output of the transition matrix **A** used in each case, the "digits" option enables high-precision output when set to 6, and the "fixed_fission_energy" allows 200 MeV per fission to be used everywhere instead of the nuclide-dependent energy release being used by default.

Example 5.1.19: ORIGEN "options" block

```
=origen
options{
    print_xs=no             %print cross sections
    digits=4                %digits=6 is high-precision
    fixed_fission_energy=no %set to yes to use 200 MeV/fission
}
case{...}
end
```

Library Building Block `build_lib`

This block allows one to create an ORIGEN library within an ORIGEN input. The basic usage is to create a library, "A.f33" in the example below, and then use this library in a calculation.

```
=origen
build_lib("A.f33"){
  ...
}
case{
  lib{ file="A.f33" pos=1 }
  ...
}
end
```

The build_lib block is composed of three main sub-blocks:

- nuclide{ ... }: nuclides to consider,
- decay{ ... }: decay data data to use, and
- neutron{ ... }: incident neutron data to use.

These blocks are designed to be extensible and will gain additional capabilities in future versions. Note that the obiwan command-line utility (see Sect. 5.2) is useful in the view mode to understand the contents of your library file.

Note: Previously, this was the purpose of the COUPLE module, which is deprecated as of SCALE 6.3.

Nuclide Block build_lib/nuclide

The build_lib/nuclide block contains the information on which nuclides to consider in the final library. One can read data from any source for any nuclide, and this will be echoed in the output file; however, only the nuclides defined here will be allowed in the final ORIGEN library. The default and only options for the nuclide block are type=NAME_SET with the nuclide set complete_v6.2, which is defined as the set of 2237 nuclides (including sub-libraries) used in SCALE v6.2.

```
=origen
build_lib("A.f33"){
  nuclide{
    type=NAMED_SET
    list="complete_v6.2"
  }
  ...
}
...
end
```

Note: The entire build_lib/nuclide block will default to the above for SCALE 6.3.

Decay Data Block build_lib/decay

The build_lib/decay block contains the fundamental decay data with which to build the library. With this block, there are currently two options:

- type=ORIGEN_LIBRARY, which loads decay data from an existing ORIGEN library specified with the file= input.
- type=ENDF_DECAY`, which loads decay data from any supported decay resource using the ``resource= input—both ORIGEN card-image formats (legacy) and ENDF-formatted data.

Creating a basic ORIGEN decay library is now trivial.

```
=origen

build_lib("my_decay.f33") {
  nuclide {
    type=NAMED_SET
```

(continues on next page)

(continued from previous page)

```
    list="complete_v6.2"
  }
  decay {
    type=ENDF_DECAY
    resource="${DATA}/origen_data/origen.rev03.decay.data"
  }
}

end
```

Note: All ORIGEN inputs that expect paths (e.g., `resource`) now expand SCALE environment variables such as `${DATA}` and `${INPDIR}`, which can be very convenient as it avoids having to use `=shell` to copy needed files to the working directory.

Updating specific decay coefficients

One final input is available in the `decay` block, `coeff_update`, which allows one to specify specific decay channels and yields to update.

The specific format is

```
coeff_update[
  parent "channel(yield)" value
  ...
]
```

where

- `parent` is the parent nuclide id or name,
- `channel` is the numeric identifier for the decay channel,
- `yield` (optional) is the isomeric state of the daughter (e.g., 0 or 1), and
- `value` is the actual value for the decay constant or yield.

As an example, the following input changes the alpha decay data for ^{238}U, after it loads the nominal data from the decay resource.

```
=origen

build_lib("end7dec.f33") {
  nuclide {
    type=NAMED_SET
    list="complete_v6.2"
  }
  decay {
    type=ENDF_DECAY
    resource="${DATA}/origen_data/origen.rev03.decay.data"
    coeff_update [
        u238  "5"        1e-12   % alpha decay (5) in 1/s
        u238  "5(0)"     0.9000  % alpha decay (5) yield to residual in ground (0)
        u238  "5(1)"     0.1000  % alpha decay (5) yield to residual in 1st meta (1)
    ]
  }
}

end
```

The decay channel identifiers are shown in the following table.

Table 5.1.6: Decay channel identifiers.

Channel Identifier	Decay Mode
1	Gamma
2	Beta Minus
3	Beta Plus
4	Isomeric Transition
5	Alpha
6	Neutron
7	Spontaneous Fission
8	Proton
9	Unknown

Note that a decay channel can be composed of multiple, chained modes. For example, a $2\beta_- + n$ decay channel would have identifier `226`.

Notes on Spontaneous Fission

Spontaneous fission has been historically accounted for in ORIGEN in an unexpected way. The spontaneous fission mode is included in the overall decay constant but the individual fission product yields are not modeled by default. With the `coeff_update` block it is possible to add spontaneous fission, but one must be careful: no matter what the input is, the yields will be renormalized to sum to 2.0, as in a physically meaningful fissioning system. For this reason, it may be beneficial to introduce a fake target for most spontaneous fissions if one's interest is just in modeling a few key fission products.

With spontaneous fission, the "yield" identifier is the target fission product nuclide identifier in IZZZAAA format.

For example, consider this fake spontaneous fission data which uses ^{12}C as a fake target nuclide.

```
=origen

build_lib("end7dec.f33") {
  nuclide {
    type=NAMED_SET
    list="complete_v6.2"
  }
  decay {
    type=ENDF_DECAY
    resource="${DATA}/origen_data/origen.rev03.decay.data"
    coeff_update [
        cf252 "7(6012)"  1.80000 % spontaneous fission (7) to fake target C-12 because yields must normalize␣
↪to 2.0
        cf252 "7(54135)" 0.1600  % 8% of FPs are Xe135
        cf252 "7(53135)" 0.0400  % 2% of FPs are  I135
    ]
  }
}
```

Neutron Data Block `build_lib/neutron`

The `build_lib/neutron` block contains the fundamental incident neutron data on which to build the library. With this block, there is currently only a single option, `type=ENDF_ENERGY_DEPENDENT`, which allows the following inputs.

- `reaction_resource`, a path to the reaction resource to load, sometimes referred to as a "JEFF" library because the current data originates from JEFF/3.0-A.
- `fp_yield_resource`, a path to the fission product yield resource, which may be an ORIGEN card-image format (legacy) or ENDF-formatted data.

With these resources loaded, one must add a flux spectrum to determine energy-integrated values for all reactions and fission product yields.

For example, the following input creates a complete library (decay and neutron data) using the 56-group reaction resource with a constant flux spectrum, 1.0 for all groups.

```
=origen

build_lib("B.f33") {

  nuclide {
    type=NAMED_SET
    list="complete_v6.2"
  }

  decay {
    type=ENDF_DECAY
    resource="${DATA}/origen_data/origen.rev03.decay.data"
  }

  neutron(1) {
    type=ENDF_ENERGY_DEPENDENT
    reaction_resource="${DATA}/origen.rev01.jeff56g"
    fp_yield_resource="${DATA}/origen_data/origen.rev05.yield.data"

    spectrum {
      type=MULTIGROUP
      flux=[56R 1.0]
    }

  }
}

end
```

The `spectrum` block currently has two types.

- `type=MULTIGROUP` to provide a `flux` in the same group structure as the reaction resource. Future versions will have additional flexibility to provide the flux spectrum in any group structure.
- `type=AMPX_LIBRARY` to provide the spectrum from an AMPX library, which requires both `file` and `mixture` inputs, which specify the AMPX library file and the mixture number, respectively.

The following input is an example of loading a spectrum directly from an AMPX multigroup library.

```
=origen

build_lib("B.f33") {
```

(continues on next page)

(continued from previous page)

```
  nuclide {
    type=NAMED_SET
    list="complete_v6.2"
  }

  decay {
    type=ENDF_DECAY
    resource="${DATA}/origen_data/origen.rev03.decay.data"
  }

  neutron(1) {
    type=ENDF_ENERGY_DEPENDENT
    reaction_resource="${DATA}/origen.rev01.jeff56g"
    fp_yield_resource="${DATA}/origen_data/origen.rev05.yield.data"

    spectrum {
      type=AMPX_LIBRARY
      file="sysin.microWorkLib_0.f44"
      mixture=1
    }
  }
}

end
```

Note that this assumes that `sysin.microWorkLib_0.f44` exists in the temporary working directory and contains mixture 1 data.

The `neutron/spectrum` is all that is needed to collapse to one-group reactions and interpolate fission product yields. However, this will neglect important cross section self-shielding effects. In general, self-shielding is very important for thermal systems and where there is a significant amount of a strong resonance absorber which will depress the flux spectrum and implicitly reduce the cross section in that energy range. This is the main purpose of the `xs_update` block which allows one to read multi-group cross sections from a file, collapse those with the flux spectrum from the `spectrum` block, and use those preferentially over any "unshielded" data from the reaction resource.

In the following input, the AMPX library is used in both the spectrum and cross section update. Note the `spectrum` and `xs_update` blocks are identical for the `AMPX_LIBRARY` type.

```
=origen

build_lib("B.f33") {

  nuclide {
    type=NAMED_SET
    list="complete_v6.2"
  }

  decay {
    type=ENDF_DECAY
    resource="${DATA}/origen_data/origen.rev03.decay.data"
  }

  neutron(1) {
    type=ENDF_ENERGY_DEPENDENT
    reaction_resource="${DATA}/origen.rev01.jeff56g"
    fp_yield_resource="${DATA}/origen_data/origen.rev05.yield.data"

    spectrum {
      type=AMPX_LIBRARY
      file="sysin.microWorkLib_0.f44"
```

(continues on next page)

(continued from previous page)

```
      mixture=1
    }
    xs_update {
      type=AMPX_LIBRARY
      file="sysin.microWorkLib_0.f44"
      mixture=1
    }
  }
}

end
```

The final optional component of the neutron block is the `coeff_update` list, which can directly set the values of transition coefficients both in terms of cross section channels and daughter yields.

The specific format is

```
coeff_update[
  parent "channel(yield)" value
  ...
]
```

where

- `parent` is the parent nuclide id or name,
- `channel` is the numeric identifier for the reaction channel, commonly called "MT" numbers (see Sect. 10.1.3.1 for details),
- `yield` (optional) is the isomeric state of the daughter (e.g., 0 or 1) or the actual nuclide identifier in the case of fission (channel=18), and
- `value` is the actual value for the one-group reaction cross section or yield.

For example, consider this code excerpt which modifies the fraction of ^{241}Am (n,γ) which results in ^{242m}Am and ^{242}Am. Note that an appropriate energy-integrated value was determined from the reaction resource and the flux spectrum, and this update overwrites that value.

```
=origen

build_lib("B.f33") {

  ...

  neutron(1) {
    ...
    coeff_update[
      am241 "102(1)" 0.7 % 70% of n,gamma go to Am-242m
      am241 "102(0)" 0.3 % 30% of n,gamma go to Am-242
    ]

  }
}

end
```

Note: Yields are always renormalized to sum to 1.0 as a final step before creating the ORIGEN library, except for fission (channel=18), which is renormalized to sum to 2.0. In the above example, if you provided only one yield (e.g., the 0.70 to ^{242m}Am), then the final yields will be renormalized to sum to 1.0, and your final yield will not be 0.70.

Data Cutoffs

The legacy COUPLE library building (see Sect. 5.1.9.4) included an internal cutoff for decay constants of approximately 2.0E-26 and for cross sections of approximately 1e-20 barns. It makes sense to have cutoffs from the perspective of computational efficiency; however, one issue with cutoffs is that as the system evolves, there may be reactions below the cutoff (and not included) that then should be included. Although we could allow for this flexibility eventually, the ability to change the nuclides and transitions considered during a depletion calculation is not allowed, and it must be fixed from the beginning. For this reason, `allow_zero` options exist in both the decay and neutron blocks to change this legacy cutoff to zero.

See example Example 5.1.32 for details.

Sensitivity Calculation Block `sens`

Sensitivity calculations in ORIGEN allow one to determine the change in a particular nuclide or group of nuclides to all nuclear data involved in the calculation. The implementation here follows that of [ORIGEN-Wil86] for the specific case where perturbations in data do not alter the neutron energy spectrum.

Consider the following complete case, which irradiates 1 gram of ^{238}U using the `transition.def` ORIGEN library file. This is a useful library to use for testing but has assumed a uniform flux spectrum and thus will not be accurate for any real scenario.

```
=origen
solver{
  type=cram
}

case(A){
  lib{ file="transition.def" }
  mat{ iso=[ u238=1.0 ] units=GRAMS }
  time=[ 20I 3 1000]
  flux=[ 22R 1e14 ]
  save=yes
}

sens{
  case=A
  response{ iso=[pu239=1.0] type=NUCLIDE step=LAST }
  threshold=1e-4

  dp_verify{
    nrank=3
    nrank_pert=1.001
  }
}

end
```

The components of the `sens` input are as follows.

- `case`: the name of the case to consider the forward calculation. Note that the default name for the first case is "1", second case is "2", etc.
- `response`: a block that defines the type of response (only `type=NUCLIDE` is currently supported).
  - `iso`: the realization vector for the nuclide response given in the same format as the `iso` array in the `mat` block.
  - `step`: the step index at which the relative change in the response will be analyzed.
- `threshold`: the minimum sensitivity coefficient to print in the output file.

- dp_verify: a block that defines "direct perturbation" cases to verify the sensitivities. Direct perturbations can point out useful issues with time steps too large for the forward/adjoint calculations or a response that is particularly difficult to integrate (e.g., rapidly changing amount over a time step). Even though the forward and adjoint solutions will be accurate on the time steps, the integration of the forward solution multiplied by the adjoint over all steps assumes a simple trapezoid rule and could be inaccurate.
  - nrank number of direct perturbations to perform per category of sensitivity (currently 6) for each sensitivity coefficient which exceeds the threshold.
  - nrank_pert perturbation factor to assume for the direct perturbation verification. For example, "1.01" would indicate to multiply the data of interest by 1.01 (i.e., increase by 1%).

Sensitivity output tables

The main output of the sensitivity calculation is sent to the .out file and is shown below.

```
------------------------------------------------------------------------
Sensitivity Calculation Summary (#1/1)
------------------------------------------------------------------------

Forward calculation case                          = A
Target step (from case)                           = 22
Corresponding target time (seconds)               = 86400000.000000
Sensitivity coefficient report threshold          = 0.000100
Response type                                     = nuclide
Number of direct perturbation checks per group    = 3
Direct perturbation factor (multiplier)           = 1.001000
Adjoint concentration file                        = adjoint.sens1-adj.f71

-------------------------------------------------------------------------------------------------------------

----------------------------------------------------------------------
Reaction Yield Sensitivity
----------------------------------------------------------------------
No sensitivities exceed the threshold.
```

The six groups of sensitivities are as follows.

1. Total decay loss sensitivity – the relative change in response per change in a nuclide's total decay constant.
2. Decay loss sensitivity – the relative change in response per change in specific decay channels (e.g., α-decay).
3. Decay yield sensitivity – the relative change in response per change in a decay yield—for example, the fraction of γ-decays that result in the ground state daughter versus a metastable daughter.
4. Total reaction loss sensitivity – the relative change in response per change in a nuclide's total loss cross section.
5. Reaction loss sensitivity – the relative change in response per change in specific reaction channels (e.g. (n,γ)).
6. Reaction yield sensitivity – the relative change in response per change in a reaction yield, (e.g., fission product yields).

Note that for each group, three direct perturbation calculations are performed because `nrank=3`. Thus, if an ORIGEN forward calculation only takes a second, and the adjoint calculation takes approximately the same, in this case there are 12 additional forward calculations performed. If there were any yield sensitivities, the number could be as high as 18. For this reason, small `nrank` is recommended.

According to the sensitivity output, the dominant sensitivities are related to reactions on ^{238}U and ^{239}Pu, which makes sense. The reaction loss sensitivity table shows eight reactions that exceeded the sensitivity coefficient threshold of `1e-4`. It is interesting to note that some comparisons of the adjoint sensitivity versus the direct sensitivity are very close, whereas the ^{238}U (n,γ) has an adjoint sensitivity of 0.66 and a direct of 0.73. This gap may decrease if the time steps for the forward calculations in case "A" are reduced; however, it may also simply be a non-linearity.

The adjoint solution utilized here is first-order perturbation theory, whereas the direct perturbation may capture additional orders of variation if the perturbation applied (nrank_pert) is "large." In this particular case, reducing the perturbation factor to 1.0001 had no effect, but adding an additional 20 time steps resulted in a closer adjoint value of 0.70 compared to an unchanged direct value of 0.73.

Sensitivity output files

A number of f71 files are produced as a result of the sensitivity calculation.

- ${BASENAME}-sens<i>-adj.f71 contains the adjoint solution for the <i>-th sensitivity calculation.
- ${BASENAME}-sens<i>-dps<k>.f71 contains the <k>-th direct perturbation solution for the <i>-th sensitivity calculation. Note the "Direct F71 File" column in the table indicates which one corresponds to which perturbation.

5.1.6 ARP MODULE

The ARP module performs multidimensional interpolation on a set of specially prepared ORIGEN libraries using interpolation methods discussed in Sect. 5.1.3.1.14, with available interpolators listed in Table 5.1.7. The ORIGEN reactor libraries distributed with this version of SCALE are described in the ORIGEN Reactor Libraries chapter, as well as details on how users can generate their own libraries. The ARP module has been validated extensively for light water reactor (LWR) spent fuel [ORIGEN-LHBP98]. Benchmarking studies for MOX fuel were also conducted [ORIGEN-Gau03].

Table 5.1.7: Interpolation options in ARP

Type	Interpolation keyword	Comments
Nearest value	nearest	Searches for closest value to the desired value
Linear interpolation	linear	Uses nearest two values bounding the desired value
Lagrangian interpolation	lagrange(N) *with order N from 1 to 4*	Uses N points near desired value and creates a polynomial of order N-1 using Eq. (5.1.54)
	lagrange *same as lagrange(4)*	The specification of lagrange(1) is equivalent to nearest and lagrange(2) to linear.
Standard cubic spline	stdspline	Standard, natural cubic spline (without monotonicity fix-up).
Monotonic cubic spline	spline	Natural cubic spline with a monotonicity fix-up designed to prevent nonphysical oscillations that in some cases may result in negative interpolated cross sections.

Parametrizations for three types of problems have been developed: uranium-based fuel, mixed-oxide (MOX) fuel, and general activation.

- The parametrization for uranium-based fuel (e.g., UO:sub:*2*), as would be found in most LWRs, can interpolate on
  - fuel enrichment,
  - moderator density, and
  - burnup.

- The parametrization for MOX fuel contains a mixture of plutonium and uranium oxide and can interpolate on
  - total plutonium content in the heavy metal,
  - plutonium isotopic vector (Pu vector) that defines the relative concentrations of the Pu isotopes,
  - moderator density, and
  - burnup.
- The parametrization for general activation problems has only one-dimensional interpolation on fluence.

Variation of the absorption cross sections was observed to be near linear as a function of Pu content. Interpolation on the Pu vector is more complex than the uranium enrichment for UO_2 fuel since the vector is composed of five different isotopes: ^{238}Pu, ^{239}Pu, ^{240}Pu, ^{241}Pu, and ^{242}Pu. Furthermore, the elements in the vector depend on one another and can therefore not be evaluated independently of one another since the entire vector must sum to 100%. The scheme developed for the Pu vector was based on an evaluation of a large database of plutonium compositions from actual MOX fuel assemblies of European origin. It might be expect edthat the parametrization would need to include all Pu isotopes. However, an evaluation of the MOX fuel database indicated that there is a strong correlation between ^{239}Pu and the other isotopes in the vector that permits cross sections for the MOX fuel to be determined to sufficient accuracy using only the ^{239}Pu concentration.

5.1.6.1 Input Description

ARP has a simple input scheme, a different line-by-line input expected for each of the three problem types—uranium, MOX, or activation—with the input required for each type shown in Table 5.1.8, Table 5.1.9, and Table 5.1.10. Available input depends on what is available in the relevant arpdata.txt file and the arplibs directory.

Table 5.1.8: Input description for uranium fuels

Entry #	**Data type**	**Entry requirements**	**Comment**
1	Data set name	Line 1 always required	Enter a uranium CONFIGNAM from the active arpdata.txt (see Table 5.1.11).
2	Enrichment	New line always	Enter the wt % ^{235}U in toal U
3	Number of cycles	Always	Enter the number of irradiation cycles N.
4	Fuel irradiation period	Always	Enter the irradiation time for each cycle in days ΔT_i, for $i = 1, 2, \ldots, N$.
5	Average power	Always	Enter the specific fission power (MW/MTHM) for each cycle P_i, for $i = 1, 2, \ldots, N$.
6	Data interpolations per cycle	Always	Enter the nummber of cross section sets to interpolate during each cycle m_i, for $i = 1, 2, \ldots, N$.
7	Moderator density	Always	Enter the moderator density (g/cm^3). Enter only one value
8	New library name	New line always	Enter the filename of the new ORIGEN library created from interpolation.

continues on next page

Table 5.1.8 – continued from previous page

Entry #	Data type	Entry requirements	Comment
9	Interpolation keyword	Optional	Enter the interpolation algorithm which will be used from Table 5.1.7 (**DEFAULT: spline**)

Table 5.1.9: Input description for MOX fuels

Entry #	Data type	Entry requirements	Comment
1	Data set name *(starts with MOX)*	Line 1 Always required	Enter a MOX CONFIGNAM from the active arpdata.txt (see Table 5.1.12)
2	Plutonium content	New line always	Enter the Pu content as wt % Pu in total heavy metal.
3	^{239}Pu isotopic vector	Always	Enter the ^{239}Pu isotopic concentration as wt % ^{239}Pu in total Pu.
4	Reserved parameter (not used)	Always	Enter a dummy value (e.g., 1.0)
5	Number of cycles	Always	Enter the number of irradiation cycles N.
6	Fuel irradiation period (days)	Always	Enter the irradiation time for each cycle days ΔT_i, for $i = 1,\ 2, \ldots, N$.
7	Average power (MW/MTHM)	Always	Enter the specific fission power (MW/MTHM) for each cycle, P_i, for $i = 1,\ 2, \ldots, N$.
8	Data interpolations per cycle	Always	Enter the number of cross section sets to interpolate during each cycle, m_i for $i = 1,\ 2, \ldots, N$.
9	Moderator density	Always	Enter the water moderator density (g/cm^3). Enter only one value.
10	New library name	New line always	Enter the name of the new interpolated library created by ARP.
11	Interpolation keyword	Optional	Enter the interpolation algorithm which will be used from Table 5.1.7 (**DEFAULT: spline**)

Table 5.1.10: Input description for activaiton problems

Entry no.	Data type	Entry requirements	Comment
1	Data set name *(starts with ACT)*	Line 1 always required	Enter an activation CONFIGNAM from the active arpdata.txt see Table 5.1.13
2	Dummy parameter	Always	Enter 1.

continues on next page

Table 5.1.10 – continued from previous page

Entry no.	Data type	Entry requirements	Comment
3	Number of cycles	Always	Enter the number of irradiation cycles N.
4	Fuel irradiation period	Always	Enter the irradiation time for each cyce time in days ΔT_i, $i = 1, 2, \ldots, N$.
5	Average neutron flux	Always	Enter the average flux level (n/cm^2-s) for each cycle, Φ_i, for $i = 1, 2, \ldots, N$.
6	Data interpolations per cycle	Always	Enter the number of cross section sets to interpolate during each cycle, m_i, for $i = 1, 2, \ldots, N$.
7	Flux type (flag)	Always	Enter 1.
8	New library name	New line always	Enter the name of the new interpolated library created by ARP.
9	Interpolation keyword	Optional	Enter the interpolation algorithm which will be used from Table 5.1.7 (**DEFAULT: spline**)

5.1.6.2 ARPDATA.TXT listing file

In addition to the user input file, ARP also reads a file named arpdata.txt when it runs. This file describes the parametrization of the ORIGEN libraries. The file is required because the cross section libraries contain no imbedded information on the reactor type, fuel type, or irradiation conditions. Both the file arpdata.txt and the directory of ORIGEN libraries named arplibs is searched for, first in the working directory so that a user can override the default libraries, and then to the SCALE data directory. An example arpdata.txt file is shown in Example 5.1.20

Example 5.1.20: Examples of arpdata.txt entries.

As shown in Example 5.1.20, the `arpdata.txt` is simply a list of entries, each beginning with a `!CONFIGNAM`, where CONFIGNAM is the name to be used to reference the entire data set. Whether the entry is for a uranium, MOX, or activation problem is dictated by the actual CONFIGNAM. If it begins with MOX, it is a MOX entry, and if it begins with ACT, it is an activation entry. Otherwise it is uranium. The ORIGEN libraries listed must reside next to `arpdata.txt`:, in a directory called arplibs. Each type of entry is described fully in Table 5.1.11, Table 5.1.12, and Table 5.1.13 for uranium, MOX, and activation, respectively.

Table 5.1.11: ARPDATA.TXT uranium-type entry

Line no.	Data name	Description	Comments
1	CONFIGNAM	Data set name	Must begin with "!" in column one, followed by the alphanumeric name this data will be referenced by.
		(40-character maximum)	May not begin with ACT or MOX
2	N1	Number of enrichments	Entries pertain to the number of parameterized cross section data points for each variable type.
	N2	Number of water densities	
	N3	Number of burnup steps	
3	ENR	Enrichment values (wt % ^{235}U); values at which ARP libraries were generated	N1 entries defining the discrete enrichment values for each library
4	DENS	Water density values (g/cm^3)	N2 entries defining the discrete moderator density values for each library
5	FILES	Filenames of ORIGEN libraries for this fuel assembly type	N1 × N2 entries
		(Enclose each filename in single quotes with at least one space between each name.)	Filenames are ordered first by density values, then by enrichment values.
6	BURN	Burnups (MWd/MTU) corresponding to each position on the ORIGEN library	N3 entries

continues on next page

Table 5.1.11 – continued from previous page

Line no.	Data name	Description	Comments
			Each set of burnup-dependent cross sections is stored within a single ORIGEN binary library file (the first burnup is usually zero).
NOTE: Repeat all of the above entries for each fuel assembly configuration type			

Table 5.1.12: ARPDATA.TXT MOX-type entry

Line no	Data name	Description	Comments
1	CONFIGNAM	Data set name (40-character maximum)	Must begin with "!" in column one, followed by the alphanumeric name by which this data set will be referenced.
			Must begin with MOX (e.g., !mox_bw15x15).
2	N1	Number of Pu content values	Entries pertain to the number of separate cross section sets generated for each parameter.
	N2	Number of ^{239}Pu values	
	N3	Not used (enter 1)	
	N4	Number of water densities	
	N5	Number of burnup steps	
3	PU	Pu content values (wt % Pu in heavy metal)	N1 entries
4	VECT	^{239}Pu | N2 entries vector values | (wt % ^{239}Pu/Pu) |	
5	RESRV	Not used (enter 1)	N3 entries; dummy entry required.
6	DENS	Water density | N4 entries values | (g/cm^3) |	
7	FILE	Filenames of ORIGEN libraries for this fuel assembly type. Enclose each filename in single quotes with at least one space between each name.	N1 × N2 × N3 × N4 entries
			Increment FILE names in the order of N1, then N2, then N3, and then N4 values
8	BURN	Burnups (MWd/MTU) corresponding to each position on the ORIGEN library	N5 entries
			(first burnup is usually zero)
NOTE: Repeat all of the above entries for each fuel assembly configuration type			

Table 5.1.13: ARPDATA.TXT activation-type entry

Line no.	Data name	Description	Comments
1	CONFIGNAM	Data set name	Must begin in columnn one followed by the alphanumeric name by which this data set will referenced.
		(40-character maximum)	Must begin with ACT (e.g., !actcntlrod).
2	N1	Reserved (enter 1)	The first two entries pertain to the number of separate cross section sets generated for each variable parameter.
	N2	Not used (enter 1)	
	N3	Number of fluence values	These are usually set to 1.
			The variable N3 corresponds to the number of fluence-dependent cross section sets available in the library.
3	RESRV	Not used (enter 1)	Enter 1.
4	FTYPE	Neutron flux type (flag)	Enter 1.
5	FILES	Filenames of ORIGEN library. Enclose filename in single quotes.	Generally only one one library name is required.
6	FLUENCE	Neutron fluence values (n/cm:sup`2`) at each of the ORIGEN libraries	N3 entries
			The fluence values are reduced by the factor 10^{-24} to avoid numerical problems during the interpolation
			(First value is usually zero.)
NOTE: Repeat all of the above entries for each fuel assembly configuration type			

5.1.7 OPUS MODULE

The analysis of ORIGEN results often involves evaluating large amounts of output data that may include time-dependent nuclide and element inventories, radiological decay properties, and neutron, alpha, beta and photon source spectra. Visualization of the output data from ORIGEN often provides a means of rapidly evaluating the dominant nuclides in a problem, identifying important trends in the results, and providing insight into the problem that is not easily obtained otherwise. The OPUS utility program has been developed to read and process ORIGEN binary concentration results file (f71) into a format easily entered into graphics-plotting packages.

5.1.7.1 Key Features

The output of OPUS is a PLT file with extension ".plt" which can be easily read by most graphics packages, including the SCALE GUI Fulcrum. An example of the PLT file is shown in Figure 5.1.28.

Figure 5.1.28. Example of the OPUS PLT file.

The various types of data that can be returned by OPUS fall into two separate classes, briefly described as (1) dominant or selected isotopes or elements and (2) photon, alpha, beta and neutron source spectra. These requested data may be extracted for either irradiation or decay time periods of interest. One key feature of the program is that by default, it will automatically extract the 40 most dominant nuclides or elements in the problem, rank them using the output response and time periods of interest as specified by the user, and give the total response. The returned data may be selected, ranked, and plotted according to the group (types) of nuclides in the problem. The groups include the actinides, fission products, activation products, fission products and actinides, or all nuclides in the problem. The totals are printed for all nuclides in the specified group, and a subtotal is generated for all nuclides in the printed list. The user may also specify any other nuclide or element to be included in the output, regardless of its importance to the problem. The nuclides may be ranked using different output units of mass, density, atomic density, activity, toxicity, decay heat, or isotopic fractions.

Default values are assigned to most input variables, allowing a comprehensive visual analysis of returned data with relatively little user input.

5.1.7.2 Input Description

OPUS input records are limited to a maximum of 80 columns. A single data entry may be entered anywhere in a record but cannot be divided between two records; however, array-data entries may be divided over many records. A data entry (from left to right) is composed of a keyword, an equal sign (=), and numeric or alphanumeric data. A data entry is illustrated in the following example:

```
title="PWR 33 GWD/MTU 3.3 wt % U-235"
```

The program identifies keywords either by using only the first four characters in the keyword name or the full keyword name. In the example above, "titl" may be used, omitting the "e."[1] Alphanumeric data (as titles or axis labels) must be enclosed in double quotes, with nuclide or element symbols being the notable exception.

Floating-point data may be entered in various forms; for example, the value 12340.0 may be entered as 12340, 12340.0, 1.234+4, 1.234E+4, 1.234E4, or 1.234E04. Also, the value 0.012 may be entered as 12E-3, 12-3, 1.2-2, etc. Numeric data must be followed immediately by one or more blanks.

Array data (alphanumeric floating-point and integer) for an array-type parameter must always be terminated with an END that does not begin in column one.

Input parameters in a single OPUS sequence input (i.e., between "=opus" and "end") may be entered in any order. Usually each sequence input produces a single plot file with the name "${OUTBASENAME}N.plt" where ${OUTBASENAME} is the base of the input file name, e.g., my.inp has the base name "my," and "N" is an 18-digit integer that is incremented with each opus plot.

The OPUS input uses keywords. Keywords, descriptions, and allowed choices for each entry are listed in Table 5.1.14 for plot setup options and Table 5.1.15 for response units and nuclide selection. Input keywords and their choices occupy the first column. The next two columns indicate the type of plot in which the keyword may be entered. The last column is a description of the input keyword.

[1] Unlike in the previous OPUS versions, it is not permitted to enter four characters followed by any alphanumeric characters: only full keyword names or four-letter short-hands are allowed.

Table 5.1.14: OPUS input for plot setup

Input keywords	Nuclide / element plot	Spectra plot	Keyword description
LIBRARY= (“”)	*	*	ORIGEN binary cross section library (.f33). Only required in order to perform reaction rate calculations (see ABSO and FISS units below).
DATA= (“ft71f001”)	*	*	ORIGEN concentrations file (.f71). If enetered, must be enclosed in double quotes.
TITLE= (“”)	*	*	Title of plot. If entered, must be enclosed in double quotes.
TYPARAMS=			Inventory data to be plotted
NUCLIDES	*	NA	individual nuclides (DEFAULT)
ELEMENTS	*	NA	elements
ASPECTRUM	NA	*	alpha spectrum
BSPECTRUM	NA	*	beta spectrum
GSPECTRUM	NA	*	photon spectrum
TYPARAMS=			Spectral data to be plotted
NSPECTRUM	NA	*	total neutron spectrum from all sources
SFSPEC	NA	*	spontaneous fission
ANSPEC	NA	*	(α, n)
DNSPEC	NA	*	delayed neutrons
FACTOR=	*	NA	User-defined multiplicative factor for all concentrations
VOLUME=	*	NA	Material volume in cm ^{3}; required when plotting in units of grams/cm ^{3} or atoms/barn-cm
XLABEL=	*	*	X- and Y-axis labels. If this parameters is not entered, a label is generated automatically. If entered, it must be enclosed in double quotes
YLABEL=			
COLS= (YES)/NO			Print nuclide edits by columnn (one nuclide per column)
ROWS= (YES)/NO			Print nuclide edits by columnn (one nuclide per row)
TIME=	*	NA	Unit of time to be plotted
SECONDS	*	NA	seconds
MINUTES	*	NA	minutes
HOURS	*	NA	hours
DAYS	*	NA	days (DEFAULT)
YEARS	*	NA	years

Table 5.1.15: OPUS input for response units and nuclide selection

Input keywords	Nuclide / element plot	Spectra plot	Keyword description
NRANK=(40)	*	N/A	Total number of nuclides or elements to be returned for the plot. If user-selected nuclides or elements are requested (see SYMNUC), output will include these nuclides plus any remaining ones with the highest rankings for the quantity specified. The total and subtotal are always printed. Default is not used if SYMNUC is entered.
UNITS= (GATO) (INTENSITY)	*	N/A	Requested data units Gram-atoms are default for nuclide / element plots, and particles / MeV-sec are default for spectrum plots
ABSORPTIONS	*	N/A	Absorption / removal rate (using removal XS on library)
AIRM**3	*	N/A	Radiotoxicity; cubic meters of air to dilute to RCG_a
APELEM	*	N/A	Atom % of element; isotopic atom percentages of all elements specified in SYMNUC
ATOMS / B-CM	*	N/A	Atoms/barn-cm; requires VOLUME entry
BECQUERELS	*	N/A	Radioactivity, Bq.
CAPTURES	*	N/A	Capture reaction rate (removal minus fission; not equivalent to radiative capture)
CURIES	*	N/A	Radioactivity, Ci
FISSIONS	*	N/A	Fission reaction rate (using XS on library).
GAMWATTS	*	N/A	Gamma-ray thermal power, watts
GATOMS	*	N/A	Gram atoms, gram-atomic weights or moles
GPERCM**3	*	N/A	Partial density, grams/cm^3; requires VOLUME entry
GRAMS	*	N/A	Mass, grams
H2OM**3	*	N/A	Radiotoxicity; cubic meters of water to required to dilute to to RCG_w
KILOGRAMS	*	N/A	Mass, kilograms
WPELEM	*	N/A	Weight % of element; isotopic weight percentages of all elements specified in SYMNUC
WATTS	*	N/A	Total thermal power, watts
PARTICLES	N/A	*	Print spectra in units of particles/sec
INTENNSITY	N/A	*	Print spectra in units of particles/MeV-sec (normalized to energy bin width)
ENERGY	N/A	*	Print spectra in units of MeV/MeV-s (normalized to energy bin width; multiplied by mean bin energy)
LIBTYPE=	*	N/A	Selects sublibrary(ies) for nuclide/elements
LITE	*	N/A	Include light-nuclide sublibrary
ACT	*	N/A	Include actinide sublibrary
FISS	*	N/A	Include fission product sublibrary
FISSACT	*	N/A	Include actinide and fission products
ALL	*	N/A	Include all (DEFAULT)

continues on next page

Table 5.1.15 – continued from previous page

Input keywords	Nuclide / element plot	Spectra plot	Keyword description
SYMNUC=	*	N/A	Symbolic notation of nuclides or elements requested in the plot data. The list is an array terminated with an END. Nuclide entry is by chemical symbol and mass number, separated by a dash "–". Metastable states are indicated with an "m" immediately following the mass number (e.g., ^{242m}Am). Element entry is by chemical symbol only (e.g., Pu) For nuclide entry, it is also allowed to use element identifiers; in such cases, all isotopes of the element found in the ORIGEN library are used.
SORT=	*	N/A	Option to sort user-requested nuclides input via the SYMNUC array by descending order of importance. If SORT is not given or is SORT=NO, the order of the nuclides in the plot table is the same order as in the input. Options that can be given to SORT are the same as for UNITS. If SORT=YES, the same units provided in the UNITS entry are used.
RESPONSE=	*	N/A	Optional, user-specified arbitrary response conversion factor array. These factors are applied to the individual nuclides after conversion to quantities in the units requested by UNITS. Entries are in nuclide ID-response factor pairs. Nuclide identifiers are entered as legacy ORIGEN ZZAAAI 6-digit integer IDs, where the isomeric state is the last digit. The array must be terminated with an END.

The default values are given in parentheses after the input keyword definitions. Only the first four characters of any keyword (the letters are in bold) plus the "=," are required; they can be used instead of the full keyword name. However, unlike in previous versions of OPUS, the only two options accepted are the full keyword name or its first four letters. The keyword default value is listed in parentheses, and values are provided for almost all numeric input and axis labels. For example, the user has the option to enter axis labels using XLABEL= and YLABEL= entries, or "built-in" axis labels based on the time units and the type of data units can be used.

The remaining sections give more detail on the nuclide/element plots, the spectra plots, and time range, and case selection to further filter the results on an f71 file.

Nuclide/element plots

Various responses may be returned either by nuclide or by element, as a function of time, for a specified time interval. By default, the top nuclides/elements contributing to the response of interest over the time range are returned. An explicit list of nuclides/elements can also be entered, in which case these nuclides will always be included, regardless of their ranking. Results for nuclides in specific sublibraries may be filtered (e.g., to only see output of ^{155}Gd the fission product (FP) sublib and not the light nuclide version [LT] sublib. The default behavior is to sum over all sublibs.

Response totals are always generated for each plot. These totals represent the sum over all nuclides or elements in the specified library type. In addition, a subtotal is printed (both in the printout and the plot file) that represents the sum over the printed nuclides or elements. The subtotal can be very useful in identifying whether the nuclides in the printed list include all of the dominant nuclides in the problem.

OPUS allows the user to sort using any of the provided concentration units. For each nuclide/element, approximate integral value over all selected time steps is calculated in the selected units; nuclides/elements are then ranked according to this value. The NRANK cutoff is applied after the sort has been performed.

It is permitted to enter SORT=YES, which is equivalent to setting SORT= to the same value as UNITS=.

If the SORT key is not entered, nuclides/elements are sorted according to their position in the SYMNUC array.

Spectra plots

Alpha, beta, photon and neutron energy spectra calculated by ORIGEN may also be stored on the f71 file, and plotted by OPUS. One difference in the units of the spectra returned by OPUS and those printed by ORIGEN is that the intensities are typically converted from units of photons/s (stored on f71 file) to *particles/s-MeV* by dividing by the energy-group width. This conversion produces intensities that are more easily comparable across different energy groups and energy-group structures. Energy-intensity spectra in units of *MeV/s-MeV* and intensity spectra in units of *particles/s* may also be requested.

Selection of plotting data

OPUS provides four basic options for selecting a subset of the data on an f71 file:

1. a range of times with TMIN and TMAX (floating point numbers),
2. a range of positions on the f71 file with MINPOSITION and MAXPOSITION (integers),
3. a single CASE selection, and
4. a list of positions in the NPOSITION list.

A full overview of keywords that can be entered for time point selection is given in Table 5.1.16.

If no selection inputs are used, all available steps on the concentration file are printed. Range bounds (CASE, TMIN, TMAX, MINPOSITION, MAXPOSITION) are used as independent constraints, so any combination of those can be supplied, in which case all of the specified constraints are applied.

In case invalid positions are specified in the NPOSITION array, an error is raised, and no valid output is produced; the same happens if no steps fit into the specified selection.

The case number is useful for ORIGEN stacked cases. Furthermore, TRITON stores the mixture number (with 0 for the sum of all depletion materials and -1 for the sum of selected materials) as the case number, so this option can be used to obtain a plot of the desired depletion mixture without actually knowing the time

step numbers=. When an ORIGEN f71 file is accessed, a table of contents is printed in the output (.out) file. This can be very useful for understanding what is contained on the f71 at each position.

Table 5.1.16: OPUS input keywords for data set selection

Input keywords	Type	Keyword description
NPOSITION=	Array	List of all requested position numbers of data (on NUMUNIT), in ascending order. No other entries are required since NPOSITION is a unique data set identifier. Terminate with END. NPOSITIONS cannot be specified together with any of TMIN, TMAX, MINPOSITION or MAXPOSITION. If none of the position selectors is entered, all available positions on the data file will be returned.
CASE=	Variable	Number of ORIGEN case (or, a mixture number for TRITON-produced f71 files).
MINPOSITION=	Variable	Minimum position number, used to request a range of positions
MAXPOSITION=	Variable	Maximum position number All positions between MINPOSITION and MAXPOSITION, inclusive, are requested. MINPOSITION and/or MAXPOSITION cannot be specified together with NPOSITIONS, but they can be specified at the same time as TMIN and/or TMAX. Up to all four conditions (TMIN, TMAX, MINPOSITION, MAXPOSITION) will be used to constraint the selected time points. If none of the position selectors is entered, all available positions on the data file will be returned.
TMAX= **TMIN**=	Variable Variable	Minimum and maximum time for selection of positions on the data file. The units of TMAX and TMIN are the same as for TIME. TMIN and/or TMAX cannot be specified together with NPOSITIONS, but they can be specified at the same time as MINPOSITION and/or MAXPOSITION. Up to all four conditions (TMIN, TMAX, MINPOSITION, MAXPOSITION) will be used to constraint the selected time points. If none of the position selectors is entered, all available positions on the data file will be returned.

5.1.7.3 Plot File Formats

The plot file produced by OPUS is a text file that contains plot information, including the title, axis labels, plot type, and the time-dependent data for inventory-type plots or energy-dependent data for spectral-type plots. The plot file is a free-format reading, so the column positions have no particular significance. However, the plot files created by OPUS are aligned by column to facilitate reading of the files by other graphics programs.

File header information

The format of the first five records of the plot file is common to all plot types. They are:

Record 1: TITL - problem title (maximum 32 characters)

Record 2: XHEA - x-axis label (maximum 20 characters)

Record 3: YHEA. y-axis label (maximum 20 characters)

Record 4: Plot type - The type of plot is selected by the words "nuclide," "element," "case," or "spec." The nuclide and element entries have the same effect and produce time-dependent plots of individual nuclides or elements in the specified units. The "case" entry is used to identify case comparisons of total quantities or individual nuclides. The "spec" entry identifies spectral-type plots.

The remaining records and formats depend on the plot type specified in Record 4.

Nuclide and element plot types

Record 5: NPTONC, KTOT - the number of time points (x-axis) for the plot data KTOT - the number of nuclides or elements in the plot; includes the last record that contains the totals, if present

Record 6: TIMES(NPTONC) - NPTONC entries for the times associated with each data point; units are in the units specified in Record 2 (XHEA)

Record 7: SYMBOL, (X(N,I), I=1, NPTONC) - symbol is the alphanumeric symbol for the nuclide or element. No spaces are permitted in PlotOPUS. This symbol entry is followed by NPTONC entries containing the plot data for the nuclide or element SYMBOL with index N.

Record 8: Record 7 is repeated for all KTOT nuclides or elements.

Record 7+KTOT: Last record - contains the totals or other related quantity for the plot. The record has the same format as Record 7.

Spectral plot types

Record 5: NPTONC, NGP - the number of entries that follow to construct the spectral histogram, where NGP=(NG+1)*2 and NG is the number of energy groups. The histogram is made using a series of connecting lines, and therefore does not require any special histogram plotting capability in the graphics code.

Record 6: EN, YY - Each record contains a pair of entries: EN is the energy (MeV), and YY is the value for energy EN.

Repeat Record 6 NGP times.

Case comparison plot types

Record 5: NCAS - the negative value of the total number of cases in the plot

Record 6: NPTONC - the number of time points (x-axis) for the plot data for the case (non-user-entered data)

Record 7: INPOIN the number of time points (x-axis) for the plot data for user-entered data

Record 8: XINP(INPOIN) - INPOIN entries for the times associated with each data point of the user-entered data

Record 9: YINP(INPOIN) - INPOIN entries containing the plot data for the user-entered data

Record 10: LEGEND - legend for the user-entered data case.

The remaining records contain the case comparison data for the non-user-input data. Repeat records 7, 8, 9, and 10 for the case comparison plots, NPTONC times (same as case comparisons with no user-entered data).

5.1.8 EXAMPLES

The main problems solvable by the ORIGEN family of codes are enumerated below (with relevant components in parentheses).

1. Decay (ORIGEN)
2. Activation (ORIGEN)
3. Fuel irradiation (ARP+ORIGEN or ORIGAMI)
4. Emission spectra from decay (ORIGEN)
5. Processing, including batch/continuous chemical removal, isotopic feed, and stream blending (ORIGEN)
6. Unit conversions (OPUS)

Examples of the six variations above are contained in the following sections, except for fuel irradiation problems with ORIGAMI, as described in its own chapter.

5.1.8.1 Decay of ^{238}U

Example 5.1.21: Decay of ^{238}U

```
=origen
case{
    % use ENDF/VII-based decay library
    lib{ file="end7dec" }

    % create a material with 1 gram U-238
    mat{
        units=GRAMS
        iso=[u238=1.0]
    }
    time=[20L 1.0 1e9] %default units are days

    % save all information to f71
    save=yes
}
end
```

Example 5.1.21 illustrates using the "end7dec" binary decay library and decaying one gram of ^{238}U for 10^9 days using the logarithmic array shortcut to put 20 logarithmically spaced values between 1.0 and 1e9 days.

5.1.8.2 ^{252}Cf neutron Emission Spectrum

Example 5.1.22: ^{252}Cf neutron emission spectrum.

```
=origen

bounds{
    neutron=[ 2.000000e+07 6.376300e+06 3.011900e+06 1.826800e+06
              1.422700e+06 9.071800e+05 4.076200e+05 1.110900e+05 1.503400e+04
              3.035400e+03 5.829500e+02 1.013000e+02 2.902300e+01 1.067700e+01
              3.059000e+00 1.855400e+00 1.300000e+00 1.125300e+00 1.000000e+00
              8.000000e-01 4.139900e-01 3.250000e-01 2.250000e-01 1.000000e-01
              5.000000e-02 3.000000e-02 1.000000e-02 1.000000e-05 ]
}

case{
    title="Cf-252 decay"

    lib{ file="end7dec" pos=1 }

    time{
       units=YEARS
       t=[ 0.01 0.03 0.1 0.3 1 3 10 ]
    }

    mat{
       units=CURIES
       iso=[cf252=1.0]
    }

    %perform neutron calculation with defaults
    neutron=yes

    print{
       neutron{
           summary=yes
           spectra=yes
           detailed=yes
       }
    }
}
end
```

Example 5.1.22 illustrates decay of 1 Ci of ^{252}Cf for ten years with calculation of the time- and energy-dependent neutron source. The case uses the binary decay library "end7dec." The neutron energy group structure is defined in the bounds block with array "neutron."

5.1.8.3 Simple Fuel Irradiation Plus Decay

Example 5.1.23 illustrates the input for irradiation of a fuel assembly for 200 days at 15 MW in case "irrad," followed by decay for 5 years in the next case, "decay." The ORIGEN library (f33) was prepared by ARP to have a single position with a burnup of 1500 MWd/MTU. The input material has been specified to have 1 MTU total with an enrichment of 4.0% in ^{235}U. Note that there are consistency requirements between ARP and ORIGEN that cannot be checked by either module. Namely, the enrichment specified in ARP should be equivalent to the effective enrichment specified in the ORIGEN input, and the burnup-dependent cross section data on the ORIGEN library should be for the *midpoint burnup of the case*, which requires consistency between the operating history (power and time) and the initial isotopics heavy metal loading. In typical fuel depletion calculations, it is most convenient to specify a metric ton (10^6 grams) of initial heavy metal, such that the power in MW may be interpreted as MW/MTIHM. In the above example, the power history does not need to be constant but when combined with the time values should produce an average burnup of 1500

MWd/MTU in order that the cross sections interpolated by ARP in position 1 are valid.

Example 5.1.23: Simple fuel irradiation plus decay.

```
=arp
'library type
w17x17
'wt%
4.0
'number of cycles
1
'number of days per cycle
200.0
'cycle-average specific power (MW/MTU)
15.0
'number of interpolated cross section sets generated per cycle
1
'moderator density (g/cc)
0.723
'interpolated output ORIGEN library
w17x17_100d.f33
end
=origen
case(irrad){
    % use xs data at pos=1 corresponds to midpoint burnup (200 d * 15MW/MTU)/2
    lib {
         file="w17x17_100d.f33" pos=1
    }
    % 1 MT of enriched uranium
    mat {
        units=GRAMS
        iso=[u234=356 u235=40000 u236=184 u238=959460]
    }
    % power history (at least 4 steps for MATREX)
    time=[ 50 100 150 200 ] %default time in days
    power=[ 15 15 15 15 ] %power in MW
}
case(decay){
    time{
        units=YEARS
        start=0 %start time at 0 in this case for ease of input for t[]
        t=[0.1 0.3 0.9 1 2 3 4 5] %observe rule of threes
    }
    save{ file="discharge.f71" steps=[0 LAST] } %only save begin and end
}
end
```

It is important to note that with the MATREX solver, used by default, the recommendation for irradiation and decay of spent fuel is to use no fewer than four steps for the irradiation and begin the decay period with a time step on the order of weeks or a month, increasing the interval for each subsequent step by no more than a factor of three. In many continuation cases, such as the decay case described here, it is convenient to specify times starting from zero for the case with “start=0” in the time block.

5.1.8.4 Three Cycles of Irradiation Plus Decay

Example 5.1.24 is similar to the previous one, except there are three sets of burnup-dependent transition cross sections (positions) generated by ARP and used in ORIGEN, and there are three cases, one corresponding to each cycle. Neutron and gamma sources are generated and saved to the f71 file for the final decay case. The maximum burnup achieved is 60 GWd/MTIHM.

Example 5.1.24: Three cycles of irradiation plus decay

```

 neutron{ alphan_medium=UO2 }
 }
 end
```

5.1.8.5 Load Isotopics from an f71 File

The "mat" block allows isotopics to be loaded from any position on an existing f71 file, as seen in Example 5.1.25. A table of contents is printed in the output file every time an f71 is read or written. Inspection of this table can help identify the appropriate position on the f71, as shown in Example 5.1.26, extracted from the output file.

Example 5.1.25: Load isotopics from an f71 file using the "mat" block and perform a follow-on decay.

```
'copy existing f71 file from input file directory to working directory
=shell
```

(continues on next page)

(continued from previous page)

```
cp ${INPDIR}/discharge.f71 discharge2.f71
end

=origen
case(restart){
    % decay only library
    lib {
        file="end7dec" pos=1
    }
    % must know correct position
    mat {
        load{ file="discharge2.f71" pos=2 }
    }
    % continue timeline from previous case ending at 5 years
    time{
        units=YEARS
        start=5
        t=[10 20 40 80 160]
    }
    % append to file
    save{
        file="discharge2.f71" steps=[1 2 3 4 5]
    }
}
end
```

Example 5.1.26: Table of contents printed when accessing the f71 file.

```
================================================================================

```

The simple input in Example 5.1.27 can be used to print contents of an existing f71 file. The file is renamed so that it does not have extension ".f71." This prevents the automatic copy back from the working directory to the input file directory. Note that the same is true with any ORIGEN libraries that have the extension ".f33." There is a rule in place that *any* file in the working directory with extension ".f71" or ".f33" is copied back to the input file's directory. To prevent this from occurring, the ".f71" or ".f33" extensions must not be used in the filename, or unneeded files with a shell command at the end must be explicitly deleted.

Example 5.1.27: Isotopics from an f71 or f33 file.

```
'avoid .f71 extension to prevent automatic copy back
=shell
cp /path/to/unknown.f71 f71
end

=origen
case(test){
    lib{ file="end7dec" pos=1 }
```

(continues on next page)

(continued from previous page)

```
    mat{ load{ file="f71" pos=1 } }
    time=[1]
}
end

'remove any *.f71 or *.f33 in the working directory to prevent automatic copy back
'(not necessary in this example, but for reference)
=shell
rm -f *.f71
rm -f *.f33
end
```

5.1.8.6 Continuous Feed and Removal

Both continuous feeding of nuclides into a system and chemical removal of elements from a system are required to simulate molten fuel systems such as the molten salt reactor (MSR). Simulation of removal can be used to represent other physical processes such as purification systems (i.e., removal of chemical species by filtration or ion-exchange columns) and ventilated systems in which the removal can be represented using a rate constant (1/s). Example 5.1.28 applies to simulation of a molten salt reactor system, and it uses both continuous feed of ^{232}Th and simultaneous removal of fission products according to their removal process. To actually simulate this system properly, an ORIGEN reactor library appropriate for the MSR must be generated.

There are 11 groups of nuclides in this example, each with the same removal constant. The groups, by element and removal rate in units of (1/s), are

- Group 1: Ca to As (3.37×10^{-9});
- Group 2: Y, La, Ce, Pr, Nd, Pm, Sm, Gd (2.31×10^{-7});
- Group 3: Eu (2.31×10^{-8});
- Group 4: Se, Nb, Mo, Tc, Ru, Rh, Pd, Ag, Sb, Te (5×10^{-2});
- Group 5: Zr, Cd, In, Sn (5.79×10^{-8}) ;
- Group 6: Kr, Xe (5×10^{-2});
- Group 7: Br, I (1.93×10^{-7});
- Group 8: Rb, Sr, Cs, Ba (3.37×10^{-9});
- Group 9: Th, Li, Be, F (3.37×10^{-9});
- Group 10: Pa (3.86×10^{-6}); and
- Group 11: Np, Pu, Am, Cm, Bk, Cf (1.98×10^{-9}).

A ^{232}Th feed rate of 2.0×10^{-2} grams/s is used.

Example 5.1.28: Demonstration of continuous feed and removal within an ORIGEN irradiation case.

```
=origen
case{
    title="Single fluid MSR depletion calculation"

    lib{
       file="msr.f33"
```

(continues on next page)

(continued from previous page)

               removal{rate=5.79e-8 ele=[40 48 49 50]}
               removal{rate=5e-2 ele=[36 54]}
               removal{rate=1.93e-7 ele=[35 53]}
               removal{rate=3.37e-9 ele=[37 38 55 56]}
               removal{rate=3.37e-9 ele=[90 3 4 9]}
               removal{rate=3.86e-6 ele=[91]}
               removal{rate=1.98e-9 ele=[93 94 95 96 97 98]}
   }

   print{
        cutoffs=[ GRAMS=0.1 ] %do not show grams < 0.1% of total
        nuc{ units=[GRAMS] total=yes }
        kinf=yes   %print k-infinity summary
        absfrac_sublib=LT %absorption fractions for light nuclides in FLiBe
   }
} %end case
end
```

The absorption rates, fission rates, and k-infinity values are printed during irradiation, which can be used to evaluate the influence of the feed rates and removal constants on the time-dependent reactor performance. For the MSR in particular, the ability to self-sustain can be assessed from the "k-infinity" summary output, enabled by "kinf=yes" in print block (as well as the absorption fractions in the light nuclides in FLiBe), and enabled by "absfrac_sublib=LT" in the print block (Example 5.1.29). This example uses pure Li-7, whereas if natural Li is used, one will see a much larger fraction of absorptions in Li-6 and much lower "k-infinity."

Example 5.1.29: Continuous feed and removal–history overview.

5.1.8.7 Calculate Fuel (α, n) Emissions in a Glass Matrix

Batch processing options are provided to separate various components of the nuclide compositions into different streams and to recombine the streams to form new compositions. This example applies to the irradiation of typical commercial fuel and subsequent storage of separated fission products and actinides from fuel in a glass matrix. The matrix is important in determining the $(alpha, n)$ component of the neutron source because the alpha particles interact with the light element constituents in the matrix, with $(alpha, n)$ yields corresponding to the medium containing the α-emitting nuclides. Therefore, an accurate calculation of the neutron source in a glass matrix requires combining the oxide fuel compositions after irradiation with the defined glass matrix. The calculation could be performed by creating a case by manually entering the calculated nuclide activities and the matrix composition. However, this is only practical if the number of source nuclides is small. This example applies batch processing and blending options to generate the required compositions.

The blending option is used to combine two streams: one stream from irradiated fuel, and the other stream defining the glass matrix composition.

An irradiation case—"irrad"—is performed first to generate spent nuclear fuel compositions. The next case "spent" decays the results for one year. At the start of the decay, only selected elements are retained in the

stream by performing processing with the "retained" array. In this example, all elements are removed except for Se (99.8%); Rb, Sr, Te, Cs, Ba, Dy (77.8%); and U, Np, Pu, Am, Cm (1%).

The glass matrix compositions are then defined in the third case, "glass."

The final case—"blend"—blends 10% of each the last step's isotopics from the "spent" and "glass" cases. To test the dependence on the time when the blend is performed, the blend can be changed to "blend=[spent(N)=0.1 glass=0.1]," where *N* is the index of the step from which to take isotopics from the spent case.

Example 5.1.30: Continuous feed and removal–blending option.

5.1.8.8 Create an ORIGEN Decay Library from a Decay Resource

The following ORIGEN input (Example 5.1.31) is all that is required to produce a binary decay library from the ORIGEN decay resource file. Note that ORIGEN decay resources can also be raw ENDF formatted data files.

Example 5.1.31: Creation of an ORIGEN decay library from the decay resource

```
=origen

build_lib("origen.end7dec") {
  nuclide {
    type=NAMED_SET
    list="complete_v6.2"
  }
  decay {
    type=ENDF_DECAY
    resource="${DATA}/origen_data/origen.rev03.decay.data"
  }
}

end
```

5.1.8.9 Create an ORIGEN Reaction Library

Example 5.1.32 creates an ORIGEN reaction library from an AMPX library created using the SCALE `t-depl-1d` sequence. This particular sequence is used to create the ORIGEN library which contains all possible reactions and decays between the standard set of nuclides used for all Polaris and TRITON calculations. For this reason, `allow_zero=yes` is important because it makes sure no reactions are eliminated. The spectrum in this case is not important because Polaris and TRITON will overwrite the values for each depletable zone at each time step.

Example 5.1.32: Creation of an ORIGEN reaction library.

```
=t-depl-1d parm=(addnux=4,bonami)

5.1.8.10 Create an ORIGEN Activation Library

Activation calculations typically do not require self-shielding, so an ORIGEN "activation" library is a means to refer to a library that is using infinitely dilute cross sections from the reaction resource. An ORIGEN activation library can be created very easily as long as the flux spectrum is available in one of the reaction resource group structures.

In the example below, we create a fast spectrum library based on the 200-group reaction resource and irradiate one gram of iron for 10 days at 1e15 flux.

Example 5.1.33: Creation of an ORIGEN activation library.

```
=origen
build_lib("ff.f33") {
    neutron(1) {
        type=ENDF_ENERGY_DEPENDENT
        reaction_resource="n200.reaction.data"
        spectrum {
          type=MULTIGROUP
          flux=[20r 1.0 180r 0.0]
        }
    }
}
case {
  lib {file="ff.f33"}
  mat { iso=[fe=1.0] units=GRAMS }
  time=[10]
  flux=[1e15]
}
end
```

5.1.8.11 Create an ORIGEN Library with User-Supplied Cross Sections

It is possible to change specific cross sections on ORIGEN libraries. The following input uses all default values for all data (the flux spectrum from the reaction resource will be used) but changes the U-238 fission (18) and n,gamma (102) reactions to 20 and 10 barns, respectively.

Example 5.1.34: Creation of an ORIGEN library with user-supplied cross sections.

```
=origen

build_lib("my.f33") {
  neutron(1) {
    type=ENDF_ENERGY_DEPENDENT
    reaction_resource="n252.reaction.data"
    coeff_update [
```

(continues on next page)

(continued from previous page)

```
        u238 18  20
        u238 102 10
    ]
  }
}

end
```

5.1.8.12 Printing library cross-section values

Print the Cross Section Values on an ORIGEN Library with OBIWAN

The `obiwan` utility was introduced in SCALE 6.3 to help users interrogate the data contained in ORIGEN binary files. From the command line, one can view all coefficients on the library with the following. See Sect. 5.2 for details.

```
obiwan view my.f33
```

Print the Cross Section Values on an ORIGEN Library in ORIGEN

Cross sections can also be printed when the library is used in ORIGEN by setting "print_xs=yes" in the options block, shown as Example 5.1.35.

Example 5.1.35: Printing cross section values on an ORIGEN library using ORIGEN.

```
=shell
cp ${INPDIR}/my_rx.f33 ft33f001
end

=origen
options{ print_xs=yes }
case{
    lib{ file="ft33f001" pos=1 }
    time=[1] %dummy time
    mat{ iso=[u235=1] } %dummy iso
}
end
```

5.1.8.13 Ranking Contribution to Toxicity

The OPUS input in Example 5.1.36 creates a plot of the volume of various nuclides with the maximum permissible concentration (MPC) in water using the "snf.f71" produced by the "Three cycle plus decay" example (Example 5.1.24). Only positions 6–16 are plotted using "minposition" and "maxposition." Three nuclides (^{242}Cm, ^{137m}Ba, and ^{99}Tc) are forced to be included via the "symnuc" list, with 17 more nuclides (for total "nrank=20") included according to their average rank in terms of the MPC in water. The total number of nuclides requested is 20. The x-axis label is set to "TIME (YEARS)," and the title is "SPENT FUEL AT 60 GWD/MTHM."

Example 5.1.36: Using OPUS to produce a ranked contribution to radiotoxicity

```
=shell
  cp ${INPDIR}/snf.f71 f71
end

=opus
```

(continues on next page)

(continued from previous page)

```
data="f71"
typarams=nucl
units=h2om**3
time=year
libtype=fisact
minposition=6  maxposition=16   nrank=20
title="SPENT FUEL AT 60 GWD/MTIHM "
xlabel="TIME (YEARS)"
symnuc=cm-242 ba-137m tc-99 end
end
```

5.1.8.14 Spectrum plots with OPUS

Photon Spectrum Plot

The OPUS input shown in Example 5.1.37 creates a plot of the photon spectrum for all times between 1 and 5 years, using "tmin=1" and "tmax=5" with "time=years."

Example 5.1.37: Plotting the photon spectrum using OPUS.

```
=shell
cp ${INPDIR}/snf.f71 f71
end

=opus
data="f71"
typarams=gspectrum
units=intensity
tmin=1 tmax=5 time=years
end
```

Example 5.1.38 shows the output of the time-dependent gamma spectrum extracted from the f71 file by OPUS.

Example 5.1.38: Photon spectrum plot from OPUS– output of the time-dependent gamma spectrum.

Neutron Spectrum Plot

The OPUS input in Example 5.1.39 creates a plot of the total neutron spectrum at all times.

Example 5.1.39: Neutron spectrum plot using OPUS

```
=opus
data="f71"
typarams=nspe
units=intensity
end
```

5.1.8.15 Isotopic Weight Percentages for Uranium and Plutonium During Decay

The isotopic distributions in uranium and plutonium, in weight percent, may be plotted with the OPUS input in Example 5.1.40.

Example 5.1.40: Isotopic weight percentages for uranium and plutonium during decay.

```
=opus
data="f71"
units=wpel
libtype=act
symnuc=u pu end
end
```

5.1.8.16 User-Specified Response Function in OPUS

In Example 5.1.41, response conversion factor data are entered in the RESPONSE= array as nuclide-response factor pairs, with the nuclide id being the legacy nuclide ID (ZZAAAI), with ZZ two digits of atomic number, AAA three digits of mass number, and I one digit of isomeric state. For example, ^{235m}U would be given as 922351 and H-1 as 10010. In this example, it is assumed that the response factors are activity based (response/Bq of nuclide), so the units of Becquerels are requested using the UNITS keyword. The user-supplied response conversion factors are applied to the Becquerel units for all nuclides in the RESPONSE= array, and the results for any nuclide for which no response factors are provided are zeroed.

Example 5.1.41: Example of a user-specified response function in OPUS.

```
=opus
data="f71"
units=becq
time=year
typarams=nucl
response=

 902280 2.06832E-02  982500 2.87199E+02  end
end
```

5.1.9 APPENDICES

5.1.9.1 PRISM

Warning: PRISM is deprecated and replaced by Sampler (see Sect. 6.4 for details).

PRISM is a utility that reads a single input template file containing generic parameter flags and replaces them with specific values designated by the user to generate any number of files containing desired combinations of specific parameter values. PRISM provides a procedure to convert a generic input file for a particular fuel assembly design into a large number of input files containing combinations of specific fuel enrichment and moderator densities and/or other parameters for generating basic cross-section libraries. The program was designed in a general manner so PRISM can be used to generate multiple files from any generic file.

The input description for PRISM is presented in Table 5.B.1. The input format is free form. The user input includes the name of the template file to be read; the pattern for the name of the output files to be generated, using the generic parameter flags; the number of generic parameter flags; the number of files to be generated; each generic parameter flag and the specific values to be substituted in each output file.

The template file contains generic parameter flags. PRISM creates copies of the template file and substitutes specific values for the generic flags. **Note that the character length of each specific value must be the same as that of the associated generic flag.**

An example using PRISM to generate input files for six fuel enrichments is presented in Example 5.1.42 and Example 5.1.43. In this example a TRITON input file for a Westinghouse 17 × 17 fuel assembly (Example 5.1.43) is processed by PRISM using the input file for PRISM listed in Example 5.1.42. The case generates 6 specific input files from the template file.

Table 5.1.17: PRISM input description

Line No.	Parameter	Description	Comments
1	TEMPLATE	Template file name	80 characters maximum
2	OUT_TEMPLATE	Pattern for output file names	80 characters maximum Must contain enough generic parameter names to create unique filename for each output file
3	NUMPARMS	Number of generic parameter types	
	NUMFILES	Number of output files to be generated	
	NOTE: Repeat the following data for each generic parameter type (i.e. a total of NUMPARMS times).		
4	PARAM_NAME	Generic parameter name as it appears in template file	80 characters maximum
5[1]	PARAMETERS	Specific values of generic parameter for each output file	NUMFILES entries required. Length of value must be same as length of PARAM_NAME

[1] May be continued on subsequent lines as needed.

Example 5.1.42: PRISM input example to generate TRITON input files.

5.1.9.2 ARPLIB

Warning: ARPLIB is deprecated and replaced by the command line utility OBIWAN (see Sect. 5.2 for details).

ARPLIB is a utility program designed to read a burnup-dependent binary ORIGEN-ARP cross-section library and copy the cross-section data from only the desired burnup positions to create a new ORIGEN-ARP cross-section library.

The input for ARPLIB is described in Table 5.1.18. A new library (OUTLIB) is created by listing the positions from one or more existing libraries to copy to the new library.

An example of the input to ARPLIB is given in Example 5.1.44, showing how to use ARPLIB to reduce the number of cross sections sets on a library by creating a new library with only certain positions retained from the old library.

Table 5.1.18: ARPLIB input description

Parameter	Description	Comments
OUTLIB	Filename of output library to create	This library should not already exist

continues on next page

Table 5.1.18 – continued from previous page

NLIB	Number of input libraries to read	
	For each input library, i up to NLIB	
LIB-NAME[i]	Filename of input library to read	
NPOS[i]	Number of positions to read from this i-th library	>0
p1 p2 ...	The list of position indices from this i-th library to put on the output library	NPOS[i] position indices are read from a single line (all position indices are >0)

Example 5.1.44: ARPLIB example input to reduce size of ORIGEN cross-section libraries.

```
'get an ORIGEN library files for testing
=shell
  cp "${DATA}/arplibs/w17_e30.f33" 1_f33
end
'create a new library (ft33f001) with every-other burnup points
=arplib
  ft33f001
  1
  1_f33
  8
  1 3 5 7 9 11 13 15
 end
```

5.1.9.3 XSECLIST

Warning: ARPLIB is deprecated and replaced by the command line utility OBIWAN (see Sect. 5.2 for details).

The XSECLIST program is intended to provide an interpreted listing of any ORIGEN-ARP cross-section library. This utility program allows users to list the absorption and/or fission cross sections of any or all nuclides in the library as a function of burnup. The absorption cross sections are given for light elements, actinides, and fission products. Some of the light-element isotopes in the library may appear also as fission products; therefore, some isotopes may be listed twice. Fission cross sections may be listed for any or all actinides for which nonzero values of the cross sections exist. ORIGEN-S cross sections are typically normalized to thermal flux, rather than the total flux.

The nuclide ID numbers used in the library listings have the form IZ*10000+IA*10+IS, where

IZ = the atomic number;

IA = the atomic weight;

IS = 0, for ground state;

IS = 1, for metastable state.

The XSECLIST input is described in Table 5.1.19. The input is free format. The user specifies the library filename, the total number of burnup positions in the library, and the burnup values (GWd/MTU)

corresponding to each burnup position. The user then indicates whether the cross-section data listings are for absorption, fission, or both; and whether the listings are for all nuclides or only certain specified ones.

An example input file for XSECLIST is shown in Example 5.1.45. This example contains two cases: The first case lists both absorption and fission cross sections for ^{240}Pu in the ORIGEN-ARP 5 wt % enriched PWR 14 × 14 basic cross-section library. The output listing for this case is displayed in Example 5.1.46. These are microscopic cross sections listed in units of barns. The second case lists the fission cross sections for all nuclides in the ORIGEN-ARP 1.5 wt % enriched PWR 14 × 14 basic cross-section library. The output from this case is not presented here because of its size.

Table 5.1.19: XSECLIST input description

Line No.	**Parameter**	**Description**	**Comments**
1	FILENAME	Library filename	30-character maximum
2	NL	Number of burnup positions in library	
3[2]	BURN	Burnup (GWd/MTU) of each burnup position in library	NL entries required
4	CHARD	Cross-section data to be printed	a = absorption f = fission b = both
5	CHARL	List entire library (all nuclides)	y = yes n = no
	NOTE: The following optional data are entered only if CHARL = n.		
6	MT	Number of nuclides for which cross-section listings are desired	
7[?]	MTRD	Nuclide IDs[3]	MT entries required

Example 5.1.45: XSECTLIB input example

```
=xseclist
ce14_e50.arplib

5.1.9.4 COUPLE Module

Warning: COUPLE is deprecated as of SCALE 6.3 with the ORIGEN `build_lib` capability replacing it. All of the capabilities of COUPLE are available and more. The legacy FIDO COUPLE input described here is still supported but a completely new computational engine is used to create the library, the same as is used for the `build_lib` block. See Sect. 5.1.5.2.21 for details.

COUPLE is a coupling code that prepares the transition matrix **A** from Eq. (5.1.2), which contains the decay and cross section transition rate constants according to the procedures defined in Sect. 5.1.3.1.1. The transition matrix and other important data are stored on an ORIGEN library (f33) file for use by other modules. COUPLE has two distinct modes of operation:

1. to create a new decay-only ORIGEN library from an ORIGEN decay resource, and
2. to add new or to update existing reaction transitions yield resource, reaction resource, and optionally an AMPX working library containing multigroup cross sections.

Details on the decay, yield, and reaction resources may be found in the ORIGEN Data Resources chapter.

Key Features

This section briefly highlights some key features in COUPLE and describes how they are used.

AMPX multi-group libraries

AMPX multigroup libraries contain multigroup cross sections by nuclide and material-zone identifiers. If the working library is the result of a multiregion transport calculation, then it is important to specify the correct zone identifier, e.g. corresponding to the fuel in a problem with moderator, clad, and fuel zones. The neutron flux is also stored on the AMPX library associated with a nuclide and a zone as are the cross sections. An AMPX library flux can be used to perform the cross section collapse as an alternative to providing a flux spectrum in the COUPLE input. New transitions may be added to the ORIGEN binary library for all reactions for which there are data in the weighted AMPX library if both the target and product nuclides are present in the ORIGEN library.

Nuclide Specification

In COUPLE, the following nuclide identifier is used:

```
Nuclide identifier = Z * 10000 + A * 10 + I
```

where

Z = atomic number,

A = mass number,

I = metastable/isomeric state (0 is ground/1 is first metastable)

Examples include 922350 for ^{235}U and 952421 for ^{242m}Am. Note that this varies from the identifiers used in other ORIGEN-related modules in which the isomeric state *I* comes first, as in 1095242 for ^{242m}Am.

Adding new transitions and user-defined transitions

The use of a transition matrix in ORIGEN allows any nuclide to transition to any other nuclide. By default, when the reaction data on the library is updated, then the transition matrix's sparse storage is expanded to include the new reaction transition if both the target and the reaction product nuclide are in the library. The user may request that the code does not add new transitions by setting Block1 `JADD=0` (`1$$ a4 0`). This option ensures that the matrix structure on the input library is identical to that of the output library. The user may explicitly set one-group transition coefficients by setting Block1 `LBUP=1` (`1$$ a3 1`) and entering Block6 and Block8 data.

Unit numbers and Aliases

In COUPLE, a unit number is used instead of a full file name to specify files, where unit number XY links to the data file "ftXYf001" in the working directory. For example, unit number 33 means file ft33f001. There are several predefined unit numbers that are controlled by a special "origen_filenames" file, which creates an alias for the local file "ftXYf001" to a file in the data directory. Table 5.1.20 shows the basic COUPLE unit numbers, their aliases, and a description of the file.

Table 5.1.20: Basic COUPLE unit numbers

Unit	Alias	Description
17	YIELDS	ORIGEN Yield Resource
21	END7DEC	ORIGEN library *ENDF/B-VII-based decay transitions only*
27	DECAY	ORIGEN Decay Resource
80	JEFF252G	ORIGEN Reaction Resource (252 groups)

An "origen_filenames" list which maps unit number 21 to alias "END7DEC" could link unit 21 to the file "${DATA}/origen.rev04.end7dec," where ${DATA} is the path to the SCALE data directory. To override this association, COUPLE must find a file named "ft21f001" in the working directory. The entire set of unit numbers is given in the ORIGEN Data Resources chapter**.**

Input Description

COUPLE uses the FIDO input system, except for title entries. The input is arranged in blocks, with each block containing one or more arrays, followed by the FIDO block terminator "t." Each input parameter is named and defined below in the order in which it appears, with the index of the parameter in the array. Some options have been deprecated over time and thus the first available entry may not correspond to index "1" and some indices may be skipped. Default values are given in parentheses. In the SCALE code system, COUPLE input appears between "=couple" and "end."

Block1: titles, unit numbers, and case controls.

TITLE — Title lines

Title lines can provide information about the ORIGEN library created and printed when the library is used. The input Block1 1\$\$ NUMA allows title lines to be copied from the input library to the output library.

The first blank line terminates the title.

A maximum of 40 lines can be included in the library.

A special title of "DONE" in the first four columns marks the completion of a COUPLE input case.

0\$\$ Array – Logical Unit Assignments

1. NOUT – Printed output unit number (6)
2. LIBDEC – Unit number of ORIGEN decay resource (27)

Only used if 1\$\$ LBIN=1

3. JD – Unit number of ORIGEN reaction resource (80)
4. ND – Input ORIGEN binary library file (21)

Only used if 1\$\$ LBIN=0

5. LD – Unit number of AMPX multigroup library file (0)

Only used if LD>0; energy group structure must be consistent with that on ORIGEN reaction resource (JD)

6. MD – Unit number for output ORIGEN library file (33)
8. NY – Unit number of ORIGEN yield resource (17)

1\$\$ Array – Control Constants [19 entries]

1. LBIN – 1/0 – Decay library creation/reaction update mode (0)

In decay library creation mode with LBIN=1, the reaction resource (0\$\$ JD) is not used, any input associated with reaction processing is ignored, and Block2 and Block8 may not be entered. In reaction update mode with LBIN=0, Block3 may not be entered.

2. PRT – 1/0 – Suppress all informational output / print informational output (0).

3. LBUP – 1/0 – Update from user input cross sections (Block6 and Block8 Arrays) / no user update (0).

4. JADD – 1/0 – Add/do not add new transitions to the library (1).

5. JEDT – 1/0 – Edit input library only/normal library generation case (0).

6. NXX – 1/0 – Allow/do not allow transitions with zero cross section (0).

7. NMO – Current month (as integer) for output library (0).

8. NDAY – Current day for output library (0).

9. NYR – Current year for output library (two digits) (0).

12. IDREF – Nuclide ID in AMPX multigroup library (0\$\$ LD) containing neutron flux weighting spectrum to use in cross section collapse (0).
If IDREF=0, uses first nuclide found in NZONE. Only used if NWGT=0.

13. NZONE – Zone ID (usually a mixture ID) in AMPX multigroup library (0\$\$ LD)

from which to add/update transitions (0).

If NZONE=0, the AMPX library must not contain zone IDs.

14. IEDOU – 1/0 – Edit/no edit of transition cross sections (0)

15. NFISW – Number of nuclides with fission yields (-1)

-1 fission yields included for all fissionable nuclides

0 no yields added

N input N nuclides with fission yields (Block2 7\$\$ Array)

16. NUMA – Number of title lines to copy from the input ORIGEN library (0\$\$ ND) to the output ORIGEN library (0\$\$ MD) (0).

18. NWGT – Flux spectrum source (0).

0 flux spectrum from AMPX multigroup library (IDREF)

N input N-group flux spectrum (Block2, 9** Array)

T – Block1 terminator.

Block2: nuclides with fission yields and weighting flux spectrum

This block is only read if in reaction update mode (Block1 `0\\$\\$` LBIN=0).

7\$\$ Array – Nuclide IDs with fission yields [Block1 1\$\$ NFISW entries]

9** Array – Weighting flux spectrum [Block1 1\$\$ NWGT entries]

The flux spectrum must be given in order of descending neutron energy according to the convention that group 1 is the highest energy group. The group structure (number of groups and group boundaries) must be consistent with the ORIGEN reaction resource (Block1 0\$\$ JD).

T – Block2 terminator.

Block3: array dimensions for decay library creation

This block is only read if in decay library creation mode (Block1 0\$\$ LBIN=1). The default values usually apply. The values are used only internally for memory allocation and may be set to a larger value than is required.

3\$\$ Array – Library constants

18. ITMAX – Total number of nuclides in library (2600)
19. ILMAX – Number of activation product nuclides (1000)

-1, omits light-element library

20. IAMAX – Number of actinide nuclides (200)

-1, omits actinide library

21. IFMAX —Number of fission-product nuclides (1400)

-1, omits fission-product library

22. IXMAX – Total number of decay transitions from one nuclide to another (40,000)

T – Block3 terminator.

Block6: number of user-defined transition coefficients

This block is only read if user-defined transition coefficients have been specified in decay library creation mode (Block1 1\$\$ LBUP=1).

15\$\$ Array – Number of user update nuclides

1. LBU – Total number of transitions to be entered in Block8 71\$\$, 72\$\$, and 73** Arrays (0)

T – Block6 terminator

Block8: user-defined transition coefficients

Block8 is only required only if a nonzero value is entered in the Block6 15\$\$ array. The three arrays (71\$\$, 72\$\$, and 73**) represent the parent, daughter, and coefficients for Block6 LBU user-defined transitions, or the quantity $f_{ij}\sigma_j$ for a given parent j and daughter i from Eq. (5.1.4).

71\$\$ Array – Parent Nuclides [LBU entries]

ISN1 – Parent Nuclide ID

72\$\$ Array – Daughter Nuclides or Reaction MT number [LBU entries]

ISN2 – Daughter Nuclide ID for the reaction product of the corresponding entry in ISN1

or reaction MT number

Note: The reaction transition will be added if it does not already exist by setting `Block1 1$$ JADD=1`. Otherwise, new transitions are omitted.

73** Array – Reaction Cross Sections [LBU entries].

SIGMA– Reaction cross section (in barns) for the reaction described by ISN1 and ISN2

There are two special rules to facilitate modifying fission cross sections σ_{fj} and removal cross sections σ_j.

if ISN1=ISN2, the removal cross section is set equal to the corresponding SIGMA. Note that this overrides the automatic calculation of the removal cross section as the sum of all transition cross sections.

if ISN1=-ISN2, the fission cross section is set equal to the corresponding SIGMA.

T -Block8 terminator.

This concludes the input for a single case in COUPLE. COUPLE allows for multiple cases in a single input and will automatically begin processing the next case's Block1 TITLE unless "DONE" (without quotes) is entered as the TITLE entry.

5.2 OBIWAN: A TOOL FOR VIEWING AND MANIPULATING ORIGEN BINARY FILES

S. E. Skutnik and W. A. Wieselquist

OBIWAN (**O**rigen **B**inary **I**nterrogation **W**ithout **A** scale i**N**put) is a command-line utility for viewing, manipulating, and converting ORIGEN binary output files.

OBIWAN can be called directly from the command line, from `${SCALE}/bin/obiwan`; in addition, it can be called within a SCALE input within a =*shell* block, i.e.:

Example 5.2.1: An OBIWAN command within a shell block

```
=shell
${PGMDIR}/obiwan [command] [file(s)]
end
...
```

OBIWAN supports the following modes:

- **convert** convert between versions of files
- **diff** diff/compare two files
- **info** print basic info about multiple files
- **interp** interpolate files
- **patch** patch data in files
- **tag** manipulate tags on a file
- **view** view a file

Each of these methods (including supported capabilities and syntax) are discussed in the following sections. OBIWAN also emits command-line help if you run it without any files/arguments.

5.2.1 OBIWAN INFO

Displays information about an on-disk binary Origen file.

Usage: `obiwan info [-type=TYPE] FILE`

`-type` `[f33 / hdf5 / f71 / yld ]`
Optionally specify OBIWAN to load only a particular file type

Options are:

- **f33**: Origen::Library
- **hdf5**: Origen::Archive
- **f71**: Origen::StateSet
- **yld**: Origen::YieldResource

By default, OBIWAN will attempt to infer the filetype by trial-and-error

`-verbose`
Verbose mode; prints extra output to STDERR

Table 5.2.1: File information output by `obiwan info`

Column	**Description**
fileName	path without the directory
dataType	type/class of the object
numSets	number of "sets" of data (e.g. burnups)
fileFormat	the format of the dataType in this file
fileType	"binary" or "text"
file/sysEndian	endian-ness for the file itself and the system (mismatches have I/O performance penalties)
appVersion	version of the application which wrote this file (some formats cannot store this and it appears as "-")
ms	time in milliseconds to load the file
directory	directory portion of path

5.2.2 OBIWAN VIEW

Displays detailed contents of ORIGEN results and data files.

Usage: `obiwan view [-type=TYPE -format=FORMAT options] FILE`

The `-type=TYPE` flag tells the loader to assume a data type for `FILE`. If not provided, trial and error is used.

`-type` `[f33 / hdf5 / f71 / yld ]`

- **f33**: *Origen::Library*

- **hdf5**: *Origen::Archive*
- **f71**: *Origen::StateSet*
- **yld**: *Origen::YieldResource*

The `-format=FORMAT` flag tells the printer to output data a certain way. If not provided, specific to the type of data.

5.2.2.1 Output formatting

`obiwan view` offers several options for formatting output which are specific to the file type being viewed (i.e., corresponding to `obiwan view -type`); these are discussed further within this section.

Note: All types and formats do not support all options.

Note: `True`/`False` values (boolean) should be specified as 1/0.

ORIGEN nuclide ID formatting

The most general form for an ORIGEN nuclide id is known as a *SIZZZAAA*, an 8-digit integer composed of four parts.

S - 1 digit for sublib integer
I - 1 digit for isomeric state
ZZZ - 3 digits of atomic number
AAA - 3 digits of mass number

Only the "sublib" is a non-standard nuclide parameter, specific to a design decision in ORIGEN where it is allowed to track two different versions of a nuclide, e.g. Gd-155 as both a fission product and fuel dopant. Below is a short description of the typical sublibs.

Table 5.2.2: Origen sublibrary definition

S	TY	DESCRIPTION
1	LT	light nuclides, typically the result of activation of common elements and structural materials, e.g. O-16, Li-6
2	AC	fissionable actinides and their immediate decay and activation products, e.g. U-235, Pu-239, Cm-244
3	FP	fission products and their decay and activation products, e.g. Te-135, Cs-135, Xe-135

When *S=0* (in most cases), this implies the sum over all versions of a nuclide.

Format options for Origen data resources

Available format options for Origen data resources (including `Origen::Library`, `Origen::Archive`, and `Origen::YieldResource`) are as-follows:

`-format`

- **coeff**: output tabular transition coefficients
- **coefft**: coeff but with transition ids
- **matrix**: output full transition matrix
- **json**: output in JSON format
- **tags**: output file tags
- **nucl**: nuclide list
- **nprodr**: neutron production ratio
- **genneu**: neutron generation
- **loxs**: loss xs
- **fisxs**: fission xs
- **burnups**: output burnup list
- **reaction**: allowed reactions
- **graphviz**: output dot file transitions to STDOUT

Default: `-format=coefft`

Format options for Origen concentrations files

`-format`

- **info**: information table
- **csv**: comma-separated values
- **ii.json**: inventory interface in JSON
- **tags**: tags stored on each state

Default: `-format=info`

5.2.2.2 Data filter options

`-pos=`

Position in `Origen::Library` or `Origen::StateSet` to output. (0 is all positions). < 0 means **normalize** output to that position (useful for viewing cross-section data across many scales).

Note: Not available for all types / formats.

Default `pos=1`

-cases=[...]
Only consider these cases (-type=f71 only)

-sizzzaaa=
Restrict data to this nuclide; e.g. u-235 is 20092235

allow_s=[...]
Allow only certain sublibs, e.g. -allow_s=[2,3] (allows only actinides and fission product sublibraries).

-allow_i=[...]
Allow only certain isomeric states, e.g. -allow_i=[1]

-allow_z=[...]
Allow only certain atomic numbers, e.g. -allow_z=[92]

-allow_a=[...]
Allow only certain mass numbers, e.g. -allow_a=[135,136]

-min_z=
Allow only atomic numbers greater or equal to Z (integer)

-tid=
Restrict data to this transition id:

dk mode (<0) or reaction MT (>0)

(use -format=coefft to see ids)

Note: Valid for -format=graphviz only

-allow_decay
Whether to display decay transitions (boolean)

Default: yes

-allow_fission=
Whether to display fission transitions (boolean)

Default: no

-allow_reaction=
Whether to display reaction transitions (boolean)

Default: yes

-include_byproducts=
Whether to include byproduct reactions arrows (boolean)

Default: no

5.2.2.3 Output control options

-prec=

Number of significant digits to output

Default: 4

-output_zeros=

Whether to output zero values (boolean)

Default: `yes`

-transpose=

Whether to transpose table (boolean)

Default: `no`

Note: Only available for some tables

-symbols=

Whether to output numeric ids (1001) or symbols (H-1)

Tip: Same as `-idform='{:TY}:{:ee}{:AAA}{:m}'`

-idform=

Controls printout of ids, the following are subsituted:

{:S} - sublib integer

{:TY} - sublib name

{:I} - isomeric state integer

{:ZZZ} - up to 3 digits of atomic number (also Z, ZZ)

{:AAA} - up to 3 digits of mass number (also A, AA)

{:EE} - up to 2 characters elemental symbol (also Ee,ee for different case)

{:M} - metastable indicator 'M' for first, 'M2' for second, etc. (also m)

Default:

- With `-symbols=0 -idform='{:S}{:I}{:ZZZ}{:AAA}'`
- With `-symbols=1 -idform='{:TY}:{:ee}{:AAA}{:m}'`

-units

Units used for printing

Note: Only applies to `-type=f71` and `-format=csv`

Available units:

- abso (total absorption xs)
- fiss (total fission xs)
- capt (total capture xs)
- airm (raditoxicity index in air, m^3)
- apel
- atom
- becq (activity in becquerels)
- curi (activity in curies)
- gamw (thermal output from gammas in watts)
- gamm
- gato (mass in gram-atoms)
- gper (isotopic mass percent by element)
- gram (mass in grams)
- h2om (radiotoxicity index in water, m^3)
- kilo (mass in kilograms)
- wpel (weight percent by element)
- watt (total thermal output in watts)
- mevs
- part
- inte
- ener

-verbose=

Display verbose output (includes echo of all input data; boolean)

Default: `-verbose=no`

5.2.2.4 Data manipulation options

-flux=

If `flux>=0`, then multiply reaction matrix coeff (one-group xs in barns) by the factor flux(n/cm^2s) * 1e-24(barns/cm) in order to display reactions/second units

---

Tip: Useful for comparing the magnitude of decay and reaction channels

---

Default: `flux=-1.0` (no flux scaling)

-lib=

Filepath to a binary Origen data library (.f33)

Tip: Needed for certain `Origen::StateSet` (.f71) unit conversions

See also:

`obiwan view -dec`

-dec=

Filepath to an on-disk Origen DecayResource (e.g., `origen.rev*.decay.data`)

Tip: Needed for certain `Origen::StateSet` (.f71) unit conversions

Default: Search for origen.rev*.decay.data in each of the following locations (in order):

1. `./obiwan/../data/origen_data/`
2. `${SCALE}/data/origen_data/`
3. `${DATA}/data/origen_data/`

See also:

`obiwan view -lib`

Note: Only one of `-lib` or `-dec` should be specified for F71 file unit conversions

---

5.2.2.5 Usage examples

Displaying a table of loss cross-section data

Note here that `pos=0` corresponds to all positions (burnups) on a library.

Example 5.2.2: Using OBIWAN to view loss cross-sections on a library

```
$ obiwan view -format=loxs -pos=0 ./a10_e15w01.bof 2>/dev/null

 nuclide  0.0000e+00  1.5000e+03  4.5000e+03  7.5000e+03  1.0500e+04  1.3500e+04
10001001  2.5724e-01  2.6172e-01  2.6315e-01  2.6400e-01  2.6582e-01  2.6731e-01
10001002  8.9254e-03  9.6637e-03  9.8350e-03  9.9177e-03  1.0278e-02  1.0590e-02
10001003  2.3025e-04  2.4988e-04  2.5428e-04  2.5635e-04  2.6587e-04  2.7415e-04
10001004  1.2445e+11  1.3507e+11  1.3744e+11  1.3856e+11  1.4371e+11  1.4818e+11
...
```

While the output can be piped through a command such as **`grep`** to filter on a specific nuclide, e.g.:

```
$ obiwan view -format=loxs -pos=0 ./a10_e15w01.bof | grep 20092235
```

in many cases, the transpose table (combined with a nuclide filter using `obiwan view -sizzzaaa` is typically a better option, such as shown below. (Note the normalization to the first position value).

Example 5.2.3: Using OBIWAN to view U-235 loss cross-sections, relative to the first burnup position

```
$ obiwan view -format=loxs -sizzzaaa=20092235 -pos=-1 -transpose=1 ./a10_e15w01.bof 2>/dev/null

         nuclide    20092235
      0.0000e+00  1.0000e+00
      1.5000e+03  9.9738e-01
      4.5000e+03  1.0177e+00
      7.5000e+03  1.0398e+00
      1.0500e+04  1.0466e+00
      1.3500e+04  1.0517e+00
      1.6500e+04  1.0560e+00
      3.1500e+04  1.0677e+00
      4.6500e+04  1.0709e+00
      5.8500e+04  1.0711e+00
      7.0500e+04  1.0707e+00
```

Output transitions to a graphical format

The following example demonstrates dumping a transition matrix set to a node-based graph (.dot) file; the **neato** program from **graphviz** works best for viewing this output.:

```
$ obiwan view -format=graphviz -allow_s="[1,2,3]" -include_byproducts=0 \
    $DATA/origen_library/pwr.rev03.orglib >transitions.dot

$ neato -n1 transitions.dot -T pdf >transitions.pdf
```

Output a JSON-based inventory interface file

The following example outputs a inventory interface file restricted to actinides and fission products:

```
$ obiwan view -format=ii.json -allow_s="[2,3]" my.f71 >my.ii.json
```

Here note that the *ii.json* output is normally directed to STDOUT; in this case, it is redirected to the file `my.ii.json`.

5.2.3 OBIWAN TAG

obiwan tag is used to add, modify, and delete "tags" on Origen binary files. These "tags" come in two types: "ID" tags used for categorical identification, and "interp" tags representing real values used to denote state points for interpolation. (Examples of typical "interpolation" tags might include features such as initial enrichment, average moderator density, etc.; i.e., characteristics that are expected to influence the shape of the neutron energy spectrum and thus the resulting one-group cross-sections.)

-idtags=

Key-value pairs corresponding to "categorical" information about a data set on a binary file. Each key is a string mapped to a string value; ID keys are used to identify common characteristics of different sets of data (e.g., assembly type, size, and other characteristic features used to identify and group together similar sets of data).

One or more values are given as key-value pairs within an array, e.g.:

`-idtags=[ tag1=val1, tag2=val2, ... ]`

-interptags=

Key-value pairs corresponding to "interpolable" information about the position on the binary file. Each

key is a string mapped to a real, floating-point point value; these interpolation values can then be used as "knots" on an interpolation grid to interpolate `Origen::Library` and `Origen::StateSet` data.

One or more values are given as an array, e.g.:

`-interptags=[ tag1=val1, tag2=val2, ... ]`

5.2.3.1 Viewing tags on on a file

To view tags present on an `Origen::Library`, call `obiwan tag [filename]` without specyfing any ID or interpolation tags, e.g.:

Example 5.2.4: Using OBIWAN to view all existing tags on a file

```
obiwan view libs/w17_15_tagged.arplib

    libs/w17_new.arplib: {
       idtags: {
          size: 17,
          vendor: Westinghouse }
       interptags: {
          enr: 1.5,    }
    }
```

Note: For `Origen::Archive`, `obiwan tag` viewing will display the "lowest common denominator" set of tags, i.e., exclusively the tags present on all `Library` objects on the `Archive`.

Note: **`obiwan tag`** modifies tags on an Origen binary file in-place.

5.2.3.2 Adding tags to a file

To add a tag to a file, specify the tag name and value as a key-value pair; multiple tags can be added simultaneously by separating each key-value pair by a comma. The entire series of key-value pairs must be enclosed by a pair of single quotes, e.g.:

```
$ obiwan tag idtags='tag1=val1, tag2=val2, ...'
```

If a tag name already exists on the file, the tag value is automatically updated to the new value provided by the user; otherwise, the tag is created and added to the `Library`.

Example 5.2.5: Adding tags to multiple `Origen::Library` files simultaneously; note that all output is directed to the file "log"

```
cp $DATA/arplibs/w17* new
obiwan tag new/\* -idtags='size=17,vendor=W' 2>log
obiwan tag new/\*e60.arplib -interptags='enr=6.0' 2>>log
obiwan tag new/\*e50.arplib -interptags='enr=5.0' 2>>log
obiwan tag new/\*e40.arplib -interptags='enr=4.0' 2>>log
obiwan tag new/\*e30.arplib -interptags='enr=3.0' 2>>log
obiwan tag new/\*e20.arplib -interptags='enr=2.0' 2>>log
obiwan tag new/\*e15.arplib -interptags='enr=1.5' 2>>log
```

The newly-created tags can be similarly viewed using a wildcard operator:

Example 5.2.6: Viewing newly-added tags on multiple files

```
$ obiwan tag new/\*.arplib

    new/w17_e15.arplib: {
       idtags: {
          size: 17,
          vendor: W   }
       interptags: {
          enr: 1.5,    }
    }

    new/w17_e20.arplib: {
       idtags: {
          size: 17,
          vendor: W   }
       interptags: {
          enr: 2,    }
    }
    ...
```

5.2.3.3 Deleting tags on a file

To delete a tag from a file, simply specify the name of an existing tag on the file with an empty value, e.g.:

```
$ obiwan tag -idtags='assembly='
```

5.2.4 OBIWAN CONVERT

Converts between different file formats for `Origen::Library` (reactor data libraries) and `Origen::StateSet` (stored concentrations).

-version=
Target output version (file format)

- **6.1**: sets -format=s61
- **6.2**: sets -format=bof

-format=
Target output format (mutually exclusive with `-version`)

- **s61**: SCALE 6.1 fortran binary
- **s62b**: SCALE 6.2 beta fortran binary
- **bof**: SCALE 6.2+ Binary Object Format
- **hdf5**: SCALE 6.3+ HDF5 format (EXPERIMENTAL)

Warning: The HDF5 format for `Origen::Library` is currently under development and may change in future releases; at present, it is provided as a convenience method for users to import `Origen::Library` data from external sources and to export data into HDF5 format for expedited viewing & processing.

-type=
Filter loading to a particular file type

- **f33**: `Origen::Library`
- **f71**: `Origen::StateSet`
- **yld**: `Origen::YieldResource`
- **dec**: `Origen::DecayResource`

-dir=
Existing directory for converted files

Default: `-dir=./` (current directory)

-i
Modify existing files in place

(By default, obiwan will not overwrite existing files)

-remove_mass
Remove masses on a library

-remove_abund
Remove abundances on a library

-verbose
Verbose mode (extra output to STDERR)

-endian=
Request for endianness of converted files

- **big**: big endian
- **little**: little endian
- otherwise: system-native endian

(will not be possible in all scenarios)

-thin=
Enable / disable library thinning (1 = thin)

"Thinning" library by interpolating to a user-specified series of burnups

Default: `thin=0` (no thinning)

interp=
Time / burnup interpolation method

near: Interpolate to nearest time / burnup point **lin**: Linearly interpolate between time / burnup points **cubic**: Cubic spline interpolaiton between time / burnup points

Default: `near` (nearest neighbor)

tvals=
List of times (MWd/MTHM) to keep/interpolate to in JSON array format, e.g. `tvals=[0,100,250,1000,50000]`

rvar=

Response variable to base thinning on: e.g., loss xs (*loxs*), fission xs (*fisxs*)

loxs: Total loss cross-section **fisxs**: Fission cross-section

Default: `rvar='loxs'`

rnuc=

Nuclide response to use for response variable (e.g., pu240) for interpolation / thinning

Default: `pu240`

-setbu=

Array of burnups to set on the library (i.e., burnup points to interpolate to)

Example: `-setbu=[1500.0, 3025.0, 10000.0]`

5.2.5 OBIWAN DIFF

Usage: `obiwan diff -format=String(y) [opts] file1 file2`

-reltol=

Relative tolerance in percent (%)

Default: `reltol=0.01`

-pos=

Position in file to output (0 corresponds to all positions)

Default: `-pos=1`

-format=

Controls output format

Options include:

- `y`: smart side-by-side
- `genneu`: neutron generation
- `eq`: fast exact match (no output)
- `approx_eq`: fast aprox match (no output)

Default: `-format=y` (smart side-by-side)

5.2.5.1 Obiwan diff examples

Take the difference between two files at the first file position, display differences using smart side-by-size, while redirecting STDERR to the file `log` and STDOUT to the file `out`:

```
$ obiwan diff -pos=1 -format=y \
              $DATA/arplibs/a10_e15w01.arplib \
              $DATA/arplibs/a10_e20w01.arplib 2>log >out
$ echo $? #return value should be 3 indicating difference
```

Same as before, but now allow for a 30% relative tolerance for reporting differences:

```
$ obiwan diff -pos=1 =format=y -reltol=30 \
              $DATA/arplibs/a10_e15w01.arplib \
              $DATA/arplibs/a10_e20w01.arplib 2>log >out
$ echo $? #return value should be 0 indicating no difference >30%
```

5.2.6 OBIWAN INTERP

obiwan interp interpolates between ORIGEN libraries based on a specified series of tag attributes to generate a new library.

Usage: `obiwan interp [-idtags='tag1=[v1],tag2=[v2]'] [-interptags='tag3=[v3],tag4=[v4]'] file1 file2 ...`

-idtags=

List of ID tags to down-select for interpolation. (i.e., Libraries without **all** of the matching ID tags are excluded from interpolation).

Accepts an array of key-value pairs separated by commas, e.g. `-idtags='tag1=[v1],tag2=[v2],...]`

Values are interpreted as strings

-interptags=

List of interpolable values to interpolate the new library to.

Accepts an array of key-value pairs separated by commas, e.g. `-interptags='tag1=[v1],tag2=[v2],...]`

Here, values are floating-point real numbers

Note: Required

5.2.6.1 Interpolation usage examples

Example 5.2.7 illustrates a basic interpolation case, selecting all libraries with ID tags `Assembly Type` matching `w17x17` and `Fuel Type` matching `UOX`, interpolating along dimensions `Enrichment` and `Moderator Density` to values of 4.5% and 0.55 g/cc, respectively.

Example 5.2.7: Interpolate all libraries with ID tags `Assembly Type=w17x17` and `Fuel Type=UOX` to an enrichment of 4.5% and moderator density of 0.55 g/cc.

```
obiwan interp
       -idtags='Assembly Type=w17x17,Fuel Type=UOX'
       -interptags='Enrichment=4.5,Moderator Density=0.55' /path/to/libraries
```

Note: When interpolating, obiwan will produce a new library file called `InterpLib.bof`.

5.2.7 OBIWAN PATCH

Patch an ORIGEN file with data from another file

Usage: `obiwan patch -from=SOURCE -data="path/to/data" [opts] file`

-from=

File to import patch data from; existing data or `NULL`

Default: `-from=ft33f001`

-data=

A special a hierarchical data description using "/" separators.

Data paths supported:

- `coeff[POS]/n_production_xs`
- `coeff[POS]/nu`

`POS=1,2,...,N` where `N` is the total number of positions

`POS=*` can be used to specify all positions

`POS=1|2|...` can be used to specify a list of positions

Note: `coeff/` and `coeff[*]/` are identical

-pos=

Position on <`file`> to apply patch

`0`: attempt to apply to all positions

-type=

Load only a particular type

Options:

- `f33`: Library

-verbose

Verbose mode (extra output to STDERR)

5.2.7.1 obiwan patch usage examples

The following examples illustrate how to use **`obiwan patch`** to patch data on Origen Library files.

Example 5.2.8 illustrates patching all neutron production cross-sections from the first position of an existing Library file.

Example 5.2.8: Patch all neutron production cross sections with a single data set (position 1 on `my.f33`)

```
$ obiwan patch -from=my.f33 -data=coeff[1]/n_production_xs patched.f33
$ obiwan view -format=genneu -type=f33 -pos=1 patched.f33
```

Example 5.2.9 nullifies (replaces with zeroes) all neutron production cross-sections as position 2 on the Library file.

Example 5.2.9: Zero out neutron production cross-sections at position #2

```
$ obiwan patch -from=NULL -data=coeff/n_production_xs -pos=2 patched.f33
```

Example 5.2.10 demonstrates replacing data on a three-position library, using data from source position 1 for the first two positions on the patched library and from source position 2 on the third position of the patched library.

Example 5.2.10: Patch a 3-position library with data from positons 1, 1, and 2 on `my.f33`, respectively

```
$ obiwan patch -from=my.f33 -data=coeff[1|1|2]/n_production_xs patched.f33
```

Example 5.2.11 and Example 5.2.11 demonstrate synonymous ways of sequentially replacing three positions on a patched library with the sequential positions from a source Library. (Note that the source library `my.f33` must have the same number of positions as the Library being patched.)

Example 5.2.11: Patch 3-position library with new data from `my.f33` in sequential order. (Note that `my.f33` must have 3 positions.)

```
$ obiwan patch -from=my.f33 -data=coeff[*]/n_production_xs patched.f33
```

Example 5.2.12: Patch 3-position library with new data from `my.f33` in sequential order. (Note that `my.f33` must have 3 positions.)

```
$ obiwan patch -from=my.f33 -data=coeff/n_production_xs patched.f33
```

Finally, Example 5.2.13 replaces only the nu portion (i.e., average neutron production per incident neutron) of the actinide neutron (i.e., average neutron production per incident neutron production data, assuming it is dominant).

Example 5.2.13: Just correct the nu portion of actinides production, assuming it is dominant, i.e. `nu=from_prodxs/from_fisxs --> to_prodxs=nu*to_fisxs`

```
$ obiwan patch -from=my.f33 -data=coeff/nu patched.f33
```

5.3 ORIGEN REACTOR LIBRARIES

B. Hiscox, B. R. Betzler, B. J. Ade

5.3.1 DESCRIPTION OF ORIGEN REACTOR LIBRARIES IN SCALE

The ARP code creates burnup-dependent ORIGEN cross-section libraries by interpolating over reactor cross-section libraries generated in advance using reactor physics transport methods. The reactor cross-section libraries distributed in SCALE include many classes of commercial power reactor designs and a range of fuel assembly designs.

Cross-section libraries suitable for use with ORIGEN are available in SCALE for the following reactor and fuel assembly designs, summarized in Table 5.3.1.

- BWR 7 × 7, 8 × 8-1, 8 × 8-2, 9 × 9-2, 9 × 9-9, 10 × 10-9, 10 × 10-8, SVEA-64, SVEA-96, and SVEA-100;
- PWR 14 × 14, 15 × 15, 16 × 16, 17 × 17, 18 × 18;
- CANDU reactor (19-, 28-, and 37-element bundle designs);
- Magnox graphite reactor;
- Advanced Gas-Cooled Reactor (AGR);
- VVER 440 and VVER 1000;

- RBMK;
- IRT;
- MOX BWR 7 × 7, 8 × 8-1, 8 × 8-2, 9 × 9-2, 9 × 9-9, 10 × 10-9, 10 × 10-8, SVEA-64, SVEA-96, and SVEA-100;
- MOX PWR 14 × 14, 15 × 15, 16 × 16, 17 × 17, 18 × 18.

All of the libraries distributed with SCALE were developed using ENDF/B-VII.1-based 252-group cross section libraries and the SCALE 6.3 TRITON module. The assembly design and the identifier for each library are summarized in Table 5.3.2. All TRITON templates used to generate these libraries are provided with the release; these templates have been developed to reflect the most recent publicly available data and to adhere to current SCALE best practices. MOX templates use the same set of BWR and PWR lattices, with MOX compositions replacing the UO:sub:*2* fuel.

Additionally, a Python script (`slig.py`) has been developed to semi-automate the process of generating sets of libraries from information in these templates. This script calls another Python script to automatically generate a PDF documentation file with LATEX. This SLIG script is made available to the user; more details are available in the SLIG manual.

Table 5.3.1: Summary of ORIGEN libraries (1470 total libraries).

Reactor type	**Assembly Design Description**	**Library Name(s)**
PWR LEU and MOX	Babcock & Wilcox 15 × 15	bw15x15, mox_bw15x15
	Siemens 14 × 14	s14x14, mox_s14x14
	Siemens 18 × 18	s18x18, mox_s18x18
	Westinghouse 14 × 14	w14x14, mox_w14x14
	Westinghouse 15 × 15	w15x15, mox_w15x15
	Westinghouse 17 × 17	w17x17, mox_w17x17
	Westinghouse 17 × 17-OFA	w17x17_ofa, mox_w17x17_ofa
	Westinghouse CE 14 × 14	ce14x14, mox_ce14x14
	Westinghouse CE 16 × 16	ce16x16, mox_ce16x16
BWR LEU and MOX	ABB 8 × 8-1	abb8x8-1, mox_abb8x8-1
	ATRIUM 9 × 9-9	atrium9x9-9, mox_atrium9x9-9
	ATRIUM 10 × 10-9	atrium10x10-9, mox_atrium10x10-9
	General Electric 7 × 7-0	ge7x7-0, mox_ge7x7-0
	General Electric 8 × 8-1	ge8x8-1, mox_ge8x8-1
	General Electric 8 × 8-2	ge8x8-2, mox_ge8x8-2
	General Electric 9 × 9-2	ge9x9-2, mox_ge9x9-2
	General Electric 10 × 10-8	ge10x10-8, mox_ge10x10-8
	SVEA 64(8 × 8-1)	svea64-1, mox_svea64-1
	SVEA 96(10 × 10-4)	svea96-0, mox_svea96-0
	SVEA 100(10 × 10-0)	svea100-0, mox_svea100-0
VVER	VVER-440 flat enrichment	vver440
	VVER-440 radial enr. profile, avg. 3.82%	vver440_3.82
	VVER-440 radial enr. profile, avg. 4.25%	vver440_4.25
	VVER-440 radial enr. profile, avg. 4.38%	vver440_4.38

continues on next page

Table 5.3.1 – continued from previous page

	VVER-1000	vver1000
RBMK	RBMK 1000, flat enrichment	rbmk1000
CANDU	19-element bundle design	candu19
	28-element bundle design	candu28
	37-element bundle design	candu37
Magnox	Magnox graphite reactor (Calder Hall)	magnox
AGR	Advanced gas-cooled reactor	agr
IRT	IRT-2M (3 tube)	irt2m3tube36enrich, irt2m3tube
	IRT-2M (4 tube)	irt2m4tube36enrich, irt2m4tube
	IRT-3M (6 tube)	irt3m6tube36enrich, irt3m6tube90enrich
	IRT-3M (8 tube)	irt3m8tube36enrich, irt3m8tube90enrich
	IRT-4M (6 tube)	irt4m6tube
	IRT-4M (8 tube)	irt4m8tube
LEU = Low-enriched uranium **MOX** = Mixed-oxide		

The libraries for BWR and RBMK assembly designs all include variable coolant density. Table 2 lists the number of cross-section files associated with each individual assembly design; this number is often a product of the number of enrichments (or Pu contents for MOX assemblies) and the number of coolant density values. Unless otherwise noted in Table 5.3.1, the PWR and BWR LEU libraries were generated for ten enrichment values: 0.5, 1.5, 2.0, 3.0, 4.0, 5.0, 6.0, 7,0, 8.0, and 8.5 wt% ^{235}U. The maximum enrichment and burnups of most of the BWR and PWR libraries were extended in SCALE 6.3 from their historical maximum values of 6.0 wt% enrichment and 70.5 GWd/MTIHM burnup to 8.5 wt% and 82.5 GWd/MTIHM, respectively.

The cross sections are represented at several burnup values in the range from 0 to the maximum burnup listed. The number of burnup values on the library has been optimized with a post-processing script to minimize the size of the data libraries without losing significant fidelity in the cross section data. Note that these optimized burnup steps are not the same burnup steps used in the TRITON calculations; more burnup steps are used to calculate the depletion of the fuel. The fuel assembly designations used for many of the BWR designs include the basic lattice type, followed optionally by the number of empty (non fuel) lattice positions. For example, the 9 × 9-9 designation refers to the Atrium design with a 9 × 9 assembly lattice with 9 non-fuel (water) locations. Additional data on the reactor libraries is available in the library information PDF file released with SCALE.

This document includes details on the fuel lattice type, the fuel vendor (where design information is specific to a vendor design), the assembly model, basic fuel design and reactor operating data, and the range of the variable parameters associated with the libraries (e.g., enrichment range, burnup range, etc.). This document references separate reports from which a more detailed description of the data for these libraries can be found.

Table 5.3.2: Additional information on ORIGEN libraries

5.3.2 HOW TO GENERATE ORIGEN CROSS-SECTION LIBRARIES

This section describes the basic procedures one needs to follow to generate ORIGEN cross-section libraries for fuel types not included in SCALE. Note that the extension of the methods and data beyond 5 wt% enrichment has only been recently investigated by ORNL [ORIGEN-RX-LIBSCSHW21, ORIGEN-RX-LIBSHCWS21]. While no unexpected or anomalous trends were observed in trends beyond the limits of previous reactor data libraries (i.e., 5.0 wt% enrichment and 60 GWd/MTIHM), there is nonetheless a current lack of accessible validation data for these higher-burnup domains. In general, effects of higher enrichment were found to offset higher burnup limits. Users are encouraged to carefully test and validate applications of these libraries in these extended domains.

The following discussion and examples relate primarily to generating commercial LWR fuel libraries. Note that the parameter ranges used as examples are not necessarily appropriate to non-LWR applications, and will need to be modified for different reactor types and fuel designs.

The first step is to construct a physics model of the fuel lattice with the descriptions of the reactor assembly under consideration. For a given initial fuel enrichment, a TRITON depletion calculation is performed using one of the depletion analysis sequences of SCALE. TRITON can use either an explicit 2-D representation of the fuel assembly using the NEWT discrete ordinates transport code, or a 3-D representation of the assembly using the KENO Monte Carlo transport code. TRITON allows multiple fuel types to be defined and depleted independently.

The depletion analysis sequences are used to simulate irradiation and depletion of the fuel over the required irradiation history. A burnup analysis is typically modeled using a series of time intervals, or cycles. During the simulation, cross-sections that are representative of the mid-point of each cycle are created and saved in the library by the depletion sequence. In addition, cross sections that are representative of fresh fuel conditions (zero burnup) are now automatically saved in the library, without the need for the user to add a small burnup step to represent initial cross sections, as required in earlier versions of SCALE.

Past experience in creating LWR fuel libraries has indicated that depletion simulations with burnup steps of 3,000 MWd/MTU are generally adequate to represent the cross section variations with burnup. Each set of burnup-dependent cross sections is stored within the single library, and each set is accessed sequentially by its position in the library. The position 1 set contains fresh-fuel cross sections and the remaining cross-section

sets (positions) correspond to burnup levels characterizing the midpoint of each burnup step in the depletion sequence calculation.

For fuels with multiple enrichment values, the above procedure is repeated for each enrichment. For fuels with a single enrichment value (e.g., natural uranium), only one depletion case is required. Cross-section changes with enrichment are generally represented using approximately 1.0 wt % increments, e.g., 0.5, 1.5, 2.0, 3.0, 4.0, 5.0, 6.0, 7.0, 8.0, and 8.5 wt % of ^{235}U. Because the cross-section variation is generally well behaved and smooth with changes in enrichment, it may be possible to maintain accuracy using fewer enrichment points. For BWR designs, or reactor designs involving considerable moderator density variations, one has also to consider the effect of water density variation on the cross sections. The recommended water density values for BWRs are typically 0.1 to 0.9 g/cm^3, with increments of about 0.2 g/cm^3. Again, fewer points may be adequate for many applications. Water density variation has typically not been included for PWR libraries developed at ORNL because of the relatively small variation in pressurized water reactors. When the variation in moderator density is considered, the libraries must be calculated for each combination of enrichment and moderator density. This may involve a considerable number of depletion analysis simulations to prepare all of the required cross-section libraries.

The SLIG utility has been created to help automate the creation of input files that represent each of the discrete parameter combinations. Instead of having to manually create input files for each parameter value, a single template input file is constructed with generic flags substituted for the parameters that vary from case-to-case (i.e., enrichment and water density). The specific values required for each parameter are specified in the header of the template file; SLIG reads the template and substitutes the values for the generic flags in the input file. SLIG generates a unique subdirectory and input file for each parameter combination. A description of SLIG and examples are provided in the SLIG manual.

Another utility provides an optional procedure that can be used to reduce the size of the cross-section libraries by eliminating some of the burnup-dependent cross-section sets in the libraries in regimes where the cross sections do not vary appreciably with burnup. In general, the change in cross-section values is more pronounced early in irradiation, and tends to approach asymptotic values at higher burnup. Therefore, interpolation of the cross sections using fewer data points may yield acceptable accuracy in this range. This utility is currently unavailable in SCALE 6.3.

As an example of this procedure, the basic steps in creating a set of cross-section libraries for a typical PWR assembly are illustrated. In this example the burnup is calculated up to 72 GWd/MTU. To generate these basic cross-section libraries, the following steps are performed for each fuel enrichment value:

1. Create a 2-D or 3-D reactor physics model using TRITON for the fuel assembly design and fuel type being considered.

2. Run a depletion analysis calculation to the maximum burnup under consideration. For example, set a maximum burnup at 72 GWd/MTU, and simulate using 24 intervals (cycles) with one library per cycle. Each of these cycles is 3 GWd/MTU in size. The library generated by this analysis will contain 25 sets of cross sections: initial fresh fuel cross sections plus 24 burnup-dependent cross sections.

3. Include as many extra nuclides in the fresh fuel composition specification as is practical in trace concentrations (e.g., 1E-20 atoms/barn-cm). This procedure ensures that updated cross sections for each nuclide added will be used in creating the ORIGEN library. The depletion analysis sequences automatically add many of the most important actinides and fission products. However, the addition of more nuclides by the user will result in more complete updating of the cross-section data. The addition of trace nuclides is handled automatically in TRITON using the ADDNUX= parameter entry.

4. The above procedure is repeated for each enrichment value. If moderator density variation is to be included, a separate calculation is required for each enrichment-moderator density value combination.

5. Finally, the ARPDATA.TXT file must be updated to include the data for the new cross-section libraries created. This file contains information on the library, including the number of values for each variable parameter, the parameter values, the burnup values for each library position, and the actual library file names. The burnup values for each set of cross sections in the library are printed in the TRITON output file to assist the user in determining the appropriate library entries. Once the library information is registered in the ARPDATA.TXT file, it can be used directly by ORIGEN.

5.3.3 APPENDICES

5.3.3.1 SCALE/ORIGEN Library Generator (SLIG)

B. R. Betzler

This Python script (`slig.py`) semi-automates the process of generating sets of cross-section libraries for ORIGEN calculations for spent fuel depletion, decay, and source term analysis. SLIG performs several tasks:

1. reads standard-format template files, obtaining information (e.g, enrichments, burnups, moderator densities, etc.) from the file header
2. generates a set of input files according to this header information;
3. builds a directory tree to house these input files;
4. writes the addition to the `arpdata.txt` file;
5. moves the final libraries to a new directory; and
6. reads the burnup list for each set of libraries and writes them in the addition to the `arpdata.txt` file.

This manual is divided into five main sections based on the desired application:

Quick Start Directions for running SCALE on a local machine or a computing cluster without a queue system;

Advanced Options for running SCALE on a cluster with a queue system;

Template File Rules and Examples for editing and writing template files;

Troubleshooting for issues running SLIG; and

Code Information for making changes to the code.

Quick Start Directions

The SLIG package is located in the SCALE source directory in `./packages/etc/slig/`. Because it is necessary to run SCALE to generate the appropriate cross-section libraries, SLIG runs in a disjointed, three-step process:

1. Copy the contents of the `./slig/src/` directory into `./slig/testing/`. Move to the `./slig/testing/` directory and use **`./slig.py -g`** to perform tasks 1) through 4). If SLIG returns an error, follow the directions in the error message (see Sect. 5.3.3.1.7). After a successful run, three new items will appear in the current directory:

runSpace/ the directory tree containing the input files,

arpLibList.txt a list of the locations of the libraries in the directory tree, and

addToArpData.txt additional lines for the arpdata.txt file.

2. Run SCALE with each input within the directory tree (runSpace/). Each input is located within the directory tree in the location ./runSpace/templateName/inputID/, where templateName is the prefix of the template file (i.e., templateName_template.inp) and inputID is a string identifying the enrichment (eNN), moderator density (wMM, if applicable), and plutonium vector (vPP, if applicable) for the input.
3. After all SCALE calculations are complete, use **./slig.py -f** to perform task 5) and 6). SLIG will identify any missing libraries. After a successful run, two changes will be made in the current directory:

   newLibraries/ this directory containing the new libraries will appear, and

   addToArpData.txt the burnup lists will be written on the this file.

The final result is an addition to the arpdata.txt file (addToArpData.txt) and a directory containing all generated libraries (newLibraries/). Do not delete any files associated with slig.py unless it directs you to do so. The following options are available to the user (see Sect. 5.3.3.1.1 for more options):

-p <PATH>, **-path**=<PATH>
: This specifies the location of the template files. SLIG will search PATH and all its subdirectories for template files. The default path is the current directory.

-x <XSLIB>, **-xsections**=<XSLIB>
: This specifies the cross section library used in all calculations. The default is v7-252.

Advanced Options

The following are more advanced options available to the user:

-e <EXT>, **-extension**=<EXT>
: This specifies the file extension that identifies a template file. By default, SLIG searches for files ending in _template.inp).

-a, -add
: This flag is used with the -g option (**./slig.py -ga**) to add input files to the current directory tree (runSpace/). It also adds library information to addToArpData.txt and adds the location of the libraries in the directory tree to file:*arpLibList.txt*.

  This flag is used with the -f option (**./slig.py -fa**) to add newly generated libraries to the current library directory (newLibraries/).

-d, -document
: This flag turns on documentation routines that automatically generate a LaTeX file (libraryInformation.tex) with data about each template file using information on the file header. This also generates a .pdf file (libraryInformation.pdf) using pdflatex (required for this to function properly). Additionally, any figures referenced within the templates must be located within the current directory or any of its subdirectories.

-s, -submit
: This flag turns on routines that generate a PBS submit script for each input file for running on clusters with a queue system. It also generates a shell script to submit these jobs (with **qsub**). The PBS submit script template (run1proc.pbs) must be placed in the current directory.

The first two steps of the three-step process for running SLIG (see Sect. 5.3.3.1.1) change:

1. Use **./slig.py -gs** to perform tasks 1) through 4). After a successful run, four new items will appear in the current directory:

   runSpace/ the directory tree containing the input files,

   arpLibList.txt a list of the locations of the libraries in the directory tree,

   addToArpData.txt additional lines for the arpdata.txt file, and

   submitSLIGjobs a shell script for submitting jobs to the queue.

2. Run the shell script (`./submitSLIGjobs`) to submit jobs to the queue. Note that this may submit a very large number of jobs to the queue.

When using **./slig.py -ga**, SLIG will check for documentation and submit scripts and will proceed with the same settings that were used for the initial run of SLIG. For example, if the user initially runs **./slig.py -gds** to generate documentation and submit scripts then later uses **./slig.py -ga**, SLIG will proceed with adding documentation for the additional templates and generating submit scripts. When SLIG generates additional submit scripts, a separate numbered file is generated for each new template (e.g., `submitSLIGjobs1`).

Template File Rules and Examples

Example templates are provided with the SCALE distribution. For creating new templates, it is best to use these templates as starter files and make incremental changes as necessary for the new application. The header at the top of each template file contains the information that will be used to generate input files and documentation. Each line of this header must start with an apostrophe; each line is a comment line according to the SCALE standard input. There are two main sections in this header:

1. The **template header** (see Example 5.3.1 and Example 5.3.2). This header has a parameter list and an option list:
   a. The *parameter list* identifies the strings within the template file that SLIG will replace as it generates input files. These parameters are found throughout the template file; SLIG will replace these with values as it generates each input files. SLIG identifies the parameter list starting from the first line containing the 'parameter' string and each line thereafter that is indented more than five blank spaces (not including the apostrophe). The following is a list of rules for entering parameters:
      - Each parameter is entered on a separate line in the form "parameter-description".
      - Each parameter must be a unique string of characters.
      - Each parameter is a single string without spaces.
      - SLIG uses the "description" to characterize the parameter. If these descriptions are changed, SLIG may not be able to properly characterize each parameter. Thus, it is suggested that the descriptions in the following list are not changed.
      - There is some flexibility in changing the parameter strings.

   b. The *option list* identifies the quantities or values that SLIG uses to determine the values that will replace the parameters in each input file. SLIG identifies the option list starting from the first line containing the 'option' string and each line thereafter that is indented more than five blank spaces (not including the apostrophe).

      The following is a list of rules for entering options:

- Each option is entered on a separate line in the form `option - values`.
- SLIG uses the "option" to recognize what to do with the values. If this is changed, SLIG may not be able to properly characterize each option. Thus, it is suggested that the options (to the left of the dash) in the following list are not changed.
- For options with multiple values, each value must be separated with a comma.
- For values to continue onto the next line, the last value in a line must end with a comma and the next line must be indented and must begin with the next value.
- The values may be changed.

2. The **documentation header** (see Example 5.3.3). The documentation header has two purposes. First, it is used to track information about the template (e.g., author, date created, and methodology) and the source documents that contributed to the template's creation. This simplifies updating input files for new versions of SCALE. Second, SLIG uses this header information to generate documentation files. SLIG identifies the documentation header starting from the first line containing 'Documentation' to the line starting with an apostrophe followed by a space and five dashes (`' -----`).

Example 5.3.1: A typical BWR template header.

UOX fuel parameters

The following (Example 5.3.4) is a list of some of the parameters available to the user for working with most PWR and BWR lattices:

Example 5.3.4: SLIG input options for UOX-based templates

```
u235wt% - wt% U235
u234wt% - wt% U234
u236wt% - wt% U236
u238wt% - wt% U238

ddd - coolant density (g/cc)

dancoff1 - dancoff factor 1
dancoff2 - dancoff factor 2

namelibrary - name of generated ORIGEN library

specpow - average specific power
daystoburn - depletion interval in days
```

Example 5.3.5: Example of a fully-specified UOX input.

```
name - abb_

enrichment - 0.5, 1.5, 2.0, 3.0, 4.0, 5.0, 6.0

cool. density - 0.1, 0.3, 0.5, 0.7, 0.9 (or mod. density - 1.65)

dancoff1 - 0.4686, 0.3429, 0.2651, 0.2122, 0.1742
dancoff2 - 0.3103, 0.2316, 0.1823, 0.1484, 0.1237

spec. power - 25.0

burnups - 0, 1, 2, 3, 4.5, 6, 7.5, 9,
          10.5, 12, 13.5, 15, 16.5, 18,

```

MOX fuel parameters

For mixed oxide (MOX) PWR and BWR assemblies, there is a different set of parameters available to the user. SLIG will recognize a file as a MOX template by searching for the Pu-239 parameter. SLIG automatically generates a MOX zoning pattern (see Fig. 5.3.1) for BWR and PWR lattices according to the values of `pin_zone`, `pin_gad`, and `avg_pin_dens.`.

Example 5.3.6: SLIG input options for MOX-based templates.

```
IcontentPu - wt% plutonium: inner
IcontentU - wt% uranium: inner

IEcontentPu - wt% plutonium: inside edge
IEcontentU - wt% uranium: inside edge

EcontentPu - wt% plutonium: edge
EcontentU - wt% uranium: edge
```

(continues on next page)

(continued from previous page)

```
CcontentPu - wt% plutonium: corner
CcontentU - wt% uranium: corner

pu238wt% - wt% Pu238
pu239wt% - wt% Pu239
pu240wt% - wt% Pu240
pu241wt% - wt% Pu241
pu242wt% - wt% Pu242

densityAm - americium density (g/cc)

ddd - coolant density (g/cc)

dancoff1 - dancoff factor 1
dancoff2 - dancoff factor 2

namelibrary - name of generated ORIGEN library

specpow - average specific power

daystoburn - depletion interval in days
```

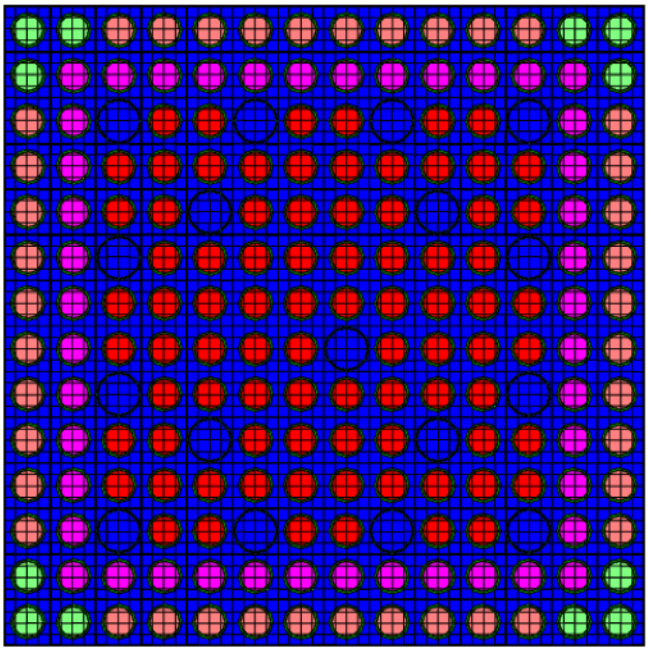

Fig. 5.3.1: MOX zoning layout for a Westinghouse 14 × 14 PWR assembly showing the corner (green), edge (salmon), inside edge (magenta), and inner (red) pin zones.

Example 5.3.7: Example of a fully-specified MOX input.

```
name - mox_abb_

pu content - 4.0, 7.0, 10.0
pu vector - 50.0, 55.0, 60.0, 65.0, 70.0

cool. density - 0.1, 0.3, 0.5, 0.7, 0.9
```

(continues on next page)

(continued from previous page)

```
dancoff1 - 0.4686, 0.3429, 0.2651, 0.2122, 0.1742
dancoff2 - 0.3103, 0.2316, 0.1823, 0.1484, 0.1237

spec. power - 25.0

burnups - 0, 1, 2, 3, 4.5, 6, 7.5, 9,
          10.5, 12, 13.5, 15, 16.5, 18,
          19.5, 21, 24, 27, 30, 33, 36,
          39, 42, 45, 48, 51, 54, 57, 60,
          63, 66, 69, 72

pin_zone - 11, 20, 16, 12

pin_gad - 4

avg_pin_dens. - 10.4
```

The following is an explanation of each option:

name
: This is the prefix for the name of the final generated libraries. It should be unique to the template (i.e., other templates should have a different name).

enrichment
: This is a list of the ^{235}U enrichments [%] for which SLIG will create separate inputs.

cool. density, mod. density
: This is a list of the coolant or moderator densities [g/cm^3] for which SLIG will create separate inputs.

dancoffN
: This is a list of dancoff factors that correspond to pin N. The length of this list must match the length of the coolant/moderator density list (the dancoff factor varies significantly with this density).

spec. power
: This is the specific power [MW/MTU] of the assembly.

burnups
: This is a list of cumulative burnup steps [GWd/MTU] that will be used to create the depletion steps. If a small step is not included, SLIG will print a warning and automatically insert one at the beginning of the calculation (for Xe equilibrium).

pu content
: This is a MOX-specific parameter that is a list of the average content of plutonium [%] in the assembly for which SLIG will create separate inputs. These quantities are calculated as a percentage of the total heavy metal loading in the assembly.

pu vector
: This is a MOX-specific parameter that is a list of the enrichments of ^{239}Pu [%] for which SLIG will create separate inputs. These quantities are calculated as a percentage of the total plutonium in the assembly and are used to calculate the entire plutonium vector [ORIGEN-Gau03].

pin_zone
: This is a MOX-specific parameter that lists of the number of pins in the inner, inside edge, edge, and corner zones (see Figure 5.A.3). This varies for each assembly.

pin_gad
: This is a MOX-specific parameter that specifies the number of Gd-bearing pins in the assembly. SLIG uses this quantity to calculate ensure that the specified Pu content of the assembly is correctly represented [ORIGEN-Gau03].

avg_pin_dens.
: This is a MOX-specific parameter that specifies the average density [g/cm^3] of the pins in the assembly. SLIG uses this quantity to calculate ensure that the specified Pu content of the assembly is correctly represented.

Documentation header

The documentation header has a free form-style entry, where sections are specified by `[Section Name]` and the text for each section follows afterward. Figures are referenced as `figure{figureName.pdf: Figure caption.}`. Any reference to the figure within the header must be in LaTeX-like form; for this, the figure is labeled as `fi:figureName`. The section name keywords `[Data Range]`, `[Libraries]`, and `[Power]` are reserved to be auto-populated by SLIG according to information provided within the vars list. All information within this header is transferred to the documentation file.

The parameters in the file headers are located within the template file in the appropriate locations. See the example templates for the proper usage. The burndata card in the input file should only be three lines:

```
read burndata
power=specpow burn=daystoburn down=0 end
end burndata
```

because it will be populated by the burnup points listed in the file header. There should also be a shell command at the end of the input file to save the cross-section library:

```
=shell
  cp ft33f001.cmbined $RTNDIR/namelibrary
end
```

Troubleshooting

If at any time an error occurs, SLIG will exit after printing the reason for the error and offer a possible solution. Following these instructions should resolve most issues with SLIG. The following is a list of factors to consider when having trouble running SLIG.

- SLIG uses the module argparse.py (see https://docs.python.org/3/library/argparse.html) to handle command line arguments; SLIG will crash if it does not have access to it. For versions of Python that do not inherently support this module, download the `argparse.py` file and include it in the directory with `slig.py`.
- If SLIG is crashing, there may be an issue with the version of Python. SLIG was developed to be functional with Python 2.7.6.
- After running **`./slig.py -g`**, the `addToArpData.txt` file will have dummy placeholders instead of the burnup lists. These placeholders are replaced with the burnup lists that are read off of the SCALE output files. The burnup lists in the documentation file are the burnup lists specified in the template files.

Code Information

SLIG consists of a `main`, one SCALE-specific class (`manageTemplate`), and three generic classes (`messenger`, `manageDirectory`, and `manageFile`):

- `main` reads and validates arguments, and contains a loop to make inputs and collect libraries
- `manageTemplate` manages templates (reads/sorts options, calculates concentrations)
- `messenger` manages all prints to the screen
- `manageDirectory` manages external directories (searching, making, etc.)
- `manageFile` manages external files (reading, writing, searching, copying, etc.)

SLIG calls a separate Python script (`collectinfov04.py`) to perform documentation functions. This script uses a template (`basedoc.v04.tex`) to generate the documentation file.

5.4 ORIGAMI: A CODE FOR COMPUTING ASSEMBLY ISOTOPICS WITH ORIGEN

ORIGAMI computes detailed isotopic compositions for light water reactor assemblies containing UO_2 fuel by using the ORIGEN transmutation code with pre-generated ORIGEN libraries, for a specified assembly power distribution. The fuel may be modeled using either lumped or pinwise representations with the option of including axial zones. In either case, ORIGAMI performs ORIGEN burnup calculations for each of the specified power regions to obtain the spatial distribution of isotopes in the burned fuel. Multiple cycles with varying burn-times and downtimes may be used. ORIGAMI produces several types of output files, including one containing stacked ORIGEN binary output data ("ft71 file") for each depletion zone; files with nuclide concentrations at the last time-step for each axial depletion region, in the format of SCALE standard composition input data or as MCNP material cards; a file containing the axial decay heat at the final time-step; and gamma and neutron radiation source spectra.

5.4.1 ACKNOWLEDGMENTS

ORIGAMI is based on the PinDeplete code developed by Steve Skutnik and also includes techniques taken from the Orella code written by Ian Gauld (retired). Support for development of ORIGAMI was provided by the U.S. Department of Energy, Office of Nuclear Energy, Nuclear Fuels Storage and Transportation Planning Project.

5.4.2 INTRODUCTION

ORIGAMI (**ORIG**EN **A**sse**m**bly **I**sotopics) provides the capability to perform isotopic depletion and decay calculations for a light water reactor fuel assembly model using one or more ORIGEN calculations. The assembly may be modeled using either lumped or pinwise representations with the option of including axial zones. ORIGAMI automates the performance of ORIGEN depletion calculations for each region and thus simulates zero-, one-, two-, and three -dimensional (0D, 1D, 2D, and 3D) modeling of a fuel assembly. Multiple cycles with different specific powers and exposure and decay times may be treated, and the power distribution is described in terms of fractional pin powers in the XY plane and axial distributions along the Z axis, which define the burnup regions for the ORIGEN computations. ORIGAMI allows for easy and flexible material composition specification through the standard SCALE mixture processor for composition input, the same as in TRITON (see XSPROC chapter). While ORIGAMI cannot presently treat axially non-uniform lattice features (e.g. axially varying enrichment or the partial-length rods found in many boiling water reactor designs) within a single input, these problems can still be easily modeled by splitting the problem across sequential ORIGAMI input cases residing on the same file.

The ORIGEN calculations performed by ORIGAMI use the methodology originally established for the SCALE sequence ORIGEN-ARP (see the ARP section). This approach provides an efficient mechanism to perform stand-alone reactor depletion calculations using pre-generated ORIGEN libraries which contain self-shielded, collapsed one-group cross sections as a function of selected independent variables, such as burnup, enrichment, and moderator density, for different reactor systems. Typically the data in these libraries are obtained from 2D, multigroup lattice transport calculations (e.g., TRITON) coupled with depletion calculations for burnup. The library cross sections may be flux-weighted over the lattice to obtain data representative of the entire homogenized assembly for lumped depletion; or alternatively, it is also possible to generate multiple ORIGEN libraries corresponding to individual or groups of pins within the lattice for multi-pin depletion. The burnup-dependent ORIGEN libraries are analogous to the parameterized cross section data produced by lattice physics codes for reactor core simulators, except that data for many more nuclides and reactions are included to allow ORIGEN to compute detailed isotopics for more than 2200 nuclides.

ORIGAMI extends the capabilities previously provided by ORIGEN-ARP to perform a suite of ORIGEN calculations in order to represent the isotopic distribution of fuel within an assembly in more detail. The pre-generated ORIGEN libraries provided with SCALE tabulate the assembly-average one-group cross sections, in order to accurately reproduce assembly-average isotopics. When performing pin-by-pin calculations in ORIGAMI, users can increase the fidelity with respect to proximity to features such as assembly edges, water holes, burnable poison rods, etc. by creating and employing zone-specific libraries for different pins. By specifying the individual library assignments for each pin, users can capture these local spectrum changes in the ORIGAMI calculation through the use of one-group libraries based on these local conditions. Currently, the specification of individual libraries is limited to pin-level specification only (i.e., the same library is used for all axial zones corresponding to a pin for 3D cases) with an allowed axial moderator density distribution and radial and axial power distributions.

ORIGAMI can produce the following output files in addition to the standard ORIGEN output for each depletion zone:

- isotopics in ORIGEN binary concentration (ft71) files
  - in each depletion zone at times specified by the **`options`** block, `ft71` key
  - in each axial zone (summed over all pins at a particular axial level) at the final time;
- nuclide concentrations by axial zone, written as a SCALE "standard composition block" that can be used directly as input for SCALE transport codes such as the KENO Monte Carlo criticality code;
- axially-dependent decay heat source for input to a thermal analysis code such as COBRA, so that the temperature distribution within a storage cask can be computed;
- nuclide concentrations for each axial zone, given in the format of MCNP material cards;
- space-dependent radiation source energy spectra and magnitudes in a simple text file.

ORIGAMI is tightly integrated with the SCALE Graphical User Interface, Fulcrum. Using Fulcrum and the "UO2 express form (configurable)", one can create a simple UO_2 assembly depletion case in seconds (see Fig. 5.4.1). Finally, ORIGAMI has the ability to perform the depletion/decay calculations for each zone in parallel using the MPI (Message Passing Interface), however this requires a special SCALE installation built with MPI in order to do so [ORIGAMISHDLG13].

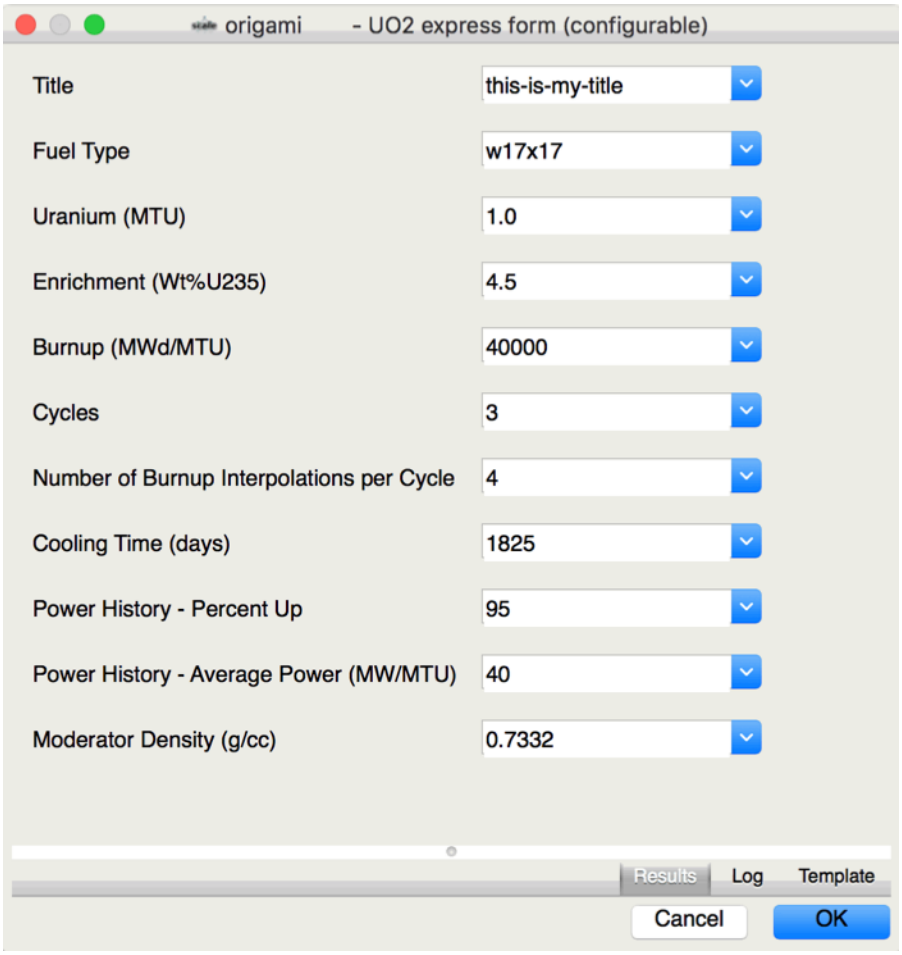

Fig. 5.4.1: Fulcrum UO_2 express form for creating ORIGAMI input.

5.4.3 COMPUTATIONAL METHODS

5.4.3.1 ORIGAMI assembly model

The basic model for ORIGAMI is a fuel assembly, which may be modeled in several ways with varying degrees of complexity. The most primitive model represents the assembly materials as a single mass lump that is depleted using the value of the specific power input in the power-history block. In this case, a single ORIGEN calculation is performed to obtain isotopics representing the entire assembly. This 0D model is equivalent to the current ORIGEN-ARP procedure. A more detailed model applies an input axial power profile to the (radially) lumped assembly materials. This lumped axial depletion model produces a 1D axially varying burnup distribution, but no allowance is made for variations in the relative pin powers within the assembly. Thus, if the axial power distribution is defined by N_Z axial zones, ORIGEN calculations are performed for N_Z different depletion regions. The 1D axial depletion model has been found to be adequate for most criticality and decay heat analysis of spent fuel assemblies [ORIGAMIRGlW12]. Note that both the 0D and 1D modes are fully consistent with the 2D TRITON calculations used to generate ORIGEN reactor libraries distributed with SCALE, in that these modes employ spatially-homogenized cross-sections to represent assembly-averaged flux and cross-sections. For 2D and 3D depletion models (wherein individual pin-specific libraries may optionally be specified), the user is advised that the ORIGEN reactor data libraries distributed with SCALE are representative of an assembly axial plane as a whole; in as much, the user is

advised to generate their own zone-specific libraries (i.e., based on individual material zones) within TRITON if they wish to capture regional neutronic effects within the assembly (such as proximity to water holes, burnable absorbers, etc.)

By specifying a radial pin-power map, a 2D or 3D calculation may be performed. Currently the axial and radial power shapes are fixed for the entire calculation but do still result in a fully 3D isotopic distribution [ORIGAMISGRT12, ORIGAMISHDLG13]. If there are N_P pins in the assembly and each has N_Z axial zones, ORIGAMI will perform ORIGEN calculations for $N_P \times N_Z$ depletion regions. For example, an assembly with a 17×17 array with 264 fuel pins and $N_Z = 24$ axial zones requires 6336 independent ORIGEN calculations. For these types of simulations, the parallel mode with MPI is highly recommended.

5.4.3.2 Definition of initial composition

The initial mass in metric tons of heavy metal is M_{mtu}, set by the input parameter `mtu`. The default value of `mtu` is equal to 1.0, so that by default the ORIGEN calculations are performed on the basis of "per metric ton of heavy metal". Given that the sum over all zones must have the total heavy metal content (M_{mtu}), one arrives at zone-wise heavy metal masses of:

$$M_{xy,z} = \frac{M_{\text{mtu}}}{\sum_{z=1}^{N_z} f_z \sum_{xy=1}^{N_P} m_{xy}} \cdot f_z \cdot m_{xy} \tag{5.4.1}$$

where the relative amount of heavy metal in each radial position, :m_{xy}, is calculated from the mixture specification; fractional axial height, f_z, from the zone specification; and N_P and N_Z are the total number of fuel pins and axial zones, respectively. Note that some pin locations in the assembly may not contain fuel, and these are not included in the value of N_P. The fractional axial height is given

$f_z = \frac{\Delta Z}{Z_{\text{tot}}}$ is the fraction of the active fuel height occupied by axial zone Z ΔZ is the length of axial zone

Z_{tot} is the total length of the active fuel.

Whenever an axial zone mesh is input (with array `meshz`), the value of f_Z is computed from the values of the zone boundaries (see input description in Sect. 5.4.4.6). If an axial mesh array is not input, the axial zones are assumed to be uniformly distributed. In this case, the axial zones all have the same height, so that $f = \frac{1}{N_Z}$, where N_Z is the number of uniform axial zones in the assembly.

The uranium mass in a single axial zone for all N_P fuel pins in the assembly (M_z) is thus:

$$M_Z = N_P \times M_{XY,Z} = M_{\text{mtu}} \times f_Z \tag{5.4.2}$$

In addition to the fuel mixture in an assembly, non-fuel materials (e.g., structural materials) may also be present. These materials contribute to the overall power production due to the energy produced by neutron capture reactions.. For a given value of the total assembly power, this reduces the power from the fuel mass and thus may slightly alter the fuel burnup and isotopics. In addition, activation of non-fuel materials produces additional radiation source terms in the spent fuel, which contribute to the decay heat and activity. Therefore ORIGAMI provides an option for including the non-fuel elements in the input array, `nonfuel`. The units of the non-fuel element masses are kg per MTU, and the materials are distributed uniformly within all fuel depletion zones. Note that the input non-fuel materials should not include oxygen in UO_2 if UO_2 is specified as the fuel material, as oxygen is already included in proportion to the uranium mass basis. Finally, because ORIGAMI accesses the StdComp library, any SCALE StdComp composition, e.g. "zirc4" for reactor cladding material Zircaloy-4, may be used in either structural or fuel materials.

5.4.3.3 Restart cases

ORIGAMI also allows the initial nuclide concentrations to be obtained from a previously produced ORIGEN binary output file. A restart case is indicated by setting **restart=yes** in the parameter array. The restart file has the name `assembly_restart.f71` and must be copied (or linked) to the SCALE temporary directory used for calculations. The restart file is normally obtained from an earlier ORIGAMI calculation, which always produces an ORIGEN restart file named `$`*OUTBASENAME*`.assm.f71`, where `${OUTBASENAME}` is an output prefix defined by the name of the input file and any user-specified prefix with the **prefix** key. Generally the restart file from ORIGAMI contains stacked concentrations, corresponding to each axial zone and then a final entry for the lumped assembly concentrations; hence, the initial composition for a restart case varies with axial zone, unlike the case for fresh fuel. ORIGAMI does not currently allow pin-dependent restart calculations. A restart case may be useful for performing decay-only calculations of spent fuel inventory, using the burned fuel composition previously computed for the assembly exposure during reactor operation. For decay-only cases, a value for the input parameter `nz` must be input in order to indicate the number of axial depletion regions in the previous burnup calculation.

5.4.3.4 Definition of power distribution

The radial power distribution is defined by the XY fractional pin powers in the input array `pxy`, and the axial fractional powers in the input array `pz`. The input values in arrays `pxy` and `pz` are normalized to unity by the code. The fractional power for a fuel pin "XY" is designated here to be r_{XY}, with the normalization $\sum_{XY=1}^{N_P} r_{XY}$. Similarly the fractional axial power for an axial zone Z is a_Z, which is normalized to $\sum_{Z=1}^{N_Z} a_Z$. The shapes of both the radial XY and axial Z distributions must be obtained prior to the ORIGAMI calculation, either from neutron transport calculations or experimental measurements. The input distributions remain constant during the ORIGEN burn calculations for all cycles; but in reality, the power distributions may vary with time—for example, the initial axial power distribution tends to flatten after a period of burnup since the higher power zones deplete the fuel faster. For this reason it is strongly recommended to use the relative burnup distribution (at final discharge) rather than the relative power density distribution for the input values. The burnup shape corresponds to the shape of the time-averaged flux distribution during the exposure period. This ensures that the final burnup distribution matches the desired shape.

For a given cycle, the assembly-specific power $P^{(SP)}$ is equal to the value of input variable `power`, read in the power-history block (see Sect. 5.4.4.4). The assembly-specific power has units of megawatts per MTU (MW/MTU). Therefore, the total power produced by the fuel assembly is:

$$P_{\text{tot}} = P_A^{(\text{SP})} \cdot M_{\text{mtu}} \tag{5.4.3}$$

where P_{tot} is the assembly total power, and $P_A^{(SP)}$ is the specific power for the assembly, read from input.

The absolute power (MW) in fuel pin "XY" is:

$$P_P = P_{\text{tot}} \cdot r_{xy} = P_A^{(\text{SP})} \cdot M_{\text{mtu}} \cdot r_{xy} \tag{5.4.4}$$

and the power produced in axial zone Z of this fuel pin XY is:

$$P_{XY,Z} = P_{\text{tot}} \cdot r_{xy} \cdot a_Z = P_A^{(\text{SP})} \cdot M_{\text{mtu}} \cdot r_{xy} \cdot a_Z \tag{5.4.5}$$

The absolute power produced in a single axial zone Z for all pins is:

$$P_Z = \sum_{XY=1}^{N_P} P_{XY,Z} = P_{\text{tot}} \times a_Z = P_A^{(\text{SP})} \times M_{\text{mtu}} \times a_Z \tag{5.4.6}$$

The ORIGEN depletion calculations are performed with the absolute powers defined in Eq. (5.4.4) and Eq. (5.4.6) for each depletion region in the 2D/3D pin-wise or 0D/1D axial depletion models, respectively. However, cross sections in the ORIGEN libraries are parameterized as a function of burnup, which depends on the specific power rather than absolute power for a given depletion region. The specific power (MW/MTU) in axial zone Z of pin XY is equal to:

$$P_{XY,Z}^{(SP)} = \frac{P_{XY,Z}}{M_{XY,Z}} \tag{5.4.7}$$

Substituting Eq. (5.4.1) and Eq. (5.4.5) into Eq. (5.4.7) gives:

$$P_{XY,Z}^{(SP)} = \frac{P_A^{(SP)} \cdot r_{\text{xy}} \cdot a_Z \cdot N_P}{f_Z} \tag{5.4.8}$$

In a similar manner, it can be shown that the specific power for all fuel pins in axial plane Z is:

$$P_Z^{(SP)} = \frac{P_A^{(SP)} \cdot a_Z}{f_Z} \tag{5.4.9}$$

ORIGAMI permits two modes for user-specified power distributions along the axial and radial meshes: *absolute* fractions (i.e., where powers along the axial mesh points are expressed as fractions of the total assembly power in MW) and *relative* normalization (i.e., in which *specific powers*— in MW/MTU — of axial zones are expressed as a relative modifiers of the assembly specific powers input in the power history block). Relative power shape modifiers assume that the specific powers expressed in the power history block represent the *average* assembly specific power(s) thus, ORIGAMI will convert these factors into axial & pin power *fractions* — i.e., the factors r_{xy} and a_{z} found in Eq. (5.4.4) and Eq. (5.4.6) used to calculate the absolute pin power and axial zone power, respectively. The conversion from *relative* specific power modifiers to *absolute* power fractions is accomplished through the following normalization procedure Eq. (5.4.10):

$$(a_Z)_i = \frac{(R_Z)_i \cdot M_{\text{MTU}} \cdot \left(\frac{\Delta Z}{Z_{\text{tot}}}\right)_i}{\sum (R_Z)_i \cdot M_{\text{MTU}} \cdot \left(\frac{\Delta Z}{Z_{\text{tot}}}\right)_i} = \frac{(R_Z)_i \cdot \left(\frac{\Delta Z}{Z_{\text{tot}}}\right)_i}{\sum (R_Z)_i \cdot \left(\frac{\Delta Z}{Z_{\text{tot}}}\right)_i} \tag{5.4.10}$$

where $(a_Z)_i$ is the axial power fraction for axial zone i and $(R_Z)_i$ is the relative axial zone specific power modifier for axial zone i. Obviously, for a uniformly-spaced axial mesh, the conversion from relative specific powers (using relative power modifiers) is precisely the same as that for absolute fractional axial zone powers; i.e., the relative power modifiers simply become axial power fractions by virtue of the fact that the term $\left(\frac{\Delta Z}{Z_{\text{tot}}}\right)_i$ becomes a constant, thereby reducing Eq. (5.4.10) back to a direct calculation of the fractional axial power based on a relative power modifier following normalization.

Because it is assumed that the assembly mass is uniformly distributed across the pins, it can similarly be shown that the use of relative power modifiers for the XY pin map $(r_{XY})_i$ will always produce the same result as using pre-normalized absolute fractional powers in the pin map, i.e. Eq. (5.4.11):

$$(r_{XY})_i = \frac{(R_{XY})_i \cdot \frac{M_{\text{MTU}}}{N_P}}{\sum (R_{XY})_i \cdot \frac{M_{\text{MTU}}}{N_P}} = \frac{(R_{XY})_i}{\sum (R_{XY})_i} \tag{5.4.11}$$

This option is provided as the `relnorm` option in the parameters block (discussed further in Sect. 5.4.4.2). The motivation for providing an alternative normalization for axial power shape factors is twofold. First, it is

generally assumed that information on the axial power shape is obtained from axial measurements relative to an assembly-average value (i.e., axial gamma scans to determine the burnup profile based upon the gross gamma intensity or isotopic ratios of burnup indicators such as ^{134}Cs / ^{137}Cs, etc.). Therefore, by using the relative normalization option (i.e., treating axial power shape factors as *relative* modifiers of the assembly specific power), users can directly input shape factors obtained from techniques such as non-destructive analysis (NDA) fuel measurements into ORIGAMI to model assembly isotopic distributions.

The second motivation for the relative normalization option comes from potential problems that can arise if treating axial power shape factors as absolute fractional powers (**`relnorm=no`**) in conjunction with non-uniform axial mesh spacing defined by the user in the **`z`** array (see Sect. 5.4.4.7 for details).

Important: If using the **`relnorm=no`** option, the fractional axial powers **must** be consistent with the axial mesh sizes defined or else **incorrect** zone-specific powers will result from Eq. (5.4.9), therefore leading to incorrect results and likely causing the ARP sequence to fail (and therefore the ORIGAMI calculation to halt) due to calculated burnup values for the depletion zone being out of the library range.

Users are thus **strongly cautioned** when using absolute fractional axial powers (**`relnorm=no`**) to ensure proper consistency between the axial power fractions and the axial mesh sizes.

For this reason, relative power shape factor normalization is **turned on** by default (**`relnorm=yes`**).

5.4.3.5 Computation of neutron and gamma energy spectra

ORIGAMI includes an option to generate multi-group neutron and gamma source spectra due to radioactive decay, for each depletion zone. Multi-group values are calculated by binning the discrete line and continuum spectra produced by radioactive decay and nuclear reactions into arbitrary energy group structures defined by user input. Whenever neutron energy group boundaries are input in array `ngrp`, neutron source spectra due to spontaneous fission, delayed neutron emission, and (α, n) reactions are calculated.

Similarly, gamma source spectra are computed if gamma energy group bounds are input in array `ggrp`. The gamma source includes photons produced by all types of radioactive decays, and also may include bremsstrahlung radiation produced by beta interactions. Input options can specify the type of nuclides included in the source term (i.e., light elements, actinides, fission products, or all nuclides), and the materials used for (α, n) reactions and bremsstrahlung production. If source spectra are calculated, the values are always included in the ORIGEN output ft71 binary file; and optionally the source spectra may also be output in a text file. The source text file only includes the average over all pins for each axial zone, while the ft71 file includes sources for all pins and axial zones.

The source spectra output by ORIGAMI are calculated in ORIGEN using the expression outlined in Eq. (5.4.12):

$$S_{\mathrm{Z.g}}^{(p)} = \sum_{i=1}^{\mathrm{itot}} Y_{i,g}^{(p)} \lambda_i \frac{M_Z^{(i)}}{A^{(i)}} \cdot N_A \tag{5.4.12}$$

where

$S_{\mathrm{Z.g}}^{(p)}$ = source spectrum (p/s) in energy group g for particles of type p and axial zone Z;

$Y_{i,g}^{(p)}$ = number of particles of type p emitted per decay of nuclide i; with energy in group g;

$M_Z^{(i)}$ = mass (g) of nuclide i in axial zone Z, obtained from ORIGEN calculation;

N_A = Avogadro's number (number atoms of nuclide i per mole);

$A^{(i)}$ = mass (g) of 1 mole of nuclide i;

λ_i = decay constant (s^{-1}) for nuclide i,

itot = total number of nuclides in burned fuel.

More details on the ORIGEN calculation of the source spectra can be found in the ORIGEN section (Sect. 5.1.5.2.7) of the SCALE documentation.

5.4.4 ORIGAMI INPUT DESCRIPTION

ORIGAMI uses free-form, keyword-driven input with the SCALE Object Notation (SON) syntax also used for ORIGEN input, and is described in more detail there. The general outline of ORIGAMI input is as follows.

(a) Case Identifier

(b) Options

(c) Fuel Composition

(d) Power-History

(e) Source-Options

(f) Output-Print Options

(g) Input Data

The above input data may be entered in any order. Data blocks and parameters which are not needed, or for which default values are desired, can be omitted. Example 5.4.1 provides a template containing all of the ORIGAMI input data blocks and arrays, with example values assigned. Note that much of the information shown in the template is optional, and typically is not needed for many cases. The following subsections provide a more detailed description of the input.

Example 5.4.1: Template for ORIGAMI input data

5.4.4.1 Case and identifier information

ORIGAMI has three optional identifiers for the case. The `title` is included as a descriptor in the printed output file. The character string `prefix` is added to the front of the output file names described in Sect. 5.4.5 and in Table 5.4.8. Finally, the integer variable `asmid` is an arbitrary assembly identifier used in defining mixture numbers in the SCALE standard composition output file. Eq. (5.4.13) in Sect. 5.4.5.1 describes how the mixture ID is determined.

`title`= <string>

Title (up to 50 characters) describing the case. Enclosed in quotes if using embedded blanks.

(**Default:** none)

prefix= <string>
Prefix (up to 16 characters) to append to output file names.

(**Default:** none)

asmid= <integer>
Integer used to identify mixture ID in generated SCALE standard composition block [see Eq. (5.4.13)].

(**Default:** 1)

Table 5.4.1: Keywords for case identifier :class: longtable :widths: 13 65 12 :name: tab-origami-id-kw

Keyword	Description	Default
title=	up to 50 characters describing the case title, quoted if embedded blanks	blank
prefix=	up to 16 characters (no embedded blanks) appended to output file names	blank
asmid=	integer used to identify mixture ID in generated SCALE standard composition block [see Eq. (5.4.13)]	1

5.4.4.2 Options block

The options block has the following form:

options {... keyword blocks ...}
The options block allows the user to control problem features such as the total mass basis (mtu), non-fuel mass (fracnf), axial power normalization (relnorm), exercise fine-grained control over depletion calculations (solver, interp, option:*nburn*, ndecay), perform restart calculations from a prior ORIGAMI run (restart), specify the number of axial zones (nz), specify optional parameters used for visualization and post-processing (pitch, temper, fdens), and control which outputs to generate (small, mcnp, stdcomp, decayheat).

Each of the allowable parameter keywords is explained below. An example parameter block would be:

```
options{ stdcomp=yes decayheat=yes }
```

mtu= <number>
Metric tons of heavy metal in the assembly.

(**Default:** *1.0*)

fracnf= <number>
Total non-fuel mass in the assembly, given as a fraction of the heavy metal mass defined in mtu.

(**Default:** *none*)

nz= <integer>
Number of axial intervals. If not input, nz is equal to the number of entries in the input axial power array pz.

Required for decay-only restarts.

(**Default:** Determined by code via pz)

nburn= <integer>
Number of substeps used in ORIGEN burn calculations

(**Default:** 10)

ndecay= <integer>
Number of substeps used in ORIGEN decay calculations

(**Default:** 10)

pitch= <real number>
Assembly pitch (cm), if > 0.0. Only used to define XY mesh in viewing results. If this parameter is input, array pxy must also be entered.

(**Default:** 0.0)

temper= <real number>
Temperature (in degrees Kelvin) for mixtures output to the SCALE Standard Composition output (compBlock).

(**Default:** 293.0)

fdens= <real number>
Fuel density in g/cm^3.

(**Default:** 10.4)

offsetz= <integer>
Axial numbering offset; used for sequential ORIGAMI cases to uniquely identify axial zones (i.e., such as when using sequential cases to modify changing axial geometry).

(**Default:** 0)

relnorm= <yes | no>
Normalization of axial power shaping factors (pz) to be used

no → axial power shape factors treated as absolute fractions (does not normalize all axial burnups to 1.0)

yes → axial power shape factors treated as relative modifiers of assembly specific power (i.e., power= entries in the power history block)

(**Default:** *yes*)

mcnp= <yes | no>
Generate MCNP input stubs containing data on material concentrations and/or gamma and neutron emissions for each depletion node in the problem.

(**Default:** *yes*)

stdcomp= <yes | no>
Generate a text-based standard composition file containing burnup-credit nuclide number densities for each axial zone.

(**Default:** *no*)

decayheat= <yes | no>

Produce a decay heat file containing decay powers (in W) for each axial zone.

(**Default:** *no*)

restart= <yes | no>
Perform a restart calculation using initial compositions from a previously-generated ORIGEN ft71 file.

(**Default:** *no*)

solver= <matrex | cram>
Use the standard ("MATREX") solver or the Chebyshev Rational Approximation Method (CRAM) solver.

(**Default:** *matrex*)

small= <yes | no>
keep .out file small by suppressing all spectra and concentrations output except for lumped, assembly-averaged concentrations and spectra

---

Note: Full results are still written to other relevant files

(**Default:** *no*)

interp= <lagrange | spline>
Method for interpolating cross sections in ARP; Lagrangian polynomial (*lagrange* or monotonic cubic spline *spline*)

(**Default:** *lagrange*)

ft71=<last,cycle,all>, **output**=<last,cycle,all>
Controls output of saved / printed output concentrations.

last saves / prints results only for the substeps in last step of the last cycle (**default**)

cycle saves results for substeps in the last irradiation and decay steps in every cycle

all saves results for all substeps of all irradiation and decay steps in every cycle

(**Default:** last)

Table 5.4.2: Keywords in ORIGAMI options

Keyword	Description	Default
mtu=	Metric tons of heavy metal in the assembly	1.0
fracnf=	Total non-fuel mass in assembly, given as fraction of heavy metal mass defined by input *mtu*= . See description of input array nonfuel	none
nz=	Number of axial intervals. If not input, *nz* is equal to the number of entries in the input axial power array pz. Required for decay-only restarts.	Determined by code
nburn=	Number of substeps used in ORIGEN burn calculations	10
ndecay=	Number of substeps used in ORIGEN decay calculations	10
pitch=	Assembly pitch (cm), if > 0.0. Only used to define XY mesh in viewing results. If this parameter is input, array pxy must also be entered.	0.0
temper=	Temperature (Kelvin) assigned to materials in standard composition file	293.0

continues on next page

Table 5.4.2 – continued from previous page

Keyword	Description	Default
offsetz=	Axial numbering offset; used for sequential ORIGAMI cases to uniquely identify axial zones (i.e., such as when using sequential cases to modify changing axial geometry). [integer]	0
relnorm=	Normalization of axial power shaping factors (`pz`) to be used **no:** axial power shape factors treated as absolute fractions (does not normalize all axial burnups to 1.00) **yes:** axial power shape factors treated as **relative** modifiers of assembly specific power (i.e., *power*= entries in the power history block) [yes/no]	Yes
mcnp=	no/yes → do not / do generate an MCNP material and gamma/neutron file	Yes
stdcomp=	no/yes → do not / do generate a standard composition file containing burnup-credit nuclide number densities for each axial zone.	No
decay-heat=	no/yes → do not / do produce a decay heat file containing decay powers (in W) for each axial zone.	No
restart=	no/yes → do not / do restart using initial compositions from a previously-generated ORIGEN ft71 file.	No
solver=	matrex/cram → use the standard ("MATREX") solver or the Chebyshev Rational Approximation Method (CRAM) solver.	Matrex
small=	no/yes → keep .out file small by suppressing all spectra and concentrations output except for lumped, assembly-averaged concentrations and spectra (**Note:** all results are still written to other relevant files).	No
interp=	lagrange/spline → method for interpolating cross sections in ARP	Lagrange
output=	last/cycle/all → time steps for output print edits	Last
ft71=	last/cycle/all → time steps included in output ft71 file	Last

Additional notes on input parameters:

(a) `pitch` is only used for visualization of the results, and may be omitted if this is not of interest;

(b) `mtu` is discussed in Sect. 5.4.4.2

(c) `nz` is not required except decay-only restart cases; it must equal the number of entries in the array `pz`;

(d) `nburn` and `ndecay` are discussed in Sect. 5.4.4.4;

(e) `fracnf` is discussed in Sect. 5.4.4.7, where the input array of non-fuel materials is described;

(f) `relnorm` is discussed in Sect. 5.4.3.4, in the definition of the assembly power distribution;

(g) `stdcomp`, `fdens`, and `temper` are discussed in Sect. 5.4.5;

(h) `offsetz` is an optional feature designed to allow for ORIGAMI cases to be split across multiple inputs to capture axially-dependent features (such as partial-length rods); its use is discussed in further detail in the context of output generation in Sect. 5.4.5;

(i) `decayheat` is discussed in Sect. 5.4.5.3;

(j) `restart` is discussed in Sect. 5.4.3.3.

(k) `output`, `ft71`, are discussed in Sect. 5.4.3.4.

5.4.4.3 Fuel composition block

The purpose of the `fuelcomp` block is to create a set of mixtures (via the **`mix`** blocks inside) to specify the pin-wise distribution of initial isotopics. The example below, defines three mixtures (with IDs 1, 2, and 3); these are referenced in the `compmap` array for this 2x2 array of fuel pins.

`fuelcomp``= { mixture blocks }`
: Specifies fuel mixtures to be used by ORIGAMI in the `compmap` array. *Numbered* `mix` blocks are used by `compmap`, which can be composed of other named mixtures.

`mix``= { SCALE standard composition }`
: Mixture blocks identify specific pin-wise composition to be used by ORIGAMI, using the standard SCALE mixture composition syntax. Mixtures must be given an integer identifier (e.g., `mix(1)`, `mix(2)`, etc.)

`compmap``= [ mixture IDs ]`
: Specifies the distribution of fuel compositions / mixtures for each pin for 2-D and 3-D depletion cases. Mixture ID numbers correspond to those in the `fuelcomp` block.

  Required if `libmap` is explicitly specified beyond one element.

  (**Default:** `[1]`)

Example 5.4.2: Example specification of uranium oxide-based fuel mixtures in ORIGAMI, including 1) Mixed urania-gadolina fuel, 2) 4% enriched UO_2 fuel, and 3) 2% enriched UO:sub:2 fuel.

```
fuelcomp{
   uox(fuel_3pct){ enrich=3.20 dens=10.42 }
   uox(fuel_4pct){ enrich=4.00 dens=10.45 }
   uox(fuel_2pct){ enrich=2.10 dens=10.43 }
   mix(1){ comps[ fuel_3pct=99.0 Gd2O3=1.0 ] }
   mix(2){ comps[ fuel_4pct=100] }
   mix(3){ comps[ fuel_2pct=100] }
}
compmap=[ 1 2
          2 3 ]
```

The *mix* block defines an array of compositions by their weight %. For example, in the case of mix 2 and 3, it is 100% the "fuel_4pct" and "fuel_2pct" compositions defined on the *uox* blocks above. In the case of mix 1, it is 99% by weight *fuel_3pct* and 1% by weight the SCALE StdComp *Gd2O3* (gadolinia). Each mixture number (defined by numbered *mix* objects) is then referenced in the *compmap* array to define an individual pin composition. For UO_x-based fuels, ORIGAMI automatically calculates the pin enrichment for cross-section library interpolation via ARP. (Interpolation for MOX-based fuels is not supported by ORIGAMI at this time.)

The *uox* keyword is an ORIGAM-specific shortcut to allow for easy specification of UO_2-based fuels along with their enrichment; ORIGAMI automatically expands the *uox* keyword into a SCALE StdComp block with a UO_2 base and explicitly-calculated uranium isotopics per Table 5.4.3. For example, the *uox* block "fuel_3pct"expands to the following (Example 5.4.3):

Example 5.4.3: Equivalent explicit expansion of the "fuel_3pct" block

```
stdcomp(fuel_3pct){
   base=uo2
   iso[92234=0.02848 92235=3.2 92236=0.01472 92238=96.7568]
}
```

For *uox*-based entries, the uranium isotopic distribution is calculated from the user-specified enrichment per the formula outlined in Table 5.4.3 [ORIGAMIOWHR94, ORIGAMIRGI10]:

Table 5.4.3: Uraniumm isotope dependent on X wt% ^{235}U

Isotope	**Isotope wt%**
^{234}U	0.0089 X
^{235}U	1.0000 X
^{236}U	0.0046 X
^{238}U	100 - 1.0135 X

Users may also specify materials directly using SCALE mixture processor conventions; for example, the user could simply enter fuel mixture 2 directly as a StdComp as shown in Example 5.4.4 and Example 5.4.5:

Example 5.4.4: Direct specification of materials in ORIGAMI (i.e., within the mixture block)

```
mix(2){
  stdcomp(fuel_4pct){
    base=uo2
    iso[92234=XXX 92235=XXX 92236=XXX 92238=XXX]
   }
}
```

Or similarly, one can refer to a composition by its alias:

Example 5.4.5: Indirect specification of fuel material mixtures (outside the mixture block)

```
stdcomp(fuel_4pct){
   base=uo2
   iso[92234=XXX 92235=XXX 92236=XXX 92238=XXX]
}
mix(2){ comps[ fuel_4pct=100.0 ] }
```

The *uox* keyword is thus useful when a user wishes to quickly specify a UO_2-based fuel; however, in cases where the user wishes to specify the isotopic fractions of each uranium isotope, the use of a StdComp object is recommended.

Caution: The mixture composition system in ORIGAMI is very flexible but the user is cautioned that ORIGAMI does not rigorously check that the specified composition is neutronically similar to that used to generate the ORIGEN library used in the calculation.

For example, use of gadolinia burnable absorbers in the ORIGAMI input will yield incorrect results if the ORIGEN library was generated without gadolinia, due to the extreme thermal flux depression that gadolinia creates. It is therefore **up to the user** to verify that the libraries specified for the depletion zone are matched neutronically to the compositions specified.

5.4.4.4 Power history block

The data contained in the power history block is the same as in the *BURNDATA* block of the TRITON lattice physics depletion sequence in SCALE (see the TRITON chapter, BURNDATA block). The power-history block describes the burnup and decay of the assembly and has the following general form:

Example 5.4.6: Origami power history block

```
hist[
   cycle{ keywords for cycle-1 }
   cycle{ keywords for cycle-2 }
   ... *(repeat for total number of cycles) ...*
]
```

Because the cycles must be processed in order, the array syntax with "[]" is used for the "hist" block. (The block syntax "{}" implies no order for its contents.) The "hist" array consists of one or more "cycle" blocks, each describing the assembly irradiation and/or decay for some period of time. Each cycle is defined by (a) the assembly total specific power; (b) number of exposure days at this power; (c) the number of ORIGEN library burnup interpolations during the exposure period; and (d) number of days of decay following the exposure period.

The keywords defining this information are:

power= <real number>
Assembly specific power (MW/MTU) for the cycle

(**Default:** 0.0)

burn= <real number>
Length of cycle exposure period in days

(**Default:** 0.0)

down= <real number>
Downtime (decay) in days following exposure

(**Default:** 0.0)

nlib= <integer>
Number of ORIGEN library burnup-interpolations during the cycle

(**Default:** 1)

Table 5.4.4: Keywords in the power history (hist) block hist-repeat

Keyword	Description	Default
power=	assembly specific power (MW/MTU) for the cycle	0.0
burn=	length of the cycle exposure period in days	0.0
nlib=	number of ORIGEN library burnup-interpolations during the cycle	1
down=	downtime in days following the exposure	0.0

Example 5.4.7 demonstrates the use of the power-history block for four cycles:

Example 5.4.7: Example of the ORIGAMI "hist" block for irradiation cycle history

```
hist[
  cycle{ power=35.6 burn=400 nlib=6 down=30 }
  cycle{ power=38.2 burn=350 nlib=6 down=30 }
  cycle{ power=30.0 burn=200 nlib=4 down=30 }
  cycle{ down=10000 }
]
```

ORIGAMI discretizes time intervals first by *cycles* (composed of a fixed power over a set burn time interval and / or decay time), where each *cycle* is composed of a number of *substeps*. The power-history block, along with values of `nburn` and `ndecay` from the input parameter block, define various types of nested time intervals (substeps) for the ORIGEN calculations. The entire time period for an ORIGAMI case is first of all divided into the cycles defined within the power-history block. Each cycle is divided into an exposure interval (`burn`) and a decay (`down`) interval. The exposure interval has a constant specific power, but it is further subdivided into a number of equally spaced burnup steps defined by `nlib` in the power-history block. This parameter specifies the number of burnup-dependent ORIGEN libraries to use during the exposure interval. Cross section values for each burnup step are interpolated using the burnup at the midpoint of the step and remain constant throughout the burnup step. The burnup period associated with a single ORIGEN library, or a decay period, is called a time "step." Finally, each burnup step, as well as the entire decay step, is divided into a number of computational "substeps"—the actual time steps used in the ORIGEN solver kernel. The number of substeps in each burnup step is given by the value of `nburn`, while the number of decay substeps is equal to the value `ndecay`. The default number of substeps for both burnup and decay is equal to 10. The substeps for irradiation are equally spaced but for decay follow the rule of threes, i.e. each substep increases in duration by a factor of three over the previous substep.

For the example given above, there are four cycles. The first three cycles include both exposure and decay intervals, while the last cycle is decay only. In the first cycle, the assembly-specific power is 35.6 MW/MTU, which remains constant over the 400-day exposure interval; therefore, the total burnup for the exposure period is 400*35.6 = 14240 MWD/MTU. This exposure period is divided into six burnup steps of 66.67 days, each with a cross-section library based on the midpoint burnup of that step. Thus, ORIGEN libraries are interpolated at 1186.7, 3560.0, 5933.3, 8306.7, 10680.0, and 13053.3 MWD/MTU. Each of the six burnup steps is further subdivided into 10 computational substeps. Likewise, the decay interval of 30 days is divided into 10 computational substeps.

5.4.4.5 Source options block

This block defines options used in computing neutron and gamma sources. The block is only used if the input energy group boundary arrays `ggrp` or `ngrp` is given, which indicates that radiation decay source spectra are to be computed. The general form of this block is:

`srcopt` `{ ... keyword-value pairs ... }`

Where the following blocks are permitted:

- `sublibs`
- `brem_medium`
- `alphan_medium`
- `print`

The following (Example 5.4.8) is an example of the `srcopt` input block:

Example 5.4.8: Template of the ORIGAMI "srcopt" block options

```
srcopt{
   sublib= ...
   brem_medium= ...
   alphan_medium= ...
   print= ...

}
```

If *print=yes*, then text files with axial neutron and gamma sources are created.

sublib= [lt / fp / ac / all]
Gamma sources from light elements / fission products / actinides / all nuclides.

(**Default:** all)

brem_medium= [H2O / UO2 / none]
Medium for Bremsstrahlung production based on water (H2O), uranium oxide (UO2), or no Bremsstrahlung calculation (none)

(**Default:** UO2)

alphan_medium= [UO2 / borosilicate / case]
Target medium used for (α, n) source caclulation; UO_2, borosilicate glass, or case-specific mixture.

(**Default:** case)

print= [yes / no]
Write text-based output file containing source information / only write radiation source terms to binary ft71 file.

(**Default:** no)

Table 5.4.5: Keywords in the ORIGAMI source options (srcopt) block

Keyword	**Description**	**Default**
sublib=	*lt / fp / ac / all* → gamma sources from: light elements / fission products / actinides / all nuclides	all
brem_medium=	*none / H2O / UO2 /* → bremsstrahlung production based on: no bremsstrahlung / water / UO_2	uo2
alphan_medium=	*UO2 / borosilicate/ case* → (alpha,n) source computed for: UO_2/ borosilicate glass / case-specific mixture	case
print=	*yes / no* → write output text file containing sources / only write sources in binary output ft71 file	no

5.4.4.6 Output print-options block

This block defines the desired ORIGEN output response edits to be printed by ORIGAMI.

The following is an example input which edits response values for the mass in grams, activities in Curies, and concentrations in atoms/barn-cm, for all nuclides (isotopes) broken down by actinides or fission products as well as curies by element, totaled over all nuclide sub-libraries (sublibs).

Example 5.4.9: Example of Origami's "print" block for specifying output print options

```
print{
   nuc{ units=[grams curies atoms-per-barn-cm] sublibs=[fp ac] }
   ele{ units=[curies] total=yes }
}
```

nuc= { }, **ele**={ }
: Block to specify print options for output by individual nuclides / elements

units= [moles / gram-atoms / grams / curies / becquerels / watts / g-watts / m3_air / m3_water / weight_ppm / atoms_ppm / atoms-per-barn-cm]

: Output concentrations in units of gram-atoms (moles), grams, curies, becquerels, total thermal power (alpha, beta, and gamma), thermal power from gammas only, radiotoxicity / dilution factors for air and water, mass fraction (in ppm), atom fraction (in ppm), atoms / barn-cm^2, respectively.

: One or more output units may be specified, separated by commas.

: (**Default:** gram-atoms)

sublibs= [le / fp / ac / all]
: Output concentration units for light element sublibrary, fission product sublibrary, actinide sublibrary, or all nuclides.

: (**Default:** all)

total= [no / yes]
: Print out total concentration for nuclides / elements for each selected unit type.

: (**Default:** yes)

Table 5.4.6: Keywords in ORIGAMI "print" block

Keyword	Description	Default
nuc / ele	Specify print options for output by individual nuclides / elements	N/A
units=	*moles / gram-atoms / grams / curies / becquerels / watts / g-watts / m3_air / m3_water / weight_ppm / atoms_ppm / atoms-per-barn-cm* Output concentrations in units of gram-atoms (moles), grams, curies, becquerels, total thermal power (alpha, beta, and gamma), thermal power from gammas only, radiotoxicity / dilution factors for air and water, mass fraction (in ppm), atom fraction (in ppm), atoms / barn-cm, respectively.	all

continues on next page

[2] Requires volume input

Table 5.4.6 – continued from previous page

Keyword	Description	Default
sublibs=	*le / fp / ac / all* → output concentration units for light element / fission product / actinide sub-libraries	all
total=	*yes / no* → print out total concentration for nuclides / elements for each output unit type	yes

5.4.4.7 Input data arrays

For all other input arrays in ORIGAMI, the input values are entered in either of the general forms (with or without =):

```
array[ ... values ... ]

array=[ ... values ... ]
```

The array `libs`, which defines the ORIGEN library files, is the only one that is strictly required for all cases. Cases that simulate 0D or 1D lumped-assembly models typically only require one entry for a single ORIGEN library (assuming uniform axial enrichment), while the simulated 3D depletion model may utilize multiple libraries if specific ORIGEN libraries are pre-generated for different pin locations (e.g., adjacent to a water hole, Gd rods, etc.). If multiple libraries are used, the array `libmap` is required to identify the pin locations associated with the input libraries. The numbering of these libraries in the libmap array corresponds to the ordering of libraries in the `libs` array; i.e., a "1" corresponds to the first library specified, "2" to the second, and so on. A zero-value entry in the array indicates that the location is not to be depleted (i.e., a non-fuel region, such as a water hole or guide tube).

For **single** array values, the array bracket syntax is not required. For example, each of the following is equivalent:

```
compmap=[1]

compmap[1]

compmap=
```

Note that the assignment operator (=) is likewise optional for arrays when using the square-bracket syntax.

Unless the 0D lumped-assembly model (i.e., lumped mass with no axial power variation) is used, at least one of the arrays (`pz`, `pxy`) describing the power variations must also be entered. The 1D axial depletion model requires that the `pz` array be entered, while the pin-wise depletion model additionally requires the array `pxy` . The data in arrays `pxy` and `pz` correspond to the variables r_{xy} and a_z, respectively, described in Sect. 5.4.3.4. The axial and XY power distributions are normalized to unity inside the code, so that only the ratios of the input array values are significant. As discussed in Sect. 5.4.3.4, it is generally recommended to use the final burnup distributions rather than the relative power distributions for the values in the `pxy` and `pz` arrays.

The array `nuccomp` defines the nuclides to be included in the output compBlock file, described in more detail in Sect. 5.4.5. The nuclides in the array are identified by their seven digit IZZZAAA identifier defined as ID = I * 1000000 + Z * 1000 + A, where Z is the atomic number; A is the mass number, and I is the isomeric state (I=0 for ground; I=1 for first metastable; etc.). For example, identifiers for ^{16}O and ^{242m}Am are 8016 and 1095242, respectively. If this array is omitted, the nuclides in Table 5.4.9 are used. This is described in more detail in Sect. 5.4.5.1.

The optional array describing the non-fuel elements in the assembly contains pairs of values (element, mass), where "element" is the chemical symbol for a particular element, and "mass" is the mass of the element in kilograms per MTU. For example, the:

```
nonfuel=[ zr=520.3 sn=8.4 ]
```

indicates that the assembly contains 520.3 kilograms of zirconium and 8.4 kilograms of tin for each metric ton of uranium (MTU) in the assembly. Note that elemental masses are specified — the isotopic masses are computed internally by the code using natural abundances in the data library. It is also possible to normalize the total mass of non-fuel elements to a specified fraction of the MTU mass using the parameter `fracnf` in the parameter block. In this case, only the relative amounts of each non-fuel element are needed for the `nonfuel` array. Non-fuel masses are distributed uniformly among all the fuel depletion regions.

libs= [...]
: List of ORIGEN one or more library file names for fuel in assembly

  Required

libmap= [integer(s)]
: XY map of library identifiers associated with each pin in assembly. Library identifiers correspond to the order of the ORIGEN libraries entered in the `libs` array (i.e., index positions)

  (**Default:** [1])

  See also:

  libs

commap= [integer(s)]
: XY map of mixture identifiers that correspond to the mixture ID in the fuelcomp block.

  (**Default:** [1])

  See also:

  fuelcomp

pxy= [real number(s)]
: XY map of pin power shaping factors / fractional powers. Must be a square array (e.g., 15×15). Defaults to lumped assembly model (no individual pins).

  (**Default:** [1.0])

pz= [real number(s)]
: Axial (Z) power shaping factors / fractional power distribution for the assembly.

  (**Default:** [1.0])

meshz= [real number(s)]
: Axial mesh boundaries (cm) for the axial relative power zones. Only required to define axial mesh for viewing results; but if entered, it must be consistent with axial power shape. The number of entries should be one greater than number of entries in pz array.

  (**Default:** *none*)

  See also:

  pz

modz= [real number(s)]
Axial variation in water density (g/cc) corresponding to the axial power zones.

(**Default:** [0.723])

nonfuel= [key-value pairs]
Non-fuel materials contained in assembly. Values are entered in pairs of element-symbol=mass (kg per mtu of HM). If parameter fracnf is input, mass of non-fuel materials is normalized to this fraction of fuel mtu.

Note:

Oxygen mass in UO_2 should not be entered here (i.e., this is pre-supplied by ORIGAMI).

(**Default:** *None*)

---

ggrp= [real numbers]
Energy boundaries (eV) for defining decay gamma source spectrum, in monotonically increasing order.

(**Default:** *None*)

ngrp= [real numbers]
Energy boundaries (eV) for defining (α, n) and fission neutron source spectrum.

(**Default:** Nuclides in Table 5.4.9)

nuccomp= [IZZZAAA values]
User-specified list of nuclides (in IZZZAAA format) to be included in the compBlock file.

(**Default:** Nuclides specified in Table 5.4.9).

Table 5.4.7: Description of ORIGAMI input arrays

Array Name	**Description**	**Default**
libs *	List of ORIGEN library file names for fuel in assembly. [characters]	None
libmap	XY map of library identifiers associated with each pin in assembly. Library identifiers correspond to the order of the ORIGEN libraries entered in the *libs* block. [integers]	1
compmap	XY map of mixture identifiers that correspond to the mixture ID in the fuelcomp block. [integers]	1
pxy	XY map of pin power shaping factors / fractional powers. Must be a square array (e.g., 15×15). Defaults to lumped assembly model (no individual pins). [real numbers]	1.0
pz	Axial (Z) power shaping factors / fractional power distribution for the assembly. [real numbers]	1.0
meshz	Axial mesh boundaries (cm) for the axial relative power zones. Only required to define axial mesh for viewing results; but if entered, it must be consistent with axial power shape. The number of entries should be one greater than number of entries in pz array. [real numbers]	None

5.4.5 ORIGAMI INPUT/OUTPUT FILES

Table 5.4.8 gives the input and output files for ORIGAMI. ORIGAMI produces printed output results as well as several optional output files described in this section. In order to reduce the potentially voluminous amount of printout, by default ORIGAMI only prints the concentrations in grams for selected actinides in each axial zone of every pin, and only for the last time step (e.g., decay step) of the last cycle in the power-history block. Time-dependent results are given for all substeps in the last step (i.e, there are `nburn` and `ndecay` substeps within a burn step or decay step, respectively) In addition, the blended actinide concentrations over all pins are printed for each axial zone, and for the entire lumped assembly. Additional types of printed output can be specified in the `print` block. The concentrations, as well as optional neutron and gamma source spectra information, for all nuclides, in all pins and axial zones are also stored in the ORIGEN binary output file, often called an "ft71" file. The contents and format of the binary file are described in the ORIGEN documentation of the SCALE manual. The binary file information can be edited by the OPUS module in SCALE. Like the printed output, the ft71 file is written by default only for the last step of the last cycle. However, both the printed output and binary file results can be obtained at additional time steps by specifying the input variables output and ft71, respectively, in the OPTIONS input block. These input parameters can have the keywords:

The output files are written in the user output directory for the calculation (i.e., the same directory where the printed output file is written — the default is the directory from where the case was submitted). File names are prefixed by an extension consisting of the input file base-name appended to an optional character string given by the input keyword `prefix` . For example, if the ORIGAMI input file is named file:*ORIGAMICase.inp*, the base-name is `ORIGAMICase`. Thus, if the keyword `prefix` is not included in the input, the file containing the axial decay heat results is named file:*ORIGAMICase_AxialDecayHeat*. On the other hand, if the input contains the keyword **`prefix=CE16X16`**, the file is named `ORIGAMICase_CE16X16_AxialDecayHeat`.

In order to capture axially dependent features of an assembly (such as partial-length rods), users may elect to construct sequential ORIGAMI cases that modify the XY pin map features (e.g., library and enrichment maps) between cases. In order to allow for these types of "continuation" cases (in which the sequential case

represents an adjacent axial span of the assembly), the `offsetz` feature is provided, which adjusts the axial numbering for ORIGAMI outputs (such as for MCNP materials & spectra cards, axial decay heat, etc.). The `offsetz` parameter offsets the axial numbering for these output files, where the (integer) value provided corresponds to the *last* axial zone number calculated by ORIGAMI (default: 0). For more details on the syntax of the **`options`** block, see Sect. 5.4.3.4.

Table 5.4.8: ORIGAMI input/output files

File Name[3]	**Description**	**Type**	**Format**
`compBlock`	Mixture compositions in standard composition format for input to SCALE codes such as KENO	out	text
`MCNP_matls.inp`	Nuclide identifiers and weight fractions in format for MCNP material cards	out	text
`MCNP_gamma.inp`	Total gamma source intensity in MCNP source format. Only output if gamma energy group boundaries are entered in input array `ggrp`	out	text
`MCNP_neutron.inp`	Total neutron source intensity in MCNP source format. Only output if neutron energy group boundaries are entered in input array `ngrp`	out	text
`AxialGammaSpec`	Gamma spectrum (photons/sec) by axial zone, enabled by "srcopt{ print=yes }".	out	text
`AxialNeutSpec`	Neutron spectrum (neutron/sec) by axial zone, enabled by "srcopt{ print=yes }".	out	text
`AxialDecayHeat`	Decay heat source (watts) by axial zone, enabled by "options{ decayheat=yes }"	out	text
`assm.f71`	Output stacked ORIGEN ft71 files for each axial zone	out	binary
`assembly_restart.f71`	Input stacked ORIGEN ft71 files for each axial zone	in	binary
`.f71`	Output of stacked ORIGEN ft71 files for each pin and axial zone	out	binary
`actinideMesh.3dmap`	Binary MeshView file of selected actinide masses by depletion cell	out	binary
`actinideMesh.ASCII.txt`	Plaintext MeshView file of selected actinide masses by depletion cell	out	text
`fpMesh.3dmap`	Binary MeshView file of selected fission product masses by depletion cell	out	binary
`fpMesh.ASCII.txt`	Plaintext MeshView file of selected fission product masses by depletion cell	out	text
`burnupMesh.3dmap`	Binary MeshView file of depletion node burnups	out	binary

[3] Note that all file names are prefixed by an identifier `${OUTBASENAME}`, where `${OUTBASENAME}` is a prefix constructed from the input file base name followed by the character string given by input keyword `prefix= *.*` For example, the input file named "my.inp" with **`prefix=sample`** would give an output prefix `my_sample`; e.g., `my_sample.f71`, `my_sample.assm.f71`, `my_sample_MCNP_matls.inp`, etc.

5.4.5.1 Generation of SCALE standard composition data file

If input parameter `stdcomp=yes` is specified, ORIGAMI produces a text file containing a SCALE standard composition description for each axial interval. The file is written in the form of a `stdcomp` block that can be directly used as input to any SCALE module that requires a composition block. If a 1D axial depletion model is used for the assembly, the composition for each axial zone is given a unique mixture number defined for an axial node "*Z*" as:

$$\text{(1D axial model)} \quad \text{mix} = 1000 + (asmid - 1) \times N_Z + Z \tag{5.4.13}$$

where N_Z is the number of axial zones and `asmid` is the input identifier. For example, if there are 12 axial zones and the input for `asmid` is 20, then the mixture number associated with axial zone number 1 is mix = 1229, and the mixture for zone 12 is mix= 1240. If an assembly is represented by a 3D multiple-pin model, the mixture number is defined,

$$\text{(3D model)} \quad \text{mix} = 1000 + (asmid - 1) \times N_Z + Z + X \times 100000 + Y \times 10000000 \tag{5.4.13}$$

where X and Y correspond to the row and column numbers of the pin.

The nuclides components of the mixtures may be specified in the input array `nuccomp`, or by default the mixture may consist of the nuclides given in Table 5.4.9, which are the nuclides recommended in [ORIGAMIRGlW12] for burnup credit analysis, plus ^{16}O.

The temperatures of the mixtures are set by the value of parameter `temper`, which defaults to a value of 293 Kelvin. The number densities of the nuclides in the mixtures are calculated using the following expressions:

$$\begin{aligned} N_Z^{(i)} &= \rho \frac{M_Z^{(i)}}{M_Z \cdot 10^6} \cdot \frac{N_A}{A^{(i)}} \cdot 0.8814 \cdot 10^{-24} \\ &= \rho \frac{M_Z^{(i)}}{M_Z \cdot A^{(i)}} \cdot 5.309 \cdot 10^{-7} \end{aligned} \tag{5.4.13}$$

Where:

$N_Z^{(i)}$ = number density of nuclide "i" in zone Z, in units of atoms of "i" per barn-cm of UO_2;

ρ = density of UO_2 (g/cc), defined by the input parameter `fdens` (default is 10.4 g/cc);

$M_Z^{(i)}$ = mass (g) of nuclide i in axial zone Z , obtained from ORIGEN calculation;

$M_Z \cdot 10^6$ = mass (g) of uranium in axial zone Z, where M_Z is given by Eq. (5.4.2);

$A^{(i)}$ = mass (g) of 1 mole of nuclide i;

0.8814 = weight fraction of uranium in UO_2;

10^{-24} = cm^3 per barn-cm.

The definitions of other parameters appearing in this equation are given in Sect. 5.4.3.4. An example of the standard composition file produced by ORIGAMI is given in Sect. 5.4.7, Example 5.4.12 (illustrated in sample problem 2, Example 5.4.11).

Table 5.4.9: Default burnup credit nuclides in Standard Composition output

Nuclide	ZAID	Nuclide type
^{16}O	8016	light element
^{234}U	92234	actinide
^{235}U	92235	actinide
^{236}U	92236	actinide
^{238}U	92238	actinide
^{237}Np	93237	actinide
^{238}Pu	94238	actinide
^{239}Pu	94239	actinide
^{240}Pu	94240	actinide
^{241}Pu	94241	actinide
^{242}Pu	94242	actinide
^{241}Am	95241	actinide
^{243}Am	95243	actinide
^{95}Mo	42095	fission product
^{99}Tc	43099	fission product
^{101}Ru	44101	fission product

^{109}Ag	47109	fission product
^{133}Cs	55133	fission product
^{143}Nd	60143	fission product
^{145}Nd	60145	fission product
^{147}Sm	62147	fission product
^{149}Sm	62149	fission product
^{150}Sm	62150	fission product
^{151}Sm	62151	fission product
^{152}Sm	62152	fission product
^{151}Eu	63151	fission product
^{153}Eu	63153	fission product
^{155}Gd	64155	fission product

5.4.5.2 MCNP data files

If the input parameter `mcnp=yes` is set in the `options` block, the computed weight fractions for the materials in each axial zone also are output in a file in the format of MCNP material cards. These material cards are designed to be coupled to a corresponding MCNP assembly geometry using the same numbering convention for the depletion zones. Sect. 5.4.7 shows an example of the MCNP material information produced by ORIGAMI. The numbering convention of the MCNP materials cards works by combining the axial and pin numbers into a material card, where pins are counted sequentially by row, starting with the bottom-left row of input, counting from left to right across each row to the top-right pin (i.e., the bottom-left pin is pin #1, etc.). The pin numbers reset with each axial zone, starting from the bottom zone, counting up from 1. The naming convention for materials cards is thus the pin number (1-999) followed by the zone number (1-99); for example, pin #15 of axial zone #12 would be **m1512**. Accompanying each material card is a list of ZAID numbers and final concentrations (following depletion/decay) for the cell expressed in weight fractions. The weight fractions are given as negative values in accordance with MCNP convention. The fuel density, which

may be used in the MCNP cell card, is equal to the value of the input parameter `fdens`.

When parameter `mcnp=yes` is set, ORIGAMI also produces output files containing the fuel assembly radiation source magnitude by depletion zone, to support modeling with MCNP. The gamma/neutron source term cards correspond to the total gamma or neutron intensity (particles/s) from each respective depletion region, using the same numbering convention as that for the MCNP material cards. The source magnitude is computed by summing over the MG source spectra defined in Eq. (5.4.12).

$$S_Z^{(p)} = \sum_g S_{Z,g}^{(p)} \tag{5.4.14}$$

Where:

$S_Z^{(p)}$ = total source magnitude (p/s) for particles of type p;

$S_{Z,g}^{(p)}$ = multigroup source magnitude (p/s) for energy group g, and particles of type p

More details on the ORIGEN calculation of the source terms can be found in the ORIGEN section of SCALE documentation.

5.4.5.3 Decay heat calculation

When input parameter `decayheat=yes` is specified in the input, a text file containing the decay heat source by axial zone, summed over all pins, is generated as output. The decay heat in zone Z is given in watts and is computed from the

$$H_Z = \sum_{i=1}^{\text{itot}} Q_i \lambda_i \frac{M_Z^{(i)}}{A^{(i)}} \cdot 1.602 \cdot 10^{-13} \cdot N_A = 9.65 \cdot 10^{10} \sum_{i=1}^{\text{itot}} Q_i \lambda_i \frac{M_Z^{(i)}}{A^{(i)}} \tag{5.4.15}$$

where:

Q_i = decay energy in MeV for nuclide i;

λ_i = decay constant (s^{-1}) for nuclide i;

$M_Z^{(i)}$ = mass (g) of nuclide i in axial zone Z, obtained from ORIGEN calculation;

$A^{(i)}$ = mass (g) of 1 mole of nuclide i;

itot = total number of nuclides in burned fuel,

1.602×10^{-19} = number of joules per MeV.

An example output decay heat file produced by ORIGAMI is shown in Sect. 5.4.7, Example 5.4.13 (from sample problem 2).

5.4.5.4 ORIGEN results files

The ORIGEN computation for each depletion region produces an ORIGEN binary concentrations output file, historically called an "ft71" because it was written on "Fortran tape" number 71. The file named `$`*`OUTBASENAME`*`.f71` contains the concentrations for all depletion regions, stacked within a single binary file, where `${OUTBASENAME}` is the base of the output file name, e.g. the "my" in `my.out`.

The order of stored cases on the f71 file corresponds to the order in which ORGAMI processes individual depletion cases, starting with the bottom-left row in the user-supplied power map (pin #1) and looping left to right, progressively up through the series of rows. This process repeats for each axial zone, starting from the bottom of the assembly and working upward (i.e., starting with pin #1, axial zone #1, looping through each pin on axial zone #1, and then proceeding to pin #1 on axial zone #2, etc.). This convention is the same as that used for TRITON arrays.

In addition, the compositions are blended over all pins for each axial zone to obtain the axially-dependent compositions for the lumped assembly, stored in a file named `$`*`OUTBASENAME`*`.assm.f71`. If saved, this file may be input as a restart file, as discussed in Sect. 5.4.3.3.

5.4.5.5 Plotting features

ORIGAMI creates three separate mesh summaries of material inventories for individual depletion regions, useful for 3D visualization and inspection. These include maps of (1) depletion region burnups, (2) selected actinide concentrations (including isotopes of U, Pu, A m, and Cm), and (3) selected fission products typically used for burnup evaluation, including isotopes of Cs, Y, Ag, Rh, Ru, Eu, Sm, Nd, Gd, and others). Additionally, ORIGAMI outputs a separate mesh tally of individual node burnups. These outputs are described in Table 5.4.8.

Note: The mesh files are only created if the user specifies the (optional) input arguments for assembly pitch (`pitch`) and axial zone locations (`meshz`).

These output mesh-dependent maps can be visualized using the Java-based Mesh File Viewer program included with SCALE. An example MeshView visualization of one of these outputs is shown in Fig. 5.4.2 and Fig. 5.4.3. MeshView is installed in `$`*`SCALE`*`/Meshview`, where `${SCALE}` is the installation directory. A script to run MeshView is located at `$`*`SCALE`*`/cmds/meshview`.

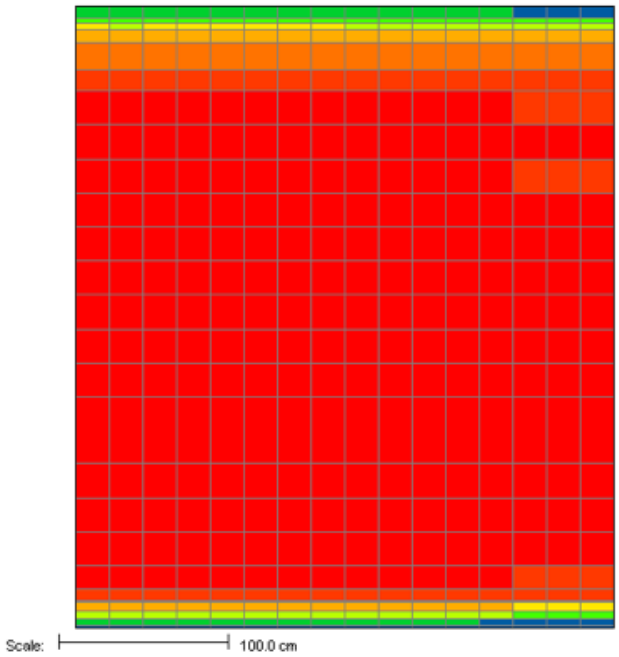

Fig. 5.4.2: MeshView plot of total plutonium content in the 3D depletion regions (XZ plane)

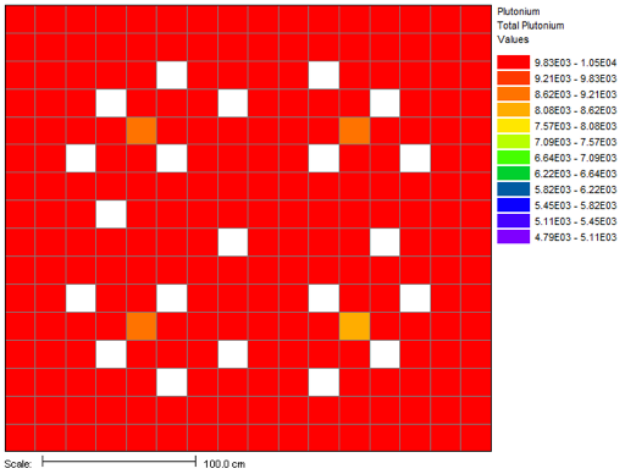

Fig. 5.4.3: MeshView plot of total plutonium content in the 3D depletion regions (XY plane).

5.4.6 PARALLEL EXECUTION ON LINUX CLUSTERS

For large 3D depletion problems it is advantageous to execute the ORIGEN calculations for different depletion regions in parallel. This can be done on Linux clusters using MPI. When parallel execution mode is enabled, ORIGAMI distributes the individual depletion cases across the pin rows, columns, and axial zones across several processors; the depletion calculation is thus split across several processors. ORIGAMI then collects the inventories from each calculation node and concatenates the output.

To execute ORIGAMI in parallel mode, a parallel-enabled MPI build of SCALE must be used and ORIGAMI should be invoked with the percent (%) prefix:

```
=%

<normal ORIGAMI input follows>
```

Additionally, for parallel jobs spanning multiple computational nodes (as opposed to those just using multiple processors on the same node, it is recommended to use the **-T** option to specify a common temporary directory (such as a network-mounted directory accessible to all nodes). This is due to the way ORIGAMI divides the problem space in parallel mode; each computational node stores its respective binary dump file of the individual pin/zone concentrations. Upon completion of execution, the master node must be able to locate these individual problem node-generated binary dump files; thus, by using a common temporary directory, ORIGAMI can correctly re-assembly the individual pinwise dumpfiles into a single consolidated "master" dump file.

The following is a typical execution command line to execute ORIGAMI in parallel.

scalerte -N [number of nodes] -M [machine file] -T [tmpdir] [input_file.inp]

For more information on executing SCALE in parallel, see the SCALE Readme file.

5.4.7 SAMPLE PROBLEMS

This section shows sample problems for each of the three types of simulated assembly models: 0D fully lumped, 2D lumped axial depletion, and 3D pinwise depletion, and also demonstrates a restart case.

5.4.7.1 Sample problem 1: fully lumped assembly model

The first example, Example 5.4.10, corresponds to a fully-lumped assembly model in which the materials are depleted with a space-independent (i.e., assembly average) flux distribution. The assembly contains 0.38 MTU, and the fuel is 2.8 wt% enriched. The assembly also includes several non-fuel materials corresponding to cladding and other structural materials. Note that the non-fuel concentrations are specified in kg/MTU, and thus are not the actual total non-fuel masses in the 0.38 MTU assembly. The assembly is depleted for three cycles with specific powers of 40.0, 38.6, and 25.2 MW/MTU, respectively. The ORIGEN library data are interpolated for eight different burnup steps during the irradiation periods of the first two cycles, and for six burnup steps in the last cycle.

Table 5.4.10 gives the calculated actinide concentrations at the end of the third cycle.

Example 5.4.10: Input for ORIGAMI sample problem 1

```
=origami
  title='fully lumped assembly model'
  libs=[ ce14x14 ]
  fuelcomp{
    stdcomp(fuel){
       base=uo2 iso[92234=0.02848 92235=3.2 92236=0.01472 92238=96.7568] }
       mix(1){ comps[fuel=100] }
   }
   options{ mtu=0.38 ft71=all }
   nonfuel=[ cr=3.366 mn=0.1525 fe=6.309 co=0.0302
             ni=2.366 zr=516.3 sn=8.412 gd=2.860 ]
   hist[
      cycle{ power=40 burn=284 nlib=4 down=54 }
      cycle{ power=38.6 burn=300 nlib=4 down=28 }
      cycle{ power=25.2 burn=250 nlib=3 down=30 }
   ]
   print{
```

(continues on next page)

(continued from previous page)

```
    nuc {
        sublibs=[ac fp]
        units=[grams moles]
        total=no }
    }
end
```

Table 5.4.10: Calculated Actinide inventories for sample problem 1

Nuclide *	Mass (g)
^{234}U	6.820E+01
^{235}U	3.621E+03
^{236}U	1.487E+03
^{238}U	3.598E+05

^{244}Cm	5.698E+00
TOTAL	6.820E+01

* Actinides with concentrations less than 0.0001 are not shown.

5.4.7.2 Sample problem 2: lumped axial depletion assembly model

The second example has the same lumped assembly and power history as sample problem 1, except in this case an axial power distribution is provided for eight zones, so that the fuel burnup will vary axially; the ORIGAMI input for this case is provided as Example 5.4.11. Also, the options to generate standard composition and decay output files are requested.

Table 5.4.11 gives the computed actinide concentrations in grams for the first four of the eight axial zones. Since the input axial power distribution is symmetrical about the assembly midplane, the last four zones have identical concentrations as the first four. The last column in the table shows actinide masses for the entire assembly.

Example 5.4.12 is a listing of the contents of the compBlock file, which contains standard composition input for the eight axial zones in the assembly at the end of cycle 3. A complete description of the SCALE standard composition input format is given in the XSPROC chapter The first entry on each line in Example 5.4.12 corresponds to the SCALE nuclide identifier. Only the default burnup credit analysis are included. The second entry is the mixture number associated with a particular axial zone. The mixture number for an axial zone is obtained using Eq. (5.4.13). The third entry is always zero in this file, and the fourth entry corresponds to the number density in atoms per barn-cm. The next entry on the line is the temperature, which has the default value of 293.0 since the input parameter `temper` was not specified. The final entry is an "end" statement. The information in this file can be used as the `read comp` input block for any SCALE module.

Example 5.4.13 shows a listing of the file AxialDecayHeat, which contains the heat source at the end of the third cycle. The entries in the file correspond to the decay power in watts for the eight axial zones, which are computed using Eq. (5.4.15).

Example 5.4.11: Input for ORIGAMI sample problem 2

```
=origami
title= 'lumped axial-deplete assembly model'
libs=[ ce14x14 ]
fuelcomp{
   uox(fuel2){ enrich=3.2 }
   mix(1){ comps[fuel2=100] }
}
options{
   mtu=0.38 stdcomp=yes decayheat=yes
 }
pz=[ 1.0 2.0 3.0 4.0 4.0 3.0 2.0 1.0 ]
nonfuel=[ cr=3.366 mn=0.1525 fe=6.309 co=0.0302
          ni=2.366 zr=516.3 sn=8.412 gd=2.860 ]
hist[
   cycle{ power=40 burn=284 nlib=4 down=54 }
   cycle{ power=38.6 burn=300 nlib=4 down=28 }
   cycle{ power=25.2 burn=250 nlib=3 down=30 }
]
end
```

Table 5.4.11: Calculated actinide inventories by axial zone for sample problem 2

Nuclide	Axial Zone 1 Mass (g)	Axial Zone 2 Mass (g)	Axial Zone 3 Mass (g)	Axial Zone 4 Mass (g)	TOTAL Mass (g)

5.4.7.3 Sample problem 3: restart decay calculation for lumped axial depletion assembly model

The third example shows a restart decay-only calculation, using the ORIGEN ft71 binary file obtained from sample problem 2. This case calculates the composition of the burned fuel produced in sample problem 2 after 100,000 additional days of decay. The input this problem is given in Example 5.4.15. Because the input parameter **`restart=yes`** is specified, the initial composition of the assembly is obtained from a file named `assembly_restart.f71`. The shell input that precedes the ORIGAMI input in Example 5.4.15 copies the output ft71 file produced in sample problem 2, which was named `assembly_dump.f71`, into a file named `assembly_restart.f71` in the temporary directory for SCALE calculations. The restart file contains the complete inventory of nuclide compositions for eight axial zones. Because this restart case is decay only (i.e., `power` value is not given in the power-history block), it is necessary to provide the input parameter **`nz=8`** because this value is used to determine how many axial zones were used in the previous burnup calculations.

Table 5.4.12 shows the actinide composition of the first four axial of the (symmetrical) eight zones after 100,000 days of decay. The initial masses of these nuclides before decay are the values given in numref:*ex-origami-prob2-stdcmp*. The last column in Table 5.4.12 shows actinide masses for the entire assembly after the decay period.

5.4.7.4 Sample problem 4: Simplified 3D multi-pin model

The fourth example is a simulation of a simplified 3D depletion model. The ORIGAMI 3D model normally includes all fuel pins within the assembly, such as a 14×14 array. However to keep this example case simple and the execution time low, only a 2×2 array of four individual pins is considered for illustrative purposes. An axial fractional power distribution is also specified for two axial zones. Therefore the total number of depletion regions will be eight – two axial for each of the four pins. Two different ORIGEN libraries are used to obtain cross sections for the four pins. This is done whenever fuel pins in different locations in the assembly have significantly different neutron spectra, such as if some pins are adjacent to a control rod. In this sample problem, ORIGEN libraries for two different types of assembly designs CE (Combustion Engineering) 14×14 and 16×16 assembly designs, respectively are used to demonstrate the use of pin-dependent libraries, although in reality the ORIGEN libraries normally would be pre-generated for different pin locations within a single type of assembly configuration. The values specified in `libmap` indicate which library is to be used for each pin location. Example 5.4.15 shows the input for this sample problem.

Example 5.4.15: Input for ORIGAMI Sample Problem 4: a simplified multi-pin, multi-axial model

```
=origami

Table 5.4.13 shows selected actinide compositions for the first row of two pins, that is, locations (1,1) and (1,2), for each of the two axial zones. The blended compositions over all fuel pins, for the two axial zones,

are given in Table 5.4.14. The output decay heat file for the assembly is shown in Table 5.4.15, as a function of axial zone, summed over all pins. Note that this file has the prefix "sample4_" appended to the standard file name, since *prefix=sample4* is specified in the input.

5.4.7.5 Sample problem 5: PWR 3D assembly model

This sample problem shows the input for a simulated full 3D pressurized water reactor (PWR) assembly-depletion model, which corresponds to a 16×16 lattice with 26 axial zones. Example 5.4.16 shows the ORIGAMI input for this case. The arrays `pxy` and `pz` define the 3D XY-Z fractional power distribution. Four different pre-processed ORIGEN libraries are used to describe the pin-averaged ORIGEN cross-sections for the assembly. The array `libmap` assigns these libraries to the appropriate pin locations. It can be seen that the `libmap` array contains values of zero at 21 locations. These correspond to non-depleting (i.e., zero power) locations. The input includes the information (parameter `pitch`, and array z=) necessary to generate 3D mesh summary maps for subsequent visualization. In this case, the axial mesh is not uniform. Since a total of 6110 ORIGEN cases are executed for the depletable pins, this ORIGAMI calculation was performed in parallel using MPI. Figure 5.4.3 shows a plot of the axial burnup distribution, summed over all pins.

6. SENSITIVITY AND UNCERTAINTY ANALYSIS

Introduction by B. T. Rearden and J. D. McDonnell

SCALE provides a suite of computational tools for sensitivity and uncertainty analysis to (1) identify important processes in safety analysis and design, (2) provide a quantifiable basis for neutronics validation for criticality safety and reactor physics analysis based on similarity assessment, and (3) quantify the effects of uncertainties in nuclear data and physical parameters for safety analysis [SU-RWJ+11, SU-WIJ+13].

Sensitivity Analysis and Uncertainty Quantification

Sensitivity analysis provides a unique insight into system performance in that the predicted response of the system to a change in some input process is quantified. Important processes can be identified as those that cause the largest changes in the response per unit change in the input. In neutron transport numerical simulations, calculating important responses such as k_{eff}, reaction rates, and reactivity coefficients requires many input parameters, including material compositions, system geometry, temperatures, and neutron cross section data. Because of the complexity of nuclear data and its evaluation process, the response of neutron transport models to the cross section data can provide valuable information to analysts. The SCALE sensitivity and uncertainty (S/U) analysis sequences-known as the Tools for Sensitivity and Uncertainty Analysis Methodology Implementation (TSUNAMI)-quantify the predicted change in k_{eff}, reaction rates, or reactivity differences due to changes in the energy-dependent, nuclide-reaction–specific cross section data, whether continuous-energy or multigroup.

Uncertainty quantification is useful for identifying potential sources of computational biases and highlighting parameters important to code validation. When applying uncertainties in the neutron cross section data, the sensitivity of the system to the cross section data can be applied to propagate the uncertainties in the cross section data to an uncertainty in the system response. Additionally, SCALE provides the ability to stochastically sample uncertainties in nuclear data or any other model input parameter (e.g., dimensions, densities, temperatures) and propagate these input uncertainties to uncertainties not only as traditional TSUNAMI responses of k_{eff}, reaction rates, and reactivity, but also in any general output quantity such as burnup isotopics, dose rates, etc. Additionally, where the same input quantities are used in multiple models, the sampling techniques can be applied to quantify the correlation in uncertainties of multiple systems due to the use of the same uncertain parameters across these systems.

Validation of Codes and Data

Modern neutron transport codes such as the KENO Monte Carlo codes in the SCALE code system can predict k_{eff} with a high degree of precision. Still, computational biases of one percent or more are often found when using these codes to model critical benchmark experiments. The primary source of this computational bias is believed to be errors in the cross section data as bounded by their uncertainties. These errors can be tabulated in cross section covariance data. To predict or bound the computational bias for a design system of interest, the *American National Standards for Nuclear Criticality Safety in Operations with Fissionable Material Outside Reactors* (ANSI/ANS-8.1-1998) [SU-AmericanNSSCWGA8198] and the *American National Standard for Validation of Neutron Transport Methods for Nuclear Criticality Safety Calculations* (ANSI/ANS-8.24-2007) [SU-AmericanNSSCWGA82407] allow calculations to be used to determine subcritical limits for the design of fissionable material systems. The standards require validation of the analytical methods and data used in nuclear criticality safety calculations to quantify any computational bias and the uncertainty in the bias. The validation procedure must be conducted through comparison of computed results with experimental data, and the design system for which the subcritical limit is established must fall within the area of applicability of the experiments chosen for validation. The ANS-8.1 standard defines the area(s) of applicability as

"the limiting ranges of material compositions, geometric arrangements, neutron-energy spectra, and other relevant parameters (e.g., heterogeneity, leakage, interaction, absorption, etc.) within which the bias of a computational method is established."

TSUNAMI Techniques for Code Validation

The TSUNAMI software provides a unique means to determine the similarity of nuclear criticality experiments to safety applications [SU-BRH+04]. The TSUNAMI validation techniques are based on the assumption that computational biases are primarily caused by errors in cross section data, the potential for which are quantified in cross section covariance data. TSUNAMI provides two methods to establish the computational bias introduced through cross section data.

For the first method, instead of using one or more average physical parameters to characterize a system, TSUNAMI determines the uncertainties in the computed response that are shared between two systems due to cross section uncertainties. These shared uncertainties directly relate to the bias shared by the two systems. To accomplish this, the sensitivity to each group-wise nuclide-reaction–specific cross section is computed for all systems considered in the analysis. Correlation coefficients are developed by propagating the uncertainties in neutron cross section data to uncertainties in the computed response for experiments and safety applications through sensitivity coefficients. The bias in the experiments, as a function of correlated uncertainty with the intended application, is extrapolated to predict the bias and bias uncertainty in the target application. This correlation coefficient extrapolation method is useful where many experiments with uncertainties that are highly correlated to the target application are available.

For the second method, data adjustment or data assimilation techniques are applied to predict computational biases, and more general responses, including but not limited to k_{eff}, can be addressed simultaneously [SU-BRH+04]. This technique uses S/U data to identify a single set of adjustments to nuclear data and experimental responses, taking into account their correlated uncertainties, which would improve the agreement between the response values from the experimental results and computational simulations. The same data adjustments are then used to predict an unbiased response (e.g., k_{eff}) value for the application and an uncertainty on the adjusted response value. The difference between the originally calculated response value and the new post-adjustment response value represents the bias in the original calculation, and the uncertainty in the adjusted value represents the uncertainty in this bias. If experiments are available to validate the use of a particular nuclide in the application, the uncertainty of the bias for this nuclide may be reduced. If similar experiments are not available, the uncertainty in the bias for the given nuclide is high. Thus, with a complete set of experiments to validate important components in the application, a precise bias with a small uncertainty can be predicted. Where the experimental coverage is lacking, a bias can be predicted with an appropriately large uncertainty. The data assimilation method presents many advantages over other techniques in that biases can be projected from an agglomeration of benchmark experiments, each of which may represent only a small component of the bias of the target application. Also, contributors to the computational bias can be analyzed on an energy-dependent nuclide-reaction–specific basis. However, this technique requires additional data that are not generally available and must be quantified or approximated by the analyst, specifically the correlation coefficients that quantify the relative independence of experimental measurements that use the same equipment, whether nuclear fuel, reactivity devices, or measurement tools.

Sensitivity and Uncertainty Analysis Tools in SCALE

The **TSUNAMI-1D** and **TSUNAMI-3D** analysis sequences compute the sensitivity of k_{eff} and reaction rates to energy-dependent cross section data for each reaction of each nuclide in a system model. The one-dimensional (1D) transport calculations are performed with XSDRNPM, two-dimensional (2D) transport calculations are preformed using NEWT, and the three-dimensional (3D) calculations are performed with KENO V.a or KENO-VI. The Monte Carlo capabilities of TSUNAMI-3D provide for S/U analysis from either

continuous-energy or multigroup neutron transport, where the deterministic capabilities of TSUNAMI-1D only operate in multigroup mode. SAMS (Sensitivity Analysis Module for SCALE) is applied within each analysis sequence to provide the requested S/U data. Whether performing a continuous-energy or multigroup calculation, energy-dependent sensitivity data are stored in multigroup-binned form in a sensitivity data file (SDF) for subsequent analysis. Additionally, these sequences use the energy-dependent cross section-covariance data to compute the uncertainty in the response value due to the cross section-covariance data.

TSAR (Tool for Sensitivity Analysis of Reactivity Responses) computes the sensitivity of the reactivity change between two k_{eff} calculations, using SDFs from TSUNAMI-1D, and/or TSUNAMI-3D. TSAR also computes the uncertainty in the reactivity difference due to the cross section covariance data.

TSUNAMI-IP (TSUNAMI Indices and Parameters) uses the SDFs generated from TSUNAMI-1D, TSUNAMI-3D, or TSAR for a series of systems to compute correlation coefficients that determine the amount of shared uncertainty between each target application and each benchmark experiment considered in the analysis. TSUNAMI-IP offers a wide range of options for more detailed assessment of system-to-system similarity. Additionally, TSUNAMI-IP can generate input for the **USLSTATS** (Upper Subcritical Limit Statistical Software) [SU-LBDH97] trending analysis and compute a penalty, or additional margin, needed for the gap analysis. USLSTATS is distributed as a graphical user interface with SCALE, but its use is documented in the TSUNAMI Primer [SU-RMB+09], not in this documentation chapter.

TSURFER (Tool for S/U Analysis of Response Functions Using Experimental Results) is a bias and bias uncertainty prediction tool that implements the generalized linear least-squares (GLLS) approach to data assimilation and cross section data adjustment that also uses the SDFs generated from TSUNAMI-1D, TSUNAMI-3D, or TSAR. The data adjustments produced by TSURFER are not used to produce adjusted cross section data libraries for subsequent use; rather, they are used only to predict biases in application systems.

The TSUNAMI Primer also documents the use of the graphical user interfaces for TSUNAMI, specifically ExSITE (Extensible SCALE Intelligent Text Editor) that facilitates analysis with TSUNAMI-IP, TSURFER, TSAR, and USLSTATS as well as VIBE (Validation, Interpretation and Bias Estimation) for examining SDF files, creating sets of benchmark experiments for subsequent analysis, and gathering additional information about each benchmark experiment.

Sampler is a "super-sequence" that performs general uncertainty analysis by stochastically sampling uncertain parameters that can be applied to any type of SCALE calculation, propagating uncertainties throughout a computational sequence. Sampler treats uncertainties from two sources: (1) nuclear data and (2) input parameters. Sampler generates the uncertainty in any result generated by any computational sequence through stochastic means by repeating numerous passes through the computational sequence, each with a randomly perturbed sample of the requested uncertain quantities. The mean value and uncertainty in each parameter is reported, along with the correlation in uncertain parameters where multiple systems are simultaneously sampled with correlated uncertainties.

Used in conjunction with nuclear data covariances available in SCALE, Sampler is a general technique to obtain uncertainties for many types of applications. SCALE includes covariances for multigroup neutron cross section data, as well as for fission product yields, and radioactive decay data, which allow uncertainty calculations to be performed for most MG computational sequences in SCALE. At the present time, nuclear data sampling cannot be applied to SCALE CE Monte Carlo calculations, although the fundamental approach is still valid.

Used in conjunction with uncertainties in input data, Sampler can determine the uncertainties and correlations in computed results due to uncertainties in dimensions, densities, distributions of material compositions, temperatures, or any quantities that are defined in the user input for any SCALE computational sequence.

This methodology was developed to produce uncertainties and correlations in criticality safety benchmark experiments, [SU-MR15] but it has a wide range of applications in numerous scenarios in nuclear safety analysis and design. The input sampling capabilities of Sampler also include a parametric capability to determine the response of a system to a systematic variation of an input parameter.

6.1 TSUNAMI-1D: CONTROL MODULE FOR ONE-DIMENSIONAL CROSS-SECTION SENSITIVITY AND UNCERTAINTY

B. T. Rearden, M. A. Jessee, L. M. Petrie, and M. L. Williams

6.1.1 ABSTRACT

TSUNAMI-1D (**T**ools for **S**ensitivity and **Un**certainty **A**nalysis **M**ethodology **I**mplementation in **One** **D**imension) is a SCALE control module that facilitates the application of sensitivity and uncertainty analysis theory to nuclear systems analyses. TSUNAMI-1D was originally developed to provide sensitivity and uncertainty analysis of k_{eff} for criticality safety applications, and subsequent updates provide for analysis of system responses other than k_{eff}, using generalized perturbation theory. TSUNAMI-1D provides for automated processing of material input, processing of cross-section data, calculation of neutron transport solutions, calculation of sensitivity coefficients, and the calculation of uncertainties in system responses due to cross-section-covariance data. The XSDRNPM module is used for the transport solver. XSDRNPM uses the method of discrete ordinates to calculate k_{eff} for applications that are appropriate for 1D modeling. The SAMS module is used to determine the sensitivities of the calculated value of k_{eff} and other system responses to the nuclear data used in the calculation as a function of nuclide, reaction type, and energy. The uncertainties in the calculated value of k_{eff} and other system responses, resulting from uncertainties in the basic nuclear data used in the calculation, are estimated using energy-dependent cross-section-covariance matrices. The implicit effects of the resonance self-shielding calculations are predicted using BONAMIST.

6.1.2 ACKNOWLEDGMENTS

The authors acknowledge Bryan Broadhead of Oak Ridge National Laboratory, and R. L. Childs, formerly of the Oak Ridge National Laboratory, for their assistance with this work. The support and encouragement of Calvin Hopper, Cecil Parks, and Don Mueller of Oak Ridge National Laboratory is also appreciated. Additionally, the authors wish to acknowledge Debbie Weaver and Sheila Walker for their assistance in preparing this document.

6.1.3 INTRODUCTION

TSUNAMI-1D (**T**ools for **S**ensitivity and **Un**certainty **A**nalysis **M**ethodology **I**mplementation in **One** **D**imension) is a SCALE control module that facilitates the application of sensitivity and uncertainty theory to nuclear system analyses. The data computed with TSUNAMI-1D are the sensitivity of a system response, such as k_{eff}, to each constituent cross-section data component used in the calculation. The sensitivity data are coupled with cross-section uncertainty data, in the form of multigroup covariance matrices, to produce an uncertainty in the system response due to uncertainties in the underlying nuclear data. The group-wise sensitivity data computed with TSUNAMI-1D are stored in a sensitivity data file (.sdf file) that is suitable for use in assessing system similarity for code validation purposes using TSUNAMI-IP, (see TSUNAMI-IP chapter), and for advanced bias assessment using TSURFER, see the TSURFER chapter.

This manual is intended to provide the user with a detailed reference on code input options and provide some examples of the application of TSUNAMI-1D to generate sensitivity and uncertainty data. A detailed description of code input is provided in Sect. 6.1.4, three sample problems are given in Sect. 6.1.5 the techniques used in each computational sequence are described in Sect. 6.1.3.1, and additional information is

provided in the appendices. A new user may wish to begin by reviewing the sample problems, and then refer to the input details in Sect. 6.1.4 to customize an input for his specific needs.

TSUNAMI-1D provides automated, problem-dependent cross sections using the same methods and input as the **C**riticality **S**afety **A**nalysis **S**equences (CSAS). The BONAMIST code computes the sensitivity of resonance self-shielded cross to the input data, the so-called "implicit sensitivities."

After the cross sections are processed, the TSUNAMI-1D sequence performs two XSDRNPM criticality calculations, one forward and one adjoint. Finally, the sequence calls the SAMS module to calculate the sensitivity coefficients that indicate the sensitivity of the calculated values to changes in the cross sections and the uncertainty in the calculated value due to uncertainties in the basic nuclear data. SAMS prints energy-integrated sensitivity coefficients and their statistical uncertainties to the SCALE output file and generates a separate data file containing the energy-dependent sensitivity coefficients.

In addition to the sensitivity and uncertainty analysis sequence, the TSUNAMI-1DC sequence can be used to verify the accuracy of the TSUNAMI-1D calculations with direct perturbation criticality calculations. The verification of computed sensitivity coefficients is imported for systems where the cell-weighted material is not the only material used in the model. By default, TSUNAMI-1DC performs the same functions as the TSUNAMI-1D sequence with PARM=CENTRM, except that it does not perform the adjoint XSDRNPM calculation and does not call the SAMS module.

6.1.3.1 TSUNAMI-1D Techniques

TSUNAMI-1D is a SCALE control module. As such, its primary function is to control a sequence of calculations that are performed by other codes. The input for each of the TSUNAMI-1D sequences is very similar to that used for CSAS1, with the addition of the system model description and optional sensitivity calculation data. TSUNAMI-1D uses the same material and cell data input as all other SCALE sequences. The control sequences available in TSUNAMI-1D are summarized in Table 6.1.1, where the functional modules executed by each control sequence are also shown. A general flow diagram of TSUNAMI-1D is shown in Fig. 6.1.1.

Table 6.1.1: TSUNAMI-1D control sequences.

Control module	**Functional modules executed by the control module**				
TSUNAMI-1D	XSProc	XSDRNPM forward	XSDRNPM adjoint*	BONAMIST	SAMS*
TSUNAMI-1DC	XSProc	XSDRNPM forward			
* The XSDRNPM adjoint calculation and SAMS calculation on are repeated for each system response defined by the user.					

TSUNAMI-1D and many other SCALE sequences apply a standardized procedure to provide appropriate cross sections for the calculation. This procedure is carried out by routines of the XSProc that generate number densities and related information, prepare geometry data for resonance self-shielding and flux-weighting cell calculations, and create data input files for the cross-section processing codes.

By default, the TSUNAMI-1D sequence performs cross-section processing with XSProc, exercising all available options there, performs the forward and adjoint XSDRNPM calculations, calls BONAMIST to produce implicit sensitivity coefficients, then calls SAMS to produce sensitivity and uncertainty output and *sdf* files. Optional sequence level parameters can be used to change methods applied in resonance self-shielding

and exclude the implicit sensitivity calculation, which detailed later in this document. If additional system responses are requested in the input, TSUNAMI-1D executes additional generalized adjoint XSDRNPM and SAMS calculations for each system response.

The input requirements for the model description are very similar to those used for multiregion cell descriptions in the cell data section of input. The definition of system responses other than k_{eff} requires both the `DEFINITIONS` and `SYSTEMRESPONSE` block of input data. These blocks of data are described in Sect. 6.1.4.4. TSUNAMI-1D also reads and prepares inputs for the SAMS calculation. The additional input blocks for the SAMS module are optional. The input format of the SAMS blocks of data are described in the SAMS chapter.

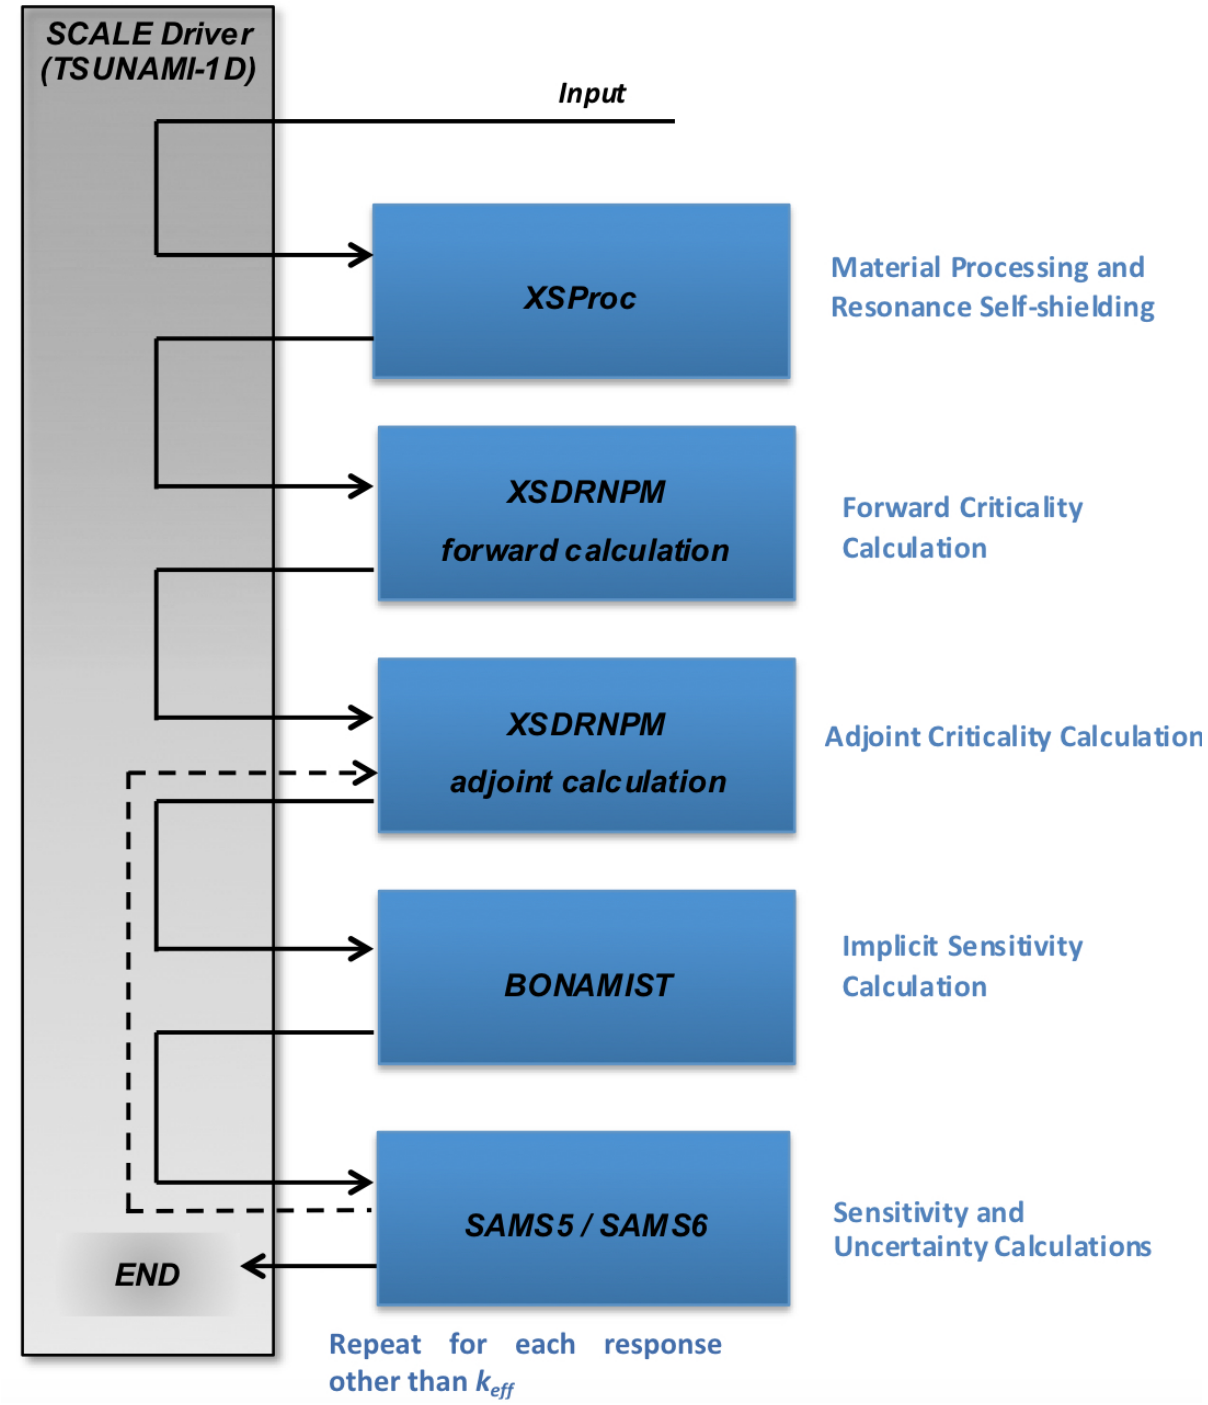

Fig. 6.1.1: General flow diagram of TSUNAMI-1D.

6.1.4 TSUNAMI-1D INPUT DESCRIPTION

The input to TSUNAMI-1D consists of a SCALE Analytical Sequence Specification Record, SCALE XSProc data, model problem data, optional sensitivity and uncertainty calculation data, and optional system response characterization data. The data for each of these segments are entered using the SCALE free-form format, allowing alphanumeric data, floating-point data, and integer data to be entered in an unstructured manner. The input is not case sensitive, so either upper- or lowercase letters may be used. A maximum of 252 columns per line may be used for input. Data can usually start or end in any column with a few exceptions. As an example, the word END beginning in column 1 and followed by two blank spaces will end the problem, any data following will be ignored. Each data entry must be followed by one or more blanks to terminate the data entry. For numeric data, either a comma or a blank can be used to terminate each data entry. Integers may be entered for floating values. For example, 10 will be interpreted as 10.0. Imbedded blanks are not allowed within a data entry unless an E precedes a single blank as in an unsigned exponent in a floating-point number. For example, 1.0E 4 would be correctly interpreted as 1.0×10^4. A comment is initiated with a single quote, `''`, and continues until the end of the input line.

6.1.4.1 Analytical sequence specification record

The analytical sequence specification begins in column 1 of the first line of the input file and must contain one of the following:

=TSUNAMI-1D
: This sequence is used for sensitivity and uncertainty calculations.

=TSUNAMI-1DC
: This sequence allows more flexibility than CSAS1 and is used for criticality calculations where the criticality problem description contains more detail than that specified in a single unit cell description.

Optional keyword input may be entered, starting after column 10 of the analytical sequence specification record. These keywords are

PARM=CHECK
: This option allows the input data to be read and checked without executing any functional modules.

PARM=CHK
: Alias for `PARM=CHECK`.

PARM=SIZE=n
: The amount of memory requested in four-byte words may be set with this entry. The default value for n is 20000000. This value only affects calculations in BONAMIST, where this value of the `SIZE` parameter is used for allocation of storage for the derivatives. Please see the documentation on BONAMIST in the Sensitivity Utility Modules chapter for more details. All other codes use dynamic memory allocation and this value has no effect.

PARM=BONAMIST
: This is the default configuration for MG TSUNAMI-1D calculations. XSProc with BONAMI and CENTRM is used for cross-section processing, and implicit sensitivities are produced with BONAMIST.

PARM=CENTRM
: XSProc with BONAMI and CENTRM is used for cross-section processing, but BONAMIST is not run. **TSUNAMI-1D sequence with `PARM=CENTRM` does not produce the implicit portions of the sensitivity coefficients, and should be used with caution.**

PARM=BONAMI

XSProc with BONAMI is used for cross-section processing, but BONAMIST is not run. **TSUNAMI-1D sequence with PARM=BONAMI does not produce the implicit portions of the sensitivity coefficients, and should be used with caution.**

PARM=2REGION

XSProc with BONAMI and CENTRM are run where Dancoff factors are to compute the escape probabilities for an accelerated, yet more approximate, CENTRM calculation. Implicit sensitivities are computed with BONAMIST.

Multiple parameters can be used simultaneously by enclosing them in parentheses and separating them with commas such as PARM=(SIZE=2000000, CHECK).

Multiple parameters can be used simultaneously by enclosing them in parentheses and separating them with commas such as PARM=(SIZE=2000000, CHECK).

6.1.4.2 XSProc

XSProc reads the standard composition specification data and the unit cell geometry specifications. It then produces the mixing table and unit cell information necessary for processing the cross sections. The XSProc chapter provides a detailed description of the input data for the Material Information Processor.

6.1.4.3 Model problem data

The model problem data are used by the TSUNAMI-1D sequences to prepare input for the XSDRNPM transport calculation. This input section consists of two data blocks, one block contains a geometry description and one contains optional parameters.

Geometry data

The TSUNAMI-1D geometry data block begins with the keywords `READ GEOM` and ends with the keywords `END GEOM`. This data block is always required. The following data is contained within this data block:

1. A line containing the geometry and boundary conditions for the XSDRNPM criticality case. The first entry on this line describes the geometry and must be SLAB, CYLINDRICAL, or SPHERICAL. The second entry is optional and describes the right-boundary condition. The default value for the right-boundary condition is VACUUM. The third entry on this line is optional and describes the left-boundary condition. The default value for the left boundary condition is REFLECTED. The last entry on this line is END. Valid entries for the boundary conditions are the following:

   VACUUM – No return at boundary

   REFLECTED – Specular (mirror-like) return at boundary

   PERIODIC – Infinite array of cells in slab geometry

   WHITE – Isotropic return at boundary

2. A line containing the following two entries for each zone of the XSDRNPM case:

   a. mixture number in the zone and

   b. zone outer dimension (in cm).

Mixture numbers and zone dimensions are entered in pairs until the entire geometry is defined. The mixture numbers must be defined in the material input processor input. Mixture 0 is used for voids, and a mixture number defined with CELLMIX= in the MIP section of the input may be used here. It should be noted that, due to a restriction in XSDRNPM, the mixture number identified with CELLMIX= may not appear in the output file, even though it is input in this section. TSUNAMI-1D automatically renumbers the cell mixed mixture to the next available mixture number for use in XSDRNPM. A message is printed in the output identifying this change. TSUNAMI-1D uses the same techniques as CSAS1X to automatically prepare a spatial mesh appropriate for the input materials and dimensions.

Parameter data

An optional data block may be entered to change parameters of the XSDRNPM forward and adjoint calculations. This data block begins with the keywords `READ PARA` or `READ PARM` and must end with either `END PARA` or `END PARM`, corresponding to the read keyword. In this data block, the user may enter optional lines that contain entries for selected XSDRNPM input parameters. A list of the parameters and their default values are found in Table 6.1.2.

Table 6.1.2: Optional parameter input for the criticality problem data.

Name	Default	Meaning
ISN=	16	Order of angular quadrature
IIM=	20	Inner-iteration maximum
ICM=	100	Outer-iteration maximum
ID1=	-1	Flux-edit option:
		-1 no flux print
		0 scalar flux print
		1 scalar and angular flux print
SCT=	5	Order of Legendre expansion for cross sections
PRT=	-2	Cross-section print option:
		-2 no cross-section print
		-1 print 1-D cross sections
		0/N print 2-D cross sections through order N
PBT=	0	Balance table print option:
		-1 no balance table print
		0 fine group balance table print
EPS=	1.E-6	Outer-iteration convergence criteria
PTC=	1.E-6	Inner-iteration convergence criteria
DY=	0	First-transverse dimension (cm) for buckling correction (i.e., height of cylinder or slab)
DZ=	0	Second-transverse dimension (cm) for buckling correction (i.e., depth of slab)
SZF=	1.5	Size factor of spatial computational mesh intervals. Increasing this number will cause the forward and adjoint XSDRNPM calculations to be conducted with larger mesh intervals and fewer mesh points. 0.0<SZF<1.5 gives a finer mesh, SZF>1.5 gives a coarser mesh.

6.1.4.4 Sensitivity and uncertainty calculation data

The data blocks for controlling the sensitivity and uncertainty calculation are optional. The optional data blocks include the SAMS block, the HTML block, the COVARIANCE block, the DEFINITIONS block, and the SYSTEMRESPONSES block. These data blocks begin with the keywords READ BLOCKNAME and end with the keywords END BLOCKNAME, where BLOCKNAME is one of SAMS, HTML, COVARIANCE, DEFINITONS, or SYSTEMRESPONSES. These data blocks can be input in any order with the following two exceptions. First, all five data blocks must appear in the input file *after* the composition and cell data blocks of data. Second, if a SAMS block is specified, the HTML and COVARIANCE data blocks must come *after* the SAMS block, if they are to be specified. In addition, both the DEFINITONS and SYSTEMRESPONSES data blocks must be present for additional analysis of system responses other than k_{eff}. If only one or both of the data blocks are omitted, then analysis is only performed for k_{eff}. The following sub-sections describe these blocks of data in detail.

Response definition data

The DEFINITIONS and SYSTEMRESPONSES blocks are used to define system responses for additional sensitivities and uncertainty analysis in SAMS. For criticality calculations, the sensitivities of system responses other than k_{eff} are calculated in TSUNAMI-1D using generalized perturbation theory (GPT). The details of the GPT methodology are provided in *General Perturbation Theory* section of the SAMS chapter. Using GPT, a *system response,* denoted R, is defined as a ratio such as:

$$R = \frac{\sum_g \int d\bar{r} H_{N,g}(\bar{r}) \phi_g(\bar{r})}{\sum_g \int d\bar{r} H_{D,g}(\bar{r}) \phi_g(\bar{r})} \tag{6.1.1}$$

In this equation, $\phi_g(\bar{r})$ is the space-dependent multi-group scalar flux and $H_{N,g}(\bar{r})$,$H_{D,g}(\bar{r})$ are referred to as the space-dependent, multi-group *response functions*. In TSUNAMI-1D, the *response functions* are specified in the DEFINITIONS data block and the *system responses* are defined in the SYSTEMRESPONSES data block. Responses (other k_{eff}) treated in TSUNAMI-1D MUST be ratios.

The DEFINITIONS data block is used by TSUNAMI-1D similarly to that of the MAVRIC and MONACO modules in SCALE. The format of the DEFINITIONS block is as follows:

```
read definitions
  response I1
    (specifications for response I1)
  end response
  response I2
    (specifications for response I2)
  end response
  ...
end definitions
```

The DEFINITIONS block of data begins with READ DEFINITIONS and terminates with END DEFINITIONS. Likewise, each response function definition begins with RESPONSE - followed by a unique, positive integer identifier - and terminates with END RESPONSE. The keyword entries summarized in Table 6.1.3 are allowed for each response specification. Keywords ending with = must be followed by the value to be assigned to the corresponding variable. All keywords are optional and can be entered in any order. However certain keywords are required depending one of the seven basic types of response functions described in the following subsections. The required keywords are summarized for each of the seven basic response function types in Table 6.1.3 at the end of this section.

Table 6.1.3: Response function keywords in DEFINITIONS block.

Keyword	Type	Default value	Description
title=	String	” “	Response function title. The title must begin and end with quotes and have a maximum of 256 characters.
macro	Logical	F	Macroscopic cross-section flag. If specified, macroscopic cross-sections are used to define the response function.
micro	Logical	T	Microscopic cross-section flag. If specified, microscopic cross-sections are used to define the response function.
nuclide= or zaid=	Integer or string	Undefined	Nuclide identifier for which cross-sections are used to define the response function. The nuclide can be specified in integer format (92235) or in character string format (u-235).
reaction= or mt=	Integer or string	Undefined	Reaction identifier for which cross-sections are used to define the response function. The reaction can be specified as an MT number (18) or as a character string (fission). Supported reaction types are listed below.
material= or mixture=	Integer	Undefined	Mixture identifier for which cross-sections are used to define the response function.
multimix ... end or multimat ... end	Integer array	Undefined	Array of mixture identifiers for which cross-sections cross-sections are used to define the response function.
unity	Logical	F	Flux response function flag. If specified, cross-sections are not used to define the response function.
multiplier	Real	1.0	Response function multiplier.
ehigh=	Real	10^{25}	Upper energy (eV) boundary of the response function.
elow=	Real	0.0	Lower energy (eV) boundary of the response function.
ehightransfer=	Real	10^{25}	Upper energy (eV) boundary used for cross-sections with secondary particle distributions (elastic, inelastic, scatter, and n,2n).
elowtransfer=	Real	0.0	Lower energy (eV) boundary used for cross-sections with secondary particle distributions (elastic, inelastic, scatter, and n,2n).

Single-mixture flux response function

A single-mixture flux response is simply the integration of the neutron flux wherever a specified mixture is defined in the problem geometry. Therefore, the response function $H_g(\bar{r})$ for a single mixture-j is defined as:

$$H_g(\bar{r}) = c^* \delta_g * \delta_j(\bar{r}) \tag{6.1.2}$$

where

$$\delta_g = \begin{cases} 1.0 & E_{\text{High}} > E_g^{\text{Lower}}, E_{\text{Low}} < E_g^{Upper} \\ 0 & \text{otherwise} \end{cases}$$

and (6.1.3)

$$\delta_j(\bar{r}) = \begin{cases} 1.0 & \text{mixture jis used at } \bar{r} \\ 0 & \text{otherwise} \end{cases}$$

In this expression, the constant c is the scalar multiplier defined by the `multiplier=` keyword. For example, the "fast" and "thermal" flux responses for mixture 5 would be:

In this example, the energy cutoff between the fast group and the thermal group is defined as 0.625 eV. Response 3 reflects the total energy-integrated flux-scaled by a factor of 2.0-because the default values of `eHigh` and `eLow` are used.

For single-mixture flux responses, keywords `unity` and `mixture` are required; `multiplier`, `eHigh`, and `eLow` are optional; `title`, `nuclide`, `reaction`, `micro`, `macro`, `eHighTransfer`, and `eLowTransfer` are optional but are not used; and `multimix` is not allowed. These keyword dependencies are outlined for each response type in Table 6.1.4.

Multiple-mixture flux response

A multiple-mixture flux response is the integration of the neutron flux wherever a set of mixtures are defined in the problem geometry. Therefore, the response function $H_g(\bar{r})$ for a set of mixtures "S" is defined as:

$$H_g(\bar{r}) = c^* \delta_g * \sum_{j \in S} \delta_j(\bar{r}) \tag{6.1.4}$$

For example, the following definition is for the energy-integrated flux response, and spatially-integrated wherever mixtures 5, 7, and 9 are used:

```
read definitions
  response 1 unity multimix 5 7 9 end end response
end definitions
```

or alternatively,

```
read definitions
  response 1 multimat 5 7 9 end unity end response
end definitions
```

For multiple-mixture flux responses, keywords `unity` and `multimix` are required; `multiplier`, `eHigh`, and `eLow` are optional; `title`, `nuclide`, `reaction`, `micro`, `macro`, `eHighTransfer`, and `eLowTransfer` are optional but are not used; and `mixture` is not allowed.

Single-mixture, single-nuclide, microscopic cross-section response

A single-mixture, single-nuclide, microscopic cross-section response is the integration of the neutron flux multiplied by a microscopic cross-section. The microscopic cross-section used in the integral is defined by a specific mixture, nuclide, and reaction type. Therefore, the response function $H_g(\bar{r})$ is defined as:

$$H_g(\bar{r}) = c^* \delta_g^* \delta_j(\bar{r})^* \sigma_{x,g}^{j,n} \tag{6.1.5}$$

In this expression, $\sigma_{x,g}^{j,n}$ is the microscopic cross-section for mixture-j, nuclide-n, reaction type-x, and energy group-g. For transfer reaction types-scatter, elastic, inelastic, and n,2n-the expression above is slightly modified so the user can define the energy range of the secondary particles, i.e.,

$$H_g(\bar{r}) = c^* \delta_g * \delta_j(\bar{r})^* \sum_{g'} \delta_{g'}^{Transfer} \sigma_{x,g\to g'}^{j,n} \tag{6.1.6}$$

where

$$\delta_g^{\text{Transfer}} = \begin{cases} 1.0 & E_{\text{HighTranser}} > E_g^{\text{Lower}}, E_{\text{LowTransfer}} < E_g^{Upper} \\ 0 & \text{otherwise} \end{cases} \tag{6.1.7}$$

Likewise, the expression for $H_g(\bar{r})$ is also modified for fission distribution responses (chi), which are usually integrated by the energy-integrated neutron production rate rather than the neutron flux:

$$H_g(\bar{r}) = c^* \delta_j(\bar{r})^* \bar{\nu}_{f,g}^{j,n} * \sigma_{f,g}^{j,n} * \sum_{g'} \delta_{g'}^* \chi_{g'}^{j,n} \tag{6.1.8}$$

For examples of this response type, the following `DEFINITION` block has response definitions for

- total nu-fission rate of U-235 in mixture 1,
- "fast" n,gamma capture rate of U-238 in mixture 1 (energy cutoff is 0.625 eV),
- downscatter rate of H-1 in mixture 2, and
- number fission neutrons born from Pu-239 fissions in mixture 1 in the intermediate energy range (E>0.625 eV and E<25 keV)

```
read definitions
  response 1
    reaction=nu-fission mixture=1 nuclide=92235
  end response
  response 2
    reaction=n,gamma mixture=1 nuclide=u-238 eLow=0.625
  end response
  response 3
    mt=0   mixture=2 zaid=1001  eLow=0.625 eHighTransfer=0.635
  end response
  response 4
    mt=chi mixture=1 zaid=pu-239 eHigh=25.0e3 eLow=0.625
  end response
end definitions
```

For single-mixture, single-nuclide microscopic cross-section responses, keywords `mixture`, `nuclide`, and `reaction` are required; `multiplier`, `eHigh`, `eLow`, `eHighTransfer`, `eLowTransfer`, and `micro`, are optional; `title` is optional but not used; and `multimix`, `macro`, and `unity` are not allowed. A list of supported cross-section reaction types is provided at the end of this section in Table 6.1.5.

Single-mixture, single-nuclide, macroscopic cross-section response

A single-mixture, single-nuclide, macroscopic cross-section response is the integration of the neutron flux multiplied by a macroscopic cross-section. The macroscopic cross-section used in the integral is defined by a specific mixture, nuclide, and reaction type. The response function $H_g(\bar{r})$ is defined as:

$$H_g(\bar{r}) = c^* \delta_g * \delta_j(\bar{r})^* \Sigma_{x,g}^{j,n} \tag{6.1.9}$$

In this expression, $\Sigma_{x,g}^{j,n}$ is the macroscopic cross-section ($N^{j,n} * \sigma_{x,g}^{j,n}$) for mixture-$j$, nuclide-$n$, reaction type-$x$, and energy group-$g$. The modifications to this expression for transfer reactions and chi are similar to that of single-mixture, single-nuclide, microscopic cross-section responses. Using the same example as above, the single-mixture, single-nuclide, macroscopic cross-section responses are given as:

```
read definitions
  response 1
    reaction=nu-fission mixture=1 nuclide=92235 macro
  end response
  response 2
    reaction=n,gamma mixture=1 nuclide=u-238 eLow=0.625 macro
  end response
  response 3
    mt=0   mixture=2 zaid=1001  eLow=0.625 eHighTransfer=0.635 macro
  end response
  response 4
    mt=chi mixture=1 zaid=pu-239 eHigh=25.0e3 eLow=0.625 macro
  end response
end definitions
```

For single-mixture, single-nuclide macroscopic cross-section responses, keywords `mixture`, `nuclide`, `macro`, and `reaction` are required; `multiplier`, `eHigh`, `eLow`, `eHighTransfer`, and `eLowTransfer`, are optional; `title` is optional but not used; and `multimix`, `micro`, and `unity` are not allowed.

Single-mixture, multiple-nuclide, macroscopic cross-section response

A single-mixture, multiple-nuclide, macroscopic cross-section response is the integration of the neutron flux multiplied by a macroscopic cross-section. The macroscopic cross-section used in the integral is defined by a specific mixture, and reaction type. The response function $H_g(\bar{r})$ is defined as:

$$H_g(\bar{r}) = c^* \delta_g * \delta_j(\bar{r})^* \Sigma^j_{x,g} \tag{6.1.10}$$

In this expression, $\Sigma^j_{x,g}$ is the mixture macroscopic cross-section defined as $\sum_n N^{j,n} * \sigma^{j,n}_{x,g}$ for mixture-j, reaction type-x, and energy group-g. The modifications to this expression for transfer reactions is similar to that defined in previous subsections. For mixture chi responses, $H_g(\bar{r})$ is rewritten as

$$H_g(\bar{r}) = c^* \delta_j(\bar{r})^* \sum_n \bar{\nu}^{j,n}_{f,g} * \Sigma^{j,n}_{f,g} * \sum_{g'} \delta_{g'} * \chi^{j,n}_{g'} \tag{6.1.11}$$

For examples of this response type, the following `DEFINITIONS` block has response definitions for

- total nu-fission rate in mixture 1,
- "fast" n,gamma capture rate in mixture 1 (energy cutoff is 0.625 eV),
- downscatter rate in mixture 2, and
- number fission neutrons born in mixture 1 in the intermediate energy range (E>0.625 eV and E<25 keV)

```
read definitions
  response 1
    reaction=nu-fission mixture=1 macro
  end response
  response 2
    reaction=n,gamma mixture=1 eLow=0.625 macro
  end response
  response 3
    mt=0   mixture=2 eLow=0.625 eHighTransfer=0.635 macro
  end response
  response 4
    mt=chi mixture=1 eHigh=25.0e3 eLow=0.625 macro
  end response
end definitions
```

For single-mixture, multiple-nuclide macroscopic cross-section responses, keywords `mixture`, `macro`, and `reaction` are required; `multiplier`, `eHigh`, `eLow`, `eHighTransfer`, and `eLowTransfer`, are optional; `title` is optional but not used; and `multimix`, `micro`, `nuclide`, and `unity` are not allowed.

Multiple-mixture, single-nuclide, macroscopic cross-section response

A multiple-mixture, single-nuclide, macroscopic cross-section response is the integration of the neutron flux multiplied by a macroscopic cross-section over a set of mixtures defined in the problem geometry. The macroscopic cross-section used in the integral is defined by a specific mixture, nuclide, and reaction type. The response function $H_g(\bar{r})$ is defined as:

$$H_g(\bar{r}) = c^* \delta_g * \sum_{j \in S} \delta_j(\bar{r})^* \Sigma_{x,g}^{j,n} \tag{6.1.12}$$

In this expression, $\Sigma_{x,g}^{j,n}$ is the macroscopic cross-section ($N^{j,n} * \sigma_{x,g}^{j,n}$) for mixture-$j$, nuclide-$n$, reaction type-$x$, and energy group-$g$. The summation of mixtures in this expression is for a set of user-defined mixtures, denoted S. The modifications to this expression for transfer reactions and chi are applied similarly to previously defined response types above.

For examples of this response type, the following `DEFINITIONS` block has response definitions for

- total nu-fission rate of U-235 in the fuel mixtures (mixtures 1,3,5)
- "fast" n,gamma capture rate of U-238 in the fuel mixtures
- downscatter rate of H-1 in the moderator mixtures (mixtures 2,4)
- number fission neutrons born in the intermediate energy range (E>0.625 eV and E<25 keV) in Pu-239 in the fuel mixtures

```
read definitions
  response 1
    reaction=nu-fission multimix 1 3 5 end macro zaid=92235
  end response
  response 2
    reaction=n,gamma multimix 1 3 5 eLow=0.625 macro zaid=u-238
  end response
  response 3
    mt=0   multimix 2 4 end eLow=0.625 eHighTransfer=0.635 macro zaid=h-1
  end response
  response 4
    mt=chi multimix 1 3 5 end eHigh=25.0e3 eLow=0.625 macro zaid=pu-239
  end response
end definitions
```

For multiple-mixture, single-nuclide macroscopic cross-section responses, keywords `multimix`, `nuclide`, `macro`, and `reaction` are required; `multiplier`, `eHigh`, `eLow`, `eHighTransfer`, and `eLowTransfer`, are optional; `title` is optional but not used; and `mixture`, `micro`, and `unity` are not allowed.

Multiple-mixture, multiple-nuclide, macroscopic cross-section response

A multiple-mixture, multiple-nuclide, macroscopic cross-section response is the integration of the neutron flux multiplied by a macroscopic cross-section over a set of mixtures defined in the problem geometry. The macroscopic cross-section used in the integral is defined by a specific mixture, and reaction type. The response function $H_g(\bar{r})$ is defined as:

$$H_g(\bar{r}) = c^* \delta_g * \sum_{j \in S} \delta_j(\bar{r})^* \Sigma_{x,g}^{j} \tag{6.1.13}$$

In this expression, $\Sigma_{x,g}^{j}$ is the mixture macroscopic cross-section for mixture-j and reaction type-x, and energy group-g. The summation of mixtures in this expression is for a set of user-defined mixtures, denoted S. The

modifications to this expression for transfer reactions and chi are applied similarly to the previously defined response types above.

For examples of this response type, the following `DEFINITIONS` block has response definitions for

- total nu-fission rate in the fuel mixtures (mixtures 1,3,5)
- "fast" n,gamma capture rate in the fuel mixtures
- downscatter rate in the moderator mixtures (mixtures 2,4)
- number fission neutrons born in the intermediate energy range (E>0.625 eV and E<25 keV) in the fuel mixtures

```
read definitions
  response 1
    reaction=nu-fission multimix 1 3 5 end macro
  end response
  response 2
    reaction=n,gamma multimix 1 3 5 eLow=0.625 macro
  end response
  response 3
    mt=0   multimix 2 4 end eLow=0.625 eHighTransfer=0.635 macro
  end response
  response 4
    mt=chi multimix 1 3 5 end eHigh=25.0e3 eLow=0.625 macro
  end response
end definitions
```

For multiple-mixture, multiple-nuclide macroscopic cross-section responses, keywords `multimix`, `macro`, and `reaction` are required; `multiplier`, `eHigh`, `eLow`, ``eHighTransfer`, and `eLowTransfer`, are optional; `title` is optional but not used; and `mixture`, `micro`, `nuclide`, and `unity` are not allowed.

Table 6.1.4: Keyword dependencies for the `DEFINITIONS` block.

Response type	**Required keywords**	**Unallowed keywords**	**Optional keywords**	**Optional, but not used keywords**
Single-mixture flux	unity, mixture	multimix	multiplier, eHigh, eLow	title, nuclide, reaction, micro, macro, eHighTransfer, eLowTransfer
Multiple-mixture flux	unity, multimix	mixture	multiplier, eHigh, eLow	title, nuclide, reaction, micro, macro, eHighTransfer, eLowTransfer
Single-mixture, single-nuclide, microscopic cross-section	mixture, nuclide, reaction	unity, macro, multimix	multiplier, eHigh, eLow, micro, eHighTransfer[a], eLowTransfer[a]	title
Single-mixture, single-nuclide, macroscopic cross-section	mixture, nuclide, reaction,macro	unity, micro, multimix	multiplier, eHigh, eLow, eHighTransfer[a], eLowTransfer[a]	title

continues on next page

Table 6.1.4 – continued from previous page

Response type	Required keywords	Unallowed keywords	Optional keywords	Optional, but not used keywords
Single-mixture, multiple-nuclide, macroscopiccross-section	mixture, reaction,macro	unity, micro, multimix, nuclide	multiplier, eHigh, eLow, eHighTransfer[a] , eLowTransfer[a]	title
Multiple-mixture, single-nuclide, macroscopic cross-section	multimix, nuclide reaction,macro	unity, micro, mixture	multiplier, eHigh, eLow, eHighTransfer[a] , eLowTransfer[a]	title
Multiple-mixture, multiple-nuclide, macroscopic cross-section	multimix, reaction,macro	unity, micro, mixture, nuclide	multiplier, eHigh, eLow, eHighTransfer[a] , eLowTransfer[a]	title
[a]Keywords `eHighTransfer` and `eLowTransfer` are only used for the following reaction types: scatter (mt=0), elastic (mt=2), inelastic (mt=4), and n,2n (mt=16) For all other reaction types, these keywords are optional, but not used				

Table 6.1.5: Supported Reaction Types in DEFINITIONS block.

MT	Reaction	String Identifier
1	total	Total
2	elastic scattering	Elastic
4	inelastic scattering	Inelastic
16[a]	effective n,2n	n,2n
0	sum of scattering (2+4+16)	Scatter
18	fission	Fission
102	n, *gamma*	n,gamma
103	n,p	n,p
104	n,d	n,d
105	n,t	n,t
106	n,^{3}he	n,he-3
107	n, *alpha*	n,alpha
101	Neutron disappearance (102+103+104+105+106+107)	capture
452	$\bar{\nu}$	nubar
1452	$\bar{\nu}$ times fission	nu-fission
1018	χ	chi

[a]The effective n,2n is defined by the summation of transfer matrices of the following reaction types: (n,2n), (n,2n+α), (n,2n+2α), (n,3n), (n,3n+α), and (n,4n). The individual transfer matrices are scaled by the number of exit channel neutrons, i.e., 2, 3, or 4.

System response definition data

The SYSTEMRESPONSES block is used to define the set of system responses for which TSUNAMI-1D will perform sensitivity and uncertainty analysis additional to k_{eff}. For SCALE 6.1, only system response ratios are supported in TSUNAMI-1D. The system response ratios are defined from the response function definitions created in the DEFINITIONS block. The format of the SYSTEMRESPONSES block is as follows:

```
read systemresponses
  ratio I1
    (specifications for response ratio I1)
  end ratio
  ratio I2
    (specifications for response ratio I2)
  end ratio
  ...
end systemresponses
```

The SYSTEMRESPONSES block of data begins with READ SYSTEMRESPONSES and terminates with END SYSTEMRESPONSES. Likewise, each system response ratio definition begins with RATIO - followed by a unique, positive integer identifier - and terminates with END RATIO. For each response ratio definition, the keywords title=, numer, and denom are allowed in any order. The title= specification is optional. However, if specified, the title must be begin and end with quotes and have a maximum of 20 characters. If omitted, the title of the ratio is "rsp ratio NNNNNNNNNN" where NNNNNNNNNN is a zero-padded 10-digit integer that is equal to the ratio identifier. The title is used as labels in both the TSUNAMI-1D text and html output. The title is also used by SAMS to generate the filename for the sensitivity data file for the ratio system response discussed further below.

The numer array is a list of integers that correlate to response function identifiers defined in the DEFINITIONS block. These response functions are added together to form the composite response function used in the numerator of the ratio. Likewise, the denom array is a list of integers that correlate to response function identifiers defined in the DEFINITIONS block. These response functions are added together to form the composite response function used in the denominator of the response ratio. Multiple response function ratios can be defined in a single input file.

For a simple example of the SYSTEMRESPONSES block, suppose the ratio system response of interest is the resonance escape probability for a given system. Using 2-group theory, this is equivalent to the following expression:

$$p = \frac{\langle \Sigma_{s,1\to 2} \rangle}{\langle \Sigma_{r,1} \rangle} = \frac{\int d\bar{r} \sum_{g\in 1} \phi_g(\bar{r}) \sum_{g'\in 2} \Sigma_{s,g\to g'}(\bar{r})}{\int d\bar{r} \sum_{g\in 1} \phi_g(\bar{r}) \Sigma_{r,g}(\bar{r})} \tag{6.1.14}$$

where $\Sigma_{r,g}(\bar{r})$ is the removal cross-section defined as the total cross-section minus the within group cross-section — $\Sigma_{t,g}(\bar{r}) - \Sigma_{s,g\to g}(\bar{r})$. The TSUNAMI-1D model uses three mixtures whose ids are 6, 7, and 10. The thermal energy cutoff is 0.625 eV.

This ratio can be defined in multiple ways. First, the ratio can be defined with three response function definitions:

```
read definitions
  response 1 title="DownScatter"
     reaction=scatter
     multimix 6 7 10 end
     macro
     eLow=0.625 eHighTransfer=0.625
  end response
  response 2 title="Fast Total"
     reaction=total
     multimix 6 7 10 end
     macro
     eLow=0.625
  end response
  response 3 title="Fast Within Group (times -1)"
     reaction=scatter
     multimix 6 7 10 end
     macro
     eLow=0.625 eLowTransfer=0.625
     factor=-1.0
  end response
end definitions
read systemresponses
  ratio 100
     title="Res Escape"
     numer 1 end
     denom 2 3 end
  end ratio
end systemresponses
```

In the above input, the numerator of the response ratio is defined by a single response function (id=1), which represents the rate at which neutrons slow down from fast energies to slow energies. The denominator of the response ratio is defined by two response functions (id=2 and id=3). The addition of these two response functions represents the "total minus within group scattering" calculation to formulate the fast neutron removal rate. In this input, the title of the response ratio is set to "Res Escape". Because only one response ratio is defined, TRITON will invoke SAMS twice, first for the k_{eff} sensitivity and uncertainty analysis and second for the analysis of the resonance escape probability. SAMS will generate two .sdf files, the first will be jobname.sdf for k_{eff} sensitivities and the second will be jobname.Res_Escape.sdf. jobname is the

name of the input file. An underscore is used to replace blanks and special characters in the response ratio title in the sdf filename.

Similarly, the resonance escape probability can be defined in a variety of different ways. For example, the numerator response function can be expressed as the sum of individual mixture downscattering rates:

```
read definitions
  response 2 title="Fast Total"
     reaction=total
     multimix 6 7 10 end
     macro
     eLow=0.625
  end response
  response 3 title="Fast Within Group (times -1)"
     reaction=scatter
     multimix 6 7 10 end
     macro
     eLow=0.625 eLowTransfer=0.625
     factor=-1.0
  end response
  response  6 mt=0 mixture= 6 macro eLow=0.625 eHighTransfer=0.625
  end response
  response  7 mt=0 mixture= 7 macro eLow=0.625 eHighTransfer=0.625
  end response
  response 10 mt=0 mixture=10 macro eLow=0.625 eHighTransfer=0.625
  end response
end definitions
read systemresponses
  ratio 100
    numer 6 7 10 end
    denom 2 3        end
  end ratio
end systemresponses
```

In this input, the numerator of the response ratio is defined by adding the individual mixture downscattering rates together. Because a title was not given for the response ratio, SAMS will generate the filename of the response ratio sdf file as `jobname.rsp_ratio_0000000100.sdf`.

SAMS data

The `SAMS` block is used for controlling certain aspects of the sensitivity and uncertainty calculation. This data block begins with the keywords `READ SAMS` and ends with the keywords `END SAMS`. Any of the optional SAMS input data may be entered in free form format between the `READ SAMS` and `END SAMS` keywords. This optional SAMS input data is shown in:

Table 6.1.6, with the default values specific to TSUNAMI-1D. Parameters used to specify default covariance data to supplement or correct values on the files specified by `coverx=` are shown in Table 6.1.7. A more detailed explanation of the SAMS parameters may be found in the SAMS chapter.

Table 6.1.6: SAMS input keywords

Keyword	Default value	Description
binsen	F	Produces SENPRO formatted binary sensitivity data file on unit 40
coverx=	56groupcov7.1	Name of covariance data file to use for uncertainty analysis
largeimp=	100.0	Value for the absolute value of implicit sensitivities, which if exceeded, will be reset to 0.0 and print a warning message.

continues on next page

Table 6.1.6 – continued from previous page

nocovar	T	Flag to cause uncertainty edit to be turned off (sets print_covar to F)
nohtml	F	Flag to cause HTML output to not be produced.
nomix	F	Flag to cause the sensitivities by mixture to be turned off
pn=	3	Legendre order for moment calculations
prtgeom	F	Flag to cause the sensitivities to be output for each geometry region
prtimp	F	Prints explicit sensitivities coefficients, implicit sensitivity coefficients and complete sensitivity coefficients
prtvols	F	Flag to cause the volumes of the regions to be printed by SAMS
unconstrainedchi	F	Flag to generate pre-SCALE 6 unconstrained chi (fission spectrum) sensitivities

Table 6.1.7: SAMS input keywords for default covariance data.

Keyword	**Default value**	**Description**
use_dcov	F	Use default covariance data
use_icov	F	Use user-input covariance data
cov_fix	F	Correct covariance data if the uncertainty is large >1000% or zero
large_cov	10.0	Relative Standard deviation to apply `cov_fix`
return_work_cov	F	Create a new covariance data file with only the cross-section covariance data used in the analysis.
udcov=	0.05	User-defined default value of standard deviation in cross-section data to use for all groups for nuclide-reaction pairs for which cross-section-covariance data are too large or not available on input covariance data library.
udcov_corr=	1.0	User-defined default correlation value to use for nuclide-reaction pairs for which cross-section-covariance data are not available on the input covariance library.
udcov_corr_type=	zone	User-defined default correlation to use for nuclide-reaction pairs for which cross-section-covariance data are not available on the input covariance library. Allowed values are `long`, `zone`, and `short`. See the table *Input Data for Covariance Block of TSAR Input* in the TSAR chapter for details on `long`, `zone`, and `short`.
udcov_therm=	0.0	User-defined default value of standard deviation in cross-section data to use for thermal data for nuclide-reaction pairs for which cross-section-covariance data are too large or not available on input covariance data library. If input, the `udcov_therm` overrides the `udcov` value in the thermal range (i.e. neutron energies below 0.625 eV).

continues on next page

Table 6.1.7 – continued from previous page

udcov_inter=	0.0	User-defined default value of standard deviation in cross-section data to use for intermediate data for nuclide-reaction pairs for which cross-section-covariance data are too large or not available on input covariance data library. If input, the udcov_inter overrides the udcov value in the intermediate range (i.e. neutron energies above 0.625 eV and below 25 keV).
udcov_fast=	0.0	User-defined default value of standard deviation in cross-section data to use for fast data for nuclide-reaction pairs for which cross-section-covariance data are too large or not available on input covariance data library. If input, the udcov_fast overrides the udcov value in the fast range (i.e. neutron energies above 25 keV).

HTML and user-input covariance data

User-defined covariance data can be specified for individual nuclides and reactions using the COVARIANCE data block. This data begins with the keywords READ COVARIANCE and ends with the keywords END COVARIANCE. Any of the optional COVARIANCE input data may be entered in free form format between the READ COVARIANCE and END COVARIANCE keywords. The specifications for the COVARIANCE data block are described in *User Input Covariance Data* of the TSUNAMI Utility Modules chapter.

As the SAMS module generates HTML output, the optional HTML data block will provides user control over some formats of the output. This data begins with the keywords READ HTML and ends with the keywords END HTML. Any of the optional HTML input data may be entered in free form format between the READ HTML and END HTML keywords. The specifications for the HTML data block are described in the TSUNAMI Utility Modules manual.

6.1.4.5 Input termination

The input specification for all TSUNAMI-1D sequences must terminate with a line containing END in column 1. This END terminates the control sequence.

6.1.5 EXAMPLE PROBLEMS

Nine TSUNAMI-1D sample problems are included in the SCALE package to verify successful installation and to provide examples for users. They are provided in the smplprbs directory of the software distribution. Three example problems are presented in this section and comparisons among the different methods for cross-section processing are discussed. The first problem presented is a variant of the TSUNAMI-1D1 k_{eff} sensitivity sample problem with some addition input parameters in the READ SAMS data block and using INFHOMMEDIUM unit cell type. The second example problem presented in this section generates k_{eff} sensitivities using the MULTIREGION unit cell type. The third example problem is similar to the TSUNAMI-1D5 sample problem that demonstrates the GPT capabilities. The five sample problems in the software package are designed to run quickly and test most code features. The three examples presented here are designed to produce accurate results, but may require more computational resources.

For all problems the validity of the sensitivity coefficients should be confirmed through the use of direct perturbation sensitivity calculations. For each sensitivity coefficient examined by direct perturbation, the k_{eff} of the system is computed first with the nominal values of the input quantities, then with a selected input

value increased by a certain percentage, and then with the value decreased by the same percentage. The direct perturbation sensitivity coefficient of k_{eff} to some input value α is computed as

$$S_{k,\alpha} = \frac{\alpha}{k} \times \frac{dk}{d\alpha} = \frac{\alpha}{k} \times \frac{k_{\alpha^+} - k_{\alpha^-}}{\alpha^+ - \alpha^-}, \tag{6.1.15}$$

whereα^+ and α^- represent the increased and decreased values, respectively, of the input quantity α and k_{α^+} and k_{α^-} represent the corresponding values of k_{eff}.

The use of direct perturbation calculations to confirm the validity of sensitivity coefficients is strongly encouraged. Inconsistent modeling between the resonance-self shielding input and the criticality problem description can lead to erroneous sensitivity results. These erroneous results can be revealed through the use of direct perturbation confirmation of the energy-integrated sensitivity results for the total cross section. The total cross-section sensitivities are equivalent to number density sensitivities on an energy-integrated basis.

The results shown here were generated with a previous version of SCALE, so current data libraries and code implementations may product different results. However, the techniques demonstrated are applicable to the current version of TSUNAMI-1D.

6.1.5.1 INFHOMMEDIUM sample problem

The selected sample problem with INFHOMMEDIUM cross-section processing is based on an unreflected rectangular parallelepiped consisting of a homogeneous mixture of UF_4 and paraffin with an enrichment of 2% in ^{235}U. The H/^{235}U atomic ratio is 294:1. The dimensions of the experiment were 56.22 cm × 56.22 cm × 122.47 cm. [TS-1D-CLP86]. For the purposes of this exercise, this experiment was modeled as a sphere with a critical radius of 38.50 cm. This model is consistent with SCALE sample problem TSUNAMI-1D1, which utilizes the 238-group ENDF/B-VII cross-section library, and the default cross-section processing with BONAMIST and CENTRM/PMC/WORKER.

An annotated TSUNAMI-1D1 input for this experiment is shown in Sect. 6.1.3.1. The composition data is input as number densities for each nuclide. Because the material is treated as INFHOMMEDIUM, no explicit unit cell model is necessary, and the READ CELL block is omitted. The criticality description contains optional parameter data to change the default S_{16} angular quadrature set to S_8. The change in angular quadrature is made only to demonstrate the input capabilities of TSUNAMI-1D and has little effect on this calculation. The criticality problem geometry uses a spherical coordinate system with the default boundary conditions (reflected left, vacuum right). The system consists of a single material zone containing mixture 1 with a radius of 38.50 cm. The optional sensitivity calculation data block was entered to request the extended edit of sensitivity by material zone (`prtgeom`), the extended edits of the explicit, implicit and complete sensitivity coefficients (`prtimp`), and corrections in the cross-section covariance data (`use_dcov`, `cov_fix`).

Prior to producing the output of the functional modules, TSUNAMI-1D produces output from the XSProc routines as it is processing the user input and creating internal inputs for the resonance processing codes. TSUNAMI-1D also prints information regarding the criticality description.

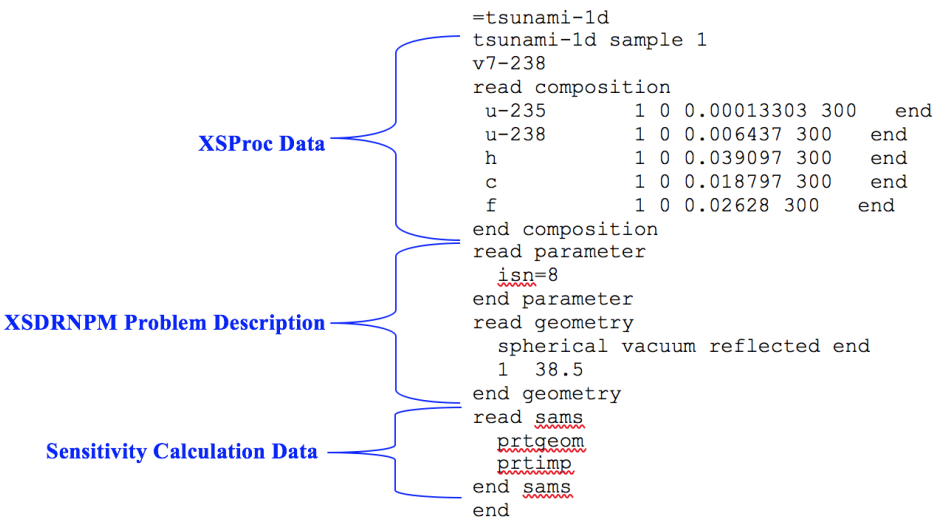

Fig. 6.1.2: TSUNAMI-1D INFHOMMEDIUM sample problem input.

For this problem, direct perturbation results were obtained for the number densities of each nuclide. In these calculations, the number density of each nuclide was perturbed by ±2% and the calculation was repeated using the TSUNAMI-1DC sequence. The sensitivity of k_{eff} to the number density is equivalent to the sensitivity of k_{eff} to the total cross section, integrated over energy. The direct perturbation sensitivity coefficients were computed by using the k_{eff} values from the unperturbed and perturbed cases in Eq. (6.1.15). To demonstrate the importance of the sensitivity to the resonance processing implicit sensitivity computed by BONAMIST, the same model shown in Fig. 6.1.2 was run with TSUNAMI-1D with `PARM=CENTRM`. The results from the `INFHOMMEDIUM` sample problem are given in Table 6.1.8. The TSUNAMI-1D results using the default codes for resonance processing show good agreement with the direct perturbation results for all nuclides. Due to omission of the implicit terms, the TSUNAMI-1D results with `PARM=CENTRM` do not show good agreement with the direct perturbation for this thermal system. The maximum difference between the direct perturbation results and the TSUNAMI-1D results occurs for ^{238}U with a magnitude of 1.5%. The maximum difference between the direct perturbation results and the TSUNAMI-1D with `PARM=CENTRM` results occurs for ^{238}U with a magnitude of 19%. Thus, the use of the default `PARM=BONAMIST` is recommended.

The uncertainty information from SAMS for the INFHOMMEDIUM sample problem is shown in Example 6.1.1. Based on the 44GROUPCOV covariance data library, documented in the COVLIB chapter, the uncertainty in k_{eff} due to these covariance data is 0.6064% $\Delta k/k$. A more detailed description of the uncertainty information is given in Chapter 6.3. Some plots of the energy-dependent sensitivity data were generated with Fulcrum. The energy-dependent data is available in the sensitivity data file, which is returned

to the same directory as the input file and given the same name as the user's input file with the extension .sdf. Energy-dependent sensitivity profiles for ^{235}U fission and ^{1}H elastic scattering are shown in Fig. 6.1.3. The ^{238}U capture sensitivity profiles from TSUNAMI-1D and TSUNAMI-1D with PARM=CENTRM are shown in Fig. 6.1.4. The effect of the implicit component of the sensitivity coefficients can be seen in the resonance region in the difference between the TSUNAMI-1D and TSUNAMI-1D PARM=CENTRM profiles.

Example 6.1.1: INFHOMMEDIUM sample problem.

6.1.5.2 Multiregion sample problem

The sample problem selected to demonstrate the use of TSUNAMI-1D with MULTIREGION cross-section processing is the FLATTOP-25 metal system from the Cross-Section Evaluation Working Group benchmark specifications. [TS-1D-AKPZ74]. The system consists of a 6.116-cm sphere of 93%-enriched uranium with a natural uranium reflector. The outer radius of the reflector is 24.13 cm. The system is used for sample problems TSUNAMI-1D4 – TSUNAMI-1D7. For this example, input for TSUNAMI-1D4 was modified to use the SCALE 238-group ENDF/B-VII library with multiregion cell data as shown in Fig. 6.1.5. The multiregion cell data processes the cross sections in the same geometry as the criticality model. Therefore, the dimensions of the system are input twice in this model: once in the unit cell specification portion of the input and once in the criticality portion of the input. The unit cell specification geometry is used to generate input for BONAMIST and CENTRM/PMC/WORKER, and the criticality model is used to generate input for the forward and adjoint XSDRNPM calculations. The optional sensitivity calculation data block was entered to request the extended edit of sensitivity by material zone (`prtgeom`), the extended edits of the explicit, implicit and complete sensitivity coefficients (`prtimp`), and to allow larger implicit sensitivity values to be computed without producing warning messages (`largeimp=1000`).

This model was executed with TSUNAMI-1D and also with TSUNAMI-1D with PARM=CENTRM. Direct perturbation sensitivity results were obtained for the number densities of all nuclides, which correspond to the sensitivity of k_{eff} to the total cross section, integrated over energy. The energy-integrated sensitivity results are shown in Table 6.1.9. The TSUNAMI-1D results agree well with the direct perturbation results for this system. The maximum difference occurs for ^{238}U in the reflector region with a magnitude of 0.9%. Because this is a fast system, the effect of the resonance processing on the sensitivity coefficients is minimal. Thus, the TSUNAMI-1D PARM=CENTRM results are almost identical to the default TSUNAMI-1D results with BONAMIST.

The uncertainty information from SAMS HTML output for the multiregion sample problem is shown in Fig. 6.1.6. Based on the 44GROUPCOV covariance data file, the uncertainty in k_{eff} due to these covariance data is 1.2743% $\Delta k/k$. The contributions to this uncertainty are listed by nuclide. These data are explained in more detail in the SAMS chapter.

Sensitivity profiles from TSUNAMI-1D for ^{235}U fission in zone 1 (core) and zone 2 (reflector) were generated with Fulcrum and are shown in Fig. 6.1.7. Additionally, sensitivity profiles for ^{238}U capture in zone 1 and zone 2 are shown in Fig. 6.1.8. Note that the capture sensitivities are negative, such that the lower curve has the greater magnitude. In ^{235}U and ^{238}U sensitivity profiles, the effect of the differing enrichments in the core and the reflector of this system are demonstrated with the much greater sensitivity to ^{235}U fission in the core and to ^{238}U capture in the reflector.

6.1.5.3 GPT sample problem

The sample problem selected to demonstrate the use of TSUNAMI-1D with Generalized Perturbation theory is from the OECD LWR Uncertainty Analysis in Modeling benchmark specification [TS-1D-IAKS07]. The system consists of a 4.85% enriched uranium PWR fuel pin modeled at 551 K. This system is used for sample problem TSUNAMI-1D9. For this example, the `DEFINITIONS` and `SYSTEMRESPONSES` blocks are used to define six additional response ratios for sensitivity and uncertainty analysis. The requested responses in the benchmark were for the energy-integrated fission and absorption microscopic cross-sections for ^{234}U, ^{235}U, and ^{238}U. The input for this sample problem is provided in Example 6.1.2. For this sample, seven separate sensitivity data files are generated, one for each of the six defined responses in addition to k_{eff}. Selected sensitivity profiles are shown in Fig. 6.1.9 for the ^{238}U (n,γ) cross-section. This figure shows the negative sensitivity of k_{eff} due to ^{238}U resonance absorption in the blue profile. The red profile shows the positive sensitivity of the energy-integrated ^{238}U absorption cross-section due to the multigroup ^{238}U (n,γ) cross-section. The large positive magnitude of this sensitivity is predominantly due to the presence of the ^{238}U (n,γ) cross-section directly in the definition of the response ratio. In contrast, the black sensitivity profile shows the negative sensitivity of the energy-integrated ^{235}U fission cross-section due to the multigroup ^{238}U (n,γ) cross-section. In this response, positive perturbations to the ^{238}U (n,γ) multigroup cross-sections induce changes in the flux spectra that lead to a decrease in the energy-integrated ^{235}U fission cross-section. These indirect sensitivity effects are determined by the solution of the generalized adjoint calculations.

6.1.6 APPENDICES

6.1.6.1 XSDRNPM Data File Formats

As part of the development of the sensitivity capabilities in SCALE, the XSDRNPM module was modified to allow the writing of a new interface file containing information needed for sensitivity calculations. This same data file is used by TSUNAMI-1D. This information is written on unit NTD in the XSDRNPM input, when NTD is positive. When TSUNAMI-1D creates the inputs for the forward and adjoint XSDRNPM criticality calculations, NTD is set to 31 for the forward case and 32 for the adjoint case. The files written are ft31f001 and ft32f001, respectively.

6.1.6.2 XSDRNPM forward output file

For a forward case, XSDRNPM writes the following unformatted records on unit NTD:

RECORD 1: IZM,IM,MXX,MS,ISCT,MM,JT,IGM

IZM - Number of zones
IM - Number of spatial intervals
MXX - Number of compositions (mixtures)

MS - Length of the XSDRNPM mixing table
ISCT - Order of the Legendre scattering expansion
MM - Number of angles in the angular quadrature
JT - Number of flux moments
IGM - Number of energy groups

RECORD 2: IGE,IBL,IBR,ISN,IFTG,MMT,NT1,T

IGE - Geometry: 1/2/3 = plane/cylinder/sphere
IBL - Left-boundary condition: 0/1/2/3 = vacuum/reflected/periodic/white
IBR - Right-boundary condition
ISN - S_n quadrature order
IFTG - First thermal group
MMT - Number of neutron groups
NT1 - Unit number of working cross-section library
T - Problem title containing 80 characters

RECORD 3: V,R

V(IM) - Volumes of the spatial mesh cells (single-precision)
R(IM+1) - Boundaries of the spatial mesh cells (single-precision)

RECORD 4: W,PNC

W(MM) - Weights in the angular quadrature (single-precision)
PNC(MM,JT) - Scattering constants used to obtain flux moments from angular fluxes (single-precision)

RECORD 5: MA,MZ

MA(IM) - Zone number by interval
MZ(IZM) - Mixture number by zone

RECORD 6: MB,MC,XMD

MB(MS) - Mixture number in the cross-section mixing table
MC(MS) - Component (nuclide) in the cross-section mixing table
XMD(MS) - Atom density in the cross-section mixing table (single-precision)

RECORD 7: CHI,FISNU

CHI(IGM,MXX) - χ for each mixture (single-precision)
FISNU(IGM,MXX) - $\bar{\nu}$ times the fission cross section for each mixture (single-precision)

RECORD 8: EIGEN

EIGEN k_{eff} (single-precision)

NEXT IGM RECORDS: XNDC

XNDC(IM,MM) - Mesh cell centered angular flux for one group (double-precision)

LAST RECORD: TLEAKAGE

TLEAKAGE(IGM) - Total leakage from the system (single-precision)

6.1.6.3 XSDRNPM adjoint output file

For an adjoint case, XSDRNPM writes the following unformatted records on unit NTD, containing the following information:

RECORD 1: EIGEN

EIGEN - k_{eff} value (single-precision)

NEXT IGM RECORDS: XNDC

XNDC(IM,MM) - Mesh cell centered angular flux for one group (double-precision)

The adjoint angular fluxes are reversed in direction such that each angular flux is the importance for that direction in the forward case. This reversal is done by using the reflected angle. Also, the records are written in forward order such that the first record corresponds to the highest-energy group.

6.2 TSUNAMI-3D: CONTROL MODULE FOR THREE-DIMENSIONAL CROSS SECTION SENSITIVITY AND UNCERTAINTY ANALYSIS FOR CRITICALITY

K. B. Bekar, T. M. Greene, S. R. Johnson, B. Langley, J. D. McDonnell, W. J. Marshall, C. M. Perfetti, B. T. Rearden, W. A. Wieselquist

ABSTRACT

TSUNAMI-3D (**T**ools for **S**ensitivity and **Un**certainty **A**nalysis **M**ethodology **I**mplementation in **Three** **D**imensions) is a SCALE control module that facilitates the application of sensitivity and uncertainty analysis theory to criticality safety analysis. In multigroup (MG) mode, TSUNAMI-3D provides for resonance self-shielding of cross section data, calculation of the implicit effects of resonance self-shielding calculations, calculation of forward and adjoint Monte Carlo neutron transport solutions, and calculation of eigenvalue sensitivity coefficients. In continuous-energy (CE) mode, sensitivity coefficients are computed in a single forward Monte Carlo neutron transport calculation for either eigenvalue or generalized reaction rate ratio responses. In both MG and CE modes, the KENO V.a or KENO-VI module is used for transport solvers, and the SAMS module is used to compute and/or create edits of the sensitivity of the calculated responses to the nuclear data used in the calculation as a function of nuclide, reaction type, and energy. SAMS also computes the uncertainty in the calculated responses resulting from uncertainties in the basic nuclear data used in the calculation through energy-dependent cross section covariance matrices. In both MG and CE calculations, a sensitivity data file is produced for use in subsequent analysis.

The following section acknowledgements appeared in the SCALE 6.2 manual.

The author wishes to acknowledge M. L. Williams, B. L. Broadhead, and K. B. Bekar, of Oak Ridge National Laboratory (ORNL), and R. L. Childs, formerly of ORNL, for their assistance with this work. The support and encouragement of C. M. Hopper, formerly of ORNL, and C. V. Parks and D. E Mueller of ORNL is also appreciated. The continued support of the U.S. Department of Energy Nuclear Criticality Safety Program and the ORNL Laboratory-Directed Research and Development Program is gratefully acknowledged.

6.2.1 INTRODUCTION

TSUNAMI-3D (**T**ools for **S**ensitivity and **Un**certainty **A**nalysis **M**ethodology **I**mplementation in **Three** **D**imensions) is a SCALE control module that facilitates the application of sensitivity and uncertainty theory to criticality safety analysis. The data computed with TSUNAMI-3D are the sensitivity of computed responses (e.g. k_{eff} and ratios of reaction rates) to each constituent nuclear data component used in the calculation. The sensitivity data are coupled with cross section uncertainty data, in the form of multigroup (MG) covariance matrices, to produce an uncertainty in the computed responses due to uncertainties in the underlying nuclear data. The group-wise sensitivity data computed with TSUNAMI-3D are stored in a sensitivity data file format (.sdf file) that is suitable for use in data visualization with Fulcrum, similarity assessment with TSUNAMI-IP, and bias assessment with TSURFER.

This manual is intended to provide the user with a detailed reference on code input options and some examples of the application of TSUNAMI-3D to generate sensitivity and uncertainty data. The techniques used in the MG and continuous-energy (CE) versions of TSUNAMI-3D are described in Sect. 6.2.2 and Sect. 6.2.3, respectively. The input for TSUNAMI-3D is presented in Sect. 6.2.4, and the use of TSUNAMI-3D to obtain accurate sensitivity coefficients for several sample problems is given in Sect. 6.2.5. Additional information is provided in the appendix. A new user may wish to review the sample problems and then refer to the input description in Sect. 6.2.4 to obtain specific guidance on preparing input for specific models.

TSUNAMI-3D provides automated, problem-dependent cross sections using the same methods and input as the **C**riticality **S**afety **A**nalysis **S**equences (CSASs). Although CE calculations with TSUNAMI do not require resonance self-shielding calculations because of its use of CE cross sections, MG TSUNAMI-3D uses self-shielding codes that are similar to those used in MG CSAS calculations. The BONAMIST code computes the sensitivity of resonance self-shielded cross to the input data, the so-called "implicit sensitivities" for MG calculations.

After the cross sections are processed, the MG TSUNAMI-3D-K5 sequence performs two KENO V.a criticality calculations, one forward and one adjoint; the MG TSUNAMI-3D-K6 sequence performs two KENO-VI calculations. Finally, the sequence calls the SAMS module to calculate the sensitivity coefficients that indicate the sensitivity of the computed responses to changes in the cross sections and the uncertainty in the computed responses that is due to uncertainties in the basic nuclear data. SAMS prints energy-integrated sensitivity coefficients and their statistical uncertainties to the SCALE output file and generates a separate data file containing the energy-dependent sensitivity coefficients. CE calculations in TSUNAMI do not require a separate adjoint criticality calculation; instead, they calculate sensitivity coefficients and produce a sensitivity data file during a single forward simulation. The SAMS module is used to print user output for CE calculations.

Choosing poor values for any of several adjustable parameters in TSUNAMI inputs may result in inaccurate sensitivity coefficient estimates; thus, users are advised to always compare their calculated sensitivity coefficients to reference values to verify the suitability of their TSUNAMI input parameters. Sect. 6.2.5 describes the direct perturbation approach for generating reference sensitivity coefficients for the total cross

section of nuclides in a system. It is difficult to calculate high fidelity, energy-dependent, reference sensitivity coefficients using direct perturbation (although possible using stochastic sampling of cross section data), but at the minimum users are advised to verify the accuracy of TSUNAMI-produced total nuclide sensitivity coefficients for all key nuclides in their application.

6.2.2 MULTIGROUP TSUNAMI-3D TECHNIQUES

TSUNAMI-3D is a SCALE control module. As such, its primary function is to control a sequence of calculations that are performed by other codes. A thorough theoretical development of MG eigenvalue sensitivity theory is described in the SAMS section of the SCALE documentation. Currently, two computational sequences are available with TSUNAMI-3D: TSUNAMI-3D-K5 and TSUNAMI-3D-K6. The input for TSUNAMI-3D-K5 is very similar to that used for CSAS5 and the input for TSUNAMI-3D-K6 is very similar to that of CSAS6. TSUNAMI-3D uses the same material and cell data input as all other SCALE sequences. TSUNAMI-3D can calculate eigenvalue sensitivity coefficients using either MG or CE Monte Carlo simulations, but the theoretical approaches for each calculation mode differ greatly. MG TSUNAMI-3D techniques will be discussed in this section, and CE TSUNAMI-3D calculations will be discussed in Sect. 6.2.3. The control sequences available in MG TSUNAMI-3D are summarized in Table 6.2.1, where the functional modules that are executed are also shown. A general flow diagram of MG TSUNAMI-3D is shown in Fig. 6.2.1.

Table 6.2.1: Multigroup TSUNAMI-3D control sequences.

Control sequence	**Functional modules executed by the control module**				
TSUNAMI-3 D-K5	XSProc	KENO V.a forward	KENO V.a adjoint	BONAMIST	SAMS5
TSUNAMI-3 D-K6	XSProc	KENO-VI forward	KENO-VI adjoint	BONAMIST	SAMS6

TSUNAMI-3D and many other SCALE sequences apply a standardized procedure to provide appropriate cross sections for the calculation. This procedure is carried out by routines of the XSProc module, which generate number densities and related information, prepare geometry data for resonance self-shielding and flux-weighting cell calculations, and create data input files for the cross section processing codes.

By default, the MG TSUNAMI-3D sequence performs cross-section processing with XSProc, exercising all available options there, performs the forward and adjoint KENO calculations, calls BONAMIST to produce implicit sensitivity coefficients, then calls SAMS to produce sensitivity and uncertainty output and *sdf* files. Optional sequence level parameters can be used to change methods applied in resonance self-shielding and exclude the implicit sensitivity calculation, which are detailed later in this document.

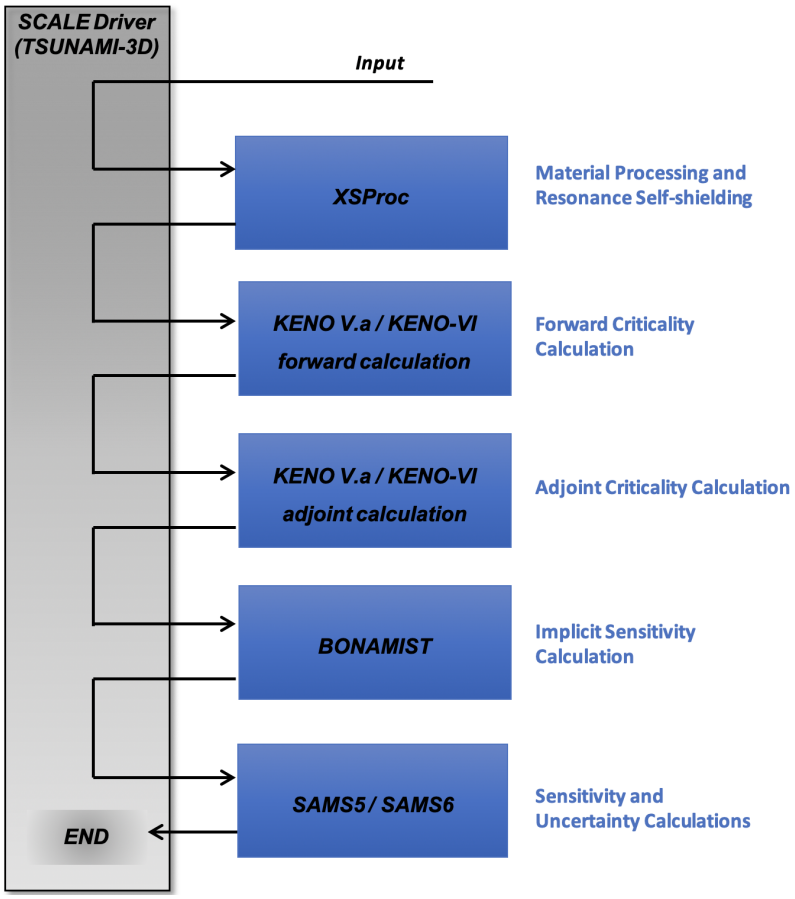

Fig. 6.2.1: General flow diagram of MG TSUNAMI-3D.

Once the appropriate AMPX libraries are prepared, TSUNAMI-3D prepares KENO V.a or KENO-VI inputs for forward and adjoint calculations from the criticality model provided by the user. The input requirements for the KENO V.a input sections are identical to those for the CSAS5 sequence, with some optional additional data. Also, the input requirements for the KENO-VI are identical to those for CSAS6, with some optional additional data. Additional input is prepared for the SAMS module using an optional user-defined input block for SAMS. TSUNAMI-3D executes forward and adjoint KENO calculations, generates implicit sensitivity data with BONAMIST, and then executes the SAMS module to compute the sensitivity and uncertainty data using the data accumulated from the codes previously executed in the sequence. Details concerning calculation of sensitivity and uncertainty data using MG forward and adjoint calculations are provided in the SAMS chapter of the SCALE manual. Of particular interest, the *filename.sdf* file, where *filename* is the name of the input file less any extensions, contains energy-dependent sensitivity coefficients. SCALE returns this file to the same directory as the input file.

The XSProc module is responsible for reading the standard composition data and other engineering-type specifications, including volume fraction or percent theoretical density, temperature, and isotopic distribution as well as the unit cell data. The techniques used in the XSProc module and their applications and limitations are discussed in the XSProc chapter. The input data for XSProc is the same for all analytical sequences available through TSUNAMI-3D, TSUNAMI-1D, CSAS, and many other SCALE sequences.

6.2.3 CONTINUOUS-ENERGY TSUNAMI-3D TECHNIQUES

Like MG TSUNAMI-3D, the CE TSUNAMI-3D capability is a control module that uses codes within the SCALE code package to calculate eigenvalue sensitivity coefficients and other information for models of eigenvalue problems. The CE and MG TSUNAMI-3D calculations differ dramatically in their approach for calculating sensitivity coefficients and as a result have different user interfaces. CE TSUNAMI calculations are automatically enabled when the user selects a CE cross-section library.

6.2.3.1 CE TSUNAMI methodology

CE TSUNAMI currently contains two separate approaches for performing eigenvalue sensitivity coefficient calculations: Iterated Fission Probability (IFP) approach and Contributon-Linked eigenvalue sensitivity/Uncertainty estimation via Tracklength importance Characterization (CLUTCH) approach. Both IFP and CLUTCH calculate sensitivity coefficients during a single forward Monte Carlo (KENO) simulation. Unlike MG TSUNAMI-3D, IFP and CLUTCH do not require the simulation of adjoint histories, calculation of angular flux moments using a flux mesh, volume calculations, or treatment of implicit sensitivity effects. The theoretical background of each method is discussed in detail in the following sections. IFP is often easier to use than CLUTCH, but CLUTCH has greater computational efficiency and a lower memory footprint.

IFP methodology

The IFP methodology, developed by Hurwitz in the 1940s and 1950s, determines the importance of events during a particle history using the notion that an event's importance is proportional to the number of neutrons descended from the original event that are present in the system during some future generation. [3d1], [3d2] In practice, the IFP method requires storing reaction rate tallies for particles for some number of generations until the average population of their descendants in the system, the "asymptotic population," is obtained. This process is illustrated in Fig. 6.2.2. Once obtained, the asymptotic population of the original neutron is used to weight reaction rate tallies for that neutron and to produce sensitivity coefficient estimates via the first-order perturbation equation. The number of fission neutrons created by progenitor p's asymptotic population,

$$\pi_p = \sum_{\tau \in p} \sum_{s \in \text{paths}} w_s \bar{\nu} \Sigma_f l_s, \tag{6.2.1}$$

takes the place of the adjoint flux ϕ^* in the first-order perturbation equations.

A number of generations, referred to as the "latent generations," must be skipped before calculating the asymptotic population for an event to guarantee that the progeny of the event have had sufficient time to impact all regions in the system and to converge to a true estimate of the asymptotic population. The number of latent generations required to calculate accurate sensitivity coefficients varies based on the complexity of the system and the desired sensitivity coefficient fidelity, but in general 20 generations is a conservative number of latent generations to ensure convergence to the asymptotic population. (Note that the current default in TSUNAMI-3D is 5 latent generations.) The IFP method is useful for benchmarking the accuracy of other sensitivity coefficient methods and is very easy to use because the only assumption of the IFP method (besides the standard CE Monte Carlo and first order perturbation theory assumptions) is that the asymptotic population that is reached after the chosen number of latent generations is representative of the importance of the original event. Thus a user who is new to sensitivity methods can assume a conservative number of latent generations and can use the IFP method to accurately calculate sensitivity coefficients for a system so long as the user's computer has sufficient computational memory for the simulation.

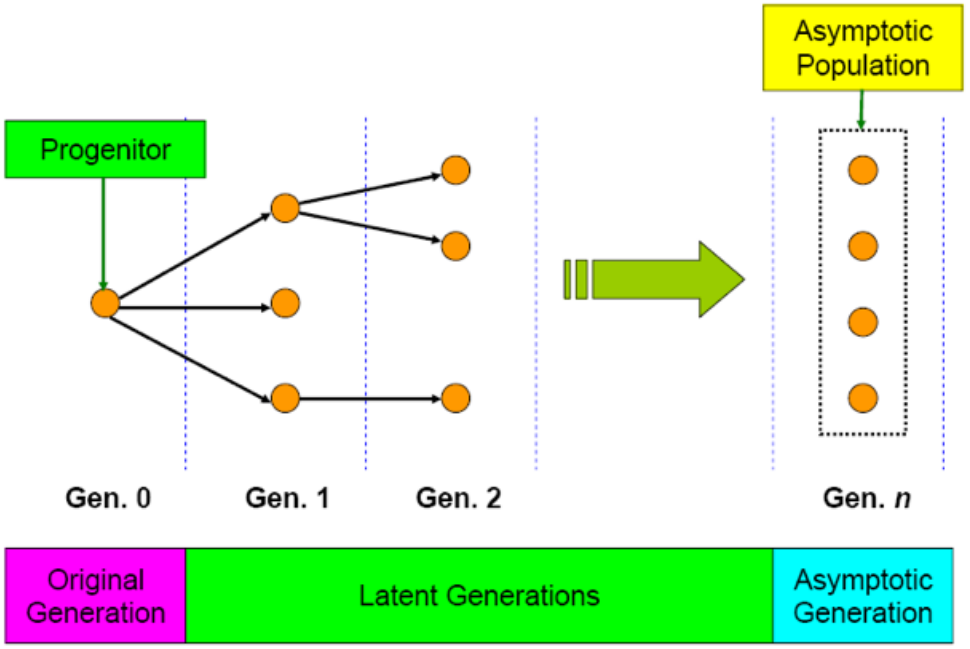

Fig. 6.2.2: Illustration of the Iterated Fission Probability process.

The IFP method requires storage of region-, isotope-, reaction-, and energy-dependent reaction rates for every particle for the specified number of latent generations. Complex problems can require simulating tens of thousands or hundreds of thousands of particles during each generation, and IFP simulations for these systems can easily require many gigabytes of computational memory storage. The IFP implementation in TSUNAMI-3D makes use of dynamic memory allocation to minimize memory requirements, but the method frequently produces large memory footprints despite these optimizations. The IFP memory requirements are proportional to the number of latent generations used in the calculations, and perhaps the best approach for minimizing the memory requirements of the IFP method is to minimize the number of latent generations used in a calculation. Twenty is typically a conservative number of latent generations, and it is recommended that the user always use as few latent generations as possible for IFP simulations. The five latent generations that IFP assumes by default is a reasonable starting guess, but users should compare IFP nuclide sensitivity coefficients with direct perturbation sensitivities to determine if they need to use more or fewer latent generations. Determining the adequate number of latent generations can be done by starting with a small number of latent generations and slowly increasing the number until the IFP-calculated sensitivity coefficients agree well with reference sensitivities. The memory requirements of the IFP method are also proportional to the number of particles used in each generation (NPG), and high-memory simulations can decrease NPG to decrease the memory requirements of the IFP method. This should be done with caution because making NPG too small can affect the fission source convergence and thus can produce poor tally Monte Carlo variance estimates.

The integration of the Shift Monte Carlo transport code has made possible the parallelization of the IFP method, so that the large amount of memory required can be distributed among several available processors. Note that this parallelism for IFP is only available when using the Shift transport code, and it is not available through KENO.

CLUTCH methodology

The CLUTCH method was developed by Perfetti in 2012, based in part on the Contributon theory explored by M. L. Williams of ORNL, to produce an accurate and efficient means for calculating eigenvalue sensitivity coefficients with a small computational memory footprint. [3d3] Like the IFP method, CLUTCH calculates sensitivities during a single forward Monte Carlo calculation and does not require tallying angular flux moments. Instead, the CLUTCH method calculates the importance of events during a particle's lifetime by examining how many fission neutrons are created by that particle after those events occur. Consider a neutron source Q that is equal to the fission source of a system:

$$Q = \lambda F \phi. \tag{6.2.2}$$

Multiplying this source by the adjoint flux and integrating over phase space gives

$$\langle \phi^* Q \rangle = \lambda \langle \phi^* F \phi \rangle \tag{6.2.3}$$

Consider now a neutron emitted in phase space τ_s such that $Q(\tau_s) = Q_s\, \delta(\tau - \tau_s)$. This source definition reduces Eq. (6.2.3) and allows the importance of the neutron in phase space τ_s to be calculated by

$$\phi^*(\tau_s) = \frac{\lambda}{Q_s} \int_V G(\tau_s \rightarrow r)\, F^*(r) dr \tag{6.2.4}$$

where the transfer function $G(\tau_s \rightarrow r)$ is equal to the expected number of fission neutrons generated in all energies and directions at r due to a neutron emitted at phase space τ_s and is given by

$$G(\tau_s \rightarrow r) = \frac{1}{Q_s} \int_E \int_\Omega \nu \Sigma_f(r, E) \phi(r, E, \Omega \mid Q(\tau_s))\, d\Omega dE \tag{6.2.5}$$

where $\phi(r, E, \Omega \mid Q(\tau_s))$ is the flux created in phase space (r, E, Ω) given the source $Q(\tau_s)$. The weighting function $F^*(r)$ is defined to be equal to the expected importance generated by a fission neutron emitted at r and is given by

$$F^*(r) = \int_E \int_\Omega \frac{\chi(r, E)}{4\pi} \phi^*(r, E, \Omega) d\Omega dE. \tag{6.2.6}$$

In practice, the CLUTCH method calculates the integral of $G(\tau_s \rightarrow r)$, weighted by $F^*(r)$, to calculate the importance of every event in a particle's lifetime. For example, the importance of a scattering event would be determined by tallying how many fission neutrons, weighted by the value of $F^*(r)$ at the sites where they are born, are created by the neutron that emerges from the scattering collision. The CLUTCH method cannot calculate the importance of events until after the particle that caused these events dies, which requires that CLUTCH store reaction rate information for every collision that a particle undergoes during its lifetime. This is a manageable amount of information because these tallies are not energy dependent (a particle's energy is constant between any two collisions) and because this information can be deleted once the particle dies. In contrast, the IFP method requires much more memory because it stores energy-dependent reaction rate tallies for every particle for the number of latent generations.

The only assumption made by the CLUTCH method (besides the standard CE Monte Carlo assumptions) is that $F^*(r)$ provides an accurate estimate of the average importance of fission neutrons at r. The current approach for calculating $F^*(r)$ takes advantage of the definition of the unconstrained fission spectrum sensitivity coefficient, which is given by

$$S_{k,\chi}(r) = \frac{1}{D} \frac{1}{k} \int_0^\infty \int_{4\pi} \bar{\nu} \Sigma_f(r, E) \phi(r, E, \Omega) d\Omega dE \int_0^\infty \int_{4\pi} \frac{\chi(r, E')}{4\pi} \phi^*(r, E', \Omega')\, d\Omega' dE' \tag{6.2.7}$$

where D is the adjoint-weighted fission source for the system. The right-most integral of Eq. (6.2.7) is recognized as the definition of $F^*(r)$ in Eq. (6.2.6) and the terms in Eq. (6.2.7) can be rearranged to define $F^*(r)$ as

$$F^*(r) = \frac{D \times S_{k,\chi}(r)}{\int_0^\infty \int_{4\pi} \frac{\overline{\upsilon}\Sigma_f(r,E)\phi(r,E,\Omega)}{k} d\Omega dE} \tag{6.2.8}$$

This approach assumes that the energy spectrum of neutrons emitted from a fission event is not strongly dependent on the parent isotope or the energy of the neutron causing the fission. The current CLUTCH implementation tallies the unconstrained chi sensitivity in the numerator of Eq. (6.2.8) during the inactive generations to estimate $F^*(r)$ for the active generation sensitivity coefficient calculations. The spatial dependence of $F^*(r)$ is currently accounted for by calculating and storing $F^*(r)$ on a spatial mesh, although kernel density estimators might be used in the future to store $F^*(r)$ using spatially continuous functional representations. [3d4] Because $F^*(r)$ is only nonzero for regions containing fissionable material, the $F^*(r)$ mesh used in a CE TSUNAMI calculation must only encompass all fissionable material in the system, rather than the entire system as required by MG TSUNAMI. The D term in Eq. (6.2.8) can be ignored because it is constant for all regions in a problem and is cancelled out by the presence of $F^*(r)$ terms in both the numerator and denominator of the first-order perturbation equation. The denominator in Eq. (6.2.8) is simply the total weight of fission neutrons born in each $F^*(r)$ mesh region, which must also be tallied during the inactive generations.

Because $F^*(r)$ describes the contribution to the chi sensitivity that is created per fission neutron born at a point, a converged fission source is not required to begin $F^*(r)$ calculations; thus, $F^*(r)$ tallies begin during the inactive generations of Monte Carlo simulations to obtain useful information from the typically discarded inactive particle histories. The fission source must converge well enough during the inactive generations so that $F^*(r)$ is tallied in all fissile regions to a desired statistical uncertainty, and it is sometimes necessary to simulate extra inactive generations to allow $F^*(r)$ tallies to fully converge; however, the ability to begin $F^*(r)$ tallies before the fission source is converged essentially provides "free" tallies while the fission source is converging.

Although several approaches exist for calculating the unconstrained chi sensitivity coefficients needed to calculate $F^*(r)$, an IFP-based approach has been determined to be the best approach. [3d3] Although the IFP method can produce large memory footprints for full sensitivity coefficient calculations, the amount of memory required by the method to calculate unconstrained chi sensitivity coefficients and $F^*(r)$ is generally negligible. The spatial dependence of $F^*(r)$ is currently described using a spatial mesh, and an interval of 1 to 2 cm mesh is typically sufficiently refined to obtain accurate $F^*(r)$ estimates. Users should simulate at least on the order of 50 to 100 inactive histories per mesh interval to allow for sufficient $F^*(r)$ convergence; sometimes this necessitates simulating a large number of additional inactive histories/generations.

6.2.3.2 CE TSUNAMI Generalized Perturbation Theory capability

The CLUTCH and IFP methods were combined in 2013 by Perfetti to enable sensitivity calculations for generalized neutronic response ratios. [3d5] This Generalized Perturbation Theory (GPT) capability is known as the GEneralized Adjoint Responses in Monte Carlo (GEAR-MC) method. Applications for GPT sensitivity coefficients differ from the traditional criticality safety applications of TSUNAMI, and may include S/U analyses for multigroup cross sections that are produced by a continuous-energy Monte Carlo code, the relative power of pins in a LWR, or ratios of foil activities in an irradiation experiment.

Two approaches for performing the GEAR-MC method have been included in this release as demonstration capabilities. One implementation relies heavily on the IFP method for sensitivity calculations and is therefore subject to the long runtimes and large memory footprint that may be encountered when using the IFP method.

The other implementation does not use the IFP method when calculating sensitivities. Instead, it uses only the CLUTCH method with an $F^*(r)$ mesh that has been modified for performing generalized response sensitivity calculations. Because it does not use the IFP method except for calculating the $F^*(r)$ function, this approach typically produces a significantly lower memory footprint than the first GEAR-MC implementation and can be performed in a parallel environment. [3d6] Both approaches are experimental capabilities and have been included in this release to demonstrate the expanding SCALE S/U capabilities. For the CLUTCH-only GPT, the current format for inputting response information allows for the sensitivity calculations for a single response in each sensitivity calculation. For GPT via CLUTCH and IFP, multiple responses may be defined.

Rather than calculating eigenvalue sensitivities, the GEAR-MC method calculates the sensitivity of a response, R, to perturbations or uncertainties in the system parameters. The generalized response sensitivity coefficient for the system parameter Σ_x is defined as

$$S_{R,\Sigma_x} = \frac{\delta R/R}{\delta\Sigma_x/\Sigma_x} \tag{6.2.9}$$

The GEAR-MC method calculates sensitivities of responses that are defined as ratios of neutron reaction rates integrated over some region of phase space such that

$$R = \frac{\langle\Sigma_1\phi\rangle}{\langle\Sigma_2\phi\rangle} \tag{6.2.10}$$

where Σ_1 and Σ_2 are nuclear cross sections. The reaction rates in Eq. (6.2.10) can be isotope- or material-dependent reaction rates and can also represent neutron flux responses if $\Sigma = 1$. The fractional change in R due to a perturbation $\delta\Sigma_x$ to the system parameter Σ_x is given by

$$\frac{\delta R}{R} = \left\langle \frac{1}{R}\frac{\partial R}{\partial\Sigma_x}\delta\Sigma_x + \frac{1}{R}\frac{\partial R}{\partial\phi}\frac{\partial\phi}{\partial\Sigma_x}\delta\Sigma_x \right\rangle \tag{6.2.11}$$

The first term in Eq. (6.2.11) is known as the "direct effect term" and describes how perturbations in Σ_x affect the response function of the response reaction rates. The second term, known as the "indirect effect term," describes how perturbations affect the neutron flux spectrum in the response region. [3d7] Calculating the sensitivity of the response to the direct effect term is relatively simple and involves tallying the fraction of the total numerator and denominator responses that is generated for each energy, region, isotope, and material in the response region(s). For example, consider a response that is defined as the ratio of the energy-integrated fission rate to the energy-integrated capture rate in a uranium fuel pin. The direct effect sensitivity of this response to the thermal fission cross section is simply the fraction of the fission reaction rate in the pin that is caused by neutrons with thermal energies.

The indirect effect term in Eq. (6.2.11) cannot be calculated as simply as the direct effect term and has historically posed a greater challenge. The GEAR-MC method offers an approach for calculating the indirect effect term during a single, unperturbed Monte Carlo transport calculation. The neutron balance equation for an eigenvalue problem is given by

$$L\phi \; - \; \lambda P\phi = 0 \tag{6.2.12}$$

where L is the neutron loss operator and P is the fission neutron production operator. The change induced in the neutron balance equation in response to a first-order perturbation is given by

$$(L - \lambda P)\,\delta\phi = \; \delta\lambda P\phi + (\lambda\delta P - \delta L)\phi \tag{6.2.13}$$

Consider now the generalized adjoint balance equation

$$(L^* - \lambda P^*)\Gamma^* = S^* \tag{6.2.14}$$

where L^* is the adjoint loss operator, P^* is the adjoint fission neutron production operator, S^* is a source of importance for the response that is defined such that $\langle \phi S^* \rangle = 0$, and Γ^* is the generalized importance function that provides the solution to this equation.[7] Multiplying Eq. (6.2.13) and Eq. (6.2.14) by Γ^* and $\delta\phi$, respectively, and taking the inner product gives, respectively,

$$\langle \Gamma^*(L - \lambda P)\delta\phi \rangle = \delta\lambda \langle \Gamma^* P\phi \rangle + \langle \Gamma^*(\lambda\delta P - \delta L)\phi \rangle \tag{6.2.15}$$

and

$$\langle \delta\phi \, (L^* - \lambda P^*) \, \Gamma^* \rangle = \langle \delta\phi S^* \rangle \tag{6.2.16}$$

The source of adjoint importance in Eq. (6.2.16) is defined to conveniently provide an expression for the indirect effect term. Defining S^* as

$$S^* \equiv \frac{1}{R}\frac{\delta R}{\delta \phi} = \frac{\Sigma_1}{\langle \Sigma_1 \phi \rangle} - \frac{\Sigma_2}{\langle \Sigma_2 \phi \rangle} \tag{6.2.17}$$

and applying the adjoint property allows Eq. (6.2.15) and Eq. (6.2.17) to be combined to express the indirect effect term as

$$\left\langle \frac{1}{R}\frac{\delta R}{\delta \phi}\delta\phi \right\rangle = \langle \delta\lambda \Gamma^* P\phi \rangle + \langle \Gamma^*(\lambda\delta P - \delta L)\phi \rangle \tag{6.2.18}$$

Eq. (6.2.18) is usually equal to zero because Γ^* is typically orthogonal to $P\phi$. The effect of this orthogonality can be interpreted in a more physical manner by realizing that perturbations to the eigenvalue of a system do not alter the steady-state neutron flux shape or spectrum of the system. As a result, perturbations affect the response numerator and denominator terms equally.

The GEAR-MC methodology uses Eq. (6.2.14) and Eq. (6.2.18) to calculate the generalized importance function Γ^* for neutrons during a single forward Monte Carlo simulation, thus enabling the calculation of the indirect effect term in Eq. (6.2.11). and thus sensitivity coefficients for generalized responses using GPT. The approach developed for calculating Γ^* is similar to the approach used by the CLUTCH method for calculating eigenvalue sensitivity coefficients.

Assuming that the fission production term, $\lambda P\phi$, in Eq. (6.2.12) is the sole source of neutron production in a system, Q, multiplying Eq. (6.2.12) and Eq. (6.2.14) by Γ^* and ϕ, respectively, and integrating over all phase space gives

$$\langle \Gamma^* L\phi \rangle = \langle \Gamma^* Q \rangle \tag{6.2.19}$$

and

$$\langle \phi L^* \Gamma^* \rangle = \lambda \langle \phi P^* \Gamma^* \rangle + \langle \phi S^* \rangle \tag{6.2.20}$$

Nonfission neutron production reactions, such as (*n,Xn*) reactions, are included in the L^* adjoint loss term in Eq. (6.2.20). Combining Eq. (6.2.19) and Eq. (6.2.20). and using the adjoint property gives

$$\langle \Gamma^* Q \rangle = \lambda \langle \Gamma^* P\phi \rangle + \langle \phi S^* \rangle \tag{6.2.21}$$

The terms in Eq. (6.2.21) are all equal to zero in inner product space, but it can be used to extract information about the importance of events by considering the neutron source to be a single neutron traveling through the phase space τ_s, such as a neutron entering or leaving a collision at some point. This concept is used similarly in Williams' Contributon theory for calculating eigenvalue sensitivity coefficients and assumes that

$$Q = Q_s \delta(\tau - \tau_s) \tag{6.2.22}$$

where Q_s is the source strength for this neutron. [3d8], [3d9] Substituting Eq. (6.2.22) into Eq. (6.2.21) produces an expression for the generalized importance function at τ_s:

$$\begin{aligned} \Gamma^*(\tau_s) &= \frac{1}{Q_S} \langle S^*(r)\phi(\tau_s \to r)\rangle + \frac{\lambda}{Q_s} \langle \Gamma^*(r) P\phi(\tau_s \to r)\rangle \\ &= \frac{1}{Q_s} \left\langle \frac{1}{R}\frac{\delta R}{\delta \phi}(r)\phi(\tau_s \to r)\right\rangle + \frac{\lambda}{Q_s} \langle \Gamma^*(r) P\phi(\tau_s \to r)\rangle \end{aligned} \tag{6.2.23}$$

where $\phi(\tau_s \to r)$ is the neutron flux created at r by the neutron originating at τ_s. The two terms on the right-hand side of Eq. (6.2.21) and Eq. (6.2.23) represent the intragenerational and intergenerational effects of an event on the importance of a particle, respectively. The intragenerational effect term describes how much importance the neutron in phase space τ_s generates in the response region(s) during its lifetime; the intergenerational effect term describes how many fission neutrons this neutron creates and how much importance these fission neutrons will generate in future generations. The intragenerational term can be determined by tallying the amount of flux generated in the response region(s) and weighted by $S^*(r)$ from Eq. (6.2.17) from the time the particle enters phase space τ_s until its death. Thus the intragenerational term is given by

$$\langle S^*(r)\phi(\tau_s \to r)\rangle = \frac{\Sigma_1 \phi(\tau_s \to r)}{\langle \Sigma_1 \phi\rangle} - \frac{\Sigma_2 \phi(\tau_s \to r)}{\langle \Sigma_2 \phi\rangle} \tag{6.2.24}$$

The approach for calculating the intragenerational importance term in Eq. (6.2.24) is similar to the approach used by the CLUTCH method during eigenvalue sensitivity coefficient calculations and requires storing tracklength information for each collision that a particle enters and determining the importance of that collision after the particle dies. The presence of both positive and negative terms in Eq. (6.2.24) allows a single event to generate either a positive or negative importance. The intergenerational contribution to the importance function can be calculated by tallying the cumulative score of $S^*(r)\,\phi(\tau_s \to r)$ that is generated by the particle's daughter fission neutrons, or "progeny," over some number of generations. The GEAR-MC method estimates the intergenerational importance by summing the intragenerational importance, Γ_i^*, generated by the fission production, F_i, of neutrons in the ith generation of a fission chain over some number of generations:

$$\lambda \langle \Gamma^*(r) P\phi(\tau_s \to r)\rangle = \Gamma_1^* F_1 + \Gamma_2^* F_2 + \Gamma_3^* F_3 + \ldots + 0 \tag{6.2.25}$$

This approach is used similarly by the IFP approach for calculating the importance of events during eigenvalue sensitivity calculations, except that the IFP method tallies the importance only one time after the daughter neutrons have established an asymptotic population in the system. The $\delta\lambda$ term in Eq. (6.2.18). demands that the $\langle \Gamma^* P\phi\rangle$ term be equal to zero, which causes the $\Gamma_i^* F_i$ terms in Eq. (6.2.25) to approach zero as i approaches infinity; therefore, the intergenerational importance term is obtained by taking the sum of the $\Gamma_i^* F_i$ terms as they asymptotically approach zero.

6.2.3.3 CE TSUNAMI sequence description

The code flow of CE calculations with TSUNAMI is significantly simpler than the flow of MG TSUNAMI because CE Monte Carlo does not require resonance self-shielding of MG cross sections or the calculation of implicit sensitivity coefficients and calculates sensitivity coefficients during a single forward calculation. The CE control sequences available in TSUNAMI are summarized in Table 6.2.2, where the functional modules executed are also shown. A general flow diagram of a CE calculation with TSUNAMI is shown in Fig. 6.2.3.

Table 6.2.2: CE TSUNAMI-3D control sequences.

Control sequence	Functional modules executed by the control module	
TSUNAMI-3D-K5	KENO V.a	SAMS5
TSUNAMI-3D-K5-SHIFT	Shift	SAMS5
TSUNAMI-3D-K6	KENO-VI	SAMS6
TSUNAMI-3D-K6-SHIFT	Shift	SAMS6

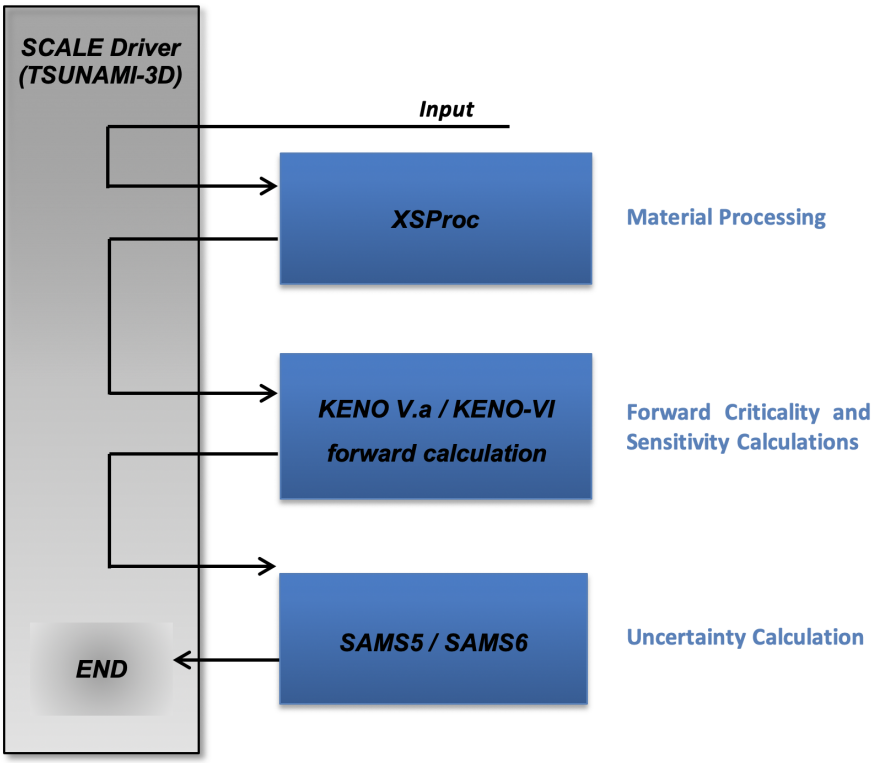

Fig. 6.2.3: General flow diagram of CE TSUNAMI-3D.

Eigenvalue sensitivity coefficients are calculated during the KENO or Shift Monte Carlo transport calculation, and the energy-dependent sensitivity coefficients are summarized in a sensitivity data file (sdf). The SAMS module then uses the *.sdf* file produced and cross section covariance data to complete the eigenvalue uncertainty analysis for the problem and estimate the data-induced eigenvalue uncertainty.

6.2.4 TSUNAMI-3D INPUT DESCRIPTION

The input for TSUNAMI-3D is designed to be very compatible with those used for the CSAS criticality safety analysis sequences. Given a CSAS input, MG TSUNAMI-3D calculations only require several input modifications to obtain adequate flux solutions, and CE TSUNAMI calculations require as little as one additional parameter. Additional optional input may be added to control the sensitivity calculations.

The input to TSUNAMI-3D consists of an input title, SCALE analytical sequence specification record, SCALE XSProc data, KENO V.a or KENO-VI input descriptions with some additional optional parameter data, and optional sensitivity and uncertainty data. These data are processed using the SCALE free-form reading routines, which allow alphanumeric data, floating-point data, and integer data to be entered in an unstructured manner. The input is not case sensitive, so either upper- or lowercase letters may be used. A maximum of 252 columns per line may be used for input, although some exceptions for this rule exist, such as the 80 character title data. Data can usually start or end in any column with a few exceptions. As an example, the word END beginning in column 1 and followed by two blank spaces will end the problem, any data following will be ignored. Each data entry must be followed by one or more blanks to terminate the data entry. For numeric data, either a comma or a blank can be used to terminate each data entry. Integers may be entered for floating values. For example, 10 will be interpreted as 10.0. Imbedded blanks are not allowed within a data entry unless an E precedes a single blank as in an unsigned exponent in a floating-point number. For example, 1.0E 4 would be correctly interpreted as 1.0×10^4.

6.2.4.1 Analytical sequence specification record

The analytical sequence specification begins in column 1 of the first line of the input file and must contain the following:

=TSUNAMI-3D-K5

This sequence is used for sensitivity and uncertainty calculations with KENO V.a.

=TSUNAMI-3D-K6

This sequence is used for sensitivity and uncertainty calculations with KENO-VI.

Either analytical sequence specification may have `-shift` appended in order to use the Shift Monte Carlo transport code. (Namely, `tsunami-3d-k5-shift` or `tsunami-3d-k6-shift`.)

Optional keyword input may be entered after the analytical sequence specification record. These keywords are

PARM=CHECK PARM=CHK	This option allows the input data to be read and checked without executing any functional modules.

Note: The following PARM settings only apply to MG calculations and are ignored for CE calculations:

`PARM=SIZE=n`

The amount of memory requested in four-byte words may be set with this entry. The default value for n is 20000000. This value only affects calculations in BONAMIST, where this value of the SIZE parameter is used for allocation of storage for the derivatives. Please see the documentation on BONAMIST in the Sensitivity Utility Modules chapter for more details. All other codes use dynamic memory allocation and this value has no effect.

PARM=BONAMIST

This is the default configuration for MG TSUNAMI-3D calculations. XSProc is used with BONAMI and CENTRM for cross section processing. Implicit sensitivities are produced with BONAMIST.

PARM=CENTRM

XSProc is used with BONAMI and CENTRM for cross section processing, but BONAMIST is not run. **MG TSUNAMI-3D calculations with PARM=CENTRM do not account for contributions by implicit sensitivity effects, and should be used with caution.**

PARM=BONAMI

XSProc is used with BONAMI for cross section processing, but BONAMIST is not run. **MG TSUNAMI-3D calculations with PARM=BONAMI do not account for contributions by implicit sensitivity effects, and should be used with caution.**

PARM=2REGION

XSProc (with BONAMI and CENTRM) use Dancoff factors to compute neutron escape probabilities for an accelerated, yet more approximate, CENTRM calculation. Implicit sensitivities are computed with BONAMIST.

Multiple parameters can be used simultaneously by enclosing them in parentheses and separating them with commas such as PARM=(SIZE=2000000, CHECK).

6.2.4.2 Title data

A *title*, a character string, must be entered as the second line of the input file. The syntax for the title is a string of characters with a length of up to 80 characters, including blanks.

6.2.4.3 XSProc Execution

XSProc reads the standard composition specification data for MG and CE and the unit cell geometry specifications for MG resonance self-shielding calculations. CE TSUNAMI calculations do not require the specification of unit cells. Please see chapters on the Material Information Processor for input specifications. The cross section data library that is to be used by TSUNAMI must also be entered as the third line of the TSUNAMI input; a list of the currently available libraries are listed in the table *Standard SCALE cross section libraries* of the XSLIB chapter.

6.2.4.4 KENO V.A or KENO-VI problem description

The KENO V.a or KENO-VI problem description follows the Material Input Processor section in the TSUNAMI-3D input. The input for KENO V.a and KENO-VI in TSUNAMI-3D is very similar to that described in section *KENO V.a Data Guide* in chapter KENO V.a or section *KENO-VI Data Guide* in the KENO-VI chapter, with only a few differences in the default values for the parameter data and a few additional parameters to control the adjoint criticality calculation. Otherwise, geometry, array, biasing, boundary, start, and plot data are entered exactly as described for KENO. Default parameter values for MG TSUNAMI-3D that are different from those used for other MG KENO calculations are shown in Table 6.2.3. Parameters that are unique to TSUNAMI-3D and are used to control to the MG adjoint calculation are shown in Table 6.2.4. These adjoint parameters are optional and can be entered with other parameters in the standard *READ PARAMETER* input block in KENO problem description. Parameters that are unique to CE TSUNAMI-3D are shown in Table 6.2.5; these parameters can also be entered in the KENO *READ PARAMETER* input block.

Several features were added to KENO V.a and KENO-VI to allow the calculation of sensitivity coefficients from the MG Monte Carlo analysis. One significant addition is the calculation of neutron flux moments and/or angular fluxes, both of which give directional components to the neutron flux solution required to compute

the sensitivity of k_{eff} to scattering cross sections. Another significant addition is the ability to compute fluxes that are subdivided over a cubic mesh or Cartesian spatial grid. These mesh fluxes simplify the accurate computation of the product of the forward and adjoint flux solutions, sometimes called the "inner product." Both of the flux moments and the spatial flux mesh options must be correctly applied to obtain accurate sensitivity coefficients. Generally, the refinement of the flux mesh to sufficiently small intervals to capture relevant spatial effects while maintaining a manageable memory footprint is the most challenging aspect of performing MG calculations with TSUNAMI-3D.

Important: It is important to note that TSUNAMI-3D provides no default mesh for these flux tallies, and the user must input a mesh using either the MSH parameter or a GridGeometry input to access this feature.

New input data that aid in the accurate calculation of sensitivity coefficients are the parameter inputs: NQD, PNM, MFX, MSH, TFM, APG, AGN, ABK, ASG, CET, CFP, CGD, FST, NNC, NMA, NMT, DNC, DMA, DMT, NMX, NMN, DMX, and DMN. Thus, these parameters may require modification when using TSUNAMI-3D. The *READ GRID* block of KENO input is used with MSH to input the planar grid for MG TSUNAMI-3D calculations and also to input the spatial grid for the calculation and storage of $F^*(r)$ for CE TSUNAMI calculations. Also, if using the coordinate transform for angular flux or flux moment calculations, use of the optional *CENTER* modifier in the KENO geometry input may be required. Users should note that when using the *xlinear*, *ylinear*, or *zlinear* options in the *READ GRID* block that KENO checks to determine whether the boundaries of each grid coincide with the global unit boundaries. If any planes in the grid boundaries are identical to the planes used in the global boundary, then KENO will extend the outermost plane in that grid by a distance equal to one-tenth of the grid mesh interval to ensure that the grid mesh covers the entire geometry.

Some KENO parameters (e.g., SCD, MFX, CDS, GFX, and CGD) may be used to assign user provided grid definitions for use with specific tallies. These are described in Sect. 8.1.3.3 of the SCALE KENO chapter. Grid IDs in the READ GRID blocks should be limited to no more than 4 integer characters (i.e., $1 \leq \text{ID} \leq 9999$).

Table 6.2.3: Default values KENO parameters in MG TSUNAMI-3D

Parameter	**Default value for TSUNAMI-3D**	**Default value for KENO in CSAS Sequences or as stand-alone code**	**Description**
CFX	YES	NO	Collect fluxes
GEN	550	203	Number of generations to be run
NSK	50	3	Number of generations to be omitted when collecting results
PNM	3	0	Highest order of flux moments tallies
TFM	YES	NO	Perform coordinate transform for flux moment and angular flux calculations

Table 6.2.4: Default values of TSUN
MG adjoint calculation.

Parameter	Default value for TSUNAMI-3D	Corresponding KENO parameter	Description
ABK	APG × 2	NBK	Number of positions in the neutr
AGN	GEN - NSK + ASK	GEN	Number of generations to be run
APG	NPG × 3	NPG	Number of particles per generati
ASG	SIG (default SIG=0)	SIG	if > 0.0, this is the standard devi
ASK	NSK × 3	NSK	Number of generations to be om

MG TSUNAMI sensitivity coefficient estimates can be very sensitive to the values of a problem's input parameters, and users should always check the accuracy of their sensitivity coefficients by comparing them with reference direct perturbation sensitivities, discussed in Sect. 6.2.5.1. The default values for parameters in Table 6.2.3 and Table 6.2.4 generally serve as good starting values for a MG TSUNAMI calculation, but users may need to use a higher order of flux moments to better capture the angular dependence of the flux (typically PNM=5 is sufficient), and may need to simulate more histories/generations to reduce the uncertainty in sensitivity coefficient estimates. The dimensions of the flux mesh are another important MG TSUNAMI parameter, and a reasonable starting guess for the width of the flux mesh intervals is $1/10^{\text{th}}$ of the diameter of the fuel-containing region. Users should take care when increasing the order of the flux moment tallies and the number of intervals in the spatial flux mesh as the memory footprint of a MG TSUNAMI calculation increases quickly as these parameters increase.

CE TSUNAMI calculations are in many respects simpler than MG TSUNAMI calculations because they use state-of-the-art sensitivity methodologies that typically require less user input to perform sensitivity calculations. CE TSUNAMI calculations do not use any of the input parameters in Table 6.2.3 or Table 6.2.4 and do not require flux moment tallies, flux mesh tallies (except for calculating $F^*(r)$), or the simulation of adjoint histories. CET, CFP, and CDG are the three parameters that control CE TSUNAMI eigenvalue sensitivity calculations. CET specifies which CE sensitivity method (either CLUTCH, IFP, or GEAR-MC) will be used in the CE TSUNAMI calculation. CFP specifies how many latent generations will be used by the IFP method for either calculating sensitivity coefficients (CET=2/5) or for calculating $F^*(r)$ during the inactive generations (CET=1/4); if CET=1 or 4 and CFP= -1, then CE TSUNAMI will perform a CLUTCH calculation assuming that $F^*(r)$ is equal to one everywhere for CET=1 and zero everywhere for CET=4. The number of latent generations (CFP) and the number of generations skipped for fission source convergence (NSK) control very different things.

The typical workflow for generating an IFP-based CE TSUNAMI k_{eff} sensitivity input is given below:

1) Set CET=2.
2) Set your number of latent generations using CFP=# (usually between 5 and 10).

The typical workflow for generating a CLUTCH-based CE TSUNAMI k_{eff} sensitivity input is given below:

1) Set CET=1.
2) Set your number of latent generations using CFP=# (usually between 5 and 10).
3) Specify a mesh size for the $F^*(r)$ mesh with CGD=yes and MSH=<value>; the width of the mesh voxels is usually between 1 and 2 cm in the X-, Y-, and Z-dimensions. Ensure that the mesh covers all fisionable regions of the problem. If the user desires to construct a specific $F^*(r)$ mesh, specify a GridGeometry with CGD=# the ID of the GridGeometry intended.

4) Consider simulating extra inactive generations to allow the $F^*(r)$ mesh to converge — most $F^*(r)$ mesh calculations require between 10 and 100 inactive histories per mesh voxel to sufficiently converge.

   Ex: A problem using a 2×30×40 $F^*(r)$ mesh contains 24,000 voxels. Assuming at least 10 inactive histories per mesh interval means this problem will require 240,000 inactive histories for the $F^*(r)$ mesh to converge. If the problem uses 1,000 particles per generation (NPG=1000), then the user should use at least 240 skipped generations (NSK=240) to allow $F^*(r)$ mesh tallies to converge.

When performing CLUTCH calculations using $F^*(r)$ (i.e., when CET=1 or 4 and CFP is not -1) a spatial grid for $F^*(r)$ is needed. CGD=yes may be used with a specification of uniform mesh size with MSH=<value>, or CGD=# to specify the ID of this a GridGeometry $F^*(r)$ grid. Failure to specify a grid results in an error message. The entries in the $F^*(r)$ grid can be printed to a 3dmap file by setting the parameter FST=YES, which is the default. This information is printed to a file with the same name as the input but with a _FStar_map.3dmap extension (i.e., *problem.inp* prints information to *problem_FStar_map.3dmap*). This .3dmap file can be viewed using the Fulcrum interface, as shown for a CLUTCH k_{eff} sensitivity test problem in Fig. 6.2.4. Values for $F^*(r)$ are set by default to one/zero in CLUTCH k_{eff}/GPT sensitivity calculations, respectively, for regions that do not contain fissionable material and/or did not generate any $F^*(r)$ tallies. When doing GPT sensitivity calculations using $F^*(r)$ CE TSUNAMI will produce two $F^*(r)$ meshes: one for the numerator term in the response of interest and another for the denominator term; therefore, 3dmaps that are produced from CE TSUNAMI GPT $F^*(r)$ calculations will contain two meshes, as shown in Fig. 6.2.5.

Table 6.2.5: CE TSUNAMI-3D parameters and default values.

Parameter	**Default value for TSUNAMI-3D**	**Description**
CET	1	Mode for CE TSUNAMI 0 = No sensitivity calculations 1 = CLUTCH sensitivity calculation 2 = IFP sensitivity calculation 4 = GEAR-MC calculation (with CLUTCH only) 5 = GEAR-MC calculation (with CLUTCH+IFP) 7 = Undersampling metric calculation
CFP	5	Number of latent generations used for IFP sensitivity or $F^*(r)$ calculations. If CET=1 and CFP= -1 then $F^*(r)$ is assumed to equal one everywhere. If CET=4 and CFP= -1 then $F^*(r)$ is assumed to equal zero everywhere.
CGD	NONE	ID of the gridgeom mesh used for CLUTCH $F^*(r)$ calculations.
FST	YES (when calculated)	Print the $F^*(r)$ grid values to a .3dmap file.

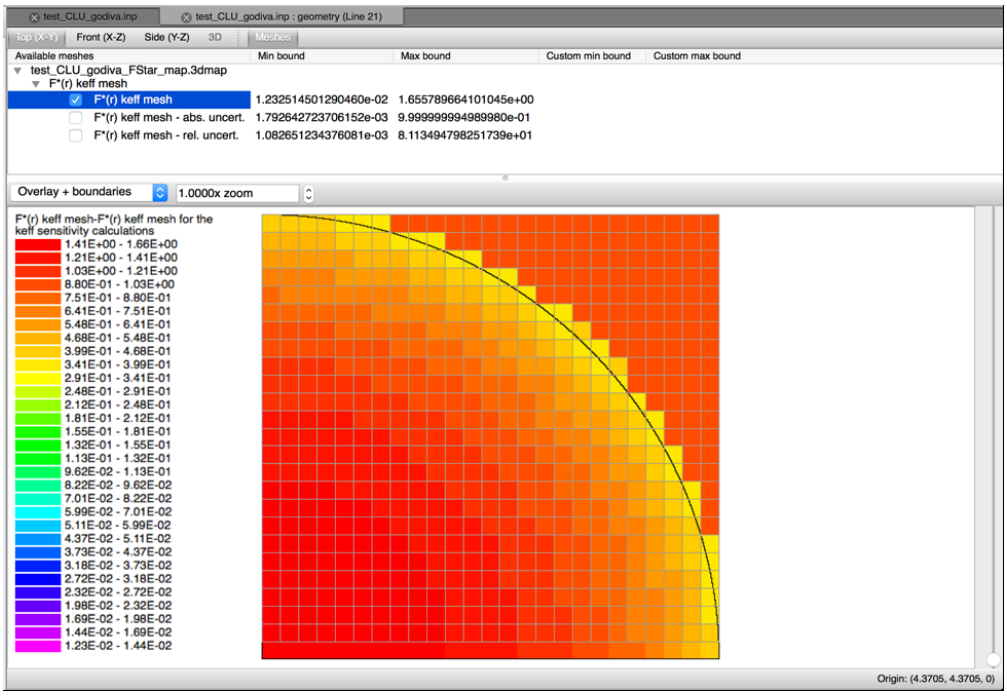

Fig. 6.2.4: $F^*(r)$ mesh from a sample CLUTCH eigenvalue sensitivity calculation.

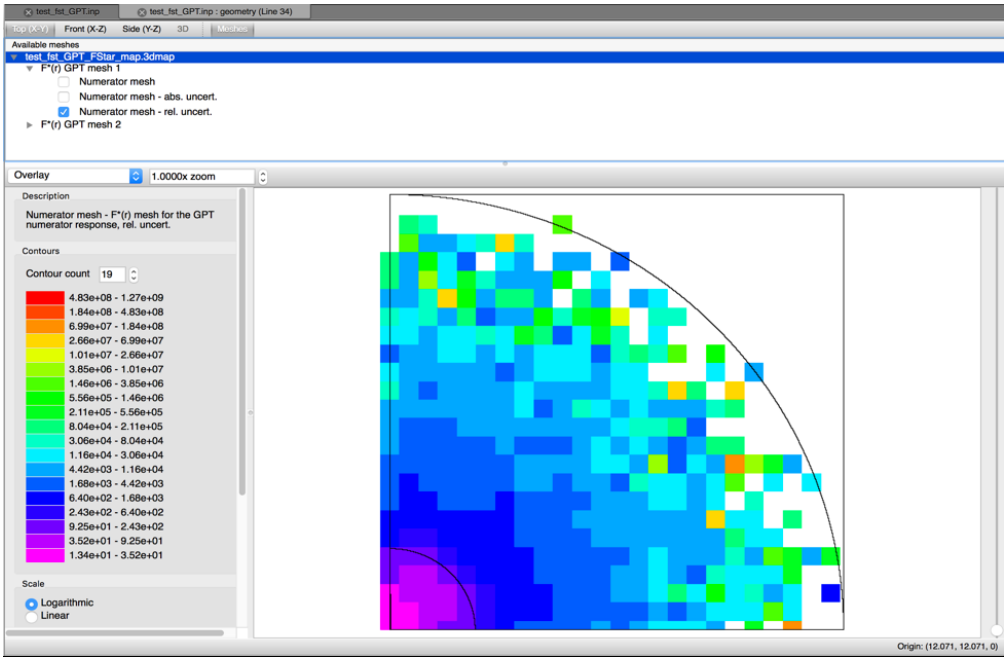

Fig. 6.2.5: $F^*(r)$ meshes from a sample CLUTCH GPT sensitivity calculation.

Setting CET=7 will activate an experimental capability for detecting computational biases due to the undersampling of fission sites and particle histories during a Monte Carlo simulation. This capability does not calculate sensitivity coefficients and does not require selecting a number of latent generations or building an F^* (r) mesh. Instead, this approach scores flux and reaction rate tallies for various materials and nuclides in a

system and reports the tallies to a *.sdf* file after the simulation ends, along with scores for various statistical metrics that may predict undersampling biases in the reported tallies. An undersampling metric calculation will produce four *.sdf* files, as described below:

*input_name*_metric1.sdf = Reaction rate and flux tallies
*input_name*_metric2.sdf = Number of nonzero scores per generation for each tally
*input_name*_metric3.sdf = Tally Entropy scores for each tally
*input_name*_metric4.sdf = Heidelberger-Welch RHW scores for each tally

Each of these undersampling metrics is described in detail in Reference [3d10]. The values reported in the _metric2/3/4.sdf files correspond to each of the tallies scored in the _metric1.sdf file. As in typical sensitivity coefficient *.sdf* files, the undersampling metric *.sdfs* report energy-dependent and energy-integrated information for various reaction rates in every material and nuclide in a system; however, the undersampling metric calculations also report information for flux tallies within each material/nuclide under the name of the fictitious isotope H-111. This undersampling metric capability is only peripherally related to the scope and application of sensitivity coefficient calculations and was included with CE TSUNAMI-3D predominantly to take advantage of the established TSUNAMI tally scoring framework and sensitivity visualization/postprocessing tools (i.e., Fulcrum).

Performing GPT sensitivity calculations with CE TSUNAMI requires the user to enter some additional input to specify the GPT response being examined in the calculation. For the IFP+CLUTCH GPT implementation (CET=5) users can define GPT reaction rate ratios using the "Definitions" and "SystemResponses" blocks (please see *Sensitivity and uncertainty calculation data* in the TSUNAMI-1D chapter), which are used similarly in TSUNAMI-1D. Both TSUNAMI-3D GPT capabilities can currently only accept total cross section (MT=1), fission (MT=18), n,gamma (MT=102), nu-fission (MT=452), or flux reaction response definitions. The CLUTCH-only GPT implementation (CET=4) currently cannot accept GPT response input from the Definitions and SystemResponses blocks, and may only calculate GPT sensitivity coefficients for one response per TSUNAMI-3D simulation. The input parameters for defining the GPT response in these (CET=4) calculations are described in Table 6.2.6. The two GEAR-MC implementations (CET=4 or CET=5) both require the user to specify a value for CFP; the CLUTCH-only GEAR-MC implementation requires the user to specify an $F^*(r)$ mesh using the gridGeom block and the CGD parameter.

Table 6.2.6: CE TSUNAMI-3D GPT sensitivity parameters and default values.

GEOMETRY (region)

Format: READ GEOM enter geometry region data here END GEOM

**Enter CHORD for *fgeom*.

***Center data are only applicable when flux moments (PNM>0) or angular fluxes (NQD>0) are requested with the coordinate transform (TFM) set to YES.

NOTE: Chord data are not applicable for SPHERE, XCYLINDER, YCYLINDER, CYLINDER, ZCYLINDER, CUBE, or CUBOID.
Origin data are not applicable for a CUBE or CUBOID.

6.2.4.5 Sensitivity calculation data

A data block for controlling the sensitivity calculation is optional. If included, this data block begins with the keywords *READ SAMS* and ends with the keywords *END SAMS*. Any of the optional SAMS input data may be entered in free-form format between the *READ SAMS* and *END SAMS* keywords. The optional SAMS input data are shown with the default values specific to TSUNAMI-3D in Table 6.2.7. Certain options in Table 6.2.8 are not available for CE calculations. Parameters used to specify default covariance data to supplement or correct values on the files specified by *coverx*= are shown in Table 6.2.8. A more detailed explanation of the SAMS parameters is provided in the SAMS chapter.

Table 6.2.7: SAMS input keywords.

Keyword	**Default value**	**Description**
binsen	F	Produces SENPRO formatted binary sensitivity data file on unit 40
coverx=	56group-cov7.1	Name of covariance data file to use for uncertainty analysis
largeimp=	100.0	Value for the absolute value of implicit sensitivities, which if exceeded, will be reset to 0.0 and print a warning message.
makeimp*	F	Flag to cause implicit sensitivity coefficients to be generated.
nocovar	T	Flag to cause uncertainty edit to be turned off (sets print_covar to F)
nohtml	F	Flag to cause HTML output to not be produced.
nomix	F	Flag to cause the sensitivities by mixture to be turned off
pn=*	3	Legendre order for moment calculations
prtgeom*	F	Flag to cause the sensitivities to be output for each geometry region
prtimp*	F	Prints explicit sensitivities coefficients, implicit sensitivity coefficients and complete sensitivity coefficients
prtvols*	F	Flag to cause the volumes of the regions to be printed by SAMS
useang*	F	Flag to cause the angular flux calculated in KENO to be used to calculate flux moments for sensitivity calculations. If angular fluxes were not computed by KENO, *useang* is set to false internally.
usemom*	T	Flag to cause the flux moments calculated with KENO to be used to in sensitivity coefficient generation. If flux moments were not computed by KENO, *usemom* is set to false internally.
unconstrainedchi	F	Flag to generate pre-SCALE 6 unconstrained chi (fission spectrum) sensitivities
sensitivity_format=	txt	Specifies desired format for the resulting sensitivity data file (SDF). May be 'txt' for text-based format or 'hdf5' for HDF5-based format.
***MG only**		

Table 6.2.8: SAMS input keywords for default covariance data.

MIXTURES	Format: READ MIXT xsec parameters mixing table data. END MIXT Multigroup mode: These data are entered only if an AMPX working format library is being used. (LIB=) in the parameter data, s ee section on Title and parameter data. Do not enter if a Monte Carlo mixed library is used, (XSC=) in the parameter data. Continuous energy mode: Only the mixing table data are entered. See sections on Mixing table and Mixing table data.			
	XSEC PARAMETERS	consists of keywords and associated values. These parameters, if entered, only need to be entered once.		
		KEYWORD	DEFAULT	DEFINITION
		SCT=	1	number of discrete scattering angles 0 is isotropic 1 is P1 2 is P3 3 is P5
		EPS=	0.1	cross section message cutoff value used to suppress message numbers K5-060 and K6-060.
	MIXING TABLE DATA consists of	(1) a keyword and mixture ID for the mixture The keyword is MIX= The desired mixture number follows the keyword (1a) optionally, a keyword and nuclide mixture ID for the rest of the current mixture The keyword is NCM= The desired nuclide mixture ID follows the keyword (1b) optionally, a keyword and temperature for the mixture (used for continuous energy problems) The keyword is TMP= or TEM= The desired temperature in Kelvin follows the keyword (2) nuclide ID** (2a) optionally a keyword and nuclide mixture ID for this nuclide The keyword is NCM= and the desired nuclide mixture ID follows the keyword (3) number density** (4) continuous energy cross section filename** ** The sequence (2) (3) (4) is repeated for each nuclide in the mixture. Entry (4) is optional and entered with XS= name where name is the filename. REPEAT the sequence (1) (2)s (3)s (4)s until all the mixtures have been described.		

Additionally, user-defined covariance data can be specified for individual nuclides and reactions using the COVARIANCE data block. This data block begins with the keywords *READ COVARIANCE* and ends with the keywords *END COVARIANCE*. Any of the optional *COVARIANCE* input data may be entered in free-form format between the *READ COVARIANCE* and *END COVARIANCE* keywords. The specifications for the COVARIANCE data block are described in the "User Input Covariance Data" section of the TSUNAMI-IP chapter of the TSUNAMI Utility Modules manual.

As the SAMS module generates HTML output, the optional HTML data block provides user control over some formats of the output. This data block begins with the keywords *READ HTML* and ends with the keywords *END HTML*. Any of the optional HTML input data may be entered in free-form format between the *READ HTML* and *END HTML* keywords. The specifications for the HTML data block are described in the "HTML Data" section or the TSUNAMI-IP chapter of the TSUNAMI Utility Modules manual.

6.2.4.6 Input termination

The input for TSUNAMI-3D must terminate with a line containing *END* in column 1. This *END* terminates the control sequence.

6.2.5 SAMPLE PROBLEMS

Five sample problems are given in this section. In each example, the use of a new feature is explained to guide the user in the proper definition of input models so that reliable sensitivity coefficients can be obtained. The user must ensure that the necessary options are employed for each model to obtain accurate results. Please note, **the results shown here were generated with a previous version of SCALE**, so current data libraries and code implementations may produce different results. However, the techniques demonstrated are applicable to the current version of TSUNAMI-3D.

6.2.5.1 Generating reference direct perturbation sensitivity coefficients

The accuracy of the energy-integrated sensitivity coefficients can be confirmed through the use of central difference direct perturbation sensitivity calculations. Through this technique, the sensitivity of k_{eff} to the number density of particular nuclide can be obtained. This sensitivity of k_{eff} to the number density is equivalent to the sensitivity of k_{eff} to the total cross section integrated over energy. Because the total cross section sensitivity coefficient tests much of the data used to compute all other sensitivity coefficients, it is considered an adequate test for verification. For each sensitivity coefficient examined by direct perturbation, the k_{eff} of the system is computed first with the nominal values of the input quantities, then with a selected nominal input value increased by a certain percentage, and then with the nominal value decreased by the same percentage. The direct perturbation sensitivity coefficient of k_{eff} to some input value α is computed as

$$S_{k,\alpha} = \frac{\alpha}{k} \times \frac{dk}{d\alpha} = \frac{\alpha}{k} \times \frac{k_{\alpha^+} - k_{\alpha^-}}{\alpha^+ - \alpha^-} \tag{6.2.26}$$

where α^+ and α^- represent the increased and decreased values, respectively, of the input quantity α and k_{α^+} and k_{α^-} represent the corresponding values of k_{eff}. In general, perturbations used for calculating direct perturbation sensitivities should be large enough to induce a statistically significant change (10 σ_{keff}) in the eigenvalue of the system but not large enough to induce second-order effects in the perturbed eigenvalue. Statistical uncertainties in the computed values of k_{eff} are propagated to uncertainties in direct perturbation sensitivity coefficients by standard error propagation techniques as

$$\sigma_S = \left(\left(\frac{\left(\sigma_{k^+}^2 + \sigma_{k^-}^2\right)}{(k^+ - k^-)^2} + \frac{\sigma_k^2}{k^2} \right) \times \left(\frac{k^+ - k^-}{k} \right)^2 \right)^{1/2} \times \frac{\alpha}{\alpha^+ - \alpha^-} \tag{6.2.27}$$

In MG TSUNAMI sensitivity calculations it is important to ensure that the k_{eff} value of the forward and adjoint solutions closely agree. If the k_{eff} values do not agree, then the quality of at least one of the transport calculations may be in question. Typically, the transport calculation of concern is the adjoint calculation. By default, TSUNAMI-3D triples the number of histories per generation requested for the forward case to produce the adjoint solution. Experience has shown that agreement to less than 0.5% difference in k_{eff} between the forward and adjoint calculations is adequate to obtain accurate sensitivity coefficients.

6.2.5.2 Simple MG Sample Problem

A simple sample problem with INFHOMMEDIUM MG cross section processing is based on an unreflected rectangular parallelepiped consisting of a homogeneous mixture UF_4 and paraffin with an enrichment of 2 wt% in ^{235}U. The H/^{235}U atomic ratio is 294:1. The dimensions of the experiment are 56.22 × 56.22 × 122.47 cm [3d11]. For consistency with a TSUNAMI-1D model of the same sample problem, this experiment was modeled as a sphere with a critical radius of 38.50 cm. This configuration is used in the TSUNAMI-3D_K5-1 and TSUNAMI-3D_K6-1 sample problems distributed with SCALE. An annotated TSUNAMI-3D-K5 input for this experiment is shown in Fig. 6.2.6. The composition data are input as number densities for each nuclide. Because the material is treated as INFHOMMEDIUM, no explicit unit cell model is necessary, and the READ CELL block is omitted. The KENO V.a problem description contains parameter data to request 10,000 generations (*gen=10000*) with 3000 neutrons per generation (*npg=3000*), deactivate the HTML output for KENO V.a (*htm=no*), stop the forward calculation when k_{eff} has converged to one standard deviation of 0.005 (*sig=0.005*), and to stop the adjoint calculation when k_{eff} has converged to one standard deviation of 0.010 (*asg=0.010*). The KENO V.a geometry consists of nine concentric spheres, up to an outer radius of 38.5 cm, with each sphere containing the material defined as mixture 1. The geometry subdivision is necessary to adequately resolve the spatial dependence of the angular moments of the forward and adjoint flux solutions. The optional sensitivity calculation data block is used to request edits of the sensitivity coefficients

for each region (*prtgeom*) and edits of the explicit, implicit, and complete sensitivity coefficients *(prtimp*). The code output from each functional module is not given here, but is described in the manual section for each functional module.

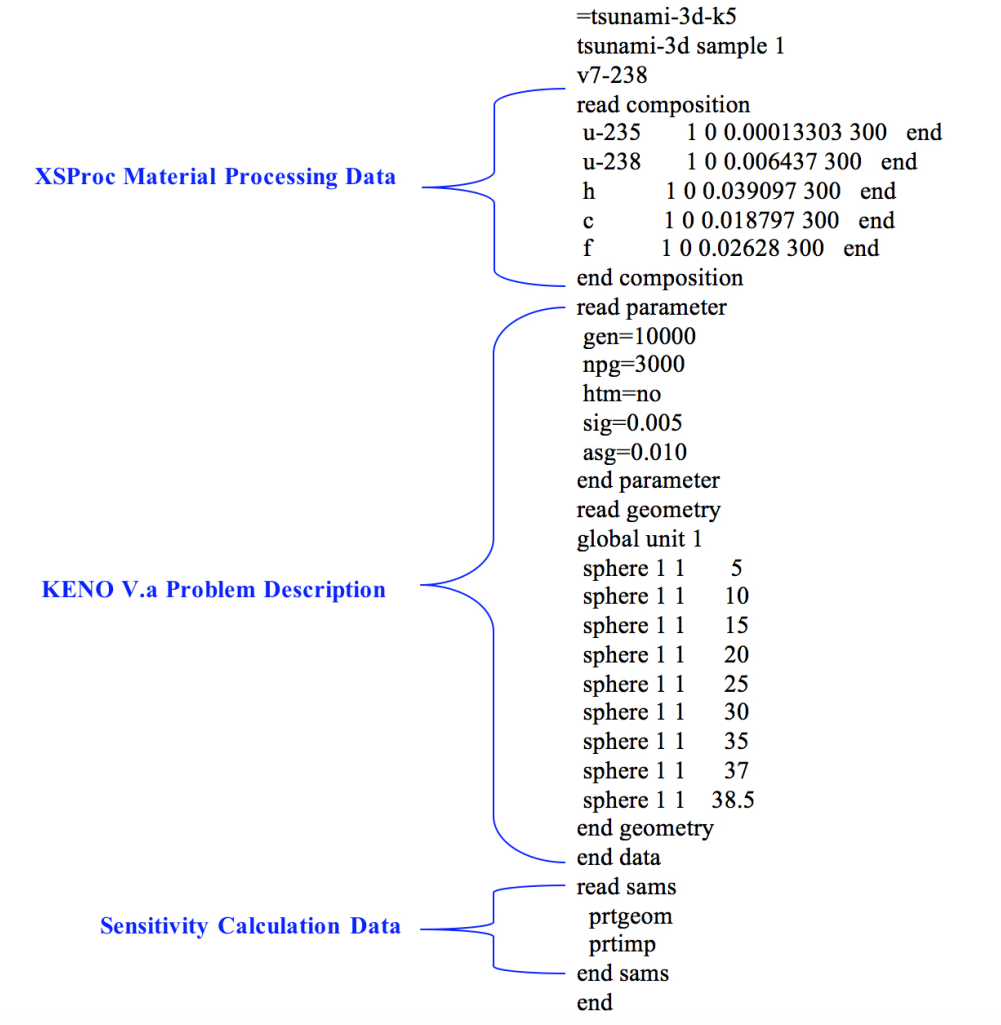

Fig. 6.2.6: TSUNAMI-3D-K5 simple sample problem input.

For this problem, direct perturbation results were obtained for the number densities of each nuclide using an equivalent 1D model. In these calculations, the number density of each nuclide was perturbed by ± to the number density is equivalent to the sensitivity of k_{eff} to the total cross section, integrated over energy. The direct perturbation sensitivity coefficients were computed by using the k_{eff} values from the unperturbed and perturbed cases in Eq. (6.2.27).

This experiment was modeled with the nine-region model shown in Fig. 6.2.6, and as a single computational region (not shown). Flux moments were expanded to third order in both cases, which is the default configuration. TSUNAMI-3D-K5 automatically increases the number of particles per generation by a factor of three for the adjoint analysis. For the single region case, the k_{eff} values for the forward and adjoint cases are in good agreement at 1.00682 +/- 0.00094, and 1.0013 +/- 0.0049, respectively. The sensitivity results shown in Table 6.2.9 were extracted from the output file from the edit titled “Energy, Region, and Mixture

Integrated Sensitivity Coefficients for this Problem." The uncertainty in the sensitivity coefficients represents one standard deviation and is present due to the use of Monte Carlo methods to compute the fluxes and k_{eff}. These results indicate similarity with the direct perturbation results for some nuclides but not for others. Differences between the TSUNAMI-3D-K5 results and the direct perturbation results vary 1% for ^{238}U up to 16% for ^{1}H. The results from the TSUNAMI-3D-K5 analysis with the model divided into nine spherical shells, with all other parameters held constant, are also shown in Table 6.2.9. These results compare much more favorably with the direct perturbation results. For this model, all TSUNAMI-3D-K5 sensitivities agree with the direct perturbation values within 0.1% for ^{1}H up to a maximum difference of 1.5% for ^{238}U.

The differences in the results from the two TSUNAMI-3D models, one region and nine regions, are due to the summation of the product of the forward and adjoint fluxes over the regions in the problem. For a region in which the flux moments vary greatly by position, subdividing the geometry will provide better resolution of the variation of the flux across the system and will produce more accurate results. The number of regions necessary for accurate computation of the sensitivity coefficients was determined through an iterative process. Models divided into more regions produce the equivalent results to those produced by the nine-region model. Increasing the number of computational regions increases the run time for this problem by about 10%.

The sensitivity results from the nine-region model using TSUNAMI-3D-K5 with PARM=CENTRM, which does not include the contributions from the implicit sensitivity coefficients, are also shown in Table 6.2.9. The differences between the TSUNAMI-3D-K5 PARM=CENTRM and the direct perturbation results are 16% for ^{1}H and 19% for ^{238}U. The use of the default cross section processing with the sensitivity versions of the resonance processing codes is strongly recommended. However, TSUNAMI-3D-K5 with PARM=CENTRM should produce accurate results for fast systems where resonance self-shielding is not important. This is illustrated with the second sample problem for TSUNAMI-1D and will not be repeated here.

Table 6.2.9: Energy- and region-integrated sensitivity coefficients from TSUNAMI-3D UF_4 sample problem.

The uncertainty information from SAMS for the UF_4 sample problem is shown in Example 6.2.1. Based on the 44GROUPCOV covariance data file, the uncertainty in k_{eff} due to these covariance data is 0.6110% $\Delta k/k$. A more detailed description of the uncertainty information is given in the SAMS chapter.

The energy-dependent sensitivity data are available in the sensitivity data file, which is returned to the same directory as the input file and given the same name as the user's input file with the extension `.sdf`. In the case of the nine-region model, the sensitivity data file contains 495 individual sensitivity profiles with varying reaction types, each in the 238-group energy structure. There are 45 profiles that are integrated over all regions, one for each reaction of each nuclide in the system. The sum of the sensitivity coefficients for the same nuclide in all mixtures is printed unless *nomix* is entered in the SAMS data block, so there are an additional 45 profiles, one for each reaction of each nuclide in mixture 1. Additionally, because *prtgeom* was entered in the SAMS data block, each reaction of each nuclide for each region in the system model is represented with a sensitivity profile. There are nine regions in the model, each with 45 sensitivity profiles, making for a total of 495 sensitivity profiles on the data file and a total of 117,810 energy-dependent sensitivity coefficients.

Some plots of the energy-dependent sensitivity data from the nine-region model of the sample problem were generated with the plotting capabilities of Fulcrum. Energy-dependent sensitivity profiles for ^{235}U fission and ^{1}H elastic scattering are shown in Fig. 6.2.7. The error bars represent one standard deviation for the statistical uncertainty due to the use of Monte Carlo methods to compute the fluxes and k_{eff}.

Note: relative standard deviation in k-eff can be computed from
individual values by adding the square of the values with positive signs and
subtracting the square of the values with negative signs, then taking the square root

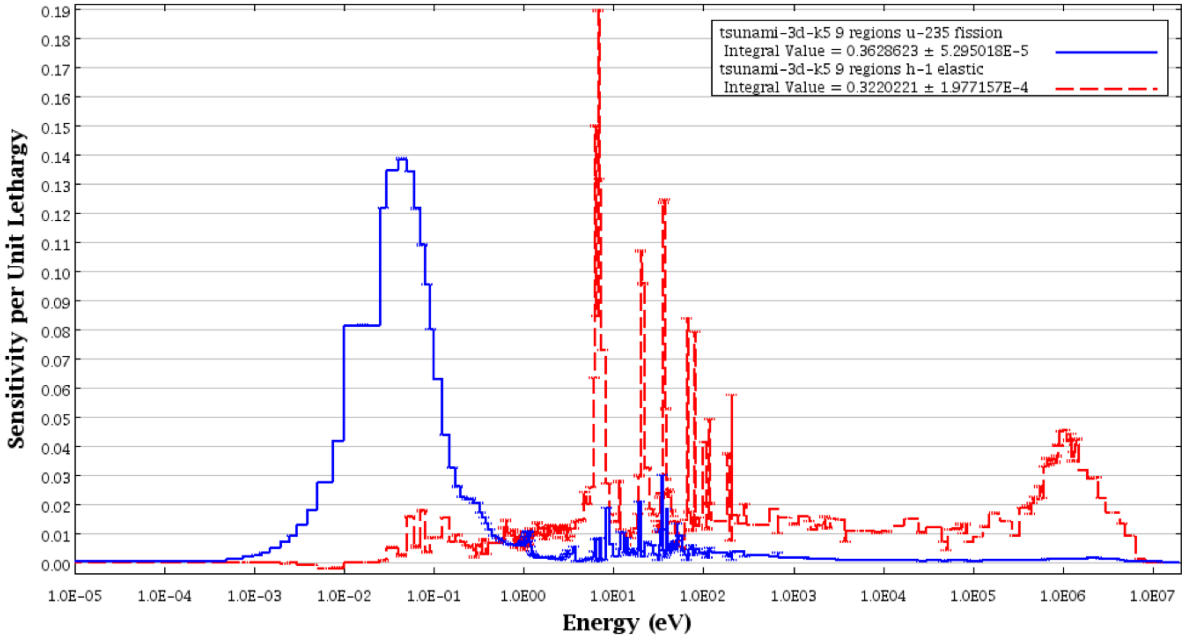

Fig. 6.2.7: Energy-dependent sensitivity profiles from TSUNAMI-3D-K5 for simple sample problem.

Multigroup sample problem with spatial flux mesh

In the previous example, subdivision of the system geometry was necessary to obtain adequate resolution of the flux solution to obtain the appropriate product of the forward and adjoint fluxes necessary for the sensitivity calculations. To simplify the geometry refinement procedure, the meshing of KENO V.a or KENO-VI is used where fluxes are tallied in a cubic mesh that is superimposed over each region of the system geometry. If mesh fluxes are generated in the KENO solution, they are automatically used by the SAMS module in the calculation of the sensitivity coefficients.

To demonstrate the use of the mesh flux option in TSUNAMI-3D-K5, another simple system has been selected. This system is an unreflected rectangular parallelepiped consisting of a homogeneous mixture of UF_4 and paraffin with an enrichment of 2 wt% in ^{235}U. The H/^{235}U atomic ratio is 972:1. The dimensions of the experiment are 81.45 × 86.70 × 88.22 cm. This system is identified as LEU-COMP-THERM-033 case 45 from the *International Handbook of Evaluated Criticality Safety Benchmark Experiments* (IHECSBE). [3d11] The model provided in the IHECSBE was converted to a TSUNAMI-3D-K5 input and is shown in Example 6.2.2. Here the experiment is modeled as a single cuboid. This model is included as an example and is not distributed as a TSUNAMI-3D sample problem.

Direct perturbation sensitivity results were obtained for ^{235}U, ^{238}U, and ^{1}H with a ± value converged to a standard deviation of 0.0001 (*sig=0.0001*). For the model shown in Example 6.2.2, the forward and adjoint k_{eff} values agreed well at 0.99250 ± 0.00056 and 0.9905 ± 0.0049, respectively. The direct perturbation results and the TSUNAMI-3D-K5 results are shown in Table 6.2.11. When modeled as a single region, the TSUNAMI-3D-K5 results differed from the direct perturbation results by 2.6% for ^{238}U, 3.1% for ^{235}U, and 15% for ^{1}H.

To improve the agreement in the values, the model was divided into 6 cuboids nested inside of each other. The input for this model is given in Example 6.2.3 and is illustrated in Fig. 6.2.8. The results for this model

are also given in Table 6.2.10. Here the TSUNAMI-3D-K5 sensitivity coefficients agree with the direct perturbation within 0.3% for ^{238}U, 1.7% for ^{235}U, and 0.8% for ^{1}H.

To simplify the generation of a refined geometrical representation of this system, the same geometry as the initial model was used with an 8 cm mesh for the flux tallies. The input for this model is shown in Example 6.2.4. The mesh is illustrated in Fig. 6.2.9, using a larger (15 cm) mesh interval for illustrative purposes. The mesh flux option is activated by entering *mfx=yes* in the input, and the size of the mesh is defined with the *msh=8* entry. The 8 following *msh=* indicates that a cubic grid with a length of 8 cm on the side of each cube will be superimposed on each geometry region. For this system, the flux will be tallied in 1728 mesh intervals. When the forward and adjoint mesh flux solutions are processed by the SAMS module, the product of the forward and adjoint solutions are produced for each mesh interval, then summed for each region. This technique provides a simple input parameter to produce accurate sensitivity coefficients. The results from TSUNAMI-3D-K5 with an 8 cm mesh flux are given in Table 6.2.11. Similar to the results with the manual subdivision, sensitivity coefficients agree with the direct perturbation within 0.7% for ^{238}U, 2.1% for ^{235}U, and 0.03% for ^{1}H.

The sensitivity results for ^{235}U and ^{238}U show little variation with modifications in the geometry subdivision. The products of the forward and adjoint flux moments, which are derived from the angular flux solution, are most impacted by the mesh flux. The flux moments are used to compute the scattering terms of the sensitivity coefficients. For isotopes with limited scattering cross sections, such as ^{235}U and ^{238}U, the impact of refinement of the flux solution is reduced.

6.2.5.3 Complex sample problem

A more complex sample problem is a critical assembly of 4.31 wt%-enriched UO_2 fuel rods with a pitch of 2.54 cm in clusters that are separated by copper plates. This system is identified as LEU-COMP-THERM-009 case 10 from the IHECSBE. This system is used for sample problem TSUNAMI-3D_K5-2 that is distributed with SCALE. The TSUNAMI-3D_K5-2 sample problem input is shown in Example 6.2.5, and the geometry is illustrated in Fig. 6.2.10. The KENO V.a input section for this model is essentially the same as that presented in the IHECSBE except that the parameter data have been modified for the TSUNAMI calculation. Also, in the IHECSBE model, all water was assigned to the same mixture. For this model, the water in the reflector region is entered as a separate mixture from the water in the pin cell to generate separate sensitivity coefficients in these regions.

For this system, direct perturbation results were obtained for ^{235}U, ^{238}U, and ^{1}H in the pin cell model (mixture 2) and for ^{1}H in the reflector (mixture 7). Direct perturbation sensitivity coefficients can be difficult to obtain for large systems using Monte Carlo techniques. For a small change in a number density (1% or 2%), the effect of k_{eff} may not be significant enough to be observed outside of statistical uncertainties. If a larger perturbation (5% or 10%) is used, the effect on k_{eff} may not be linear and may produce misleading results. Also, if the magnitude of the difference in k_{eff} between the baseline value and the increased density perturbed model is different from the magnitude of the difference in k_{eff} between the baseline model and the decreased density perturbed model, the response may be nonlinear. In these calculations, the amount of the perturbation was carefully chosen to produce approximately 10 standard deviations of change in k_{eff} between the perturbed and unperturbed case. The amount of perturbation for each nuclide is shown in Table 6.2.12.

TSUNAMI-3D-K5 was executed with no flux mesh, a 15 cm flux mesh, and a 5 cm flux mesh using the default coordinate transform setting (*tfm=yes*). Also, the 15 cm and 5 cm mesh cases were run with the coordinate transform turned off (*tfm=no*).

Where a region is repeatedly used in KENO, the flux data are averaged over all occurrences of a region. In this model, only one fuel pin is explicitly modeled. This single pin is used repeatedly in arrays to create the system model. The flux data for this single pin are averaged over all occurrences throughout the system to create the sensitivity data. Using the mesh flux option, the flux is accumulated for the fuel pin in each mesh interval. For the model with no mesh, the flux in the UO_2 portion of the fuel pin is averaged over a single region. With the 15 cm mesh, the flux in UO_2 is accumulated in 126 separate mesh intervals distributed across the core. For the 5 cm mesh, the flux in UO_2 is accumulated in 2280 mesh intervals. For all regions of the model with no mesh, the flux is only stored for 17 unique locations, one for each region. For the 15 cm mesh, the flux is stored in 1968 unique mesh intervals. For the 5 cm mesh mode, the flux is stored in 34,298 unique mesh intervals.

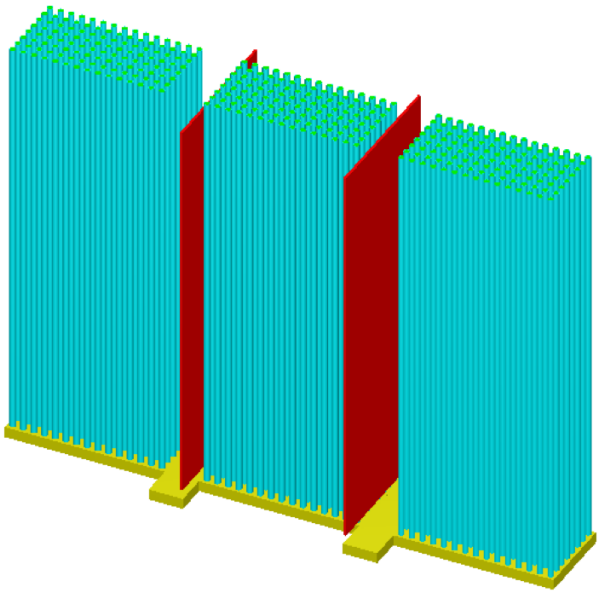

Fig. 6.2.10: Graphical representation of KENO V.a geometry for LEU-COMP-THERM-009 case 10 sample problem.

Sensitivity coefficients and their statistical uncertainties are shown in Table 6.2.12. For ^{235}U, the TSUNAMI-

3D and direct perturbation results agree within one standard deviation for all cases. For ^{238}U, TSUNAMI-3D agrees within two standard deviations for all cases except the no-mesh case, which disagrees by more than four standard deviations. Similarly for ^{1}H in the pin cell, all meshed cases agree with the direct perturbation results to less than one standard deviation, but the case with no geometrical subdivision disagrees by five standard deviations. For ^{1}H in the reflector, again, the meshed cases all agree well with the direct perturbation results, but the non-mesh case shows large discrepancy of 21 standard deviations.

Also, only small differences are observed with and without the transform where an adequate flux mesh is used. Because of the computational resources required for computing the transform while performing neutron tracking, setting *tfm=no* can decrease runtime by ~50%. However, in cases where an adequate computational mesh is not used, setting *tfm=no* can lead to erroneous results.

The energy-dependent sensitivity profiles for ^{1}H elastic scattering for the three TSUNAMI-3D models are shown in Fig. 6.2.11. The differences in the groupwise sensitivity coefficients are most pronounced in the intermediate- to high-energy regions.

Table 6.2.12: Energy- and region-integrated total sensitivity coefficients for LEU-COMP-THERM-009 case 10.

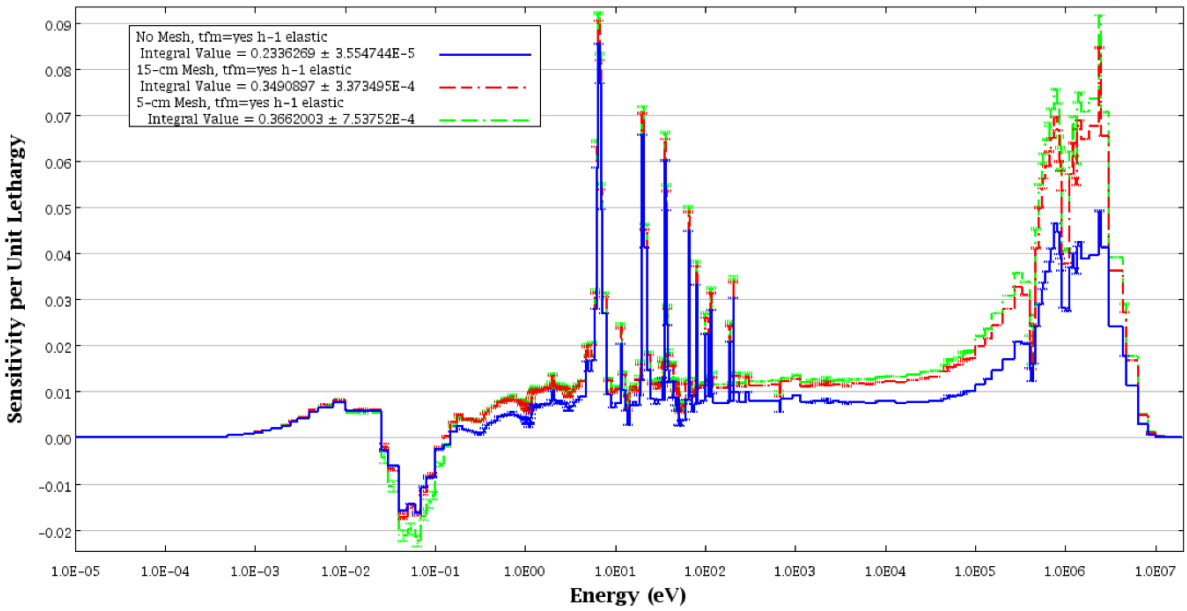

Fig. 6.2.11: Sensitivity profiles from TSUNAMI-3D for ^{1}H elastic scattering in mixture 2 of LEU-COMP-THERM-009 case 10 sample problem.

Loosely coupled sample problem

Another sample problem demonstrates the use of the *GRID* input block to input a nonuniform mesh. This sample problem consists of three tanks containing plutonium nitrate solution that are suspended in air inside of a large concrete room. This system is identified as PU-SOL-THERM-014 case 19 in the IHECSBE. A TSUNAMI-3D-K5 input for this system is shown in Example 6.2.6. The system geometry is illustrated in Fig. 6.2.12, where the concrete room is shown in light blue and the solution tanks are shown in dark blue. A single tank is shown in Fig. 6.2.13, where the tank wall is shown in dark blue and the plutonium nitrate solution is shown in gray.

The KENO V.a option to compute the matrix k_{eff} by hole was used (*mkh=yes)* to give the self-multiplication of each tank. This analysis revealed a system k_{eff} of 1.0049 ± 0.0003 for the forward case and 1.002 ± 0.002 for the adjoint case. The k_{eff} of a single tank for the forward solution was found to be 1.0044 ± 0.0017. Thus the interaction between the tanks has a limited effect on the system multiplication factor.

Direct perturbation sensitivity coefficients were generated for ^{239}Pu, ^{240}Pu, and ^{1}H in the solution using number density perturbations to produce a 20 standard deviation change in k_{eff}, where the requested k_{eff} convergence for the CSAS direct perturbation calculation was 10^{-4}. These values are shown in Table 6.2.13 along with the corresponding TSUNAMI-3D results. The results generated by the model shown in Example 6.2.6, which has no geometric subdivision, agree well with the direct perturbation results for ^{239}Pu, but the ^{1}H values differ by more than six standard deviations, indicating poor agreement.

Example 6.2.6: TSUNAMI-3D-K5 input for sample problem PU-SOL-THERM-014 case 19.

	^{1}H	^{239}Pu
Percent change in number density for direct perturbation	0.32	2.39
Direct perturbation	5.99E-01 ± 2.56E-02	7.57E-02 ± 8.29E-03
TSUNAMI-3D-K5 base model	4.34E-01 ± 1.82E-05	7.58E-02 ± 4.42E-06
TSUNAMI-3D-K5 grid geometry model	6.05E-01 ± 3.42E-04	7.84E-02 ± 3.80E-05

Because of the large size of the room included in this model relative to the size of the fuel tanks, use of the uniform mesh flux proved to be impractical due to excessive memory requirements. The directional dependence of the flux needs to be computed separately for each tank through the use of adequate spatial refinement with the flux mesh through the use of the grid geometry input.

The *GRID* block in KENO V.a and KENO-VI enables the use of a nonuniform mesh for this problem that is coarse throughout the room to save memory, yet refined within the fueled regions to obtain accurate results. As with previous examples, the use of a sufficiently fine mesh provides accurate results without the use of the transform (*tfm=no*). The TSUNAMI-3D-K5 input listing for this model using the user-defined *GRID* is shown in Example 6.2.7, where the transform is disabled with *tfm=no*, the mesh fluxes are requested with *mfx=yes*, and the grid is defined in the *read grid* block. The *msh* parameter that defines a uniform mesh is not used. The input requirements for the grid are described in the READ GRID section of the KENO documentation and will not be repeated here. It is required that the user-defined mesh completely encloses the geometry of the system. In the model in Example 6.2.11, the grid extends past the geometry by 1 cm in each direction to ensure that potential round-off errors do not cause the grid to appear to terminate inside the geometry at any point.

When the user-defined grid is used without the transform, the TSUNAMI-3D-K5 and direct perturbation sensitivities agree within one standard deviation for both ^{1}H and ^{239}Pu, as shown in Table 6.2.13.

Example 6.2.7: TSUNAMI-3D-K5 input with *GRID* input for sample problem PU SOL-THERM-014 case 19.

6.2.5.4 CE TSUNAMI Sample Problem

The last sample problem focuses on performing CE TSUNAMI sensitivity calculations starting from a CE KENO-VI model. The model used in this example is a highly enriched uranium sphere (Godiva) using one-eighth symmetry; this case is identified as HEU-MET-FAST-001 in IHECSBE [3d11]. CE TSUNAMI inputs are in many ways easier to prepare than MG TSUNAMI inputs because CE TSUNAMI does not require flux moment calculations, a flux mesh (except for CLUTCH $F^*(r)$ calculations), implicit sensitivity calculations, or an adjoint transport calculation, and thus requires much less user input. Example 6.2.8 shows the CE TSUNAMI input for this system. The input lines that differ from those in the CE KENO-VI input are highlighted in blue. This simulation uses the IFP sensitivity method (cet=2) and assumes that daughter fission neutrons diffuse through the system and produce an asymptotic population after five latent generations (cfp=5). In general, IFP simulations require a cfp between 5 and 10 generations to produce accurate sensitivity estimates, although IFP sensitivity calculations can produce accurate sensitivities for this

system using as few as 2 latent generations. The runtime and memory requirements of the IFP method are proportional to cfp, and users should minimize cfp when performing IFP sensitivity calculations to maximize calculation efficiency and minimize calculation memory footprint.

Example 6.2.8: CE TSUNAMI-3D-K6 input for the Godiva system using the IFP method.

Example 6.2.9 shows the CE TSUNAMI input for the Godiva system using the CLUTCH sensitivity method (cet=1). This input is different from the IFP input in that the CLUTCH method requires a spatial grid for tallying the CLUTCH $F^*(r)$ function. This grid is specified in the "read gridGeometry" block and the ID of the grid specified in this block is passed to CLUTCH in the parameter block (cgd=11). In general, CLUTCH calculations are much faster than IFP calculations and produce a significantly smaller memory footprint, but CLUTCH calculations must have an accurate $F^*(r)$ mesh to obtain accurate sensitivity coefficients. The $F^*(r)$ mesh is currently calculated during inactive generations using the IFP method, and the cfp=5 card specifies how many latent generations are used in this calculation. Using more latent generations will increase the accuracy of the $F^*(r)$ mesh and will not significantly affect the memory footprint of the CLUTCH method, but it will increase the variance of the $F^*(r)$ mesh values. In general an $F^*(r)$ mesh with 1 cm to 2 cm mesh intervals is sufficiently refined to obtain accurate sensitivity coefficients. $F^*(r)$ is calculated during the inactive generations, and in general users should simulate at least on the order of 10 to 100 inactive histories per mesh interval to allow for sufficient $F^*(r)$ convergence. This sometimes necessitates simulating a large number of additional inactive histories/generations. Fission source convergence is not necessary to begin accurate $F^*(r)$ estimates. Therefore, $F^*(r)$ can be tallied during the inactive generations while the fission source is still converging.

Example 6.2.9: CE TSUNAMI-3D-K6 input for the Godiva system using the CLUTCH method.

It is possible to perform a CE TSUNAMI CLUTCH sensitivity calculation using the assumption that $F^*(r)$ equals one everywhere. This will not produce accurate sensitivity coefficient estimates for systems where the importance of fission neutrons varies significantly as a function of space, but it will produce accurate sensitivity coefficients for systems with relatively flat importance functions, such as an infinitely reflected model of a single fuel pin or an infinite media problem. This calculation mode requires no additional inactive generations for the calculation of $F^*(r)$ and is useful for estimating the runtime or memory requirements of a CLUTCH calculation and for obtaining rough estimates of the sensitivity coefficients of complicated systems. Example 6.2.10 shows the CE TSUNAMI input for the Godiva system using the CLUTCH sensitivity method (cet=1). The $F^*(r)$ mesh calculation is disabled using cfp=-1, making the "read gridGeometry" and "cgd=###" inputs not required.

Example 6.2.10: CE TSUNAMI-3D-K6 input for the Godiva system using the CLUTCH method with no F*(r) mesh.

The three previously described CE TSUNAMI inputs were simulated. The total nuclide sensitivity coefficients from these runs are compared with reference direct perturbation and MG TSUNAMI-3D sensitivities in Table 6.2.14. The difference between the calculated and reference sensitivities, in terms of the effective number of standard deviations, is given in the table in parentheses below each calculated sensitivity coefficient. Although the reference direct perturbation sensitivity estimates had uncertainties that were a bit large (it is recommended that their relative uncertainties are less than 5%), the four TSUNAMI calculations all produced sensitivity coefficients that seem to agree well with the reference sensitivities.

Table 6.2.14: CE TSUNAMI Godiva sensitivity coefficient comparison.

Nuclide	Direct Perturbation	MG TSUNAMI-3D	IFP	CLUTCH	CLUTCH (no mesh)
^{234}U	0.00646 ± 0.00050	0.00727 ± 0.000005 (1.62 σ_{eff})	0.00725 ± 0.00030 (1.35 σ_{eff})	0.00738 ± 0.00006 (1.83 σ_{eff})	0.00708 ± 0.00006 (1.23 σ_{eff})
^{235}U	0.80959 ± 0.06937	0.79648 ± 0.00048 (-0.19 σ_{eff})	0.80378 ± 0.00289 (-0.08 σ_{eff})	0.80359 ± 0.00062 (-0.09 σ_{eff})	0.77705 ± 0.00059 (-0.47 σ_{eff})
^{238}U	0.01896 ± 0.00178	0.01768 ± 0.00002 (-0.72 σ_{eff})	0.01816 ± 0.00064 (-0.42 σ_{eff})	0.01792 ± 0.00013 (-0.58 σ_{eff})	0.01633 ± 0.00012 (-1.47 σ_{eff})

Two sample inputs have been included to illustrate how a user can run GEAR-MC sensitivity calculations starting from the CE KENO-VI Godiva model. The first, CLUTCH-only GPT input requires specifying a number of latent generations for the GPT $F^*(r)$ calculation (cfp=4), creating a gridGeom for the $F^*(r)$ mesh, and specifying reaction rates, materials, and energy ranges for the numerator and denominator response terms. The generalized response examined in this problem is the ^{235}U fast (> 0.6 MeV and < 20 MeV) fission cross section; in other words:

$$R = \frac{\left\langle \Sigma_f^{U-235} \phi \right\rangle^{\text{fast}}}{\langle \phi \rangle^{\text{fast}}}. \tag{6.2.28}$$

Therefore, the reaction rate in the numerator term of this response is the ^{235}U fast fission reaction rate in material 1 (`nnc=92235`, `nma=1`, `nmt=18`, `nmx=20e7`, and `nmn=600000`) and the denominator term is the fast flux in material 1 (`dnc=-1`, `dma=1`, `dmt=0`, `dmx=20e7`, and `dmn=600000`).

Example 6.2.11: CE TSUNAMI-3D-K6 input for the Godiva system using GEAR-MC with only the CLUTCH method.

This problem can be specified using the input option `cet=5`, which uses the IFP method to estimate the intergenerational effect term on the fly rather than tallying the effect in an $F^*(r)$ mesh. For this cet=5 case the Definitions and SystemResponses blocks (found in the SystemResponses block sections in the TSUNAMI-1D chapter of the SCALE manual) are used to specify the GPT responses rather than using KENO input parameters.

Example 6.2.12: CE TSUNAMI-3D-K6 input for the Godiva system using GEAR-MC with the CLUTCH and IFP methods.

6.3 TSUNAMI UTILITY MODULES

B. T. Rearden, M. A. Jessee, and J. D. McDonnell

ABSTRACT

Several modules have been developed to assist with the sensitivity and uncertainty analysis techniques included in SCALE. TSUNAMI-IP (**T**ools for **S**ensitivity and **U**ncertainty **A**nalysis **M**ethodology **I**mplementation-**I**ndices and **P**arameters) uses sensitivity data generated by TSUNAMI-1D, -2D, or -3D to propagate the effect of uncertainty in nuclear data to a response of interest, and to generate several relational parameters and indices that predict the degree of similarity between two systems. Additionally, the formats of files used by SCALE for sensitivity analyses are described herein.

ACKNOWLEDGMENTS

The author wishes to acknowledge C. M. Hopper, B. L. Broadhead of the Oak Ridge National Laboratory (ORNL), S. Goluoglu, and R. L. Childs, formerly of the ORNL, and J. J. Wagschal of The Hebrew University of Jerusalem, for their assistance with the development of TSUNAMI-IP and L. M. Petrie, I. C. Gauld, and J. E. Horwedel of the Oak Ridge National Laboratory for their assistance in the development of SENLIB and BONAMIST.

6.3.1 TSUNAMI-IP

TSUNAMI-IP (**T**ools for **S**ensitivity and **U**ncertainty **A**nalysis **M**ethodology **I**mplementation-**I**ndices and **P**arameters) uses sensitivity data generated by TSUNAMI-1D, -2D, or -3D and cross section covariance data described in the SCALE Nuclear Data Covariance Library chapter to generate several relational parameters and indices that can be used to determine the degree of similarity between two systems. TSUNAMI-IP combines many techniques developed over several years into a comprehensive package with simplified input. Most of the techniques developed for TSUNAMI-IP are documented in Ref. [refTsip1], other techniques are documented in Refs. [refTsip2], [refTsip3] and [refTsip4], and others are originally presented in this document.

Depending on the user selected options, voluminous output can be generated by TSUNAMI-IP. To assist with review of these data, TSUNAMI-IP was the first SCALE module to offer HTML formatted output. This document first describes the indices and parameters that are computed, presents a description of the user input, then finally a sample problem is presented where the standard text output and the HTML formatted output are described.

TSUNAMI-IP was introduced in SCALE 5.0 and improved in SCALE 5.1. In SCALE 6.0, TSUNAMI-IP now includes an individual c_k to better quantify uncertainty-based similarity on a nuclide-reaction specific level. The E_{sum} parameter has since been replaced with a sensitivity-only parameter, simply called E, which is based on more rigorous mathematical definition. The input format has been expanded with additional keywords to identify sensitivity data and a *RESPONSE* data block that allows users to define applications and experiments within the same input block. Uncertainty and penalty edits can also be presented with relative or absolute values, where previously only relative values were available. The input of user-defined covariance data now allows much greater flexibility, and the covariance data used in the problem can now be exported to a COVERX formatted data file for subsequent plotting in Fulcrum.

6.3.1.1 Global integral indices

Three global integral indices that assess the similarity of a particular application and a single experiment on a system-wide basis for all nuclides and reactions are defined in this section. The integral indices are c_k, E, and G. Each of these indices is defined in subsequent subsections, and TSUNAMI-IP input options used to generate these indices and produce specific output edits are explained. Each integral index is normalized such that a value of 1.0 indicates complete similarity between the application and the experiment and a value of 0.0 indicates no similarity.

Integral index c_k

A rigorous approach to assessing the similarity of two systems for purposes of criticality code validation is the use of uncertainty analysis, which propagates the tabulated cross section uncertainty information to the calculated k_{eff} value of a given system via the energy-dependent sensitivity coefficients.X1X Mathematically, the system uncertainty is computed with a quadratic product of the group-wise sensitivity profile vectors by nuclide and reaction type with the group-wise cross section uncertainty matrices by nuclide and reaction type. The result of this procedure is not only an estimate of the uncertainty in the system k_{eff} due to cross sections, but also an estimate of the correlated uncertainty between systems. These correlated uncertainties

can be represented by correlation coefficients, which represent the degree of correlation in the uncertainties between the two systems. This correlation coefficient index, denoted as c_k, not only has the desirability of a single quantity relating the two systems, but also measures the similarity of the systems in terms of related uncertainty. These correlation coefficients are particularly useful when used in traditional trending analyses for criticality safety validation in that the correlation coefficient relates the degree in which the uncertainties in the critical benchmarks are coupled with the uncertainties in the application of interest. This coupling with the common uncertainties in the various systems is expected to closely mimic the coupling in predicted biases between the various systems, since they should both be related to the cross section uncertainties.

The cross section covariance data are read from a COVERX formatted data file identified by *coverx*= in the *PARAMETER* input. The cross section covariance data files distributed with SCALE are discussed in the SCALE Nuclear Data Covariance Library chapter, and the format of the COVERX data file is presented in COVERX format. A prerequisite in the uncertainty analysis approach is that cross section uncertainty data for all nuclides and reactions of interest have been evaluated and processed for use by these procedures. However, evaluated cross section uncertainty data are not available for all nuclide-reaction pairs. Nuclide-reaction pairs without data are omitted from this analysis, but it is assumed that either the cross section data values from these pairs are well known (i.e., small uncertainties), or that the sensitivity of the system k_{eff} to these nuclide-reaction pairs is small. Where these assumptions hold, the nuclide-reaction pairs without cross section-uncertainty data present a negligible contribution to the uncertainty-based analysis. For situations where this negligible contribution assumption is judged to be invalid, the use of uncertainty analysis is not appropriate. However, the *COVARIANCE* data block can be used to input uncertainty values for the cross section data for particular nuclide-reaction pairs to assess the impact of additional covariance data. To utilize the covariance data generated by user input in the *COVARIANCE* data block, the keyword *use_icov* must be entered in the *PARAMETER* data block. Additionally, default uncertainty values can be assigned for all unknown covariance data. This default uncertainty data is input in the *PARAMETER* data block and the keyword *use_dcov* must be entered to activate its use. Warning messages are printed to identify substituted covariance matrices.

When *use_dcov* and/or *use_icov* and *cov_fix* are specified in the *PARAMETER* data block, and a reaction has zero or large (standard deviation > 1000%) values on the diagonal of the covariance matrix, these values are replaced with the square of the user input or default standard deviation values, and the corresponding off-diagonal terms are substituted according to the user input or default correlation values. Warning messages are printed to identify which values were replaced and which standard deviation value was used in the replacement.

The mathematical development of the integral index c_{k} is presented here based on the development given in [refTsip1]. The nuclear data parameters (i.e., group wise nuclide-reaction specific cross sections) are represented by the vector $\alpha \equiv (\alpha_m), m = 1, 2, \ldots, M$, where M is the number of nuclide-reaction pairs × the number of energy groups. The corresponding symmetric $M \times M$ matrix containing the relative variances (diagonal elements) and covariances (off-diagonal elements) in the nuclear data are

$$\mathbf{C}_{\alpha\alpha} \equiv \left[\frac{\text{COV}(\alpha_m, \alpha_p)}{\alpha_m \alpha_p}\right], m = 1, 2, \ldots, M; p = 1, 2, \ldots, M, \tag{6.3.1}$$

where

$$\text{COV}(\alpha_m, \alpha_p) = \left\langle \delta\alpha_m \delta\alpha_p \right\rangle \tag{6.3.2}$$

where $\delta\alpha_m$ and $\delta\alpha_p$ represent the difference between the values and expectation values of the nuclear data parameters and represents integration over the ranges of α_m and α_p weighted with a probability density function. A rigorous definition of the cross section covariance data are given in [refTsip5].

The matrix containing sensitivities of the calculated k_{eff} to the α parameters is given as

$$\mathbf{S_k} \equiv \left[\frac{\alpha_m}{k_i} \frac{\partial k_i}{\partial \alpha_m} \right], i = 1, 2, \ldots, I; m = 1, 2, \ldots, M, \tag{6.3.3}$$

where I is the number of critical systems being considered. In TSUNAMI-IP, the elements of S_k are the sensitivity coefficients read from the sensitivity data files identified in the *APPLICATIONS* and *EXPERIMENTS* data blocks. The uncertainty matrix for the system k_{eff} values, C_{kk}, is given as

$$\mathbf{C_{kk}} = \mathbf{S_k} \mathbf{C}_{\alpha\alpha} \mathbf{S}_\mathbf{k}^\dagger \tag{6.3.4}$$

where † indicates a transpose.

S_k is an I × M matrix; $C_{\alpha\alpha}$ is an M × M matrix; and the resulting C_{kk} matrix is of dimension I × I. The C_{kk} matrix consists of relative variance values, σ_i^2, for each of the systems under consideration (the diagonal elements), as well as the relative covariance between systems, σ_{ij}^2 (the off-diagonal elements). These off-diagonal elements represent the shared or common variance between two systems. The off diagonal elements are typically divided by the square root of the corresponding diagonal elements (i.e., the respective standard deviations) to generate a correlation coefficient matrix. Thus, the correlation coefficient is defined as

$$c_k = \frac{\sigma_{ij}^2}{\left(\sigma_i \sigma_j\right)} \tag{6.3.5}$$

such that the single c_k value represents the correlation coefficient between uncertainties in system i and system j.

These correlations are primarily due to the fact that the uncertainties in the calculated k_{eff} values for two different systems are related, since they contain the same materials. Cross section uncertainties propagate to all systems containing these materials. Systems with the same materials and similar spectra would be correlated, while systems with different materials or spectra would not be correlated. The interpretation of the correlation coefficient is the following: a value of 0.0 represents no correlation between the systems, a value of 1.0 represents full correlation between the systems, and a value of -1.0 represents a full anti-correlation.

To request the computation of c_k for each application identified in the *APPLICATIONS* section of the input in relation to each experiment in the *EXPERIMENTS* portion of the input, simply enter the input *c* in the *PARAMETER* section of the input. Additionally, the *values* table must be requested to output the full listing of c_k values. The *csummary* edit prints a listing of all experiments that have a c_k value exceeding the criteria value set by *cvalue*=.

Integral index $\mathbf{c}_r$

The integral index c_k is intended for investigative analysis and is defined as c_k with user-defined reactions removed from consideration. The *EXCLUSIONS* data block is used to identify which reactions will be excluded from consideration in the calculation of c_k. If the user identifies no reactions, then c_r will compute the same value as c_k. Using c_r is equivalent to removing all sensitivities for a given reaction or series of reactions for all nuclides from the sensitivity data file for all applications and all experiments considered in the analysis.

To request the computation of c_r for each application identified in the *APPLICATIONS* section of the input in relation to each experiment in the *EXPERIMENTS* portion of the input, simply enter the input *cr* in the *PARAMETER* section of the input. Additionally, the *values* table must be requested to output the full listing of c_r values. The *crsummary* edit prints a listing of all experiments that have a c_r value exceeding the criteria value set by *crvalue*=.

***Integral index* E**

The E index is a replacement for the previous E_{sum} index, which was present in TSUNAMI-IP for SCALE 5.0 and 5.1.1. If the group-wise sensitivity data for all nuclides and reactions for each system is thought of as a vector, then the integral index E is the cosine of the angle between the two sensitivity vectors for the analyzed systems. If the two sensitivity vectors are parallel, i.e., proportional, the systems are similar. E does not require cross section covariance data and is normalized such that an E value of 0.0 indicates the systems are totally dissimilar, and an E value of 1.0 indicates the two systems are the same. Mathematically, an E value as low as -1.0 could be generated, but this would be the result of a rare combination of system sensitivity coefficients such that the sensitivity of the respective system responses would have to be exactly proportional in magnitude and opposite in sign, which seems not to be physically feasible. The E parameter is considered global in nature because its single quantity assesses similarity between two systems based on the magnitude and shape of all sensitivity profiles. The vector $\mathbf{S_i}$ is defined as the sensitivity *vector* (not matrix) for a particular application or experiment "i." The magnitude of the sensitivity vector corresponds to the L2 norm: $|\mathbf{S_i}| = \sqrt{\mathbf{S_i^T S_i}}$. The E value for a given application a with experiment e is then

$$E \equiv \frac{\mathbf{S_a^T S_e}}{|\mathbf{S_a}|\,|\mathbf{S_e}|} \tag{6.3.6}$$

The similarity of systems in terms of their sensitivities to only the fission, capture or scatter reactions can also be evaluated as

$$E_x \equiv \frac{\mathbf{S_{x,a}^T S_{x,e}}}{\left|\mathbf{S_{x,a}}\right|\left|\mathbf{S_{x,e}}\right|}, \tag{6.3.7}$$

where the vectors $S_{x,a}$ and $S_{x,e}$ represent the sensitivity of application and experiment to fission, capture, or scatter reaction x.

To request the computation of E for each application identified in the *APPLICATIONS* section of the input in relation to each experiment in the *EXPERIMENTS* portion of the input, simply enter the input e in the *PARAMETER* section of the input. Additionally, the *values* table must be requested to output the full listing of E values. The reaction components of E (i.e., E_{f}, E_{c} and E_{s}) are included in the *values* table if *prtparts* is entered in the input. The reaction-specific components of E are each normalized between -1 and 1, the same as E itself. The *esummary* edit prints a listing of all experiments that have an E value exceeding the criteria value set by *evalue*=.

***Integral index* G**

The G index assesses the similarity of two systems based on normalized differences in the energy-dependent sensitivity data for fission, capture, and scatter [refTsip2]. The similarity measure used for G is based on the concept of coverage of the application by an experiment. A physical interpretation of the G index is the ratio of the sum of the sensitivity coefficients of the application that are covered by the experiment to the sum of the sensitivity coefficients for the application. The G index, sometimes referred to as "big G" is defined as:

$$G = 1 - \frac{\sum_n \sum_x \sum_j \left(S_{x,j}^{a,n} - S_{x,j}^{e',n}\right)}{\sum_n \sum_x \sum_j S_{x,j}^{a,n}} \tag{6.3.8}$$

where,

$$S_{x,j}^{e',n} = \begin{cases} S_{x,j}^{e,n}, \text{ where} & \left|S_{x,j}^{a,n}\right| \geq \left|S_{x,j}^{e,n}\right| \text{ and } \frac{S_{x,j}^{a,n}}{\left|S_{x,j}^{a,n}\right|} = \frac{S_{x,j}^{e,n}}{\left|S_{x,j}^{e,n}\right|} \\ S_{x,j}^{a,n}, \text{ where} & \left|S_{x,j}^{a,n}\right| < \left|S_{x,j}^{e,n}\right| \text{ and } \frac{S_{x,j}^{a,n}}{\left|S_{x,j}^{a,n}\right|} = \frac{S_{x,j}^{e,n}}{\left|S_{x,j}^{e,n}\right|} \\ 0, & \text{otherwise} \end{cases} \tag{6.3.9}$$

the n summation is performed over all nuclides present in the application system,

the x summation is performed over fission, capture and scatter reactions (f, c, and s) as appropriate for each nuclide, and

the j summation is performed over all energy groups.

The use of 1 minus the normalized difference makes the range of this index consistent with c_k and E_{sum}. Hence, a G of 1 indicates complete similarity and a G value of 0 indicates no similarity.

The definition of $S_{x,j}^{e',n}$ restricts the coverage of the application by the experiment to the portion of the experiment's sensitivity coefficient that does not exceed that of the application in magnitude. Additionally, the application's sensitivity coefficient and that of the experiment must have the same sign. The coverage for ^{1}H scatter for an example application and experiment is illustrated in Fig. 6.3.1 where the energy-dependent sensitivity profiles for the application, the experiment and the coverage of the application by the experiment are shown in green, red and blue, respectively. Because the sensitivity coefficients for the application and the experiment have opposite signs at energies just above 1×10^{-2} eV, the application provides no coverage for the experiment for these groups. Also, for several groups, the sensitivity of the application exceeds that of the experiment and only partial coverage is provided. Partial coverage is illustrated where the application data (green) exceeds the coverage (blue). In other groups, the sensitivity of the experiment exceeds that of the application. In these groups, full coverage is provided, but the coverage is not allowed to exceed the sensitivity of the application. This is illustrated in groups where the experiment data (red) exceeds the coverage data (blue). With the limitation of the coverage as the value of the applications sensitivity coefficient, the experiment cannot provide "extra credit" in coverage for sensitivity coefficients that exceed those of the application.

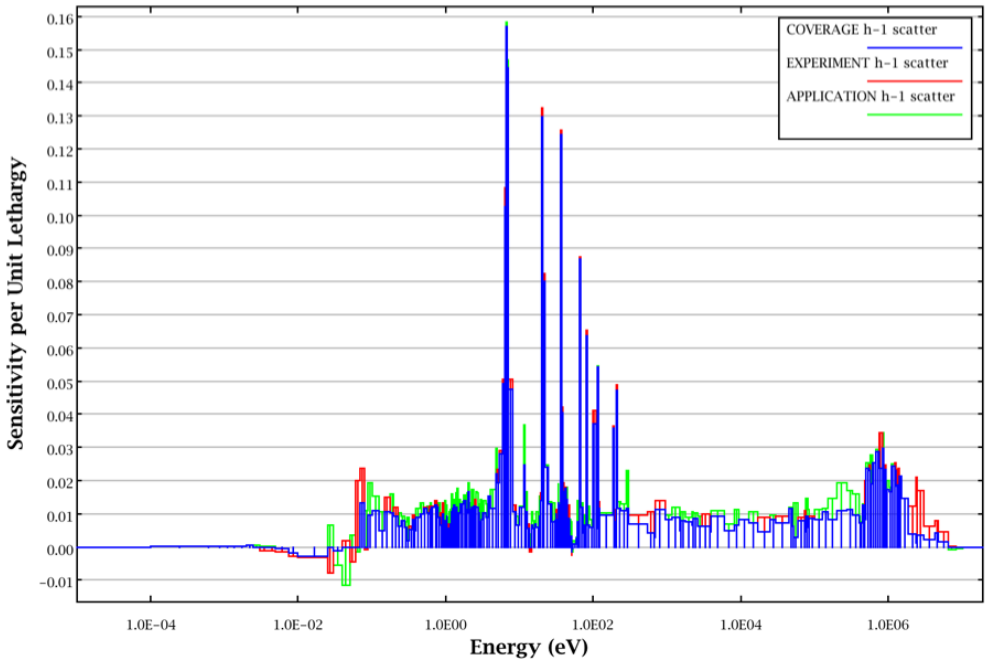

Fig. 6.3.1: Illustration of coverage for ^{1}H scatter.

The coverage for ^{10}B capture for an example application and experiment is illustrated in Fig. 6.3.2. In this figure, the sensitivity coefficients are all negative. The magnitudes of the sensitivity coefficients for the experiment far exceed those of the application at thermal energies. However, coverage is only provided to the magnitudes of the sensitivity coefficients of the application.

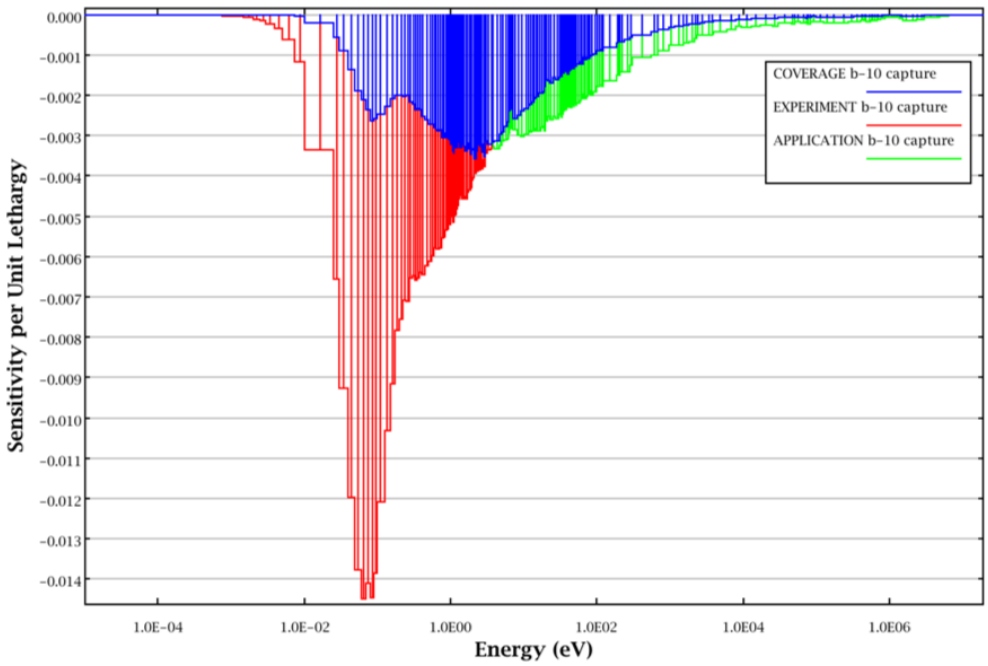

Fig. 6.3.2: Illustration of coverage for ^{10}B capture.

Assessment of similarity over a particular reaction type (fission, capture or scatter) can be made with a partial G value. A G_x value can be computed by eliminating the sum over reactions, x in Eq. (6.3.11), as

$$G_x = 1 - \frac{\sum_n \sum_j \left(S_{x,j}^{a,n} - S_{x,j}^{e',n} \right)}{\sum_n \sum_j S_{x,j}^{a,n}} \tag{6.3.10}$$

where

x is f, c, or s.

To request the computation of G for each application identified in the *APPLICATIONS* section of the input in relation to each experiment in the *EXPERIMENTS* portion of the input, simply enter the input g in the *PARAMETER* section of the input. Additionally, the *values* table must be requested to output the full listing of G values. The reaction components of G (i.e., G_f, G_c and G_s) are included in the *values* table if *prtparts* is entered in the input. The G_x indices are normalized such they also have a range of 0 to 1, where a G_x of 1 indicates complete similarity of sensitivity coefficients for that particular reaction type x between the application and experiment. The *gsummary* edit prints a listing of all experiments that have a G value exceeding the criteria value set by *gvalue*=.

6.3.1.2 Nuclide-reaction specific integral indices

The global integral indices described in Sect. 6.3.1.1 assess system similarity for all nuclides and reactions in the application system. It is also possible and sometimes desirable to produce values analogous to G, E, and c_k for each nuclide-reaction pair, such that similarity can be assessed on a nuclide-reaction-specific level.

***Nuclide-reaction specific integral index* g**

The nuclide-reaction specific integral index based on the same coverage criteria as G is denoted g, and sometimes referred to as "little g." [2] It is defined in terms of the normalized differences of the group wise sensitivity coefficients for a particular nuclide, n, and reaction, x, summed over all energy groups, j, as

$$g_x^n = 1 - \frac{\sum_j \left(S_{x,j}^{a,n} - S_{x,j}^{e',n} \right)}{\sum_j S_{x,j}^{a,n}} \tag{6.3.11}$$

where,

$$S_{x,j}^{e',n} = \begin{cases} S_{x,j}^{e,n}, \text{ where} & \left| S_{x,j}^{a,n} \right| \geq \left| S_{x,j}^{e,n} \right| \text{ and } \frac{S_{x,j}^{a,n}}{\left| S_{x,j}^{a,n} \right|} = \frac{S_{x,j}^{e,n}}{\left| S_{x,j}^{e,n} \right|} \\ S_{x,j}^{a,n}, \text{ where} & \left| S_{x,j}^{a,n} \right| < \left| S_{x,j}^{e,n} \right| \text{ and } \frac{S_{x,j}^{a,n}}{\left| S_{x,j}^{a,n} \right|} = \frac{S_{x,j}^{e,n}}{\left| S_{x,j}^{e,n} \right|} \\ 0, & \text{otherwise} \end{cases} \tag{6.3.12}$$

and the j summation is performed over all energy groups.

The criteria for g are the same as those explained in Sect. 6.3.1.1.3. The only difference in g and G is that the summations over nuclide and reaction have been removed. As with other integral indices, the g index is normalized such that a g value of 1 indicates complete coverage of the application by the experiment for the particular nuclide-reaction pair. A g value of 0 indicates no coverage of the application by the experiment for the particular nuclide-reaction pair.

To request the computation of g ("little g") for each application identified in the APPLICATIONS section of the input in relation to each experiment in the EXPERIMENTS portion of the input for fission, capture and scatter reactions for each nuclide in the application, simply enter the input *lg* in the PARAMETER section of the input. The *lg* data appears in the nuclide-reaction specific edit for each application and only includes nuclide-reaction pairs with energy integrated sensitivity coefficients with at least the magnitude of *sencut*. Additionally, g values are printed for each nuclide-reaction pair specified in the REACTIONS data block. The *lgall* edit prints all the g values for fission, capture and scatter for all nuclides in the application in relation to all experiments regardless of the magnitude of the energy-integrated sensitivity value. The *lgsum* edit prints a listing of all g values exceeding the criteria value set by *lgvalue*= for fission, capture and scatter reactions for each nuclide. The *lggroups* edit prints a long table listing the numbers of experiments that are at least as sensitive as the application for each group for each nuclide-reaction pair requested in the REACTIONS data block.

Extended c_k

The extended c_k edit lists the contribution of each nuclide-reaction-to-nuclide-reaction energy covariance matrix to the global integral index c_k. A single entry in this edit is computed by utilizing a subset of the $\mathbf{C}_{\alpha\alpha}$ matrix and the $\mathbf{S_k}$ sensitivity vectors for the application and the experiment. Thus, the extended c_k for a nuclide-reaction pair in the application in relation to a nuclide-reaction pair in the experiment is defined as

$$c^{contribution}_{k,(n-j)_a,(m-k)_e} = \frac{\sigma^2_{(n-j)_a,(m-k)_e}}{(\sigma_a \sigma_e)} \tag{6.3.13}$$

where,

> $(n\text{-}j)_a$ represents the nuclide n and reaction j of the application a, $(m\text{-}k)_e$ represents the nuclide m and reaction k of the experiment e, $\sigma^2_{(n-j)_a,(m-k)_e}$ represents the covariance between application a and experiment e due to this nuclide-reaction pairs, σ_a is the standard deviation in keff for the application due to all cross section covariance data, and σ_e is the standard deviation in keff for the experiment due to all cross section covariance data.

The global integral index c_k can be reconstructed from the extended c_k components by summing the extended c_k over all nuclide-reaction-to-nuclide-reaction values. Thus, the extended c_k allows the user to determine the contribution of nuclide-reaction-to-nuclide-reaction covariances to c_k. All covariance data, default covariance data and user-input covariance data used in the calculation of c_k, as outlined in Sect. 6.3.1.1, are also applied to the extended c_k data. Nuclide-reaction-to-nuclide-reaction covariances using default and user-input values are identified with one and two asterisks, respectively, in the text output, and are identified with unique colors in the HTML output. Nuclide-reaction-to-nuclide-reaction covariances using default and user-input values for *cov_fix* adjustments are identified with three and four asterisks, respectively, in the text output, and are identified with unique colors in the HTML output. Warning messages are printed to identify which zero values were replaced and which standard deviation value was used in the substitution.

The extended c_k edit also includes an individual c_k to examine the similarity of an application and experiment based only on a single nuclide-reaction pair. The individual c_k is similar to the c_k contribution from Eq. (6.3.13), except that it is normalized between -1 and 1 for each nuclide-reaction pair as

$$c^{individual}_{k,(n-j)_a,(m-k)_e} = \frac{\sigma^2_{(n-j)_a,(m-k)_e}}{\left(\sigma_{(n-j)_a} \sigma_{(m-k)_e}\right)} \tag{6.3.14}$$

Note that individual c_k values computed for a nuclide-reaction pair in an application to the same nuclide-reaction pair in the experiment. Although cross-reaction and cross-nuclide covariance data are available, the cross-relationship has no physical interpretation for assessing for assessing the similarity of systems for a specific nuclide-reaction pair.

To request the computation of extended c_k for each application identified in the APPLICATIONS section of the input in relation to each experiment in the EXPERIMENTS portion of the input, simply enter the input *c_long* in the PARAMETER section of the input.

Extended $\mathbf{c}_r$

Similar to the extended c_k edit, the extended c_r edit lists the contribution of each nuclide-reaction-to-nuclide-reaction energy covariance matrix to the global integral index c_k. An individual c_r evaluating the similarity of each application to each experiment in terms of only one nuclide-reaction pair, normalized from -1 to 1, is also available. The computation of the extended c_r is the same as that of extended c_k, but with user-defined reactions removed from consideration. The *EXCLUSIONS* data block is used to identify which reactions will be excluded from consideration in the calculation of c_r and its components as presented in extended c_r. If the user identifies no reactions, then c_r and extended c_r will be computed the same as c_k and extended c_k. The c_r parameter and extended c_r edit are equivalent to removing all sensitivities for a given reaction or series of reactions from the sensitivity data file for all applications and all experiments considered in the analysis.

As with extended c_k, nuclide-reaction-to-nuclide-reaction covariances using default and user-input values are identified with one and two asterisks, respectively, in the text output, and are identified with unique colors in the HTML output. Nuclide-reaction-to-nuclide-reaction covariances using default and user-input values for *cov_fix* adjustments are identified with three and four asterisks, respectively, in the text output, and are identified with unique colors in the HTML output. Warning messages are printed to identify which values were replaced and which standard deviation value was used in the substitution.

To request the computation of extended c_r for each application identified in the *APPLICATIONS* section of the input in relation to each experiment in the *EXPERIMENTS* portion of the input, simply enter the input *cr_long* in the *PARAMETER* section of the input.

6.3.1.3 Penalty assessment

A method is available to assess an additional margin to subcriticality, or penalty, where sufficient experiments are not available to provide complete coverage for a particular application [refTsip3]. This penalty is intended as an additional uncertainty component that can be added to the calculated value of k_{eff} to provide an added measure of safety for application systems where validation coverage is lacking. The penalty calculation is based on the criteria for coverage explained in Sect. 6.3.1.1.3. The criteria for coverage in this implementation of the penalty assessment is that if a single experiment that passes qualification tests for the particular application exhibits a sensitivity coefficient for a particular energy group for a particular nuclide-reaction pair that is at least as great in magnitude and has the same sign as the corresponding sensitivity coefficient for the application, then adequate coverage exists for the code validation of the application. For group-wise nuclide-reaction specific sensitivity coefficients for the application that are not fully covered by the experiments, the uncovered portion of the sensitivity coefficient is used to compute an uncertainty in k_{eff} though the cross section covariance data.

Any experiment used in the penalty assessment calculation must pass a qualification test to determine global similarity of the experiment, based on a global integral index (c_k, E, or G), and may also have to pass a nuclide-reaction specific qualification test based on the g integral index. Thus, only experiments that exhibit a certain degree of similarity to the application can be considered in this calculation, unless the tests are deactivated at the user's discretion. Additionally, a number of similar experiments may be required before any penalty assessment is produced.

To compute the penalty, a vector of the minimum differences in the sensitivity coefficients, $\mathbf{Z_a}$, for the application with respect to all experiments can be obtained as

$$\mathbf{Z_a} \equiv \left[Z_{x,j}^{a,n}\right] n = 1, \ldots, N, x = 1, \ldots, X, j = 1, .., J \tag{6.3.15}$$

where,

$Z^{a,n}_{x,j} = S^{a,n}_{x,j} - C^{a,n}_{x,j}$,

$C^{a,n}_{x,j}$ is a composite of the best available sensitivity data from all experiments and is defined as

$C^{a,n}_{x,j} = S^{e',n}_{x,j}$ for the experiment that satisfies min $\left|S^{a,n}_{x,j} - S^{e',n}_{x,j}\right|$, e′ =1,. . . ,E,

$$S^{e',n}_{x,j} = \begin{cases} S^{e,n}_{x,j}, \text{ where} & \left|S^{a,n}_{x,j}\right| \geq \left|S^{e,n}_{x,j}\right| \text{ and } \frac{S^{a,n}_{x,j}}{\left|S^{a,n}_{x,j}\right|} = \frac{S^{e,n}_{x,j}}{\left|S^{e,n}_{x,j}\right|} \\ S^{a,n}_{x,j}, \text{ where} & \left|S^{a,n}_{x,j}\right| < \left|S^{e,n}_{x,j}\right| \text{ and } \frac{S^{a,n}_{x,j}}{\left|S^{a,n}_{x,j}\right|} = \frac{S^{e,n}_{x,j}}{\left|S^{e,n}_{x,j}\right|} \\ 0, & \text{otherwise} \end{cases} \tag{6.3.16}$$

a represents a particular application,

e represents a particular experiment,

n represents a particular nuclide,

x represents a particular reaction,

j represents a particular energy group,

N = number of nuclides in the application system,

X = number of reactions for each nuclide,

J = number of energy groups, and

E = number of experiments meeting the qualification tests.

Once $\mathbf{Z_a}$ is computed, the portion of the sensitivity of the application that is not covered by the experiments can be used to propagate the uncertainty in the cross section data to a relative uncertainty in k_{eff} as

$$\Delta k_{\text{eff}}/k_{\text{eff}} = \sqrt{\mathbf{Z_a}\mathbf{C}_{\alpha\alpha}\mathbf{Z_a}^{\dagger}} \tag{6.3.17}$$

where † indicates a transpose and $\mathbf{C}_{\alpha\alpha}$ is the matrix of the cross section covariance data defined in Eq. (6.3.1). In the above equation, the elements of $Z_{\mathbf{a}}$ are each expressed in terms of $(\Delta k_{\text{eff}}/k_{\text{eff}})/(\Delta\Sigma/\Sigma)$, and the elements of $C_{\alpha\alpha}$ are expressed in terms of relative variances or covariances as $(\Delta\Sigma/\Sigma)^2$, so that the final penalty is expressed as a relative uncertainty in k_{eff} , $\Delta k_{\text{eff}}/k_{\text{eff}}$. This relative uncertainty in k_{eff} is written to the output file in the penalty calculations.

To request the penalty computation for each application identified in the *APPLICATIONS* section of the input in relation to all experiments in the *EXPERIMENTS* section of the input, simply enter the input *penalty* in the *PARAMETER* section of the input. Additionally, a list of the contribution each nuclide-reaction-to-nuclide-reaction covariance matrix to the total penalty can be viewed by entering *penlong* in the *PARAMETER* input. This creates an edit similar to the Uncertainty Information edit of the SAMS module. Each value shown in this output edit represents the relative penalty in percent (% $\Delta k/k$) due to the specified nuclide-reaction-to-nuclide-reaction covariance matrix. The values are sorted in order of descending magnitude. The cumulative penalty can be constructed by squaring the individual values, then adding those that had positive signs and subtracting those that had negative signs, then taking the square root. Negative values in the table result from covariance matrices that have anticorrelated values.

The qualification test for including or excluding experiments from the development of the penalty for a particular application is set by several input parameters. The purpose of the qualification test is to ensure that some relevant data are used in the calculation. Otherwise, in the limit that no relevant data are used in

the penalty calculation, the Z_a minimum difference sensitivity vector becomes S_a, the sensitivity vector for the application. In this case, the maximum penalty assessed is simply the uncertainty in the application's criticality calculation due to cross section covariance data.

A global qualification test, to test the similarity of a particular experiment to the given application based on a global integral index, is configured with the keywords: *penusec*, *penusee* and *penuseg*. These keywords are used to produce a penalty calculation that only includes experiments with c_k, *E,* or *G* values at least as great as *cvalue*, *evalue* or *gvalue*, respectively. The default value is *penusec*. If more than one of the keywords *penusec*, *penusee* or *penuseg* are included in the input, only the last one entered will be used. The penalty is only computed for a given application if the number of experiments passing the global integral index qualification test is at least as great as *penminx* (default = 10). If no global test is desired, enter *penminx=0*.

The *pencut*= keyword allows the user to set a discriminator for excluding nuclide-reaction pairs from the application with small sensitivity coefficients from the penalty calculation. If the sum of the absolute values of the group-wise sensitivity coefficients is below *pencut*, the nuclide reaction pair is excluded from the penalty calculation. The default value is 0.0, which includes all nuclide-reaction pairs in the penalty calculation. Additionally, *penlgv*= sets a discriminator that only includes experiments with a *g* value relative to the application for a given nuclide-reaction pair that meets or exceeds *penlgv*. Thus, using *penlgv* may allow some nuclide-reaction pairs from a given experiment to be included in the penalty calculation, but exclude others from the same experiment that do not meet the criteria. The default value is 0.0, which means include all nuclide-reaction pairs that pass the other qualification tests.

The keyword *penwarn* activates a penalty warning edit that details which experiments were excluded from the penalty calculation based on failing the global qualification test, and which nuclide-reaction pairs were excluded from the penalty calculation based on failing the nuclide-reaction specific tests.

The composite of the best available sensitivity data from all experiments that meet the requested criteria, as used in the calculation of the penalty, can be viewed with the composite sensitivity data for nuclides and reactions requested in the *REACTIONS* input data block with the input keyword *prtcomp* described in Sect. 6.3.1.4.3.

The $\mathbf{C}_{\alpha\alpha}$ matrix in Eq. (6.3.17) is the cross section covariance data read in the COVERX formatted data file identified by *coverx*=. As in the calculation of c_k, nuclide-reaction pairs without available covariance data are omitted from this analysis, but it is assumed that either the cross section data values from these pairs are well known (i.e., small uncertainties), or that the sensitivity of the system k_{eff} to these nuclide-reaction pairs is small. Where these assumptions hold, the nuclide-reaction pairs without cross section uncertainty data present a negligible contribution to the penalty calculation. For situations where this negligible contribution assumption is judged not to be valid, the use of uncertainty analysis for the computation of a penalty is not appropriate. However, the *COVARIANCE* data block can be used to input uncertainty values for the cross section data for particular nuclide-reaction pairs to assess the impact of additional covariance data. To utilize the covariance data generated by user input in the *COVARIANCE* data block, the keyword *use_icov* must be entered in the *PARAMETER* data block. Additionally, default uncertainty values can be assigned for all unknown covariance data. The default uncertainty data input in the *PARAMETER* data block and the keyword *use_dcov* must be entered to activate its use. In the extended penalty edit, nuclide-reaction-to-nuclide-reaction covariances using default and user-input values are identified with one and two asterisks, respectively, in the text output, and are identified with unique colors in the HTML output. Warning messages are also printed to identify substituted covariance matrices.

When *use_dcov* and/or *use_icov* and *cov_fix* are specified in the *PARAMETER* data block, and a reaction has zero or large (standard deviation > 1000%) values on the diagonal of the covariance matrix, these values are replaced with the square of the user input or default standard deviation values, and the corresponding

off-diagonal terms are substituted according to the user input or default correlation values. In the extended penalty edit, nuclide-reaction-to-nuclide-reaction covariances using default and user-input values for *cov_fix* adjustments are identified with three and four asterisks, respectively, in the text output, and are identified with unique colors in the HTML output. Warning messages are printed to identify which values were replaced and which standard deviation value was used in the substitution.

6.3.1.4 Other parameters

TSUNAMI-IP can produce a number of other parameters that are useful for analysis of systems. These are briefly explained in this section.

Uncertainty information

The keyword *uncert* activates the calculation of the uncertainty in k_{eff} due to the cross section covariance data read from the COVERX formatted data file identified by *coverx*=. The uncertainty is computed for each application and each experiment and is printed in the *values* table as a standard deviation value with its statistical uncertainty, if appropriate. The uncertainty value printed is a relative uncertainty in percent (i.e., $\Delta k_{\text{eff}}/k_{\text{eff}} \times 100\%$).

Nuclide-reaction pairs without available data are omitted from this analysis, but it is assumed that either the cross section data values from these pairs are well known (i.e., small uncertainties), or that the sensitivity of the system k_{eff} to these nuclide-reaction pairs is small. Where these assumptions hold, the nuclide-reaction pairs without cross section uncertainty data present a negligible contribution to the uncertainty-based analysis. For situations where this negligible contribution assumption is judged not to be valid, the use of uncertainty analysis is not appropriate. However, the *COVARIANCE* data block can be used to input uncertainty values for the cross section data for particular nuclide-reaction pairs to assess the impact of additional covariance data. To utilize the covariance data generated by user input in the *COVARIANCE* data block, the keyword *use_icov* must be entered in the *PARAMETER* data block. Additionally, default uncertainty data can be assigned for all unknown covariance data. This default data is input in the *PARAMETER* data block and the keyword *use_dcov* must be entered to activate its use.

To request a listing of the contributions nuclide-reaction-to-nuclide-reaction covariance matrix to the uncertainty in the k_{eff} value for each application identified in the *APPLICATIONS* section of the input enter the input keyword *uncert_long* in the *PARAMETER* section of the input. This creates an edit similar to the Uncertainty Information edit of the SAMS module. Each value shown in this output edit represents the relative uncertainty in percent ($\%\Delta k/k$) due to the specified nuclide-reaction-to-nuclide-reaction covariance matrix. The values are sorted in order of descending magnitude. The cumulative uncertainty can be constructed by squaring the individual values, then adding those that had positive signs and subtracting those that had negative signs, then taking the square root. Negative values in the table result from covariance matrices that have anticorrelated values.

In the extended uncertainty edit, nuclide-reaction-to-nuclide-reaction covariances using default and user-input values are identified with one and two asterisks, respectively, in the text output, and are identified with unique colors in the HTML output. Nuclide-reaction-to-nuclide-reaction covariances using default and user-input values for *cov_fix* adjustments are identified with three and four asterisks, respectively, in the text output, and are identified with unique colors in the HTML output. Warning messages are printed to identify which values were replaced and which standard deviation value was used in the substitution.

Completeness parameter

A parameter has been developed to assess the completeness of a set of experiments for the code validation of a given application. [4] The set of experiments is "complete" in the sense that it completely tests all the important cross section elements in the particular application of interest. The availability of sensitivity coefficients provides a key element in the definition of this completeness parameter.

The completeness parameter, R, is defined as follows:

$$R = S_a / S_t, \tag{6.3.18}$$

where

$$\begin{aligned} \mathrm{S_t} &= \sum_{\mathrm{n}} \sum_{\mathrm{x}} \sum_{\mathrm{j}} \left| \mathrm{S}^{\mathrm{a,n}}_{\mathrm{x,j}} \right| \\ S_a &= \sum_{n} \sum_{x} \sum_{j} \left| dS^{a,n}_{x,j} \right| \end{aligned} \tag{6.3.19}$$

and

$$d = \begin{cases} 1, \text{ if } N^n_{x,j} \geq nix\lim \\ 0, \text{ if } N^n_{x,j} < nix\lim \end{cases} \tag{6.3.20}$$

$N^n_{x,j}$ = number of systems for which $S^{e,n}_{x,j} >$ | senfac $\times S^{a,n}_{x,j}$|

e = experiment,

a = application,

$S^{e,n}_{x,j}$ = the sensitivity of k_{eff} of an experiment to the cross sections of the constituent material nuclide n, reaction x, and energy group j,

$S^{a,n}_{x,j}$ = the sensitivity of k_{eff} of the application to the cross sections of the constituent material nuclide n, reaction x, and energy group j,

nixlim = an integer, and

senfac = a real number such that $0.0 \leq senfac \leq 1.0$.

The completeness parameter is designed to give the effective fraction of the total sensitivity for each application system that is "covered" by the benchmark set. This coverage is defined by comparing the magnitude of each group-wise sensitivity coefficient for the application with respect to each of the corresponding sensitivities of the benchmark systems. The completeness parameter is computed for each application for each experiment if the keyword *cp* is entered in the *PARAMETER* data. The minimum coverage of the sensitivity coefficients for the experiment systems is defined as *senfac*$\times$ 100% of the application sensitivity in the definition of $N^n_{x,j}$. The value of *senfac* is set with the keyword input *senfac*=, and the default value is 0.9. Thus, the experiment must have a sensitivity coefficient at least 90% as great as that of the application for the particular nuclide, reaction and energy group to count in $N^n_{x,j}$. The number of experiments counted in $N^n_{x,j}$ must be at least *nixlim* to change d from 0 to 1, which indicates coverage for the particular nuclide, reaction and group of the application. The value of *nixlim* is set by the *nixlim*= keyword, and it has a default value of 10

Composite sensitivity data

A composite of the best available sensitivity data from all experiments included in the analysis, based on the coverage criteria used for the G integral index in Sect. 6.3.1.1.4 is produced for each application for each nuclide-reaction pair in the *REACTIONS* input if the keyword *prtcomp* is entered. The composite profile for a particular application a for nuclide n and reaction x is defined as the vector

$$\mathbf{C}_{\mathbf{x}}^{\mathbf{a,n}} \equiv \left[C_{x,j}^{a,n}\right], j = 1, .., J \tag{6.3.21}$$

where,

$C_{x,j}^{a,n}$ is $S_{x,j}^{e',n}$ for the experiment that satisfies $\min \left|S_{x,j}^{a,n} - S_{x,j}^{e',n}\right| \; e' = 1, \ldots, E$,

$$S_{x,j}^{e',n} = \begin{cases} S_{x,j}^{e,n}, \text{ where} & \left|S_{x,j}^{a,n}\right| \geq \left|S_{x,j}^{e,n}\right| \text{ and } \frac{S_{x,j}^{a,n}}{\left|S_{x,j}^{a,n}\right|} = \frac{S_{x,j}^{e,n}}{\left|S_{x,j}^{e,n}\right|} \\ S_{x,j}^{a,n}, \text{ where} & \left|S_{x,j}^{a,n}\right| < \left|S_{x,j}^{e,n}\right| \text{ and } \frac{S_{x,j}^{a,n}}{\left|S_{x,j}^{a,n}\right|} = \frac{S_{x,j}^{e,n}}{\left|S_{x,j}^{e,n}\right|} \\ 0, & \text{otherwise} \end{cases} \tag{6.3.22}$$

a represents a particular application,

e represents a particular experiment,

n represents a particular nuclide,

x represents a particular reaction,

j represents a particular energy group,

J = number of energy groups, and

E = number of experiments.

An example composite sensitivity profile for ^{1}H total is shown in Fig. 6.3.3. Here, the composite sensitivity profile comprised of the best available data from unidentified experiments 1–5 is shown in black. The sensitivity of the unidentified application is shown in red. The areas where the red application curve exceeds the black composite curve are considered uncovered. Areas where the experiment data exceed the application data are considered fully covered. Note that the composite data does not exceed the application data.

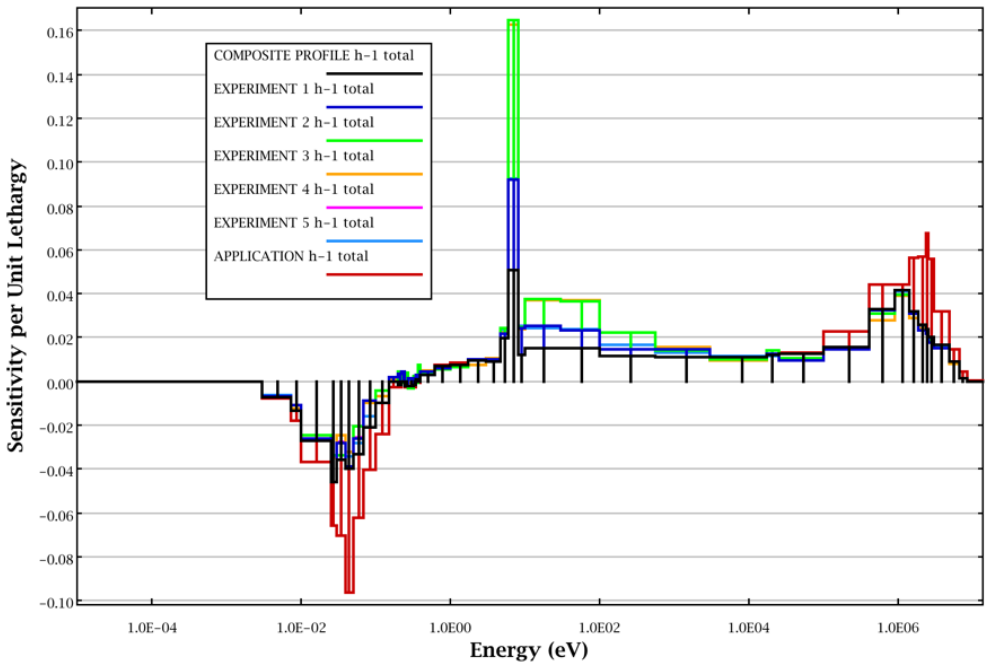

Fig. 6.3.3: Example composite sensitivity profile.

If the composite data for a particular nuclide-reaction pair for a particular energy group are added to the minimum difference data as defined in Eq. (6.3.15), the sensitivity of the application would result as

$$C_{x,j}^{a,n} + Z_{x,j}^{a,n} = S_{x,j}^{a,n} \tag{6.3.23}$$

A sensitivity data file containing the composite sensitivity data is generated to permit further analysis. Only data for those nuclides and reaction identified in the *REACTIONS* input block are included in the composite sensitivity data file. The data file is identified with the TSUNAMI-IP input file name with the extension ".sdf" and is suitable for use with Fulcrum. This data file is presented as an interactive plot in the HTML output. The following data are included on the composite sensitivity data file for each nuclide-reaction pair identified in the *REACTIONS* input block for each application: the sensitivity of the application identified with "Application" and the application number, the composite sensitivity data as defined in Eq. (6.3.21) , and the composite profile used in the definition of the minimum difference profile from the penalty calculation (Sect. 6.3.1.3), which may be reduced from the full composite by excluding experiments not meeting the cutoff criteria for the penalty calculation. The composite data as used in the penalty calculation are identified as "Cut Composite."

Non-coverage

A summary of non-coverage for the nuclide-reaction pairs entered in the *REACTIONS* section of the input can be produced if the keyword *prtnotcv* is entered in the *PARAMETER* data. The non-coverage edit gives the number of groups that are not fully covered according to the *G* criteria and gives the sum of the non-covered portion of the sensitivity coefficients. It also lists the group with largest sensitivity, regardless of whether or not it is covered, and gives the sensitivity value for this group. The experiment that best covers the group with the maximum sensitivity is given and the sensitivity of this group for the best matching experiment is given.

6.3.1.5 Miscellaneous options

Several input parameters that provide a wide range of options in TSUNAMI-IP are explained here. These keywords are entered in the *PARAMETER* data block.

VADER input files

VADER (formerly USLSTATS) is a data regression tool described in Ref. [refTsip6] and in the VADER chapter of the SCALE manual. The *uslstats* keyword requests input files for VADER to be generated from all integral indices computed by TSUNAMI-IP. The *uslsummary* keyword requests VADER input files to be generated from all integral indices exceeding their particular acceptance criteria (*cvalue, evalue,* and *gvalue*). The uncertainties in the k_{eff} values for VADER can be adjusted with two options. The default setting is that the uncertainty for each k_{eff} value included in the VADER input file consists of the square root of the sum of the squares of the Monte Carlo uncertainty and a uniform experimental uncertainty of 0.3%. To quadratically add the uncertainty in k_{eff} due to cross section covariance data to this uncertainty, enter the keyword *usl_uncert*. To modify the uniform experimental uncertainty, use the *usl_sigs*= keyword. When a positive value is entered for *usl_sigs*, this value is treated as the total uncertainty for each experiment, and no other contributions, Monte Carlo or cross section, are considered. When a negative value is entered for *usl_sigs*, this value is treated as the experimental uncertainty for each experiment and Monte Carlo and cross section uncertainties are added as appropriate. Currently, no option exists to input a unique experimental uncertainty for each experiment.

The VADER input files contain the extension `.usl` and the filenames are presented in a descriptive format as *title_xxxx_p_yyyy.usl*, where *title* is the *filename* of the TSUNAMI-IP input case, *xxxx* is the application number in the TSUNAMI-IP input, *p* is the name of the integral index (*ck* for c_k, *e* for *E*, and *g* for *G*), and *yyyyy* is the TSUNAMI-IP execution number (typically 0001). When the summary inputs are requested with *uslsummary*, the filename is of the format *title_xxxx_p_sum_yyyy.usl*, where *sum* denotes that this VADER input file contains only the summary of experiments that exceed the requested criteria for the specific integral index.

Covariance data directory listing

The *prtmtrix* keyword causes a listing of the energy covariances of the COVERX formatted cross section data file, identified by *coverx*=, to be printed.

HTML output

The keyword *html* causes TSUNAMI-IP to create an html formatted output. This output edit is accessed by opening the *root*.html file, where *root* is the name of the user's input file without extensions. Additional resources for the html output are placed in new directories called *root*.htmd and *applet_resources*. The *root*.html directory contains files needed to display data produced by the current case and the *applet_resources* directory contains Java applets for data plotting within the HTML interface and can be shared by multiple output files within the same directory. The *root*.html file and associated directories are placed in the same location as the user's input file. The html formatted output is color coded and more easily navigated than the standard plain text formatted output file. The html output can be customized with the *HTML* data block.

Case sensitive input

The *inptcase* keyword sets a flag in the SCALE free form input reader to prevent SCALE from translating all input to lower case. The purpose of this keyword is the identification of file and directory names that have upper case characters on a case-sensitive operating system. By default, the SCALE input reader translates all text to lower case. However, any input entered after *inptcase* is treated as case sensitive. All subsequent keyword entries and data block names must be entered in lower case, or errors will result.

Print filenames

The *usename* keyword causes TSUNAMI-IP to identify files with their file names in the code output. By default, TSUNAMI-IP identifies files according to the title on the TSUNAMI-A or TSUNAMI-B sensitivity data files. For files that have the same titles, or have long or non-descriptive titles, *usename* can provide for simplified interpretation of the output.

c_k and* E *differences

The keywords *cechk*= and *cediff*= allow the user to input discriminators that govern the output of warning messages when c_k and E values for a particular application and experiment differ by more than *cediff* and c_k and E are both at least as great as *cechk.*

Plots

The keyword *plot* causes Javapeño formatted plot (.plt) files of the global integral indices to be generated. A plot file containing all computed integral index values for each application as a function of experiment number is titled *rootxxxx.plt*, where *root* is the base name of the input file and *xxxx* is the TSUNAMI-IP execution number (typically 0001). Plot file containing the number of integral index values that exceeded the acceptance criteria for each application is titled *rootsummaryxxxx.plt*, where *summary* indicated it is a summary plot. Both plots are displayed in the HTML output or can be view with Fulcrum. If the .plt files are opened in Fulcrum with "Open Dataset…" each set of data can be manually added to the plot as desired by the user. If the .plt files are opened with "Open Plot…," all data are immediately displayed.

Absolute sensitivity option

All global indices and parameters can also be calculated using absolute sensitivities. This capability is useful when working with TSAR-generated reactivity sensitivity data files. TSAR creates a sensitivity data file with reactivity sensitivities tabulated in either relative format or absolute format $(\Delta\rho/|\rho|)/\Delta\sigma/\sigma)$. If keyword *relative* is specified in the PARAMETER block, any absolute reactivity sensitivities are internally converted to $(\Delta\rho)$ / $(\Delta\sigma/\sigma)$. (Note that the reactivity sensitivity is normalized by ρ rather than $|\rho$. Normalizing by $|\rho|$ can potentially lead to c_k and E indices with the wrong sign.) Likewise, if the keyword *absolute* is specified, any relative reactivity sensitivities are internally converted to $(\Delta\rho \cdot \rho/ (\Delta\sigma/\sigma)$, and the SAMS-generated relative *k*eff sensitivities are internally converted to $\left(\Delta k_{eff}/k_{eff}\right)$ / $(\Delta\sigma/\sigma)$. If both the *relative* and *absolute* keywords are specified, the last keyword entered in the PARAMETER block is used to determine the sensitivity format. If neither keyword is entered, the default relative format is applied.

It is important to note that the absolute sensitivity option has been added for user control over the format of the uncertainty edit and the extended uncertainty edit. Using absolute sensitivities, the absolute standard deviation in k_{eff} or ρ is edited. Using relative sensitivities, the relative standard deviation in k_{eff} or ρ is edited. The global indices c_k and E are the same regardless of the sensitivity format option. For other indices and parameters (i.e., G, penalty assessment, and completeness parameter), their respective values can change depending on sensitivity format option. These indices and parameters play an important role in nuclear criticality safety validation, and the default relative format option is recommended.

6.3.1.6 User input

The user input for TSUNAMI-IP is described in this section. The input consists of an optional title on a single line followed by one required and six optional blocks of data which are identified in Table 6.3.1 and individually described in subsequent subsections. These data blocks must begin with **READ KEYNAME**and end with **END KEYNAME**, where **KEYNAME** is the name of an individual data block. The required PARAMETER data block should be entered first, followed by the remaining blocks of data in any order. Note that this is different than the SCALE 5 and SCALE 5.1 versions of TSUNAMI-IP, which allowed the blocks of data to be in any order. The SCALE 6 version will continue if the PARAMETER data block is not entered first, but the keywords *absolute* and *use_diff_groups* (explained below) will have no effect.

Table 6.3.1: Keynames and descriptions for TSUNAMI-IP input data blocks*.

Keyname	Description	Required/Optional
PARAMETER	Indices and parameters to be computed are input in this section. Output edits are requested, and user-input criteria values for numeric data are entered.	Required
APPLICATIONS	File paths to sensitivity data files representing application systems for which validation by the experiments are assessed are input in this section.	Optional*
EXPERIMENTS	File paths to sensitivity data files representing experiments to be used in the analysis are input in this section.	Optional*
RESPONSE	File paths to sensitivity data files representing experiments or applications to be used in the analysis are input in this section.	Optional*
REACTIONS	Specific nuclide-reaction pairs for which analysis with certain indices and parameters are desired can be entered in this section.	Optional
COVARIANCE	User input standard deviation for nuclide-reaction pairs for which cross-section-covariance data are not available can be entered in this section.	Optional
EXCLUSIONS	User input reactions to exclude from c_r and Extended c_r calculations.	Optional
HTML	Parameters to customize the HTML formatted output can be entered in this section.	Optional

*Although the EXPERIMENTS, APPLICATIONS, and RESPONSE data blocks are optional, at least one application and one experiment must be specified on the TSUNAMI-IP input file. This can be done in a variety of ways explained below.

Parameter data

The *PARAMETER* data block is used to request the calculation of the various indices and parameters available in TSUNAMI-IP, request output edits and set criteria values. The parameter block must begin with *READ PARAMETER* and end with *END PARAMETER*. The data input to the parameter data block consist of numerous keywords that are shown, along with their default values and descriptions, in Table 6.3.2. A keyword that ends with = must be followed by numeric data. Keywords that do not end with = are Boolean flags that are used to turn on certain features of the code, such as the computation of certain data or certain output edits. If the keyword is present for a Boolean entry, the value is set to true. Otherwise, the Boolean flag is set to its default value. If no data are requested in the *PARAMETER* section using the Boolean flags, then no data will be produced by the code. The input is designed to maximize user control over the operation of the code. A more detailed description of the indices and parameters is given in Sect. 6.3.1.1 through Sect. 6.3.1.4.

Table 6.3.2: Input data for parameter block of TSUNAMI-IP input.

Keyword	**Default value**	**Description**
absolute	False	Use absolute sensitivities [e.g. $\left(\Delta k_{eff}/\Delta\sigma/\sigma\right)$] for all applications and experiments in the analysis. If *absolute* is entered, the keyword *relative* is set to *False*.
c	False	Compute c_k values for each application compared to each experiment.
c_long	False	Produces extended c_k output edit for each application compared to each experiment.
cechck=	0.5	Level of E and c_k values that trigger the *cediff* warning. If E or c_k are below this value, no warning is printed.
cediff=	0.1	If the E and c_k values for a given application and experiment differ by more than *cediff*, a warning message is printed.
cov_fix	False	Replace zero and large (standard deviation >1000%) values on diagonal of cross-section covariance data with user input values and default values.
coverx=	56group-cov7.1	Name of cross-section covariance data file to use in analysis.
cp	False	Compute and print completeness parameter for each application.
cr	False	Compute c_r values for each application compared to each experiment.
cr_long	False	Produces extended c_r output edit for each application compared to each experiment.

continues on next page

Table 6.3.2 – continued from previous page

inptcase	False	This sets the SCALE free form reader to leave the case of the input data as read. This is useful when sensitivity data file names have upper case letters. If this option is set, all other input keywords MUST be in lower case to be correctly interpreted by SCALE. This keyword must be entered in the input prior to the reading of any titles of the sensitivity data files with capital letters.
large_cov=	10	Cutoff fractional standard deviation value for *cov_fix*. Covariance data with uncertainties larger than *large_cov* are replaced with user-defined or default values. Default = 10, which is 1000% uncertainty.
lg	False	Compute *g* values for fission, capture and scatter for each nuclide for each experiment compared to each application and print them in a table if the application's sensitivity for the corresponding nuclide-reaction pair is greater than or equal to *sencut*. Also compute *g* values for reactions specified in the *REACTIONS* data block.
lgall	False	Print *g* values for fission, capture and scatter for all nuclides for all experiments for each application.
lggroups	False	Print a table listing the numbers of experiments that are at least as sensitive as the application for each group for each reaction requested in the *REACTIONS* data block.
lgsum	False	Print a summary table of *g* for each application for each experiment that exceeds *lgvalue* for each nuclide's capture, fission and scatter reactions
lgvalue=	0.9	Threshold value of *g* for inclusion in summary table.
nixlim=	10	Minimum number of experiments with group-wise values exceeding *senfac* times the group-wise value for the application for the group-wise value to be added to the completeness parameter.
penalty	False	Create penalty assessment based on differences in the application's sensitivity profile for a particular nuclide-reaction pair, and the corresponding composite profile for all qualifying experiments.

continues on next page

Table 6.3.2 – continued from previous page

pencut=	0.0	Cutoff value for excluding sensitivities from the penalty calculation. If the sum of the absolute values of the energy-dependent sensitivity data for a particular nuclide-reaction pair is below this number, the nuclide-reaction pair will not be included in the penalty calculation.
penlgv=	0.0	Use only nuclide-reaction pairs with g values exceeding *penlgv* in the penalty assessment.
penlong	False	Print detailed edits of components of penalty assessments showing each component of the penalty.
penminx=	10	Minimum number of qualifying experiments for each application for penalty calculation.
pensusec	True	Use only experiments with c_k values exceeding *cvalue* in the penalty assessment. If *penusec* is entered, the keywords *penusee* and *penuseg* are set to False.
penusee	False	Use only experiments with E values exceeding *evalue* in the penalty assessment. If *penusee* is entered, the keywords *penusec* and *penuseg* are set to False.
penuseg	False	Use only experiments with G values exceeding *gvalue* in the penalty assessment. If *penuseg* is entered, the keywords *penusec* and *penusee* are set to False.
penwarn	False	Print list of warning messages noting the experiments and nuclide-reaction pairs that were excluded from the penalty calculation.
plot	False	Produces Javapeño formatted plot (.plt) files for integral values and composite sensitivity data.
prtcomp	False	Print "composite" of experiment sensitivity profiles for reactions selected in *REACTIONS* data block. Also write data to sensitivity data file.
prtmtrix	False	Print directory of data available on the cross-section-covariance data library.
prtnotcv	False	Print a table summarizing the non-coverage for the nuclide-reaction pairs entered in the *REACTIONS* data block.
prtparts	False	Print the components of E and G for fission capture in scatter in the *values* table.

continues on next page

Table 6.3.2 – continued from previous page

relative	True	Use relative sensitivities [e.g., $\left(\Delta k_{eff} k_{eff}\right) / (\Delta\sigma/\sigma)$ for all applications and experiments in the analysis. If *relative* is entered, the keyword *absolute* is set to False.
return_work_cov	False	Copy the working covariance library to the return directory with the file name *job_name.wrk.cov,* where *job_name* is the name of the input file. If *return_work_cov* is not present, the working covariance library remains in the temporary working directory with the file name *job_name.wrk*.
sencut=	0.01	Cutoff value for ignoring low valued sensitivities in nuclide-reaction specific edit tables. If the absolute value of the sum of the energy-dependent sensitivity data for a particular nuclide-reaction pair is below this number, the nuclide-reaction pair will not be included in the edit.
senfac=	0.9	Value used in calculation of completeness parameter. Group-wise sensitivity for the application is counted as validated by the experiment if the sensitivity from the experiment is greater than the application sensitivity times *senfac*.
udcov=	0.05	User-defined default value of standard deviation in cross-section data to use for all groups for nuclide-reaction pairs for which covariance data are not available on the selected data file.
udcov_corr=	1.0	User-defined default correlation value to use for nuclide-reaction pairs for which covariance data are not available on the selected data file.
udcov_corr_type=	*zone*	User-defined default correlation in cross-section data to use for nuclide-reaction pairs for which covariance data are not available on the selected data file. Allowed values are *long*, *zone*, and *short.* (See Sect. 6.3.1.6.3 for details on *long*, *zone* and *short.*)
udcov_fast=	0.0	User-defined default value of standard deviation in cross-section data to use for fast data for nuclide-reaction pairs for which covariance data are too large or not available on the selected data file.

continues on next page

Table 6.3.2 – continued from previous page

ud-cov_inter=	0.0	User-defined default value of standard deviation in cross-section data to use for intermediate data for nuclide-reaction pairs for which covariance data are too large or not available on the selected data file.
ud-cov_therm=	0.0	User-defined default value of standard deviation in cross-section data to use for thermal data for nuclide-reaction pairs for which covariance data are too large or not available on the selected data file.
uncert	False	Computes uncertainty in k_{eff} due to covariance data
uncert_long	False	Prints extended table of uncertainty in k_{eff}due to covariance data.
use_dcov	False	Use user-defined default covariance data for nuclide reaction pairs not included on the covariance data file. The user-defined data will be used in the penalty assessment as well as the computation of c_{k} and uncertainty calculations.
use_diff_groups	True	Allow sensitivity data files to have different energy groups. Data files with different energy groups will be internally converted to the energy group structure of the covariance data file. This parameter is now always equal *true* and does not need to be set.
use_icov	False	Use user-defined data input in *COVARIANCE* input data block in place of default values for user input nuclide-reaction pairs that are not on the covariance data file. The user-defined data will be used in the penalty assessment as well as the computation of c_{k} and uncertainty calculations.
usename	False	Use the name of the sensitivity data file in place of its title in all output.
uslstats	False	Produces VADER input files for trending analysis with all experiments for each global integral index (c_{k}, E, and G) requested for each application
uslsummary	False	Produces VADER input files for trending analysis with experiments exceeding cutoff value (*cvalue*, *evalue* or *gvalue*) for each global integral index (c_{k}, E, and G) requested for each application

continues on next page

Table 6.3.2 – continued from previous page

usl_p=	0.9990	Value of P in VADER input files. P is the portion of the population falling above the lower tolerance level
usl_1-g=	0.9500	Value of 1-γ in VADER input files. 1-γ is the confidence on the fit.
usl_alpha=	0.9990	Value of α in VADER input files. α is the confidence on the proportion of P.
usl_xmin=	0.0000	Value of x(min) in VADER input files. x(min) is the minimum value of the parameter x.
usl_xmax=	1.0000	Value of x(max) in VADER input files. x(max) is the maximum value of the parameter x.
usl_sigs=	-0.0030	Value of σ_s in VADER input files. If a positive value is entered, it is applied as the total uncertainty for each experiment. If a negative or zero value is entered, it is used as the experimental measurement uncertainty and any Monte Carlo and cross section uncertainties are added quadratically to the absolute value of *usl_sigs* for each experiment.
usl_dkm=	0.0500	Value of Δk_m in VADER input files. Δk_m is the administrative margin used to ensure subcriticality.
usl_uncert	False	Includes uncertainty in k_{eff} due to cross section covariance data from k_{eff} uncertainty written to VADER input files.
values	False	Print all computed "global" indices (E, c_k, and G) in a table for each application. If *prtparts* is input, also include the partial values

Reaction data

The *REACTIONS* data block is used to specify nuclide-reaction pairs for the *lg* and *lggroups* edits. The reactions block must begin with *READ REACTIONS* and end with *END REACTIONS*. Data are entered in pairs with the nuclide number (e.g., 92235) followed by the reaction MT number (e.g., 18). Alphanumeric input is also accepted (e.g., u-235 fission) for the nuclide-reaction pairs. Mixed input is also acceptable (e.g., 92235 fission). Available reaction types are given in Table 6.3.4.

User input covariance data

The *COVARIANCE* data block allows the user to specify a covariance matrix for specific nuclide-reaction pairs for which covariance data are not present on the covariance data file or that have zero or large values on the diagonal. The *COVARIANCE* data block must begin with *READ COVARIANCE* and end with *END COVARIANCE*.

Table 6.3.3: Input options for user-defined covariance data.

Input Parameter	**Requirement**	**Default Value**	**Allowed Values**	**Description**
Nuclide	Required	none	Nuclide name or ZA number	Nuclide for which covariance data are to be entered
Reaction	Required	none	Reaction name or MT number	Reaction for which covariance data are to be entered. See Table 6.3.4 for available reaction types.
all=	Optional	0.0	any number	Fractional standard deviation value to be applied to all groups.
fast=	Optional	0.0	any number	Fractional standard deviation value to be applied to fast groups. The *fast* value overrides the *all* value in the fast groups.
therm=	Optional	0.0	any number	Fractional standard deviation value to be applied to thermal groups. The *therm* value overrides the *all* value in the thermal groups.
inter=	Optional	0.0	any number	Fractional standard deviation value to be applied to intermediate groups. The *inter* value overrides the *all* value in the intermediate groups.
corr=	Optional	1.0	any number from -1.0 to 1.0	Correlation between groups (see *corr_type* for use)
corr_type	Optional	*zone*	*long*, *short*, *zone*	Type of correlation applied form group-to-group covariance values. *long* – correlation is applied between all groups *short* – correlation is applied only between adjacent groups *zone* – correlation is applied within fast, intermediate and thermal groups, but no correlation is applied between zones
end	Required			Denotes end of input for current nuclide/reaction

Any MT number or reaction name will be treated as a valid input, but only those present on the sensitivity data

files will produce useful information. The reaction sensitivity types computed by SAMS from TSUNAMI-1D and TSUNAMI-3D are shown in Table 6.3.4. An energy-covariance matrix is created for the specified nuclide-reaction pair with the square of the entered standard deviation for the diagonal terms for all groups using the *all*= value. Groups in the fast, intermediate and thermal energies are then set to the square of the standard deviation value entered for *fast*=, *inter*=, and *therm*=, respectively. The off-diagonal terms of the energy matrix are generated according to the input for *corr*=, and *corr_type*=, with default settings of *1.0* and *zone.* Data entered in this block do not override data present on the covariance data file. The SCALE 5.1 input format is supported where data are entered in triplets with the nuclide name (e.g., u-235), then the reaction MT number or name (e.g., 18 or fission), and then a standard deviation value. In this case, the *end* card must not be entered. The standard deviation value is applied to all groups with default setting for correlations. These data are only used if *use_icov* is specified in the *PARAMETER* data block.

Table 6.3.4: Reaction sensitivity types computed by SAMS.

MT	**Reaction**	**SCALE identifier**
0	Sum of scattering	scatter
1	Total	total
2	Elastic scattering	elastic
4	Inelastic scattering	n,n'
16	n,2n	n,2n
18	Fission	fission
101	Neutron disappearance	capture
102	n,γ	n,gamma
103	n,p	n,p
104	n,d	n,d
105	n,t	n,t
106	n,^{3}He	n,he-3
107	n,α	n,alpha
452	$\bar{\nu}$	nubar
1018	χ	Chi

If *use_icov* is specified, these data are used for the calculation of the uncertainty in k_{eff} (*uncert* and *uncert_long* edits), calculation of c_k, Extended c_k, and the penalty assessment for each application. These user input values are only applied where an application has a sensitivity profile for which there is no corresponding covariance matrix on the covariance data file. When both *use_icov* and *cov_fix* are specified in the *PARAMETER* data block, and a reaction has zero or large (standard deviation > 1000%) values on the diagonal of the covariance matrix, these values are replaced with the square of the user input standard deviation value, and the corresponding off-diagonal terms are substituted according to the values of *corr* and *corr_type*.

Specifying user input covariance data for the summative reactions total, scatter and capture have no affect on the results of TSUNAMI-IP, as the summative reactions are not used in uncertainty analysis calculations.

Application, experiment, and response data

Sensitivity data files are designated as either application systems or experiment systems by the *APPLICATIONS, EXPERIMENTS,* or *RESPONSE* data blocks. For each application system, TSUNAMI-IP will calculate integral parameters against each experiment system. Each data block must begin with *READ KEYNAME* and end with *END KEYNAME* where *KEYNAME* can be *APPLICATIONS, EXPERIMENTS,* or *RESPONSE*.

Inside each data block, sensitivity data files are listed using response definition records. A response definition record is a single line of input that contains the sensitivity data filename and nine optional keyword specifications. The sensitivity data filename and optional keywords can be entered in any order, with the following format:

filename (name=N)(use=U)(type=T) (omit) (ev=E) (uv=U) (nu=P) (absolute or abs) (relative or rel)

where

filename = sensitivity data filename. The filename can include the file path.

N = A descriptive identifier for the sensitivity data file in TSUNAMI-IP output edits. The identifier is limited to 20 alphanumeric characters (spaces are not allowed).

U = The file usage. Allowed values are *appl, expt*, and *omit*, signifying the use of the file as an application or an experiment or to exclude the file from the analysis, respectively. The default values for the *use* keyword are described below.

T = 8-character alphanumeric identifier for the response type (e.g. '*keff*'). The response type is used in various output edits along with the *name=N* identifier.

omit - Optional keyword used to omit *filename* from the analysis, can be used independent of *use=*.

E = experimental value of the response (e.g. k_{eff}).

U = uncertainty value of the response.

P = number of uncertainty components to characterize the experiment uncertainty for this response.

absolute - Optional keyword that specifies absolute sensitivities will be used for *filename*.

relative - Optional keyword that specifies relative sensitivities will be used for *filename*.

By default, filenames listed in the *APPLICATIONS* data block are designated as application systems. Likewise, filenames listed in the *EXPERIMENTS* or *RESPONSE* data blocks are designated as experiment systems. The sensitivity data files must be in either the TSUNAMI-A or TSUNAMI-B file format, detailed in Appendix Data File Formats. (TSUNAMI-IP is not currently compatible with, for example, sensitivity data files in the "ABBN" format.) Only the region-integrated sensitivity coefficients from the sensitivity data files are used by TSUNAMI-IP. These data are energy-dependent, but any mixture-dependent or region-dependent data present on the data files are not used. Case-sensitive filenames and their file paths are allowed. However, **spaces are not allowed in the filenames or file paths.**

The nine optional keywords provide more user control over how each sensitivity data file is used in the analysis, and how each sensitivity data file is identified in the TSUNAMI-IP output. By default, TSUNAMI-IP identifies files in the output according to the title on the sensitivity data files. For files that have the same

titles, or have long or non-descriptive titles, the *usename* keyword in the *PARAMETER* data block can be used to identify sensitivity data files by their filename. Although file names are unique, they can also be non-descriptive. For this reason, the *name* keyword on the response definition record can be used to create a new identifier for the sensitivity data file in the TSUNAMI-IP output. Similarly, the *type* keyword can be used to identify the response type in the output. Because TSUNAMI-IP was initially intended for similarity assessment of critical systems, the default response type identifier is '*keff*'; the type identifier for Generalized Perturbation Theory reaction rate sensitivity responses is *'gpt'*. For reactivity sensitivity data files produced by the TSAR module (Chapter 6.4H), the default response type identifier is ρ. The *type* keyword can be used to specify a descriptive response type identifier, such as *type=k_sdm* or *type=alpha_t*.

The *use* keyword specifies how the sensitivity data file is used in the analysis. Allowed values are *expt, appl,* or *omit*. All sensitivity data files on response definition records with *use=expt* are designated as experiment systems, regardless of what data block it is in. Likewise, all sensitivity data files on response definition records with *use=appl* are designated as application systems. In addition, the user can omit the sensitivity data file from the analysis by entering either *use=omit* or simply *omit* on the response definition record.

The experiment value of the response (*ev*=) and the experiment uncertainty of the response (*uv*=) are used in generating VADER input files for trending analysis. If the experiment value is not provided, then the default value used in VADER is 1.0. If the experiment uncertainty value is not provided, then the default used in VADER is the absolute value of the *usl_sigs* value in the *PARAMETER* data block.

The *ev*= and *uv*= keywords do not impact the computed results in TSUNAMI-IP and are only used if the *uslstats* keyword is included in the *PARAMETER* data block. Experiment values of k_{eff} or reactivity only need to be provided for experiment systems. TSUNAMI-IP skips over *ev*= and *uv*= keyword specifications given for application or omitted systems.

In addition to the *uv*= keyword specification, TSUNAMI-IP allows for the experiment uncertainty value to be given in terms of uncertainty components. The *nu*= keyword defines the number of uncertainty components that characterize the experiment uncertainty. If the experiment response uncertainty is given in terms of uncertainty components, the *uv*= keyword specification is optional. An uncertainty component definition record follows the response definition record if the *nu*= keyword specification is given. The uncertainty component definition record has the following format:

uncmp1 val1 uncmp2 val2 …….. uncmpP valP

where

uncmp1 =4-character alphanumeric identifier for the 1st uncertainty component.

val1 =experiment uncertainty for component *uncmp1*.

uncmp2 =4-character alphanumeric identifier for the 2nd uncertainty component.

val2 =experiment uncertainty for component *uncmp2*.

uncmpP =4-character alphanumeric identifier for the Pth uncertainty component.

valP =experiment uncertainty for component *uncmpP*.

The uncertainty component definition record contains *nu=P* pairs of alphanumeric identifiers and numeric values. The experiment uncertainty value is determined by taking the square root of the sum of the squares of each uncertainty component value.

The final optional keywords *abs* and *rel* are used to determine the format of sensitivity and uncertainty data on the response definition record and the uncertainty component definition record. For a k_{eff} response, the following four input definitions produce equivalent uncertainties:

```
1)    name=exp_001 ev=1.001 uv=0.005000 rel C:\sensitivity\k_critical_a.sdf

2)    name=exp_001 ev=1.001 uv=0.005005 abs C:\sensitivity\k_critical_a.sdf

3)    name=exp_001 ev=1.001 nu=2        rel C:\sensitivity\k_critical_a.sdf
       enri 0.003000 sden 0.004000

4)    name=exp_001 ev=1.001 nu=2        abs C:\sensitivity\k_critical_a.sdf
       enri 0.003003 sden 0.004004
```

In the example above, the measured k_{eff} is 1.001 ± 0.5% or 1.001 ± 0.005005. The sensitivity data filename is given as *C:sensitivityk_critical_a.sdf*, and the experiment response is referred to as *exp_001* in the TSUNAMI-IP output. In 1), the *relative* format is used to specify the relative standard deviation of the measured response as 0.005. In 2), the *absolute* format is used to specify the absolute standard deviation of the measured response as 0.005005. Because the TSUNAMI-generated sensitivity data file is in relative format, TSUNAMI-IP internally renormalizes the relative sensitivities to absolute sensitivities. In 3), the *relative* format is used to specify the relative standard deviation of k_{eff} due to two components (*enri* and *sden*) as 0.003 and 0.004 respectively. Using the square root of the sum of the squares approach, the relative standard deviation of k_{eff} is computed to be 0.005. In 4), the *absolute* format is used to specify the absolute standard deviation of k_{eff} due to two components (*enri* and *sden*) as 0.003003 and 0.004004 respectively. The absolute standard deviation of k_{eff} is computed to be 0.005005. Like 2), the sensitivity data file is internally converted to contain absolute sensitivities.

Because of the high-degree of flexibility in designating application systems and experiment systems in the TSUNAMI-IP input, the following two methods are recommended. The first method is consistent with previous versions of TSUNAMI-IP. That is, application systems are listed in the APPLICATIONS data block and experiment systems are listed in the EXPERIMENTS data block. The second method would be to list both sets of systems in a single RESPONSE data block and use the *use=U* keyword specification to designate how each file is to be used. Sample input files for both methods are given for the TSUNAMI-IP example problem in Sect. 6.3.1.6.7.

Reactions excluded from c_r

The *EXCLUSIONS* data block contains lists of reaction types that will be removed from consideration in the calculation of the c_r integral index and in the extended c_r edit. Valid input for this block are reaction MT numbers or names (e.g., 18 or fission). Values must be separated by a space or a line break. Any MT number or reaction name will be treated as a valid input, but only those present on the sensitivity data files will produce useful information. The reaction sensitivity types computed by SAMS from TSUNAMI-1D and TSUNAMI-3D are shown in Table 6.3.4.

HTML data

The optional *HTML* data block is used to customize HTML formatted output. The *HTML* data block must begin with *READ HTML* and end with *END HTML*. The data input to the *HTML* data block consist of several keywords that are shown, along with their default values and descriptions, in Table 6.3.5. A keyword that ends with = must be followed by text data. For color entries, any valid html color name can be entered or the hexadecimal representation can be used if preceded by a # sign. For example, to change the background color of the html output to white, *bg_clr=white* and *bg_clr=#ffffff* have the same effect, because ffffff is the hexadecimal representation of white. An extensive list of available colors for customized output is shown in Appendix BH. Please note that not all features are supported by all browsers.

Table 6.3.5: Input data for html block of TSUNAMI-IP input.

Keyword	Default value	Description
bg_clr=	papayawhip	Background color.
h1_clr=	maroon	Color used for major headings.
h2_clr=	navy	Color used for sub-headings.
txt_clr=	black	Color for plain text.
lnk_clr=	maroon	Color for hyperlinks.
lnk_dec=	none	Decoration for hyperlinks. (none, underline, overline, line-through, blink).
vlnk_clr	navy	Color for visited hyperlinks.
max_clr=	maroon	Color for maximum values in tables.
cut_clr=	navy	Color for values in tables that exceed cutoff values.
ud_clr=	blue	Color for values in tables that use default covariance data.
ui_clr=	Red	Color for values in tables that use user-input covariance data.
udfix_clr=	royalblue	Color for values in tables that use default corrected covariance data.
uifix_clr=	green	Color for values in tables that use user-input corrected covariance data.

Example TSUNAMI-IP input

An example TSUNAMI-IP input listing is given in Example 6.3.1. In this example, the optional title for this analysis is entered as "tsunami-ip example". The parameter data are used to request that E, c_k, G, and g be computed (e, c, g, and lg, respectively). The integral indices E, c_k, and G will be listed in a table for each application containing the values of each index for each experiment (*values*). The cutoff values for E and c_k for inclusion in the summary tables are set to 0.8 (*evalue=0.8* and *cvalue=0.8*). Summary tables listing experiments with E values exceeding *evalue*, $c_k$values exceeding *cvalue* will be produced (*esummary*, and *csummary*, respectively). The *REACTIONS* data block requests that the n,γ reaction for ^{235}U and the elastic scattering reaction for ^{1}H be assessed for coverage with the g index.

Example 6.3.1: Example TSUNAMI-IP input listing.

```

The application systems are represented by the sensitivity data files named 1sen.sdf, 2sen.sdf and 3sen.sdf. In this example input, these data files are copied (or they could be linked in UNIX) to the temporary directory where SCALE executes and writes its scratch files via system commands that are input to the SHELL utility at the top of the input file.

The experiments for which the indices will be computed for each application are listed in the *experiments* data block. Here, an explicit file path is specified in the input. This could also have been done in the APPLICATIONS data block. In this case, the 5 data files would have to exist in a directory called c:\sensitivity. An equivalent input file using a single *RESPONSE* data block is given in Example 6.3.2.

6.3.1.7 Example PROBLEM

An example problem to demonstrate the use of TSUNAMI-IP is based on the TSUNAMI-1D and TSUNAMI-3D sample problems available with the SCALE distribution. The systems included in the sample problem are not intended to provide a rigorous demonstration of the methodologies of TSUNAMI-IP, but merely to demonstrate how to use the software and read the output. The problem does not correspond to the sample problem distributed with SCALE and is included for illustrative purposes only.

Input description

The example problem input listing is shown in Example 6.3.3. The input begins with the SCALE shell module, which executes a series of copy commands to move the sensitivity data files required for code execution from the user's directory (${INPDIR}) to the current working directory. Next TSUNAMI-IP is called with =tsunami-ip. The optional title card is entered as "tsunami-ip example 2." In the *PARAMETER* data block, the *values* table is requested and it will contain c_k, E and G, since *c e g* are entered on the next line of input. The cutoff value for inclusion of c_k values in the summary table is set at 0.8 with *cvalue=0.8* and the c_k summary table is requested with *csummary*. The nuclide-reaction specific integral indices extended c_k and g are requested with the input *c_long* and *lg*. The summary table of g values exceeding the cutoff is requested with *lgsum*, and the cutoff value for this table is set to 0.75 with *lgvalue=0.75.* The composite sensitivity profiles for the reactions entered in the *REACTIONS* input section are requested with *prtcomp*, and the summary of non-coverage edit is requested with *prtnotcv*. The uncertainty in the k_{eff} values for the experiments and applications due to cross section uncertainties is requested with *uncert* and the extended uncertainty edits for the applications are requested with *uncert_long*. The penalty assessment is requested with *penalty*, the minimum number of experiments exceeding the global integral index; the cutoff value is set to 0 with *penminx=0*. In this way, the limited number of experiments used in this sample problem will still produce a penalty edit. The detailed edit of the components of the penalty are requested with *penlong*. The user-defined default value for covariance data are set to 100% uncertainty for cross sections without covariance data with *udcov*=1.0. The *use_dcov* input keyword activates the use of the *udcov* value in the computation of c_k and the penalty assessment. The use of filenames in place of the titles on the data files is requested with *usename*.

This input defines two systems as applications in the *APPLICATIONS* data block. The application systems are defined as the system with sensitivity data in the data files tsunami-3d_k5-1.sdf and tsunami-3d_k5-2.sdf. Three experiments are defined in the *EXPERIMENTS* data block. These systems have sensitivity data in the data files tsunami-1d1.sdf, tsunami-1d4.sdf, and tsunami-3d_k5-3.sdf.

Example 6.3.3: TSUNAMI-IP sample problem input.

```

Output Description

The output listings shown here are for descriptive purposes only. The data generated from an actual execution of this problem may differ from that shown below. The Applications List and the Experiments List provide some details from the sensitivity data files. These include the title on the data files, the filename, the number of energy groups and the number of sensitivity profiles. After the Experiments List, Covariance Warnings are printed during the creation of the working (i.e., problem-dependent) covariance library. The nuclide-reactions pairs present on the sensitivity data files for which covariance data are not available on the *coverx* file are detailed. This edit is shown in Example 6.3.5.

The next output edit, shown in Example 6.3.6 details the global integral indices for the current application compared to all experiments. The edit is only present if *values* is entered in the *PARAMETER* data block. The first row of data in the table displays the application compared to itself. This is useful to confirm the normalization of the integral indices. The data detailing the application compared to itself is not displayed in the HTML output. The next rows display the values of the integral indices requested by the user for each experiment as compared to the current application. The values of the response (i.e., k_{eff} or reactivity) for the application and each experiment are also shown in this table. If the sensitivity data were computed with Monte Carlo methods, the statistical uncertainties are shown. In Example 6.3.6, the k_{eff} value for tsunami-1d1 does not show a statistical uncertainty because these sensitivity data were computed with TSUNAMI-1D. The integral values of the application compared to tsunami-1d1 do show statistical uncertainties because the application system was computed with TSUNAMI-3D. The column titles "xsec unc %" gives the relative uncertainty in the response due to cross section data uncertainties, in percent.

The next output edit is the extended uncertainty edit for the application and is shown in Example 6.3.7. This edit details the uncertainty in the response due to each nuclide-reaction to nuclide-reaction covariance matrix. Where default or user input values for covariance data are used, they are indicated in the output edit. The total uncertainty can be computed from the individual values by squaring each term, adding the values that had positive signs, subtracting the values that had negative signs, then taking the square root. The edit is present because *uncert_long* was included in the parameter input.

The next output edit is the extended c_k edit, and an example edit for Application 1 with Experiment 1 is shown in Example 6.3.8. This edit details the contribution to c_k due to each nuclide-reaction to nuclide-reaction covariance matrix. Where default or user input values for covariance data are used, they are indicated in the output edit. The edit is present because *c_long* was included in the parameter input. The c_k value can be computed by summing the individual values. Similar tables present the output for each application compared to each experiment.

The next output edit includes the nuclide-reaction specific integral indices and is shown in Example 6.3.9. In this sample problem, g indices for fission capture and scatter reactions for each nuclide-reaction pair with

a sensitivity coefficient exceeding *sencut* in magnitude are printed for each experiment compared to the application. The first table of values is for the application compared to itself. This initial edit is useful to test the normalization of the integral indices for the application. This initial table of the application compared with itself is not available in the HTML output. The energy-integrated sensitivity coefficient for the application is also shown for each reaction. Statistical uncertainties in these integral values are not available in this version of TSUNAMI-IP. This table is repeated for each experiment compared to the application. Because some reactions were requested in the *REACTIONS* section of the input, and the *g* integral index was computed, a table of the user requested *g* values for the application compared to each experiment is given. In this sample problem, ^{10}B was not present in the application, even though it was requested in the input. TSUNAMI-IP lists all requested reactions in this table, but leaves the values blank when the nuclide or reaction is not available on the sensitivity data file for the application.

The next output edit, shown in Example 6.3.10, gives the extended penalty assessment for application 1. This edit is present because *penlong* was entered in the parameter data block. The penalty edit utilizes the user defined default uncertainties defined by *udcov* because *use_dcov* was entered in the *PARAMETER* data block. Nuclide reaction pairs that utilized default uncertainty data are indicated with *. In this case, when the sensitivity coefficients of the application that are not covered by the experiments are propagated to an uncertainty in the application response with the cross section covariance data value of 0.0097% ± 0.00007% results. Next a listing of the contributions to the penalty from each nuclide-reaction to nuclide-reaction covariance matrix is given. As with the extended uncertainty edit, the cumulative penalty can be computed from the individual values by squaring each term, adding the values that had positive signs, subtracting the values that had negative signs, then taking the square root.

Each of the previous edits would repeat in the full output listing for each application. The next series of output edits, shown in Example 6.3.11, are the summary edits requested by the user. The c_k summary table, requested with the keyword *csummary*, indicates that one experiment has a c_k value at least as great as 0.8 compared to each application. The *g* summary table lists the *g* values that exceed *lgvalue* for the fission, capture and scatter reactions for each nuclide in the application with an energy-integrated sensitivity coefficient exceeding *sencut* in magnitude. The value of the sensitivity coefficient for the application is also given. The summary of non-coverage edit is present because *prtnotcv* was entered in the *PARAMETER* input data block. This edit lists a number of properties of each reaction input in the *REACTIONS* input data block. The final summary table is the penalty summary table, which is activated when *penalty* is listed in the *PARAMETER* data block. The penalties for all applications identified in the *APPLICATIONS* input data block are listed in the penalty summary table.

The composite sensitivity data are listed next in the TSUNAMI-IP output as shown in Example 6.3.12 The group-wise values for the composite profiles for each nuclide-reaction pair identified in the *REACTIONS* data block are listed here for each application identified in the *APPLICATIONS* data block. If a reaction is requested that is not present in the application, the reaction is left blank in the table, as is the case in this sample problem for ^{10}B capture. The composite sensitivity profiles are also written to a TSUNAMI-B formatted sensitivity data file. In this data file, the composite sensitivity profiles are written for each application in the order they were requested in the *REACTIONS* data block. If a requested reaction is not available in the application, it is not written to the data file. The application number is listed on the data file in the position of the material number but with a value that is the negative of the application number. All unit and region information are entered as zeros as is the k_{eff} value. This data file can be correctly read by Javapeño such that the composite data can be plotted. In Javapeño, the application number appears in the list of available sensitivity profiles identified as "composite." The application sensitivity data and the composite data as used in the penalty calculation are also included on the composite sensitivity data file. These new data are identified as "application" and "cut composite" respectively.

Example 6.3.4: Input echo from TSUNAMI-IP output.

|                                input values and dcov value.                                                          |
|                                                                                                                      |
|  cp             false          Compute and print completeness parameter for each application.                        |
|                                                                                                                      |
|  csummary       true           Print summary table of c(k) values that meet or exceed the cvalue limit.  Sets c to true. |
|                                                                                                                      |
|  cvalue=        .8000          Threshold value of c(k) for inclusion in the summary table.                           |
|                                                                                                                      |
|  cr             false          Compute c(r) values for each application compared to each experiment.                  |
|                                                                                                                      |
|  cr_long        false          Produces extended c(r) output edit for each application compared to each experiment.   |
|                                Sets cr to true.                                                                      |
|                                                                                                                      |
```

(continues on next page)

(continued from previous page)

crsummary	false	Print summary table of c(r) values that meet or exceed the crvalue limit. Sets cr to true.	
crvalue=	.9000	Threshold value of c(r) for inclusion in the summary table.	
e	true	Compute E(sum) values for each application compared to each experiment.	
esummary	false	Print summary table of E(sum) values that meet or exceed the evalue limit. Sets e to true.	
evalue=	.9000	Threshold value of E(sum) for inclusion in the summary table.	
g	true	Compute G values.	
gsummary	false	Print summary table of G values that meet or exceed the gvalue limit. Sets g to true.	
gvalue=	.9000	Threshold value of G for inclusion in summary table.	
html	true	Generate output in html format in addition to the standard text output.	
inptcase	false	Set the SCALE free form reader to leave the case of the input data as read.	
large_cov=	10.0000	Cutoff fractional standard deviation value for cov_fix. Covariance data with uncertainties larger than large_cov are replaced with user-defined or default values.	
lg	true	Compute g values for fission, capture and scatter for each nuclide for each experiment compared to each application and print them in a table if the application's sensitivity for the corresponding nuclide-reaction pair is greater than or equal to sencut.	
lgall	false	Print g values for fission, capture and scatter for all nuclides for all experiments for each application.	
lggroups	false	Print a table listing the number of experiments that are at least as sensitive as the application for each group for each reaction requested in the REACTIONS input block.	
lgsum	true	Prints a summary table of g for each application for each experiment that exceeds lgvalue for each nuclide's capture, fission and scatter reactions.	
lgvalue=	.7500	Threshold value of g for inclusion in summary table.	
nixlim=	10	Minimum number of experiments with group-wise values exceeding senfac times the group-wise value for the application for the group-wise value to be added to the completeness parameter.	
penalty	true	Creates penalty assessment based on differences in the application's sensitivity profile for a particular nuclide-reaction pair, and the corresponding composite profile for all	

(continues on next page)

(continued from previous page)

		qualifying experiments.
pencut=	0.0000E+00	Cutoff value for excluding sensitivities from the penalty calculation. If the sum of the absolute values of the energy-dependent sensitivity data for a particular nuclide-reaction pair is below this number, the nuclide-reaction pair will not be included in the penalty calculation.
penlgv=	0.0000E+00	Use only nuclide-reaction pairs with g values exceeding penlgv in the penalty assessment.
penlong	true	Print detailed edits of components of penalty assessments.
penminx=	0	Minimum number of qualifying experiments for each application for penalty calculation.
penusec	true	Use only experiments with c(k) values exceeding cvalue in the penalty assessment. Sets c to true.
penusee	false	Use only experiments with E(sum) values exceeding evalue in the penalty assessment. Sets e to true.
penuseg	false	Use only experiments with G values exceeding gvalue in the penalty assessment. Sets g to true.
penwarn	false	Print list of warning messages noting the experiments and nuclide-reaction pairs that were excluded from the penalty calculation.
plot	false	Produces Ptolemy formatted plot (.ptp) files for integral values and composite sensitivity data.
prtcomp	true	Print "composite" of experiment sensitivity profiles for reactions selected in REACTIONS input block and write data to sensitivity data file. Sets g to true.
prtmtrix	false	Prints directory of data available on the cross section covariance data library.
prtnotcv	true	Print a table summarizing the non-coverage for the nuclide-reaction pairs entered in the REACTIONS input block. Sets g to true.
prtparts	false	Print the components of E and G for fission capture in scatter in the values table.
relative	true	Print uncertainty values and penalty assessments in relative format. This is the default format. Absolute format can be specified using the "abs" keyword in the APPLICATIONS, EXPERIMENTS, or RESPONSE input blocks.
return_work_cov	false	Option to copy the working covariance data file back to the return directory.
sencut=	.0100	Cutoff value for ignoring low valued sensitivities in nuclide-reaction specific edit tables.

(continues on next page)

(continued from previous page)

senfac=	.9000	Value used in calculation of completeness parameter. Group-wise sensitivity for the application is counted as validated by the experiment if the sensitivity from the experiment is greater than the application sensitivity times senfac.
uncert	true	Computes uncertainty in response due to covariance data.
uncert_long	true	Prints extended table of uncertainty in response due to covariance data. sets uncert to true.
use_dcov	true	Use user-defined default covariance data, udcov, for nuclide reaction pairs not included on the covariance data file. The user-defined data will be used in the fourth penalty assessment as well as the computation of c(k) and uncertainty calculations.
udcov=	1.0000	User-defined default value of standard deviation in cross-section data to use for nuclide-reaction pairs for which covariance data are not available on the selected data file.
udcov_corr=	1.0000	User-defined default correlation value to use for nuclide-reaction pairs for which covariance data are not available on the selected data file.
udcov_corr_type	zone	User-defined default correlation in cross-section data to use for nuclide-reaction pairs for which covariance data are not available on the selected data file. (long, zone, short)
udcov_fast=	0.0000	User-defined default value of standard deviation in cross-section data to use for fast data for nuclide-reaction pairs for which covariance data are not available on the selected data file.
udcov_inter=	0.0000	User-defined default value of standard deviation in cross-section data to use for intermediate data for nuclide-reaction pairs for which covariance data are not available on the selected data file.
udcov_therm=	0.0000	User-defined default value of standard deviation in cross-section data to use for thermal data for nuclide-reaction pairs for which covariance data are not available on the selected data file.
use_diff_groups	true	Allow sensitivity data files to have different energy group structures.
use_icov	true	Use user-defined data input in COVARIANCE input data block in place of udcov value for user input nuclide-reaction pairs that are not on the covariance data file. The user-defined data will be used in the fourth penalty assessment as well as the computation of c(k) and uncertainty calculations.
usename	true	Use the name of the sensitivity data file in place of its title in all output.

(continues on next page)

(continued from previous page)

uslstats	false	Produces USLSTATS input files for trending analysis with all experiments for each global integral index (c(k), E, and G) requested for each application
uslsummary	false	Produces USLSTATS input files for trending analysis with experiments exceeding cutoff value (cvalue, crvalue, evalue or gvalue) for each global integral index (c(k), E, and G) requested for each application
usl_uncert	false	Includes uncertainty in k-eff due to cross section covariance data from k-eff uncertainty written to USLSTATS input files.
usl_p=	.9990	Value of P in USLSTATS input files. P is the portion of the population falling above the lower tolerance level
usl_1-g=	.9500	Value of 1-gamma in USLSTATS input files. 1-gamma is the confidence on the fit.
usl_alpha=	.9990	Value of alpha in USLSTATS input files. Alpha is the confidence on the proportion of P.
usl_xmin=	.0000	Value of x(min) in USLSTATS input files. X(min) is the minimum value of the parameter x.
usl_xmax=	1.0000	Value of x(max) in USLSTATS input files. X(max) is the maximum value of the parameter x.
usl_sigs=	-.0030	Value of sigma(s) in USLSTATS input files. If a positive value is entered, it is applied as the total uncertainty for each experiment. If a negative or zero value is entered, it is used as the experimental measurement uncertainty and any Monte Carlo and cross section uncertainties are added quadratically to the absolute value of usl_sigs for each experiment.
usl_dkm=	.0500	Value of delta-k(m) in USLSTATS input files. Delta-k(m) is the administrative margin used to ensure subcriticality.
values	true	Print all computed "global" indices (E, c(k), and G) in a table for each application. If prtparts is input, also include the partial values.

User Requested Reactions for g Analysis

NUCLIDE ID	NUCLIDE	REACTION	MT
92235	u-235	nubar	452
92238	u-238	capture	101
1001	h-1	total	1

TSUNAMI-IP Execution Complete
-------------------------------------------------------------------------------------------
```

HTML output description

The HTML formatted output from the TSUNAMI-IP sample problem is described in this section. The HTML output is generated when the *html* keyword is included in the *PARAMETER* block keyword The input for this sample problem is named tsunami-ip.input. In this case, the HTML formatted output is stored in a file called tsunami-ip.html and additional resources are stored in directories called tsunami-ip.htmd and applet_resources. These sections contain example TSUNAMI-IP HTML formatted output only for demonstration of the interface. When tsunami-ip.html is opened in a web browser, the information shown in Fig. 6.3.4 is displayed. The title of the input file is displayed between the two SCALE logos. Because this SCALE input file only executed tsunami-ip, only a single output listing is available. The text "1. TSUNAMI-IP" is a hyperlink to view the output from TSUNAMI-IP. Clicking on the "1. TSUNAMI-IP" hyperlink will present the information shown in Fig. 6.3.5

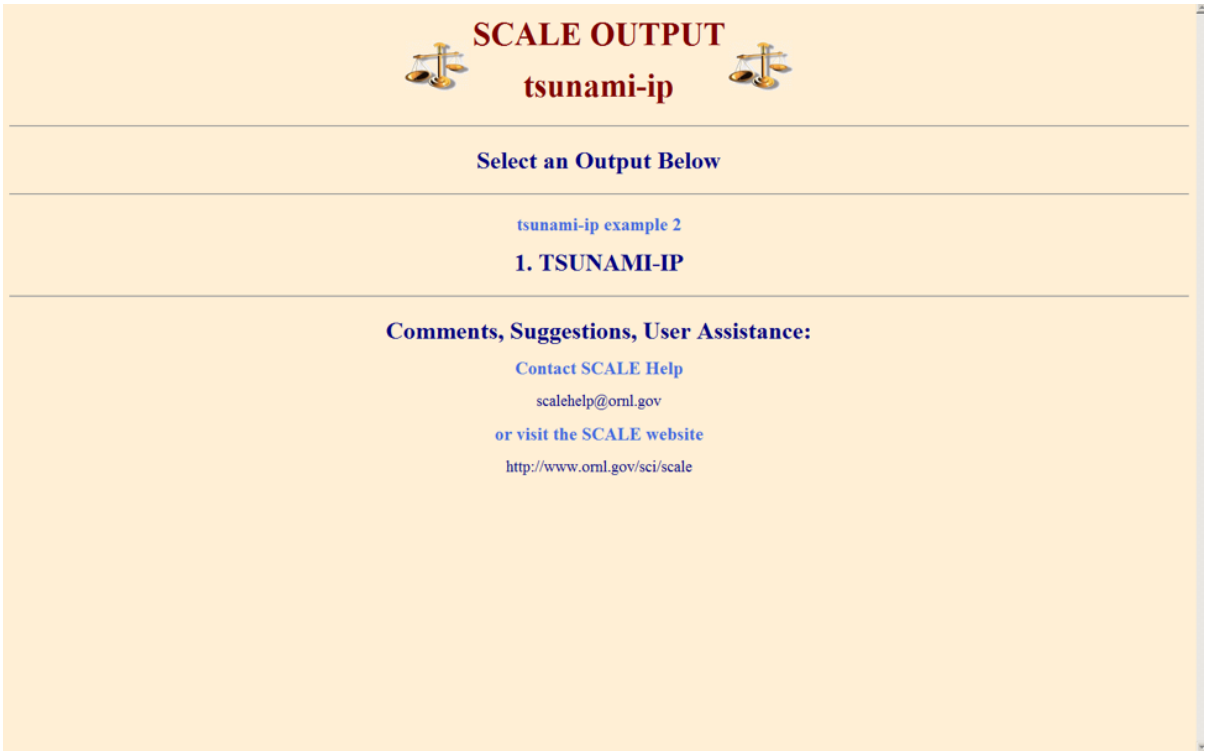

Fig. 6.3.4: Initial screen from TSUNAMI-IP HTML output.

The initial page of output from TSUNAMI-IP is shown in Fig. 6.3.5. Program verification information is shown in the table under the TSUNAMI logo. This table includes information about the code that was executed and the date and time it was run. The menu on the left side of the screen contains hyperlinks to specific portions of the code output. Echoes of the input data are available in the Input Data section. Any errors or warning messages are available in the Messages sections. Results from the code execution are shown in the results section.

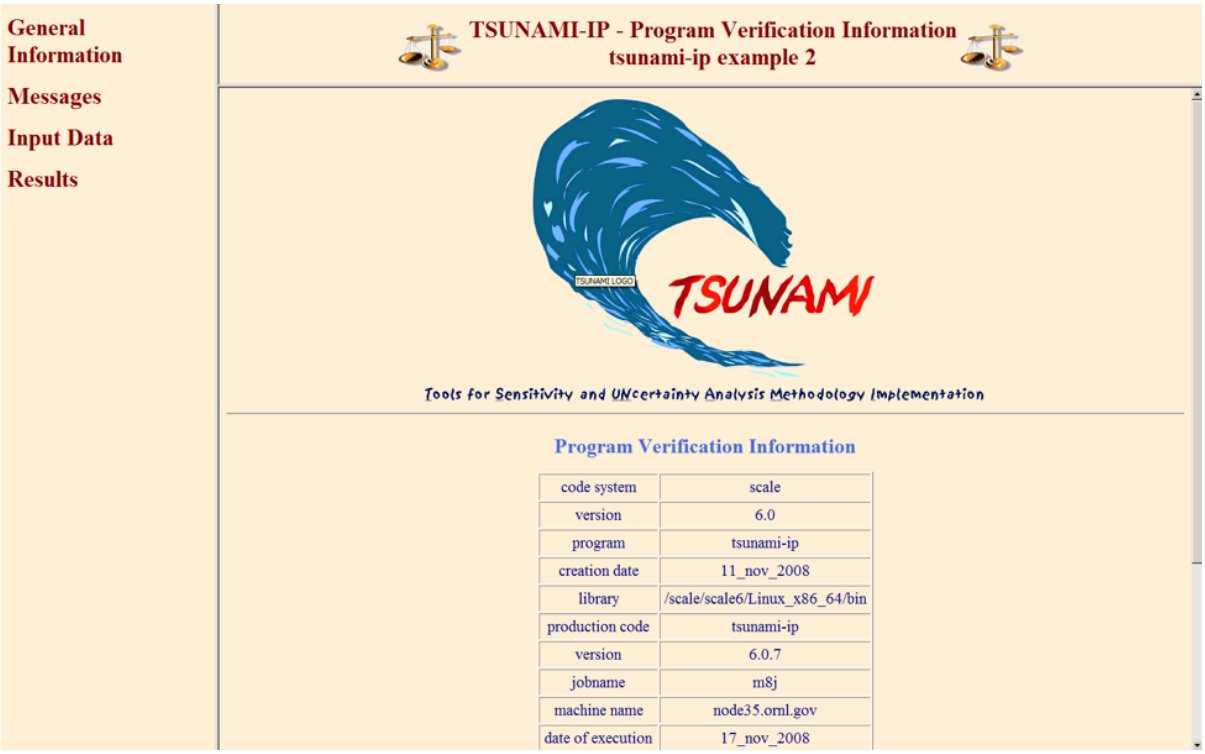

Fig. 6.3.5: Program verification screen from TSUNAMI-IP HTML output.

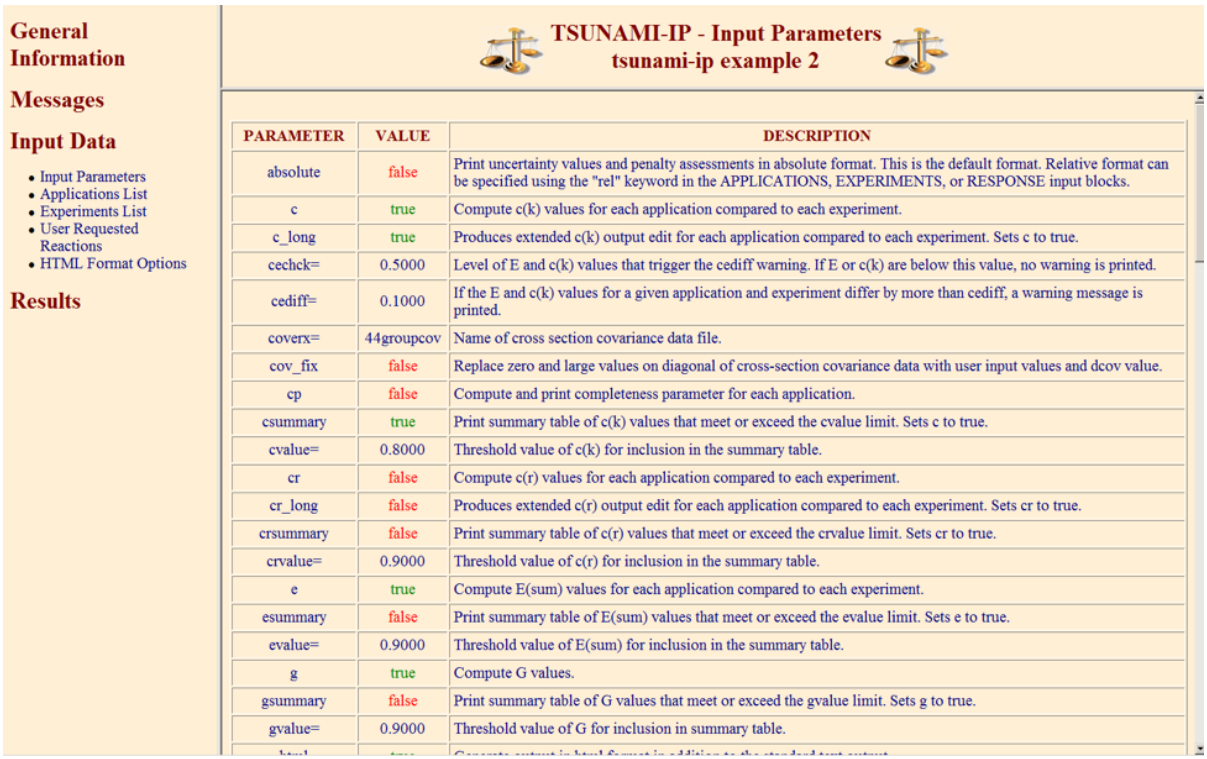
Selecting Input Parameters will reveal the menu of available input data. Selecting Input Parameters causes the table shown in Fig. 6.3.6 to be displayed. Other input data can also be displayed by selecting the desired data from the menu.



PARAMETER	VALUE	DESCRIPTION
absolute	false	Print uncertainty values and penalty assessments in absolute format. This is the default format. Relative format can be specified using the "rel" keyword in the APPLICATIONS, EXPERIMENTS, or RESPONSE input blocks.
c	true	Compute c(k) values for each application compared to each experiment.
c_long	true	Produces extended c(k) output edit for each application compared to each experiment. Sets c to true.
cechck=	0.5000	Level of E and c(k) values that trigger the cediff warning. If E or c(k) are below this value, no warning is printed.
cediff=	0.1000	If the E and c(k) values for a given application and experiment differ by more than cediff, a warning message is printed.
coverx=	44groupcov	Name of cross section covariance data file.
cov_fix	false	Replace zero and large values on diagonal of cross-section covariance data with user input values and dcov value.
cp	false	Compute and print completeness parameter for each application.
csummary	true	Print summary table of c(k) values that meet or exceed the cvalue limit. Sets c to true.
cvalue=	0.8000	Threshold value of c(k) for inclusion in the summary table.
cr	false	Compute c(r) values for each application compared to each experiment.
cr_long	false	Produces extended c(r) output edit for each application compared to each experiment. Sets cr to true.
crsummary	false	Print summary table of c(r) values that meet or exceed the crvalue limit. Sets cr to true.
crvalue=	0.9000	Threshold value of c(r) for inclusion in the summary table.
e	true	Compute E(sum) values for each application compared to each experiment.
esummary	false	Print summary table of E(sum) values that meet or exceed the evalue limit. Sets e to true.
evalue=	0.9000	Threshold value of E(sum) for inclusion in the summary table.
g	true	Compute G values.
gsummary	false	Print summary table of G values that meet or exceed the gvalue limit. Sets g to true.
gvalue=	0.9000	Threshold value of G for inclusion in summary table.

Fig. 6.3.6: Input parameters from TSUNAMI-IP HTML output.

Selecting Messages will reveal a menu of available messages. Selecting Warning Messages from the Messages section of the menu causes the information shown in Fig. 6.3.7 to appear. The Warning Messages edit contains all warning messages that were generated during the execution of the code. If errors were encountered in the code execution, an Error Messages item would have also been available in the menu under Messages.

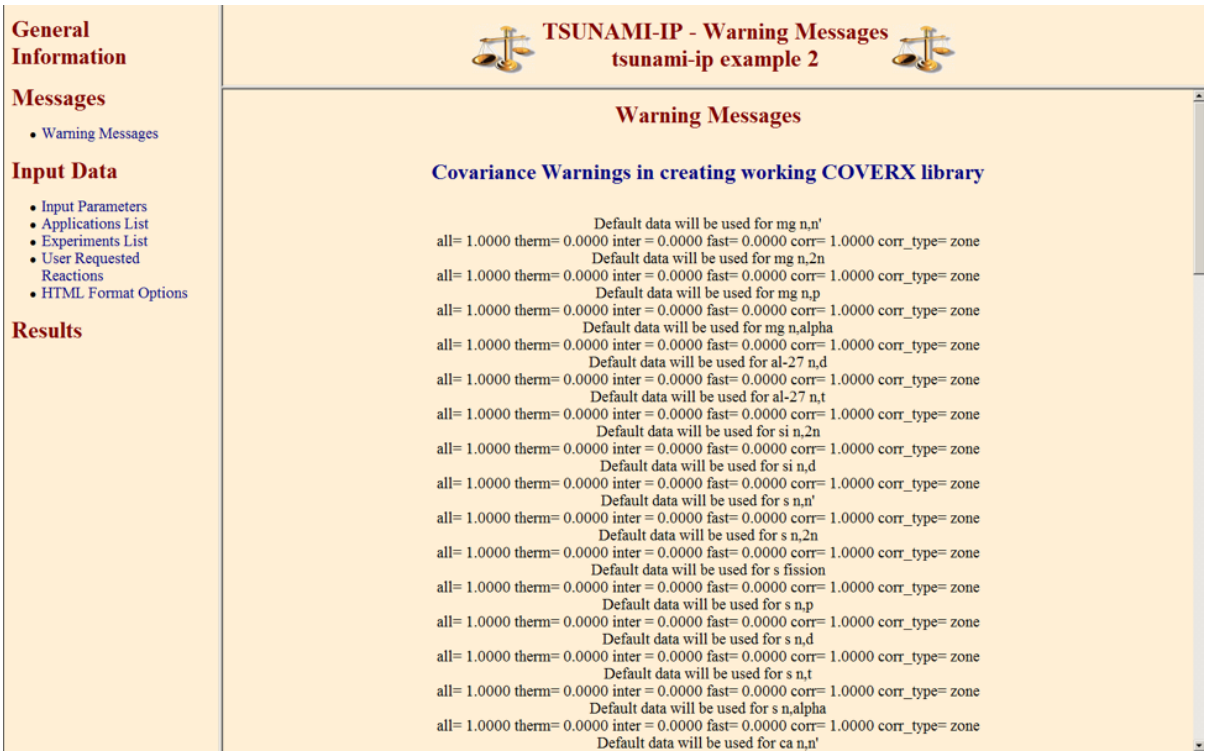


Fig. 6.3.7: Warning messages from TSUNAMI-IP HTML output.

Selecting Results causes a menu of available results to be revealed. From this menu, selecting Global Integral Indices causes a submenu of available global integral indices to be revealed. Selecting Integral Index Values from this submenu causes the information shown in Fig. 6.3.8 to appear. In certain results edits, a second menu appears on the right such that the information for a particular application can be quickly reached. The table shown in Fig. 6.3.8 corresponds to the *values* table from the standard output file. One advantage of the HTML output is the use of color coding. Values exceeding the cutoff value for a particular integral index are printed in the color that is set by the *HMTL* data block input *cut_clr*=. The maximum value for each index for each application is printed in the color that is set by the *HMTL* data block input *max_clr*=. In this case, the values that exceed the cutoff values are also the maximum values and are colored as such. Edits for each type of data requested in the *PARAMETER* data block are available in the results section by selecting the appropriate submenu.

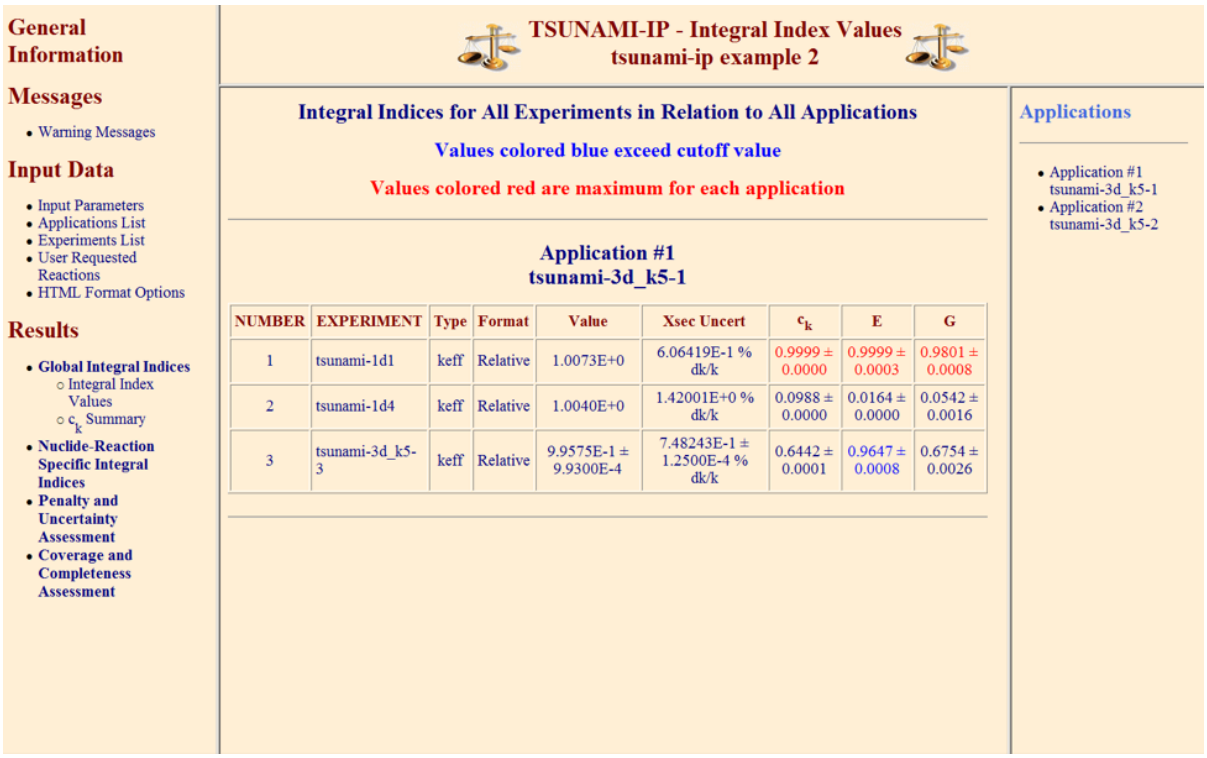

Fig. 6.3.8: Global integral indices from TSUNAMI-IP HTML output.

Data plots can also be directly viewed in the HTML output. The composite data can be viewed by selecting Coverage and Completeness Assessment then Composite Sensitivity Data Plot. A Java applet version of Javapeño will appear in the browser window with the appropriate datafile preloaded. Data can be added to the plot by double-clicking on the list of available data on the right side of Javapeño. The plot shown in Fig. 6.3.9 was produced with this procedure.

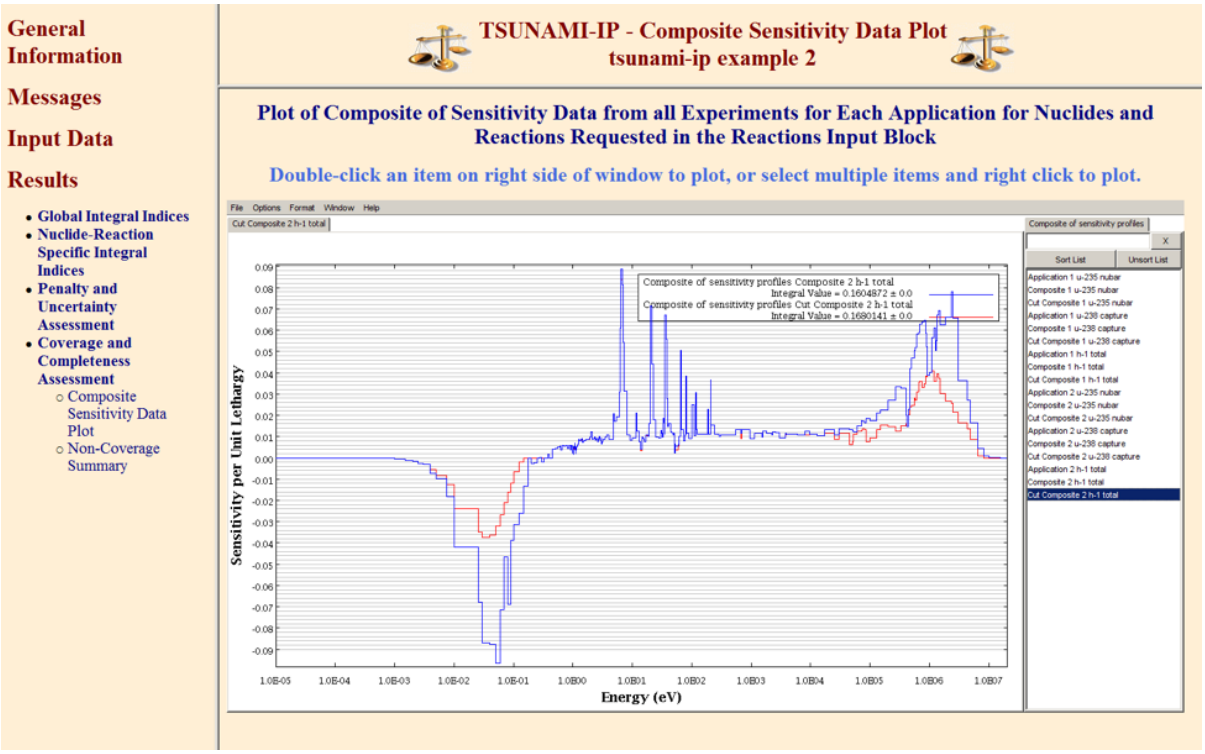

Fig. 6.3.9: Composite sensitivity data plot from TSUNAMI-IP HTML output.

6.3.2 BONAMIST

BONAMIST is a sensitivity version of the SCALE 4.4a BONAMI module. BONAMI performs Bondarenko calculations for resonance self-shielding. The entire FORTRAN 77 source for BONAMI was processed with the GRESS pre-compiler so that the sensitivities of the self-shielded cross sections to the data input to the code are computed. BONAMIST utilizes many of the routines from SCALELIB. BONAMIST writes the resonance self-shielded cross sections to an AMPX formatted data file, just as BONAMI does. However, an additional data file, *bonamist.sen*, is also written. The *bonamist.sen* file contains the sensitivities of resonance self-shielded cross sections generated by BONAMIST to the quantities input to BONAMIST.

The methodologies for computing the resonance self-shielded cross sections in BONAMIST are identical to those used in BONAMI, and equivalent cross section results are obtained. The *bonamist.sen* data file contains the sensitivity of the self-shielded cross sections to the number density of each nuclide and the extra cross section input to BONAMIST. The extra cross section is used by TSUNAMI-1D, TSUNAMI-3D, CSAS and other SCALE sequences to pass the Dancoff factor computed in MIPLIB or SENLIB to BONAMI. The format of the *bonamist.sen* data file is given in Format of BONAMIST.SEN data file.

The input, output, methodologies and program flow of BONAMIST are not described here. The user is referred to the BONAMI chapter. The input of BONAMIST is identical to that required for BONAMI. The sensitivities are automatically computed and the *bonamist.sen* data file is automatically generated without user intervention.

6.3.3 REFERENCES

6.3.4 APPENDICES

6.3.4.1 Data File Formats

Several data file formats that are used by the sensitivity and uncertainty analysis codes are presented in this appendix.

Format of TSUNAMI-A sensitivity data file

The format of the TSUNAMI-A sensitivity data file produced by SAMS for cases with deterministic transport solutions is given in Table 6.3.6. The occurrence of each entry in the data file is followed by an identification of the data contained on each line of the file and the FORTRAN edit descriptor denoting the format of each line. A brief description of each line is also presented.

A sample of the TSUNAMI-A data file for the Flattop-25 sample problem is provided in Example 6.3.13. Here, only two profiles out of the 130 computed are shown.

Table 6.3.6: Format specification for TSUNAMI-A sensitivity data file.

Occurrence	Data	Format	Description
Once at beginning of file.	title	a80	Title extracted from transport calculation
	number of neutron groups	i10	Number of neutron groups in calculation
	total number of profiles, text descriptor, number of total profiles that are region integrated	i10, a35, i10	Total number of sensitivity profiles in data file, separated by a text descriptor, then the number of profiles that contain region-integrated data
	k_{eff}	f10.6	Value of k_{eff} from the forward transport calculation
	'energy boundaries:'	a	Text
	energy boundary data	5es14.6 (repeats until all data is printed)	Values of boundaries of energy groups. Begins with upper value for highest energy group and ends with lower value of lowest energy group.
Repeats for each profile.	isotope name, sensitivity reaction name, nuclide ID, MT number, Zone number or negative of material number, zone volume	a12, 1x, a15, 3i12, es14.6	Provides data identifying the sensitivity data that follows. Note, if sensitivity data is region-integrated, zone number and zone volume are both 0. If data is integrated over all zones containing the same material, the material number is given in place of the zone number as a negative number.
	Energy integrated sensitivity coefficient, sum of absolute value of group-wise sensitivities, sum of the group-wise sensitivities with opposite sign as energy integrated value (osc)	3es14.6	Energy-integrated sensitivity coefficients for this profile.
	group-wise sensitivity coefficients	5es14.6 (repeats until all data is printed)	Energy-dependent sensitivity coefficients. Begins with highest energy group.
Once at end of file.			Block of file verification information.

Format of TSUNAMI-B sensitivity data file

The format of the TSUNAMI-B sensitivity data file produced by SAMS for cases with Monte Carlo transport solutions is given in Table 6.3.7. The occurrence of each entry in the data file is followed by an identification of the data contained on each line of the file and the FORTRAN edit descriptor denoting the format of each line. A brief description of each line is also presented.

A sample of the TSUNAMI-B data file for the LEU-COMP-THERM-009 case 10 sample problem is provided in Example 6.3.14. Here, only two profiles out of the 3389 computed are shown.

Table 6.3.7 – continued from previous page

Table 6.3.7: Format specification for TSUNAMI-B sensitivity data file.

ARRAY Format: READ ARRAY array parameters data type orientation data END ARRAY See Sections on ARRAY Data, Geometry, and alternative sample problem mockups

Repeat the sequence ARRAY PARAMETERS DATA TYPE ORIENTATION DATA for each array used in the problem.

ARRAY PARAMETERS

KEYWORD	DEFAULT	DEFINITION
ARA=	none[a]	no. defining the array
TYP=	Cuboidal[c]	array type (cuboidal or square, hexagonal or triangular, shexagonal, rhexagonal, dodecahedral)
NUX=	none[a]	no. of units in X direction
NUY=	none[a]	no. of units in Y direction
NUZ=	none[a]	no. of units in Z direction
GBL=	none[b]	global or overall array number
PRT=	YES	print any label
COM=	none	delim comment delim optional, maximum of 132 characters

ORIENTATION DATA FOR FILL

Enter unit numbers to define every position in the array. When entering data using the options in this table, the count and option fields must be adjacent with no imbedded blanks. The operand field may be separated from the option field by one or more blanks. Orientation data for FILL is terminated by entering END FILL.

COUNT FIELD	OPTION FIELD	OPERAND FIELD	COMMENTS
		j	stores j at the current position in the array
i	R, *, $	j	stores j in the next i positions in the array
	F	j	fills remainder of the array with unit no. j starting with the current array position
	A	j	sets the current position in the array to j
i	S		increments current position in the array by i (This allows skipping i positions. The value of i may be positive or negative.)
i	Q	j	repeats the previous j entries i times. The default value of i is 1
i	N	j	repeats the previous j entries i times, inverting the sequence each time. The default value of i is 1.
i	B	j	starting with the entry at -i from the current position, store entries in inverse order until position -(i+j) is reached. Default value of i=1.
i	I	j k	provides the end points (j, k) with i entries linearly interpolated between them (i.e., a total of i+2 points). At least one blank must separate j and k. When used for an integer array, the i option should only be used to generate integer steps (i.e., (k-j)/(i+1) should be a whole number).

ORIENTATION DATA FOR LOOP

Enter the unit number and nine numbers that define the position(s) of that unit. Data for each of these ten entries are repeated until every position in the array has been defined. Orientation data for LOOP are terminated by entering END LOOP.
ENTER DATA IN THE FORM:

DATA ENTRY	COMMENTS
LTYPE	The unit type. LTYPE must be greater than 0.
IX1	Starting position in the X direction. IX1 must be at least 1 and no larger than the value entered for NUX.
IX2	Ending position in the X direction. IX2 must be at least 1 and no larger than the value of NUX.
INCX	The number of units by which increments are made in the X direction.
IY1	The starting position in the Y direction. IY1 must be at least 1 and less than the value entered for NUY.
IY2	Ending position in the Y direction. IY2 must be at least 1 and no larger than the value of NUY.
INCY	The number of units by which increments are made in the positive Y direction.
IZ1	Starting position in the Z direction. IZ1 must be at least 1 and no larger than NUZ.
IZ2	Ending position in the Z direction. IZ2 must be at least 1 and no larger than NUZ.
INCZ	The number of units by which increments are made in the positive Z direction.

[a] In KENO V.a the default is 1

[b] In KENO V.a the default is the largest array number, *maxara*

Table 6.3.7 – continued from previous page

Occurrence	Data	Format	Description
	energy integrated sensitivity coefficient, standard deviation for energy integrated sensitivity coefficient, sum of absolute value of group-wise sensitivities, sum of the group-wise sensitivities with opposite sign as energy integrated value (osc), standard deviation for osc.	5es14.6	Energy-integrated sensitivity coefficients and their standard deviations for this profile.
	group-wise sensitivity coefficients	5es14.6 (repeats until all data is printed)	Energy-dependent sensitivity coefficients. Begins with highest energy group.
	standard deviation in group-wise sensitivity coefficients	5es14.6 (repeats until all data is printed)	Standard deviation for energy-dependent sensitivity coefficients. Begins with highest energy group.
Once at end of file.			Block of file verification information.

Example 6.3.14: Truncated sensitivity data file for LEU-COMP-THERM-009 sample problem.

Format of HDF5-based sensitivity data file

An HDF5-based format for the sensitivity data files has been introduced. The format used here has been found to improve I/O speed for TSUNAMI-IP cases that read many SDF files. The HDF5-based SDF can be loaded in Fulcrum to produce the same plots that the text-based SDF can. The HDF5-based SDF may also be read with standard HDF5 tools such as h5dump, h5py, and HDFview.

The tao utility includes a feature that facilitates conversion between the HDF5-based SDF and the text-based SDF.

For example, the tao utility may be used to convert a batch of text-based SDF files in a directory into HDF5-based SDF files by:

```
tao convert *.sdf
```

Each HDF5-based SDF file has a file extension ".sdf.h5". The tao convert tool may also be used to convert from HDF5 to the text-based format via

```
tao convert -fromFormat=sdf.h5 -toFormat=sdf <filename>.sdf.h5
```

For tao convert, the `-fromFormat` and `-toFormat` options take the intended *file extension* as the arguments.

The HDF5-based SDF may be requested as output from TSUNAMI calculations by including the `sensitivity_format` keyword in the SAMS block of the calculation input. For example:

```
read sams
  sensitivity_format=hdf5
end sams
```

will produce the result senstivity file in HDF5 format, with extension ".sdf.h5". The default sensitivity output for TSUNAMI calculations is the text-based format described previously. This may be requested by removing the `sensitivity_format` keyword from the input file, or by

```
read sams
  sensitivity_format=txt
end sams
```

Brief Description of Data Layout

The HDF5 attributes are defined as

Table 6.3.8: HDF5-based SDF attributes

Name	Datatype	Comments: *MC* denotes "only in Monte Carlo-derived files"
`file_type`	string	The type of file - should be `SDF_ARCHIVE`
`file_version`	string	The version of the SDF HDF5 format used for this file
`id_chk_sum`	string	A simple checksum
`id_spec`	string	A link to the specification
`title`	string	The SDF title
`sdf_type`	enumeration	"MonteCarlo" or "Deterministic"
`reference_quantity`	string	The quantity of interest, e.g. k_{eff}
`reference_comment`	string	Any comment about the reference quantity
`reference_value`	double	The value of the reference quantity in the transport calculation
`reference_sigma`	double	*MC* Uncertainty in the reference value
`number_profiles`	int	The number of sensitivity profiles
`number_region_integrated`	int	The number of region-integrated sensitivity profiles
`number_neutron_groups`	int	The number of neutron groups for the sensitivity calculation
`constrained_chi`	bool	Whether the χ (fission neutron spectrum, MT=1018) sensitivities are constrained
`list_energies`	vector<double>	Energy group boundaries, with size = `number_neutron_groups` + 1

The datasets are stored as vectors, each of size `number_profiles`. The exceptions are `profile_values` and `profile_sigmas` – in order to optimize I/O time (especially in TSUNAMI-IP and TSURFER calculations that read many SDFs), both of these datasets are *hyperslabs* of dimension `number_profiles` ×

number_neutron_groups.

Table 6.3.9: SDF datasets

Name	Datatype	Comments: *MC* denotes "only present in Monte Carlo-derived files"
profile_values	double	The sensitivity coefficients
profile_sigmas	double	*MC* The uncertainties in the sensitivity coefficients
nuclide_id	int	The numerical IDs of the nuclides, in ZZAAA form
mt	int	The reaction ID (MT) values
comment	string	Any comment
region	int	Same conventions as text-based region values
region_uses	int	Number of times region has been used
material	int	Same conventions as text-based material values
unit	int	Same conventions as text-based unit values
volume	double	Volume of region
values_sum	double	Energy-integrated value of the sensitivity coefficients for corresponding profile
values_sigma	double	*MC* Uncertainty in energy-integrated value of the sensitivity coefficients for corresponding profile
values_abs_sum	double	Sum of *absolute values* of the sensitivity coefficients for corresponding profile
values_osc_sum	double	Sum of the sensitivity coefficients *with sign opposite* values_sigma for corresponding profile
values_osc_sigma	double	*MC* Uncertainty in values_osc_sum for corresponding profile

An example of the output of h5dump --header CE-TSUNAMI_test_k6_IFP_godiva.sdf.h5:

```

Format of SENLIB.SEN data file

The SENLIB.SEN data file is generated by the SENLIB routines used in the TSUNAMI modules to compute implicit sensitivity effects. The data file contains the sensitivity of data computed in SENLIB and input to the resonance processing code BONAMIST. This file also contains the sensitivities of the extra cross sections input to BONAMIST to the number densities of each nuclide for each region of the BONAMIST input. In BONAMIST, the extra cross section contains data for the Dancoff factor. Each of the parameters for which sensitivity coefficients are computed has a unique identification number. The parameter identification numbers, corresponding parameters, and their locations in the resonance processing code input are shown in Table 6.3.10. The format of the records of the SENLIB.SEN data file is given in Table 6.3.11. Each sensitivity coefficient is identified by three records. These records are repeated until all sensitivities are listed on the data file.

Table 6.3.10: Parameter identifiers for SENLIB.SEN data file.

Identifier number	Parameter	Location of parameter in resonance processing code input
-1004	Extra cross section (cm^{-1}) by zone, account for Dancoff factor in BONAMIST	9* array in data block 2 of BONAMIST input

Table 6.3.11: Record format for SENLIB.SEN data file.

Record number	Data	Format	Description
1	Region for BONAMIST data and parameter	2i12	BONAMIST region and parameter for which sensitivity coefficient is computed.
2	Nuclide and reaction MT number to which sensitivity coefficient is computed	2i12	Nuclide and reaction MT number to which the sensitivity of the parameter is computed. For data currently computed by SENLIB, only the sensitivities of the parameters to the number densities of the nuclides are computed. Thus, the reaction MT number is always 1.

continues on next page

Table 6.3.11 – continued from previous page

3	Sensitivity coefficient	es14.6	Relative sensitivity of parameter identified in first record to nuclide and reaction identified in second record.

Format of BONAMIST.SEN data file

The BONAMIST.SEN data file is generated by the BONAMIST code, which is executed as part of the TSUNAMI-1D sequence. This data file contains the sensitivities of the groupwise cross sections that are resonance shielded in BONAMIST to the certain data input to BONAMIST. The data to which the sensitivity coefficients are computed are the number densities of the nuclides and the extra cross section by region, which contains data for the Dancoff factor. These data are listed in the data file according to the identifiers listed in Table 6.3.10. Additionally, the sensitivity of group cross sections to the number density of a particular nuclide is identified with the nuclide number from the AMPX cross-section data library.

The format of the records in the data file is identified in Table 6.3.12. Blocks of these records are printed for the non-zero sensitivities for all nuclides and reactions for which resolved resonances are processed.

Table 6.3.12: Record format for BONAMIST.SEN data file.

Record number	Data	Format	Description
1	Nuclide and MT number for cross sections for which sensitivity coefficients are computed	2i12	Nuclide identifier and MT number of reaction for which sensitivity data are computed.
2	Parameter or nuclide and the MT number to which the sensitivity data are computed	2i12	Parameter identifier for scattering cross sections and Dancoff factor or nuclide identifier and MT number to which the sensitivity coefficients are computed. If a parameter identifier is used, the MT number is set to 1. Currently only the sensitivities to number densities are computed in BONAMIST, so the only MT number printed is 1.
3	First and last group for which sensitivity coefficients are printed	2i12	First and last group for the sensitivity coefficients that follow.
4	Sensitivity coefficients, record repeats until all groups identified by record 3 are printed	5es14.6	Relative sensitivities of cross sections for nuclide and process identified by record 1 to parameter or nuclide identified in record 2 for groups corresponding to those identified by record 3.

COVERX format

The COVERX data file format for storing multigroup cross-section uncertainty information is presented in this section. The COVERX format was used with the FORSS code system at ORNL. The covariance data processing code PUFF-III outputs multigroup data in the COVERX format. This the only covariance format available for use with the sensitivity and uncertainty analysis codes in SCALE.

The overall structure of a COVERX file is given in Table 6.3.13. The occurrence of the particular record type, the name of the record type and when a given record type is present on the file are identified.

Table 6.3.13: COVERX file structure.

Occurrence	Record type	Present if
Once at beginning of file	File Identification	Always
	File Control	Always
	File Description	NHOLL > 0
	Neutron Group Boundaries	NNGRUP > 0
	Gamma Group Boundaries	NGGRUP > 0
	Material-Reaction Control	Always
Repeat for all material-reaction type pairs	Material-Reaction Type Cross Sections and Error Files	Always
Repeat for all matrices	Matrix Control	Always
	Block Control	Always
Repeat for all blocks	Matrix Data	Always

The details of each record type identified in Table 6.3.13 are presented in Table 6.3.14. Here, the name of the record type, the variables present on the record, the length of the record, the format of the record in FORTRAN context and a description of the content of the record are given.

6.4 SAMPLER: STATISTICAL UNCERTAINTY ANALYSIS WITH SCALE SEQUENCES

U. Mertyurek, W. A. Wieselquist, F. Bostelmann, M. L. Williams, F. Havlůj[1], *R. A. Lefebvre, W. Zwermann*[2], *D. Wiarda, M. T. Pigni, I. C. Gauld, M. A. Jessee, J. P. Lefebvre, K. J. Dugan*[3], *and B. T. Rearden*

ABSTRACT

Sampler is a "super-sequence" that performs general uncertainty analysis for SCALE sequences by statistically sampling the input data and analyzing the output distributions for specified responses. Among the input parameters that can be sampled are multigroup nuclear data, resonance self-shielding data (shielding factors and CENTRM pointwise cross sections), depletion data such as fission product yields and decay data, and model parameters such as nuclide concentrations, temperatures, and simple dimension specifications. Random perturbation factors for nuclear cross sections and depletion data are pre-computed with the XSUSA module Medusa by sampling covariance information and are stored in libraries read during the Sampler execution, while model parameters are sampled "on the fly". A wide variety of output response types for virtually all SCALE sequences can be specified for the uncertainty analysis, and correlations in uncertain parameters between multiple systems are also generated.

ACKNOWLEDGMENTS

Contributions from the Gesellschaft fur Anlagen- und Reaktorsicherheit (GRS) in Germany are gratefully acknowledged. The development of the SCALE Sampler module is based on GRS's suggestion that their XSUSA code could be used in conjunction with SCALE for stochastic uncertainty calculations. The original Sampler sequence was developed based on the XSUSA sampling sequence as well as collaboration and knowledge exchange with GRS staff members. The GRS module Medusa is used to generate perturbations of the MG cross sections, fission yields, and decay data.

The U.S. Nuclear Regulatory Commission Office of Nuclear Regulatory Research, the U.S. DOE Nuclear Fuel Storage and Transportation Planning Project, and the U.S. DOE Nuclear Criticality Safety Program supported the development of Sampler.

6.4.1 INTRODUCTION

The SCALE nuclear analysis code system provides a unified set of computational tools and data libraries to address a wide range of applications, including criticality safety, reactor physics, spent fuel characterization, burnup credit, national security, and neutron/photon radiation shielding [SAMPLER-RWJ+11]. In addition to determining the problem solutions, SCALE also provides tools to compute uncertainties in the results, arising from uncertainties in the data used for the calculations. Due to the diverse types of computational methods in SCALE, robust sensitivity/uncertainty (S/U) methods are necessary. Sampler implements stochastic sampling of uncertain parameters that can be applied to any type of SCALE calculation, propagating uncertainties throughout a computational sequence. Sampler treats uncertainties from two sources: 1) nuclear data and 2) input parameters. Sampler generates the uncertainty in any result generated by the computational sequence through stochastic means by repeating numerous passes through the computational sequence, each with a randomly perturbed sample of the requested uncertain quantities. The mean value and uncertainty in each parameter is reported along with the correlation in uncertain parameters where multiple systems are simultaneously sampled with correlated uncertainties.

Used in conjunction with nuclear data covariances available in SCALE, Sampler is a general, overarching sequence for obtaining uncertainties for many types of applications. SCALE includes covariances for

[1] ÚJV Řež, a. s., Czech Republic
[2] Gesellschaft fur Anlagen- und Reaktorsicherheit (GRS)
[3] Texas A&M University

multigroup neutron cross-section data, as well as for fission product yields and radioactive decay data, which allows uncertainty calculations to be performed for most multigroup (MG) computational sequences in SCALE. At the present time, nuclear data sampling cannot be applied to SCALE continuous energy (CE) Monte Carlo calculations (i.e., CE-KENO and CE-Monaco), although the fundamental approach is still valid.

Used in conjunction with uncertainties in input data, Sampler can determine the uncertainties and correlations in computed results due to uncertainties in dimensions, densities, distributions of material compositions, temperatures, or many other quantities that are defined in the user input for any SCALE computational sequence. This methodology was especially developed to produce uncertainties and correlations in criticality safety benchmark experiments, but it has a wide range of applications in numerous scenarios in nuclear safety analysis and design. The input sampling capabilities of Sampler also include a parametric capability to determine the response of a system to a systematic variation of an arbitrary number of input parameters.

6.4.1.1 Uncertainty analysis with stochastic versus perturbation methods

Two quite different approaches may be used for uncertainty analysis. One method uses first order perturbation theory expressions to compute sensitivity coefficients for a given response. This requires performing a forward transport calculation for the specified system and (sometimes) adjoint calculations for each response of interest. After the forward and adjoint transport solutions are obtained, sensitivity coefficients for all nuclear cross sections and material concentrations can be computed very efficiently with perturbation theory [SAMPLER-RWJ+11]. The sensitivities may be folded with covariance matrices to obtain response uncertainties due to nuclear data. The TSUNAMI modules and sequences in SCALE use perturbation theory for S/U analysis in this manner (see TSUNAMI-1D and TSUNAMI-3D).

For some types of applications, the adjoint-based perturbation methodology is not adequate or is inefficient. These include:

(a) Cases requiring codes with no adjoint functionality. SCALE has capability for critical eigenvalue adjoint solutions and generalized adjoint calculations using XSDRN, NEWT or KENO, but adjoint methods are not currently available for coupled neutronics-depletion calculations.

(b) Cases for which first order perturbation theory is not valid (i.e., problems with significant second order effects).

The Sampler module described in this section provides an alternative method for uncertainty analysis based on stochastic sampling (Monte Carlo) and does not require adjoint calculations. This approach samples joint probability density functions (PDFs) — such as given in the SCALE nuclear data covariance library — to produce a random sample for the nuclear cross sections used a transport calculation. If PDFs are available for other parameters such as depletion data or model parameters, etc., then these too can be sampled and included in the perturbed input vector. The perturbed data vector can be input to any SCALE sequence or functional module to obtain a single forward solution for all desired perturbed responses. The process is repeated for the desired number of samples-typically a few hundred; and the output distributions of results are analyzed to obtain standard deviations and correlation coefficients for all responses. The stochastic sampling method is not restricted to current SCALE modules; any new sequences or codes can be used for the forward calculations, without having to develop the capability for adjoint calculations.

Output distributions from the SCALE sampling also may be propagated to downstream codes for follow-on uncertainty analysis. For example, input for the TRITON lattice physics sequence can be sampled to produce a random set of output assembly-averaged, two-group cross section libraries. The two-group libraries can be input to a 3D core simulator that performs steady-state or transient calculations, and statistical analysis of the simulator output provides response uncertainties (possibly time-dependent) due to the SCALE input data

uncertainties. Response uncertainties computed with this approach are not limited to first order accuracy; i.e., they account for all non-linearities and discontinuities with the same accuracy as the original codes.

Thus there are several advantages to the statistical sampling method because it requires only forward calculations. The typical Sampler computational procedure perturbs the entire input data vector simultaneously, so that the total uncertainty in all responses, due to all data uncertainties, is obtained. This standard approach does not provide individual data sensitivity coefficients, unlike the perturbation theory method. In this sense, the statistical sampling method is complementary to the adjoint-based sensitivity method in the TSUNAMI modules. Computation of sensitivities using only forward calculations requires that each input parameter be varied individually, rather than collectively; and this may require a large number of simulations to obtain a full set of sensitivity coefficients.

6.4.2 METHODOLOGY

The main components of a Sampler calculation are the procedures for perturbing input data, obtaining the desired responses, and performing statistical analysis of the output distributions.

6.4.2.1 Definition of input data perturbations

The input data for a SCALE computation will generally be one of three types:

(a) *Nuclear data for transport calculations*. This includes multigroup (MG) and continuous energy (CE) cross sections, multiplicities, secondary particle distributions, and data used for resonance self-shielding of MG cross sections.

(b) *Nuclide transmutation data for depletion and burnup calculations*. This includes fission product yield data, decay constants, branching ratios to excited states, decay energies and distributions.

(c) *Modeling parameters for the system*. This includes information for defining nuclide number densities (e.g., density, weight fractions, enrichment, void fraction, etc.), temperature, and dimensions.

In principle Sampler can perform uncertainty analysis for all the above types of input data if uncertainties and correlations are known. The main restriction at this time is that CE cross sections for Monte Carlo calculations are not sampled (although the continuous data used for self-shielding *are* treated), so data perturbation applications are limited to MG calculations. Perturbations to input number densities and model dimensions are not impacted by this data limitation.

6.4.2.2 Nuclear data perturbations for multigroup calculations

Input MG nuclear data for SCALE sequences are obtained from an AMPX Master formatted library, which contains infinitely-dilute one-dimensional (1D) cross sections, two-dimensional (2D) scattering distributions, and Bondarenko self-shielding factors for various types of reactions. Only the 1D data and Bondarenko factors are varied in Sampler because no covariance data are available for the 2D scattering distributions; however, the 2D data are renormalized to be consistent the perturbed 1D scattering cross sections.

The Medusa module of the XSUSA program [SAMPLER-KHK94] is used to generate perturbation factors for the 1D cross sections on the MG library, assuming that the probability density functions are multivariate normal distributions with covariances given in the SCALE nuclear data covariance library. The library covariance data are given as infinitely-dilute, relative values; therefore a random sample for cross section $\sigma_{x,g}$ corresponds to $\frac{\Delta\sigma_{x,g}}{\sigma_{x,g}}$, where subscript x defines the nuclide/reaction type and g is the group number. The relative variations are transformed to multiplicative perturbation factors, defined by

$$Q_{x,g} = 1 + \frac{\Delta\sigma_{x,g}}{\sigma_{x,g}} \tag{6.4.1}$$

that can be applied to the reference data to obtain the altered infinitely-dilute values. A master sample file containing perturbation factors for 1000 samples (see note below) of the infinitely-dilute 1D data has been pre-computed and stored in the SCALE data directory. Each sample in the file contains perturbation factors for all groups and reactions in all materials. The master sample file is used for all cases, which avoids having to perform the data sampling during SCALE execution.

Because the 1D data in the MG library are infinitely-dilute (i.e., problem-independent), SCALE sequences include modules that compute resonance shielding corrections for the MG data. The self-shielding calculations generally require two additional types of input data: (a) Bondarenko self-shielding factors for the BONAMI module, which typically performs self-shielding calculations outside of the resolved resonance range; and (b) CE cross sections for the CENTRM/PMC modules, which compute pointwise (PW) flux spectra and process self-shielded cross sections for the resolved resonance range. Perturbations in the Bondarenko factors and CE cross sections used in self-shielding calculations must be consistent with perturbations made to the infinitely dilute 1D cross sections since all these data are based on the same fundamental ENDF/B information. It was shown in reference [SAMPLER-WIJ+13] that consistent perturbations can be obtained by using the same perturbation factors $Q_{x,g}$ in following expressions:

(a) infinitely-dilute MG cross sections $\sigma_{x,g}$:

$$\sigma'_{x,g} = Q_{x,g}\sigma_{x,g} \tag{6.4.2}$$

(b) Bondarenko factors f (σ_0, T), at background cross section σ_0 and temperature T:

$$f'_{x,g}(\sigma_0,\ T) = f_{x,g}\left(\sigma'_0, T\right); \quad \text{where } \sigma'_0 = \sigma_0/Q_{x,g} \tag{6.4.3}$$

(c) CE data σ_x(E):

$$\sigma'_x(E) = Q_{x,g}\sigma_x(E),\ \text{for } E \in g \tag{6.4.4}$$

In the above expressions, subscript x defines the nuclide/reaction type and g is the group number.

During Sampler execution the module ClarolPlus reads perturbation factors ($Q_{x,g}$) for a specified sample number from the master sample file, and evaluates Equations Eq. (6.4.2) and Eq. (6.4.3). ClarolPlus also writes a file containing perturbation factors only for the particular sample number used by the CrawdadPlus module, as described below.

Note: The tradeoff of size on disk of the pre-calculated samples distributed with SCALE versus the maximum number of perturbations required in practice has led to the current maximum of 1000 samples. Based on limited experience, correlation coefficients of near zero require the most samples to converge and typically about 1000 samples has been sufficient.

6.4.2.3 Depletion data perturbations

Multiplicative perturbation factors for fission product yields have been generated with XSUSA by sampling the covariances for the independent yield uncertainties. The yield uncertainties are taken from ENDF/B VII.1, which in general are given by fissionable nuclide and for up to three energies: 0.025 eV, 0.5 MeV, and 14 MeV. The ENDF/B yield uncertainties do not include correlations between fission products, which may arise due to constraints such as (a) the sum of all yields must always be two (i.e., the uncertainty in the yield sum is zero), and (b) the uncertainties in independent yields should be consistent with uncertainties given for cumulative yields. The constraints generally introduce positive and negative correlations into the yields

covariance matrix. A method developed by Pigni [SAMPLER-PFG15] was used to determine the correlations in ^{235}U yields. Correlations in yields from other fissionable nuclides are not available in SCALE at this time.

During Sampler execution the perturbation factors are read for a given data sample, compute a complete set of perturbed independent yields for all fissionable nuclides and energies, and renormalize the yields to ensure that they sum to two. An output file containing the perturbed yield data is written to an external file in the format read by ORIGEN. The perturbation factors are read once each time a sequence executed (i.e., for each data sample).

A set of 1,000 decay data perturbations has also been generated with XSUSA and stored in decay-only ORIGEN library files. Sampler automatically aliases the appropriate sample to the file "end7dec".

Note: In order for decay data perturbations to be performed, the "end7dec" decay library must be used **directly**. Typical TRITON and Polaris calculations **do not use "**end7dec" directly, due to using the unperturbed decay data embedded in a special ORIGEN reaction library aliased to "transition.def" as the basis for all coupled transport/depletion calculations. Experience has been that decay data contributes very little additional uncertainty compared to yield data and cross section data.

6.4.2.4 Model data perturbations

An approach presented by Areva NP GmbH utilizes statistical sampling on uncertain parameters to assess the uncertainty in individual system as well as correlations between multiple systems [SAMPLER-BHNS10]. In this approach, values for individual parameters in the input model are randomly modified within the reported uncertainty and distribution function and a series of perturbed values are obtained. Where sufficient samples are made, the distribution of the perturbed values is used to determine the uncertainty in the computed quantity due to uncertainties in the input parameters. In cases where the same uncertain parameters influence multiple experiments the simultaneous perturbation of the parameter for multiple cases will provide the correlation in uncertainties between the different configurations.

To obtain the uncertainty and correlation due to all uncertain parameters, all parameters are randomly perturbed for each calculation and the uncertainties and correlations are determined. Mathematically, the uncertainty in an individual output parameter k is determined as shown in Eq. Eq. (6.4.5).

$$\Delta k^{\exp}(i) = \hat{\mu}_i = \sqrt{\frac{1}{n-1}\sum_{a=1}^{n}\left(\left(k_{calc}^{MC}(i)\right)_a - \overline{k_{\text{calc}}^{MC}(i)}\right)^2}, \tag{6.4.5}$$

where $\Delta k^{\exp}(i)$ is the uncertainty (in terms of standard deviation) in system i due to uncertainties in the input parameters. $\left(k_{calc}^{MC}(i)\right)_a$ is the a^{th} Monte Carlo (MC) sample of system i, where all uncertain input parameters have been randomly varied within the specified distribution.

The covariance between two systems, i and j, is determined as shown in Eq. Eq. (6.4.6).

$$\hat{\Sigma}_{ij} = \sqrt{\frac{1}{n-1}\sum_{a=1}^{n}\left(\left(k_{\text{calc}}^{MC}(i)\right)_a - \overline{k_{\text{calc}}^{MC}(i)}\right)\left(\left(k_{\text{calc}}^{MC}(j)\right)_a - \overline{k_{\text{calc}}^{MC}(j)}\right)}. \tag{6.4.6}$$

The correlation coefficient between systems i and j can be determined from Eqs. Eq. (6.4.5) and Eq. (6.4.6) as shown in Eq. Eq. (6.4.7).

$$c_{ij} = \frac{\hat{\Sigma}_{ij}}{\hat{\mu}_i\hat{\mu}_j}. \tag{6.4.7}$$

The correlation coefficients determined with Eq. Eq. (6.4.7) are the values needed to perform the Generalized Least Linear Square (GLLS) analysis using TSURFER, which solves for a set of cross section data perturbations that would improve agreement between the computational simulations and experimental benchmark results. The correlation coefficients can be shown to be analogous to sensitivity/sensitivity coefficients (i.e., c:sub:k) calculated by SAMS [SAMPLER-HMAK20].

6.4.2.5 Importance Ranking R^2 Methodology

Sampler allows the analysis of the impact of cross section uncertainties on any output quantity of a reactor physics calculation. However, identification of top contributing nuclide reactions to this uncertainty, requires a more detailed analysis. Such rankings can be used for recommendations for additional measurements and evaluations of nuclear data can be made.

A ranking of important nuclide reactions to the uncertainty of response y can be obtained by the determination of the squared multiple correlation coefficient R^2 [SAMPLER-BWAW22]. All the cross sections of all nuclides that are relevant for the model of interest are divided into group A, the nuclide reaction of interest, and group B, all other nuclide reactions. Then R^2 is calculated as follows:

$$R^2_{y,A} = \bar{\rho}_{\bar{\sigma}_A,y} \cdot \bar{\bar{\rho}}_{\bar{\sigma}_A,\bar{\sigma}_A} \cdot \bar{\rho}^t_{\bar{\sigma}_A,y} \tag{6.4.8}$$

$\bar{\rho}_{\bar{\sigma}_A,y}$: vector of correlation coefficients between sampled input parameters of group A and response y

$\bar{\bar{\rho}}_{\bar{\sigma}_A,\bar{\sigma}_A}$: sample correlation matrix between input parameters of group A

R^2 values are between 0 and 1. It is important to note that $\bar{\bar{\rho}}$ is a matrix consisting of correlation coefficients between the input parameters. It is not to be confused with a correlation matrix derived from the original covariance matrix used for sampling the parameters. However, if the sample size approaches infinity, then the sample correlation matrix converges toward the correlation matrix that can be derived from the original covariance matrix and that is used for sampling the cross sections.

R^2 can be interpreted as the expected amount by which the total output variance would be reduced in case the true values of the input parameter group A would become known. The sample size for the determination of R^2 must be larger than the number of independently sampled input cross sections in group A.

Since R^2 is determined based on a statistical approach, they are provided with a statistical error estimate. Both values are accompanied with a 95% confidence interval. The R^2 values are additionally provided with a 95% significance level; only values above this level are considered statistically significant.

6.4.3 INPUT DESCRIPTION

This section describes the Sampler input file format.

6.4.3.1 Overall input structure

The order of the blocks is arbitrary, with the exception of dependent variables (see Sect. 6.4.3.6.3. Below is the layout of a typical sampler input.

```
=sampler

read parameters
  (control flags)
end parameters
read parametric
  (parametric studies definitions)
end parametric
```

(continues on next page)

(continued from previous page)

```
read case[casename]
  sequence=(sequence name)
    (sequence input)
  end sequence
  ... (more sequences) ...
  read variable[id1]
    (variable definition)
  end variable
  ... (more variables) ...

  read response[name1]
    (response definition)
  end response
  ... (more responses) ...
  end case
  ... (more cases) ...

read analysis[name1]
  (analysis definition)
end analysis
... (more analysis) ...

read save
  (file save definition)
end save
... (more saves) ...

end
```

Every Sampler input file has to contain the parameters block and at least one case block. Other input blocks are optional.

Cases and sequences

Within Sampler, multiple independent SCALE calculations, or *cases*, can be included. Since the same set of responses is extracted from each of the cases, these should have the same structure (i.e. produce the same kind of output files); the benefit of having multiple cases within one Sampler input deck is that it is possible to generate cross-correlations between cases as an output.

Every *case* contains one or more stacked *sequences*. The whole case is always run together.

Each case has an unique *identifier*. The identifier is a single word beginning with a letter followed by letters, numbers and underscores. Note that the dash "-" cannot be used in a case identifier.

Within the case block, the user can enter any number of sequences, which contain the actual user input. The format of each sequence block is:

```
sequence=(sequence name) (optional parm= setting)
 (sequence data)
end sequence
```

The sequence data is a SCALE input that is not processed by Sampler, except to substitute sampled values for variable placeholders (see Sect. 6.4.3.6.4 for more information). For `parm=` settings, no limit on column number is enforced.

Importing input data from external files

Instead of directly specifying the SCALE sequence input within the Sampler input file, the user can specify the path to a previously generated input file which can be imported for use within Sampler as:

```
read case[c1]
  import = "/home/usr/sampler_samples/sampler_1x_case.inp"
end case
```

In this case, absolute paths should be used (or a `shell` sequence before invoking Sampler, to copy the appropriate files into the temporary directory). This approach provides concise input files and is advantageous for quality assurance controlled input data.

6.4.3.2 Configuration parameters

In the parameters block the user can control the main workflow and output parameters for sampler. Valid keywords are shown in Table 6.4.1.

Important: Note that of the major perturbation modes, only "perturb_geometry=yes" is on by default. (Bondarenko factor and pointwise data perturbation for CENTRM controls how "perturb_xs=yes" is performed.)

Table 6.4.1: Parameter input for Sampler.

KEYWORD	DESCRIPTION	DEFAULT
`n_samples=N`	Number of samples (1–1000 for nuclear data perturbations, unlimited for input file perturbations)	none
`first_sample=N`	Number of the first sample	1
`perturb_geometry=(yes/no)`	Perform input file/model data/geometry perturbations	yes
`perturb_xs=(yes/no)`	Perform cross-section (XS) perturbation	no
`perturb_yields=(yes/no)`	Perform fission yield perturbation	no
`perturb_decay=(yes/no)`	Perform decay data perturbation	*no*
`perturb_bondarenko=(yes/no)`	When perturbing XS, perturb Bondarenko factors	yes
`perturb_pointwise=(yes/no)`	When perturbing XS, perturb pointwise data	yes
`perturb_kinetics=(yes/no)`	When perturbing XS, perturb decay constants of delayed neutron groups	no
`library=".."`	Name of the master XS library (in quotes), it is possible to use the filename or an alias (e.g. " v7.1-252n")	none
`perturbed_library=".."`	Name of the perturbed library (in quotes); this is the perturbed XS library used by the actual computational sequences	(same as `library`)
`mg_factors_library=".."`	Name of the multigroup XS perturbation factors library (in quotes); if not given, built-in library is used	(blank)

continues on next page

Table 6.4.1 – continued from previous page

KEYWORD	DESCRIPTION	DEFAULT
coverx_library=".."	Name of the covariance library (in quotes); this is the covariance library, that was used to generate the samples, and required for R^2 analysis	56groupcov7.1
run_cases=(yes/no)	Actually run inputs through SCALERTE or just generates them.	yes
force_run=(yes/no)	Enforce running SCALE even when the output files are present	no
plt=(yes/no)	Produce plot file histograms (PTP format) with response distributions that can be viewed with Fulcrum	yes
csv=(yes/no)	Produce CSV files with individual tables	yes
print_data=(yes/no)	Print per-sample values in the main output	no
print_chi2=(yes/no)	Print chi-square normality test in the main output	no

Notes on sample numbers:

The samples are selected from the perturbation factor libraries (except for geometry perturbation); it is up to the user to fit inside the range of samples available (i.e. n_samples+first_sample-1 must be less or equal to the number of samples). The built-in perturbation libraries based nuclear data covariances contain 1000 samples.

Note on perturbed library name:

The default behavior for Sampler is to set `perturbed_library` to the same name as `library`. Since Sampler creates a local file in the temporary directory, which is used by SCALE instead of the library in the lookup table, it in general results in the desired behavior. SCALE sequences only provide pre-defined resonance self-shielding options for known libraries, so where `perturbed_library` differs from the name of a standard SCALE library, the type of resonance self-shielding calculation desired must be specified (via the *PARM=* setting). Please review the documentation of the specified sequence for available options, such as *PARM=CENTRM*.

Warning: The library name must result in a valid filename. In some cases the use of "`xn252`" instead of "`v7.1-252`" is recommended because the dash might result in improper links to the perturbed library. This guidance applies only to the cases when `perturb_xs=yes` is used; otherwise, Sampler does not generate a perturbed library.

6.4.3.3 Sampler responses

For every case run within Sampler any number of responses can be extracted. A response can be a single number or a time-dependent series, which is assigned a name and optionally several parameters. The responses can be entered entered once and shared across all selected cases, i.e. every selected case returns the same set of responses or can be entered inside a case block and only returned for that case.

Sampler recognizes these kinds of responses:

- `opus_plt` – data from an OPUS-generated PLT file

- `triton` - TRITON homogenized cross-sections (xfile016)
- `stdcmp` – standard composition files
- `f71` – concentrations from the F71 ORIGEN dump
- `grep` – general expression from the text output file
- `variables` – the geometry perturbation sampled values

The general format of the response block is:

```
read response[(response id)]
  type = (response type)
  (response parameters)
  cases = (case list) end
end response
```

The *(response id)* is an arbitrary identifier (a single word) by which the the response is denoted in the results. The *(response type)* is one of the keywords `opus_plt`, `triton`, `stdcmp`, `f71`, variables and `grep`. Response parameters are different for each response type and are explained in Sect. 6.4.3.3.1 through Sect. 6.4.3.3.6 . The `cases=` specification applies only to the response defined at the global scope.

The response block can be placed either:

a) inside a case block. This response is collected only to this particular case.

In the following example, response `x` is only collected for the case `c1` and the response `y` is collected for the case `c2`.

```
read case[c1]
  sequence=...
    ...
  end sequence
  read response[x]
    ...
  end response
end case
read case[c2]
  sequence=...
    ...
  end sequence
  read response[y]
    ...
  end response
end case
```

b) at the global scope. The `cases=... end` has to be used to specify the cases for which this response is collected.

In this example, response `x` is collected for the both cases `c1` and `c2` and the response `y` is only collected the case `c1`. Since no `cases=` entry is provided, the response `z` is collected for all cases.

```
read case[c1]
  sequence=...
    ...
  end sequence
end case
read case[c2]
  sequence=...
    ...
```

(continues on next page)

(continued from previous page)

```
  end sequence
end case
read response[x]
  ...
  cases = c1 c2 end
end response
read response[y]
  ...
  cases = c1 end
end response
read response[z]
  ...
end response
```

OPUS PLT file responses

This response extracts any data from a PLT file generated by OPUS. The user specifies which PLT file should be used and which elements/nuclides should be used.

Parameter `ndataset` provides the number of the selected PLT file, i.e. `ndataset=1` will read data from the file ending with .00000000000000001.plt (which is the second generated PLT file in the given case).

Parameter `nuclides=...end` specifies the list of nuclides (or elements) which are read from the PLT file; nuclides can be specified as alphanumeric identifiers (U-235, ba137m) or six-digit ZAI identifiers (922350). In addition to that, any other PLT file response identifiers (i.e. the character strings in the first column of the plot table) may be used, which allows for example the usage of `total` and `subtotal` keywords.

Example

```
read response[fisrates]
  type = opus_plt
  ndataset = 1
  nuclides = u238 pu239 total end
end response
```

TRITON homogenized cross-section responses

This response extracts the homogenized cross-section data saved by TRITON on the `xfile016`.

Responses are retrieved for a selected homogenized mixture and all branches (which are then denoted by response name suffixes).

Using a `data= ... end` assignment specifies which data types are to be saved.

The available options for data entries are:

```
kinf sigma_total sigma_fission sigma_absorption
sigma_capture sigma_transport_out sigma_transport_in
sigma_transport sigma_elastic sigma_n2n nu_fission
kappa_fission nu chi flux diffusion
```

Example:

```
read response[xs]
  type = triton
  mixture = 1
  data = kinf sigma_absorption end
end response
```

Standard composition file responses

This response retrieves isotopic concentrations (in atoms/barn-cm) from the standard composition file. Parameter `nuclides=...end` specifies which nuclides should be retrieved. The parameter mixture specifies the number of the StdCmpMix file, so `mixture=10` would load concentrations from the file `StdCmpMix00010_*` (for all time steps).

Example:

```
read response[mix10]
  nuclides = u-235 pu-239 end
  mixture = 10
end response
```

ORIGEN concentration (F71) responses

This response retrieves the isotopic concentrations (in gram-atoms) from the ORIGEN concentration edit in the `ft71f001` file.

Parameter `nuclides=...end` specifies the list of nuclides (or elements) which are read from the F71 file; nuclides can be specified as alphanumeric identifiers (U-235, ba137m) or six-digit ZAI identifiers (922350).

Two options are available to choose the positions on the file from which data should be retrieved. Either `step_from=start` and `step_to=end` can be used to select a range of positions, or `mixture=N` can be used to choose either an ORIGEN case or a TRITON case mixture. This is convenient for TRITON cases where step numbers are usually not known in advance.

Example:

```
read response[concentrations]
  type=origen_nuclides
  nuclides = u-235 pu-239 pu-240 pu-241 end
  mixture = 10
end response
```

Generic regular expression (GREP) responses

In order to allow the user to collect other responses from the SCALE output, a generic regular expression (regexp) mechanism is provided by Sampler. For every response the user can enter one (or more) regular expressions, which are applied (using the "grep" system tool) to the main output file. "grep" is executed with the "-o" option, which returns only the matched portion of the line (and not the whole line). Usually it is necessary to use two expressions, one to find the line of interest and another to extract only the desired value. The POSIX character classes are supported in the grep used-the most commonly used are "[[:digit:]]" to match a single digit 0-9 and [[:space:]] to match a single space or tab. The "+" and "*" are used to match one or more and zero or more repeats, respectively. Note that as per standard regexp rules, "." matches any character and an escape is necessary, i.e. ".", in order to match a period.

Each regular expression is defined by the keyword `regexp="..."`. The result of the last regular expressions should be a single number (and is treated as such by Sampler).

The following example defines regular expression for extraction of k-effective from a CSAS5/6 output file:

```
read response[keff]
  type = grep
  regexp = "best estimate system k-eff[[:space:]]+[[:digit:]]+\.[[:digit:]]+"
  regexp = "[[:digit:]]+\.[[:digit:]]+"
end response
```

With the first `regexp` statement, a line containing "best estimate system k-eff" followed by a number is found, and then just the number part is extracted with the second `regexp` statement.

For ease of use, Sampler provides several regular expression shortcuts shown in Table 6.4.2.

Table 6.4.2: Regular expression shortcuts for SCALE sequences.

`regexp` = "`:kenova.keff:`"	keff from KENO5 / CSAS5 sequence
`regexp` = "`:kenova.ealf:`"	EALF from KENO5 / CSAS5 sequence
`regexp` = "`:kenova.nubar:`"	nu-bar from KENO5 / CSAS5 sequence
`regexp` = "`:kenovi.keff:`"	keff from KENO6 / CSAS6 sequence
`regexp` = "`:xsdrn.lambda:`"	lambda from XSDRN / CSAS1 sequence
`regexp` = "`:scale.number:`"	matches any number (e.g. "1", "1.0", "1.23e-7", "-0.3")

Thus, the previous example may be alternately rephrased as such:

```
read response[keff]
  type = grep
  regexp = ":kenova.keff:"
end response
```

In addition to this, the `grep` response also supports extraction of data with uncertainties. In order to get the response uncertainty, use the `eregexp=` keyword, which follows the same rules as `regexp=`. The same shortcuts as for `regexp=` may be used as well (for KENO V.a/VI multiplication coefficient). Therefore, to get KENO multiplication factor including the uncertainty, one might define the response like this:

```
read response[keff]
  type = grep
  regexp = ":kenova.keff:"
  eregexp = ":kenova.keff:"
end response
```

Sampled variable values

Using the `variables` response, the user can extract information from the sampled values of the geometry/material perturbation variables. The `data=` key contains the list of variable identifiers of interest.

This option is useful to generate the correlations between geometry/material perturbations and the responses of interest.

Example:

```
read variable[r1]
  ...
end variable
read response[r]
  type=variables
  data = r1 end
end response
```

Quick response definition overview

Table 6.4.3 summarizes the available options for the different response types. The nuclides specification can either be in terms of the standard alphanumeric identifier, e.g. "u235m" for ^{235m}U, or the IZZZAAA integer identifier, e.g. "1092235" for ^{235m}U.

Table 6.4.3: Response definition overview.

Key	**Description**
response type `opus_plt`	
Ndataset	Number of the PTP file
Nuclides	List of nuclides (alphanumeric/IZZZAAA, terminated by end)
response type `stdcmp`	
`Mixture`	Number of the StdCmpMix file
`Nuclides`	List of nuclides (alphanumeric/IZZZAAA, terminated by end)
response type `triton`	
Mixture	Homogenized mixture index
`Nuclides`	List of nuclides (alphanumeric/IZZZAAA, terminated by end)
`Data`	List of homogenized data types (terminated by end)
response type `f71`	
`Nuclides`	List of nuclides (alphanumeric/IZZZAAA, terminated by end)
`Mixture`	ORIGEN case number / TRITON mixture number
`step_from`	Lower bound of position range
`step_to`	Upper bound
response type `grep`	
`regexp`	Regular expression for the response value (quoted)
`eregexp`	Regular expression for the response uncertainty (quoted)
response type `variables`	
`data`	List of variable names (terminated by end)

6.4.3.4 Saving files

By default, Sampler saves from each run the input, output, message and terminal log files. In addition to that, if respective responses are requested, it saves the `ft71f001` as basename`.f71`, x``file016`` as basename`.x16` and the `StdCmpMix*` files.

The user might specify additional files to be saved into the sample subdirectory; this is achieved by defining one or more `save` blocks.

Each save block contains a `file="..."` parameter, which specifies the filename in the sample run temporary directory. Optionally, the user can specify `name="..."` to let Sampler rename the file to *basename.extension*, where *extension* is the value of the `name` parameter. If `name` is not specified, the file is not renamed and is just copied to the sample subdirectory. The `name` parameter cannot be used if wildcards are used in the `file` parameter.

The quotes for both `name` and `file` parameter values are mandatory.

Example 1:

```
read save
  name = "ft2"
  file = "ft71f002"
end save
```

Example 2:

```
read save
  file = "StdCmpMix*"
end save
```

6.4.3.5 Parametric studies

The Sampler infrastructure allows an efficient implementation of studies of parameter variation effects on various responses. This mode is activated by entering the `read parametric ... end parametric` block.

This block contains two arrays: `variables = ... end` and `n_samples = ... end`. The variables array lists the variables of the parametric study. The variables must have "`distribution=uniform`", and the minimum and maximum becomes the range for that variable in the parametric study. For each variable, the corresponding value in the `n_samples = ... end` array indicates the number of evenly spaced values to assume *in that dimension.* The total number of calculations is therefore the multiplication of all the `n_samples` values. Note that for a single sample with `n_samples=1`, only the minimum value is used. Below is as an example of the parametric block.

```
read parametric
  variables = density temperature end
  n_samples =      10           6 end
end parametric
```

The two variables are `density ``and ``temperature`, and there will be 10 evenly spaced density values (including the minimum and maximum) and 6 evenly spaced temperature values, for a total of $10 \times 6 = 60$ calculations. To perform the same number of samples in each dimension, the keyword `n_samples` in the parameters block may also be used.

Sampler generates a summary table of the parametric study, including values for which the minimum and maximum of each response occurs. Sampler also generates PTP plot files showing the dependency of each response on each variable.

6.4.3.6 Geometry and material perturbations

In addition to data perturbations, Sampler also allows the user to include geometry and material uncertainties in the calculation. This is achieved by defining `variable` blocks. Each variable may be linked to a particular value in the input and is associated either with a random variable distribution or with an arithmetic expression. The expression capability allows for dependent or derived parameters, such as ^{238}U content depending on enrichment or outer clad radius depending on the inner radius.

For each sample, Sampler creates a perturbed input by generating a set of variable values and substituting them into the input. For every variable, the user has to define the variable and specify its distribution (using one of the predefined random variable distributions described in Sect. 6.4.3.1.1) or its dependence on other variables (using an arithmetic expression). If desired, the user can also specify which part of the input will be replaced by the variable. This can be achieved either by specifying a SCALE Input Retrieval ENgine (SIREN) expression or by putting placeholders directly inside the input deck (see Appendix A for details on SIREN).

Variable definition

Variables are defined by a `read variable..end variable` block. The general format of the block is:

```
read variable[(variable id)]
  distribution = (distribution type)
  siren = "(siren expression)"
  (distribution-specific parameters)
  cases = (case list) end
end variable
```

The variable id is an arbitrary, single word consisting of letters, numbers and underscores (with number not being the first character). The variable id has to be unique and is case dependent. `distribution` is one of the distribution-type keywords (see Sect. 6.4.3.6.2) or `expression` for the dependent variable definition. The `cases=` specification applies only to the variables defined at the global scope (see below). The `siren=` specification is optional, see below.

The block can be placed either:

a) inside a case block. This variable applies only to this particular case.

In the following example, variable `x` applies to the case `c1` and the variable `y` applies to the case `c2`.

```
read case[c1]
  sequence=...
    ...
  end sequence
  read variable[x]
    ...
  end variable
end case
read case[c2]
  sequence=...
    ...
  end sequence
  read variable[y]
    ...
  end variable
end case
```

b) at the global scope. The `cases=... end` has to be used to specify the cases to which this variable applies.

In this example, variable `x` applies to the both cases `c1` and `c2` and the variable `y` applies only to the case `c1`.

```
read case[c1]
  sequence=...
    ...
  end sequence
end case
read case[c2]
  sequence=...
    ...
  end sequence
end case
read variable[x]
  ...
  cases = c1 c2 end
end variable
read variable[y]
  ...
  cases = c1 end
end variable
```

Distribution types

Sampler supports three random `distribution` types, selected using the distribution= keyword.

1) `uniform`: uniform distribution over a (closed) interval.

Additional parameters for a uniform distribution are shown in Table 6.4.4.

Table 6.4.4: Parameters for uniform distributions.

KEYWORD	DESCRIPTION	NOTE
minimum=	Lower bound value	required
maximum=	Upper bound value	required

Example:

```
read variable[rfuel]
  distribution=uniform
  minimum = 0.40
  value = 0.41
  maximum = 0.42
end variable
```

2) `normal`: normal (optionally truncated) distribution.

Additional parameters for normal distribution are shown in Table 6.4.5.

Table 6.4.5: Parameters for normal distributions.

KEYWORD	DESCRIPTION	NOTE
value=	Mean value	required
stddev=	Standard deviation	required
minimum=	Lower cutoff value	optional
maximum=	Upper cutoff value	optional

The user can specify both `minimum` and `maximum`, one of them, or neither. If a cutoff is not specified, the distribution is not truncated on that side.

Example:

```
read variable[c1_u235]
  distribution=normal
  value=95.0
  stddev=0.05
end variable
```

3) `beta`: beta distribution.

Additional parameters for the beta distribution are shown in Table 6.4.6.

Table 6.4.6: Parameters for beta distributions.

KEYWORD	DESCRIPTION	NOTE
minimum=	Lower cutoff value	required
maximum=	Upper cutoff value	required
beta_a=	First parameter for distribution	required
beta_b=	Second parameter for distribution	required

The Beta distribution is defined in the standard way given by Eq. Eq. (6.4.9). The parameters for the distribution determine where the peak is located in the interval [`minimum`, `maximum`] and the variance of the distribution; the parameters α and β are required to be integer values.

$$f(x;\alpha,\beta) = \frac{\Gamma(\alpha+\beta)}{\Gamma(\alpha)\Gamma(\beta)} x^{\alpha-1}(1-x)^{\beta-1}, \tag{6.4.9}$$

Example:

```
read variable[rclad]
  distribution=beta
  value=0.47
  minimum=0.45
  maximum=0.50
  beta_a=2
  beta_b=6
end variable
```

Dependent variables (expressions)

Using `distribution=expression` allows the user to specify a variable using the values of other variables. Setting `expression`="(expression)" then specifies how to evaluate the variable. Sampler supports basic arithmetic operators and other variables can be used as well. However, Sampler currently provides no variable dependency resolution and therefore only variables that were defined (using the variable block) previously in the input deck can be referenced in an expression.

Example:

```
read variable[c1_u238]
  distribution = expression
  expression="100.0-c1_u235"
end variable
```

Using placeholders

Inside the `sequence`= blocks, a #{*variable id*} placeholder can be used. This will be replaced by a variable value when Sampler builds the particular input deck. Only a simple variable reference can be used; no expressions are allowed here.

Example:

```
sequence=csas5
...
uranium  1 den=18.76 1 300 92235 #{u235} 92238 #{u238} end
...
end sequence
read variable[u235]
...
end variable
read variable[u238]
...
end variable
```

In the input deck snippet the ^{235}U and ^{238}U content are inserted directly to the respective places (defined by variables u235 and u238).

Using placeholders is straightforward and simple; however, if for input deck quality assurance or other reasons it is not desirable to modify the input deck directly, SIREN expressions can be used.

Using SIREN expressions

SIREN is a package which provides an XPath-like interface to the SCALE input deck represented by a Document Object Model (DOM). In Sampler, the user can specify `siren`="*path*" to have the respective token(s) replaced by a variable value.

Please refer to Appendix A for more details on specifying the SIREN path expressions.

Example:

```
read variable[c1_u235]
  distribution=normal
  value=95.0
  stddev=0.05
  siren="/csas5/comps/stdcomp[decl='uranium']/wtpt_pair[id='92235']/wtpt"
end variable
```

The variable `c1_u235` value is inserted as the weight percent of ^{235}U in the basic standard composition declared as "uranium" in the CSAS5 sequence.

6.4.3.7 Response analysis

Sampler provides several statistical post processing options to analyze results of propagated uncertainties. Variations in a user selected response, mutual variations between two different responses with respect to perturbed data can provide insight to dependecy to input data or any correlation between responses.

The general format of the analysis block is:

```
read analysis[(analysis id)]
  type = (analysis type)
  targets = (list of target responses) end
  sources = (list of source responses or nuclides) end
end analysis
```

The analysis block mainly provides three input fields: target response, source response, and analysis type. Both the target and source responses can be a list of responses. The calculation of the selected analysis type is performed between the source and target response lists.

Sampler reconizes the following analysis types:

- `pearson_corr` - pearson correlation coefficient (similarity index) calculation between each response in the sources response list and the target response list
- `covariances` - covariance calculation between each response in the sources response list and the target response list
- `correlation_matrix` - pearson correlation coefficient calculation between responses in the sources response list (target responses are ignored for this type)
- `covariance_matrix` - covariance calculation between responses in the sources response list (target responses are ignored for this type)
- `r2` - sensitivity indices R^2 are calculated for responses in the target response list for the isotopes listed in the sources response list

Responses in target and sources lists are specified using the CASE:RESPONSE.SUB(INSTANCE) notation

where

- CASE : User-selected Sampler case name in the case block from which the response is collected.
- RESPONSE : Response name in the response block
- SUB : Sub-response listed in the specified response block, such as isotope names in origen or opus response types. If the response type has no sub-response (e.g., in the case of a grep response), then it is not used.
- INSTANCE : Index of occurrence in the collected response, such as the depletion step index for a burnup dependent response, or the line number in which the selected response occurs in the case of grep type responses. Note that the instance counting starts with 0 in case of grep responses. A missing index field is interpreted as if the response is requested for index=0. In addtion to integer indexes the following special keywords are also accepted
  - last : the last occurence
  - all : all occurences. This keyword populates the requested sub response for all occurence indices. For example, case:response.sub(all) is the same as case:response.sub(0) case:response.sub(1) ... case:response.sub(last)

The following input example calculates the similarity indices between ^{235}U concentration at the 15th time step in the MOX depletion model with ^{235}U, ^{239}Pu , ^{243}Am, and ^{109}Ag concentrations at the 14th depletion step from the UO2 model:

Pearson Correlation Example

```
read case[c1]
 import = "/home/usr/samples/moxdepletion.inp"
end case

read case[c2]
 import = "/home/usr/samples/uo2depletion.inp"
 read response [experiments]
   type = origen_nuclides
   nuclides = u-235 pu-239 am-243 ag-109 end
   mixture = 5
 end response
end case

read response [application]
  type = origen_nuclides
  nuclides = u-235 end
  mixture = 10
  cases = c1 end
end response

read analysis [iso_ck]
  type = pearson_corr
  targets = c1:application.u-235(15)   end
  sources = c2:experiments.u-235(last) c2:experiments.pu-239(14)  end
end analysis
```

Correlation Matrix Example

Correlation and covariance matrices only require the sources card since they are symmetric

```
read analysis [corr-covmatrix]
  type = correlation_matrix
  sources = c2:experiments.u-235(all)  end
end analysis
```

Squared Correlation Example

For the analysis of R^2, isotopes need to be entered as sources:

```
read analysis [sensindex]
  type = r2
  targets = c1:application.u-235(15) end
  sources = h-1 u-235 u-238  end
end analysis
```

6.4.3.8 Converting a standard SCALE input to a Sampler input

In this section, a short walkthrough is provided on how to convert a "normal" SCALE input into a Sampler input for cross section uncertainty propagation.

Beginning with a simple CSAS5 input deck:

```
=csas5
  sample problem 1  case 2c8 bare
  v7.1-252
  read comp
    uranium  1 den=18.76 1 300 92235 93.2 92238 5.6 92234 1.0 92236 0.2 end
  end comp

  read geometry
    unit 1
      cylinder 1 1 5.748 5.3825 -5.3825
      cuboid  0 1 6.87 -6.87 6.87 -6.87 6.505 -6.505
  end geometry
    read array
      gbl=1 ara=1 nux=2 nuy=2 nuz=2 fill f1  end fill
    end array
  end data
end
```

First, wrap the given input in sequence and case blocks and assign the case an arbitrary identifier (`c1`). It is also recommended to change the library alias to the actual filename.

```
=sampler
read case[c1]
  sequence=csas5
    sample problem 1  case 2c8 bare
    xn252
    read comp
      uranium  1 den=18.76 1 300 92235 93.2 92238 5.6 92234 1.0 92236 0.2 end
    end comp

    read geometry
      unit 1
        cylinder 1 1 5.748 5.3825 -5.3825
        cuboid  0 1 6.87 -6.87 6.87 -6.87 6.505 -6.505
    end geometry
      read array
```

(continues on next page)

(continued from previous page)

```
        gbl=1 ara=1 nux=2 nuy=2 nuz=2 fill f1  end fill
      end array
    end data
  end sequence
end case
end
```

Second, add the parameters block to identify the base cross-section library used for building the perturbed ones. Note that this is the only SCALE module that uses the plural form of parameters and that the reference to the library matches exactly the one inside the CSAS5 input.

```
=sampler
read parameters
  library="xn252"
end parameters
read case[c1]
  sequence=csas5
    sample problem 1  case 2c8 bare
    xn252
    read comp
      uranium  1 den=18.76 1 300 92235 93.2 92238 5.6 92234 1.0 92236 0.2 end
    end comp
    read geometry
      unit 1
        cylinder 1 1 5.748 5.3825 -5.3825
        cuboid  0 1 6.87 -6.87 6.87 -6.87 6.505 -6.505
    end geometry
      read array
        gbl=1 ara=1 nux=2 nuy=2 nuz=2 fill f1  end fill
      end array
    end data
  end sequence
end case
end
```

Finally, set up the perturbations (number of samples and what to perturb):

```
=sampler
read parameters
  library="xn252"
  n_samples = 40
  perturb_xs = yes
end parameters
read case[c1]
  sequence=csas5
    sample problem 1  case 2c8 bare
    xn252
    read comp
      uranium  1 den=18.76 1 300 92235 93.2 92238 5.6 92234 1.0 92236 0.2 end
    end comp
    read geometry
      unit 1
        cylinder 1 1 5.748 5.3825 -5.3825
        cuboid  0 1 6.87 -6.87 6.87 -6.87 6.505 -6.505
    end geometry
      read array
        gbl=1 ara=1 nux=2 nuy=2 nuz=2 fill f1  end fill
      end array
    end data
  end sequence
end case
end
```

6.4.4 EXECUTION DETAILS

6.4.4.1 General workflow

The overall workflow for Sampler is as follows:

- for each sample, pick the perturbation factors and generate geometry perturbations
  - for each case, build SCALE input decks, which include:
    - calls to the perturbation modules, which generate the perturbed data libraries (based on the perturbation factors for this sample)
    - user sequence inputs
    - output data retrieval
  - insert each of the constructed input decks into the processing queue
- run all SCALE cases from the queue (serial or parallel, as available)
- perform data extraction (using the response mechanism) and statistical analysis
- print output and generate data files

The advantage of this workflow is that the individual SCALE runs are completely identified by the sample number (so they are reproducible) and they are independent. Each of the runs is executed within its own environment (with SCALE runtime as a subprocess), with its own decay data, fission yield and cross section library. This arrangement is very robust and, as there is no coupling between the runs, can be effectively parallelized.

6.4.4.2 File management

For every SCALE run, Sampler creates a subdirectory within its own temporary directory. Each subdirectory has a name in the form *(casename)* `_pert_` *(sample number)*. Within this directory all the useful data for the particular run are stored: the input file, the output file, the message file, the terminal log file (which is a joint capture of SCALE both standard output and standard error stream) along with the saved data files (ft71, xfile016, PTP files etc.)

By retaining the temporary directory, the user can then examine and possibly reuse saved files for the individual SCALE runs.

6.4.4.3 Parallel execution

Since the Sampler calculations usually consist of several hundred mutually completely independent calculations, it is desirable to run the subcases in parallel.

In SCALE 6.3, Sampler only supports threading for parallel calculations.

In order to run Sampler in parallel simply specify the `-I` command line arguments to ScaleRTE. .

6.4.4.4 Behavior when encountering errors

Any time a parameter within a SCALE input is perturbed, there is the possibility that the perturbation will cause unrealistic behavior (fuel pellet passing through cladding, etc.) that will cause SCALE to fail. The default behavior of Sampler is to finish all perturbed cases and check whether there are errors present for each case once all cases have been run.

6.4.5 EXAMPLE PROBLEMS AND OUTPUT DESCRIPTION

This section describes output files created by Sampler and provides several sample cases.

6.4.5.1 Output description

This section describes the contents of the main Sampler output file, as well as the other files generated by Sampler.

All of the CSV, PTP and SDF files are, for convenience, copied into a separate directory called *$ {OUTBASENAME}*.`samplerfiles`, where *$ {OUTBASENAME}* is the base name of the main SCALE output file, e.g. "my" in "my.out".

Main text output

The main text output summarizes the Sampler run progress and presents the most important results.

Sampler banner

The program verification information banner shows the program version and the main execution information (date and time, user name, computer name).

```

(continues on next page)

(continued from previous page)

```
--- Master process needs to run 41 SCALE runs.
```

The table shows case name, sample index, sample number (i.e. the number in the perturbation factor library), whether the case has to be executed (if not it means that the results were already available in the samplerfiles directory) and the full path to the run subdirectory.

Response tables

According to the print flags set by the user in the parameters block, Sampler prints the following tables:

- values of all responses for all samples (printed if `print_data=yes`)
- average values and standard deviation over the samples population (always printed)
- comparison of average and baseline value (always printed)
- chi-square normality test (printed if `print_chi2=yes`)
- covariance matrices (printed if `print_cov=yes`)
- correlation matrices (printed if `print_corr=yes`)
- case- and response- specific tables

The case-specific tables contain only responses for a given case (so it is possible to explore correlations only within a given case). The response-specific tables are, on the other hand, contain responses across all cases, so they are useful for case cross-correlation analysis.

All of the tables are, regardless of the print flags, saved in the CSV files (see the following section).

CSV tables

Every table produced by Sampler is (regardless of whether it has been selected for the main text output) saved also in the CSV (comma separated values) format, which makes it convenient to process Sampler results with a spreadsheet program, plotting package, or any scripting workflow.

These types of tables are created:

- values for every sample for time-independent responses

  (`response_table.static.val.all.csv`)
- values for every sample for time-independent responses for each case

  (`response_table.static.val.case-*.csv`)
- values for every sample for time-independent responses for each response

  (`response_table.static.val.response-*.csv`)
- values for every sample for time-dependent responses

  (`response_table.*.csv`)
- average values for time-dependent responses

  (`response_table.*.avg.csv`)
- standard deviations for time-dependent responses

  (`response_table.*.stddev.csv`)
- analysis results for the analysis named myAnalysis

  (`response_table.analysis.myAnalysis.csv`)

Sampling histograms and running averages

In order to provide information on sampling convergence, Sampler provides two plots for each response at every time step:

- histogram plot – distribution of the response values in directory *${OUTBASENAME}*.samplerfiles/histogram
- running average plot – average and standard deviation for first N samples of the population in directory *${OUTBASENAME}*.samplerfiles/running_averages

Both plots are in the PTP format and can be plotted by Fulcrum, as shown in Fig. 6.4.1 and Fig. 6.4.2.

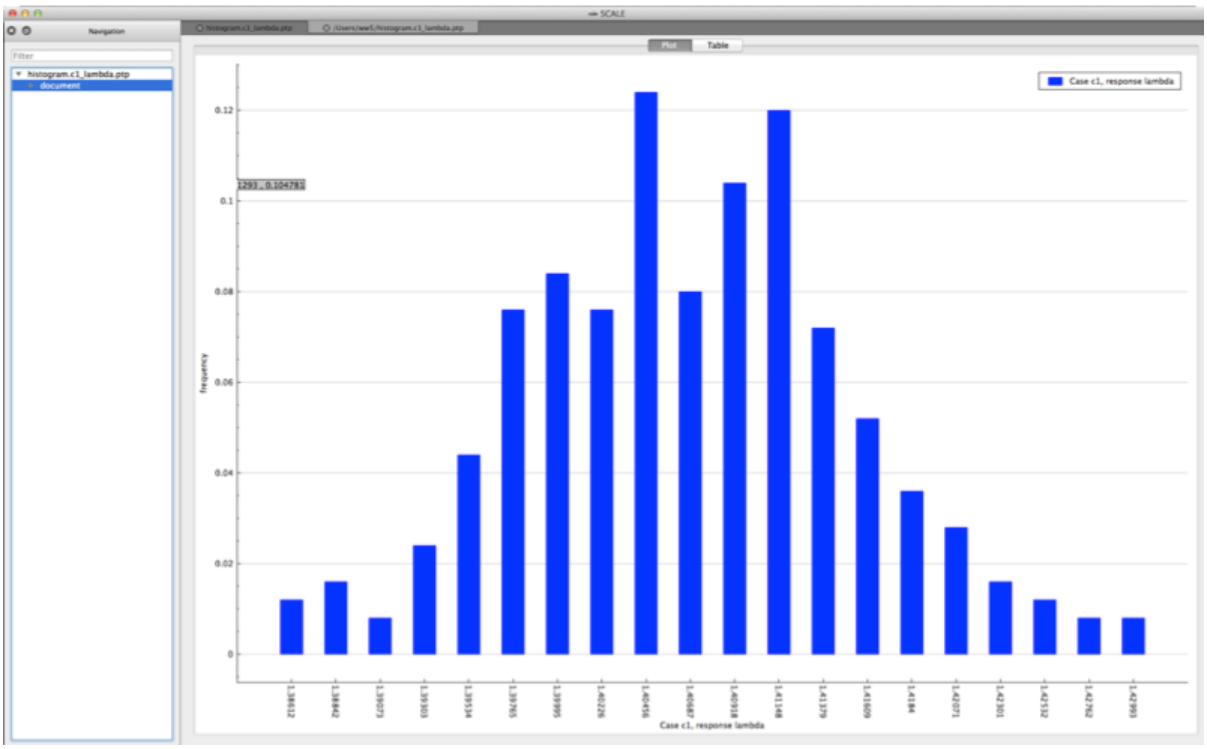

Fig. 6.4.1: Example histogram viewed in Fulcrum.

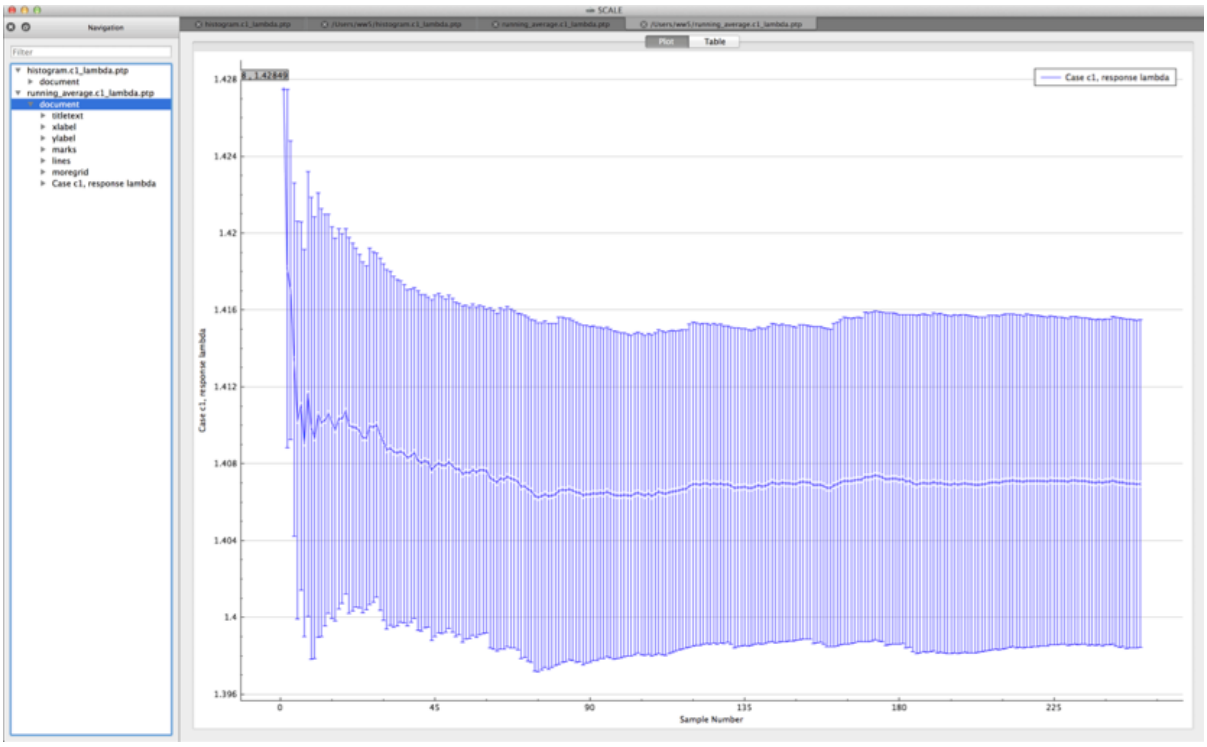

Fig. 6.4.2: Example running average viewed in Fulcrum.

Response histories

For time-dependent responses, Sampler produces two plots with time-dependent summary data.

- standard deviation plot – time-dependent average response with 1-sigma uncertainty bars in directory *$ {OUTBASENAME}*.samplerfiles/histories/history.avg.*
- min/max plot – time-dependent average response with min/max error bars in directory *$ {OUTBASE-NAME}*.samplerfiles/ histories/history.min_max.*

An example of the standard deviation plot is shown Fig. 6.4.3 and the min/max plot in Fig. 6.4.4.

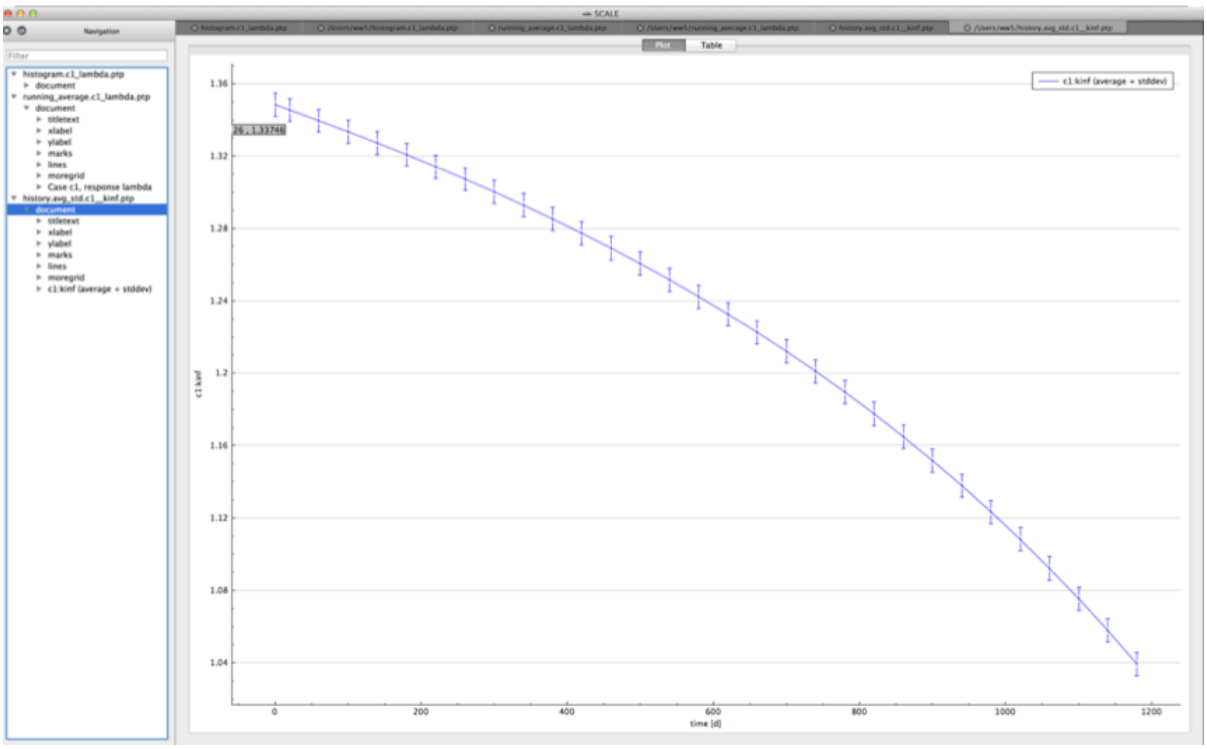

Fig. 6.4.3: Time-dependent average plus standard deviation plot.

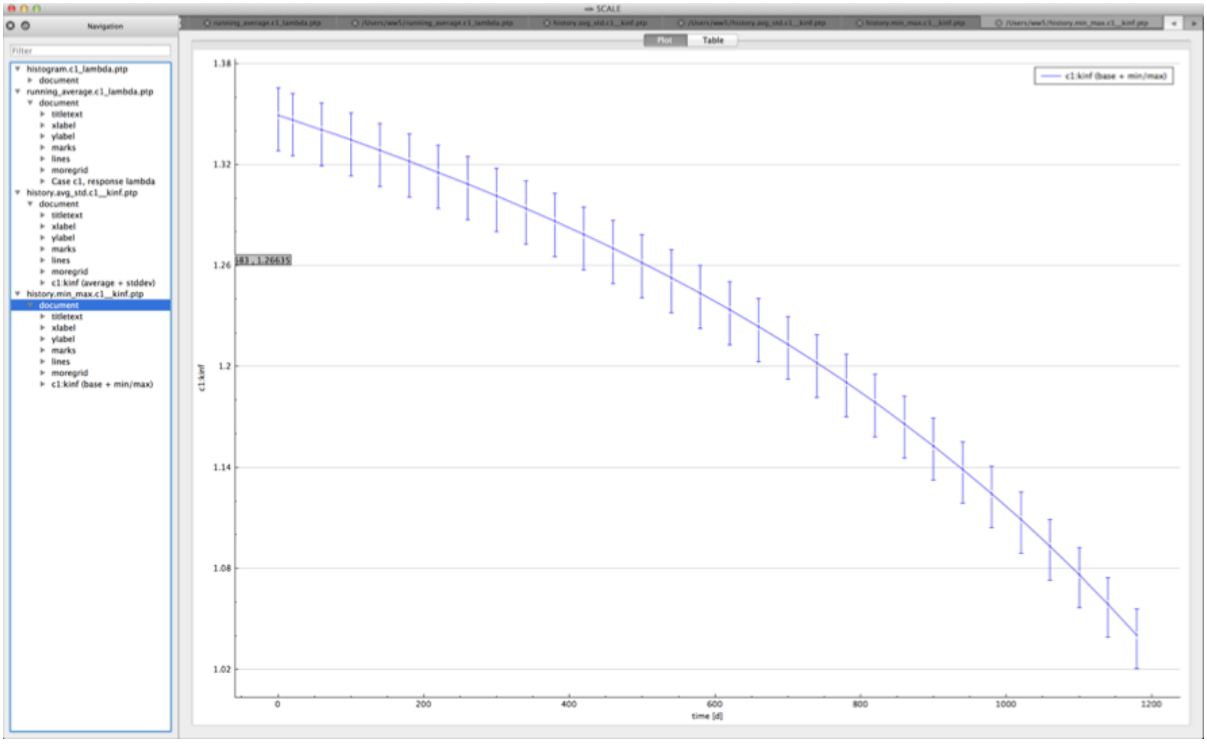

Fig. 6.4.4: Time-dependent average plus min/max plot.

6.4.5.2 Sample problems

The following sample problems demonstrate various computational and output capabilities of Sampler in various situations, for both uncertainty and parametric calculations.

Input files for those sample problems can be found in the `samples/input` directory of the SCALE installation. The naming convention for the inputs is sampler_*N*.inp, where *N* is the sample problem number. The number of samples (n_samples) shown here may vary from the number included in the sample inputs.

Sample problem 1

This simple, single-case problem, evaluates uncertainty in eigenvalue for a T-XSDRN calculation of a MOX pincell. Only the cross-sections are perturbed.

```
=sampler

read parameters
  n_samples=250
  library="xn252"
  perturb_xs = yes
end parameters

read case[c1]
  sequence=t-xsdrn           parm=2region
    pin-cell model with MOX
    xn252
    read comp
      uo2   1 0.95 900 92235 4.5 92238 95.5   end
      zirc2 2 1 600   end
      h2o   3 den=0.75 0.9991 540   end
    end comp
    read cell
      latticecell squarepitch pitch=1.3127 3 fuelr=0.42 1 cladd=0.9500 2 end
    end cell
    read model
    pin-cell model with MOX
    read parm
      sn=16
    end parm
    read materials
      mix=1 com='fuel' end
      mix=2 com='clad' end
      mix=3 com='moderator' end
    end materials
    read geom
      geom=cylinder
      rightBC=white
      zoneIDs 1 2 3 end zoneids
      zoneDimensions 0.42 0.475 0.7406117 end zoneDimensions
      zoneIntervals 3r10 end zoneIntervals
    end geom
    end model
  end sequence
end case

read response[lambda]
  type = grep
  regexp = ":xsdrn.lambda:"
end response

end
```

The distribution of lambda (k-eff) from sample problem 1 is shown in Fig. 6.4.5.

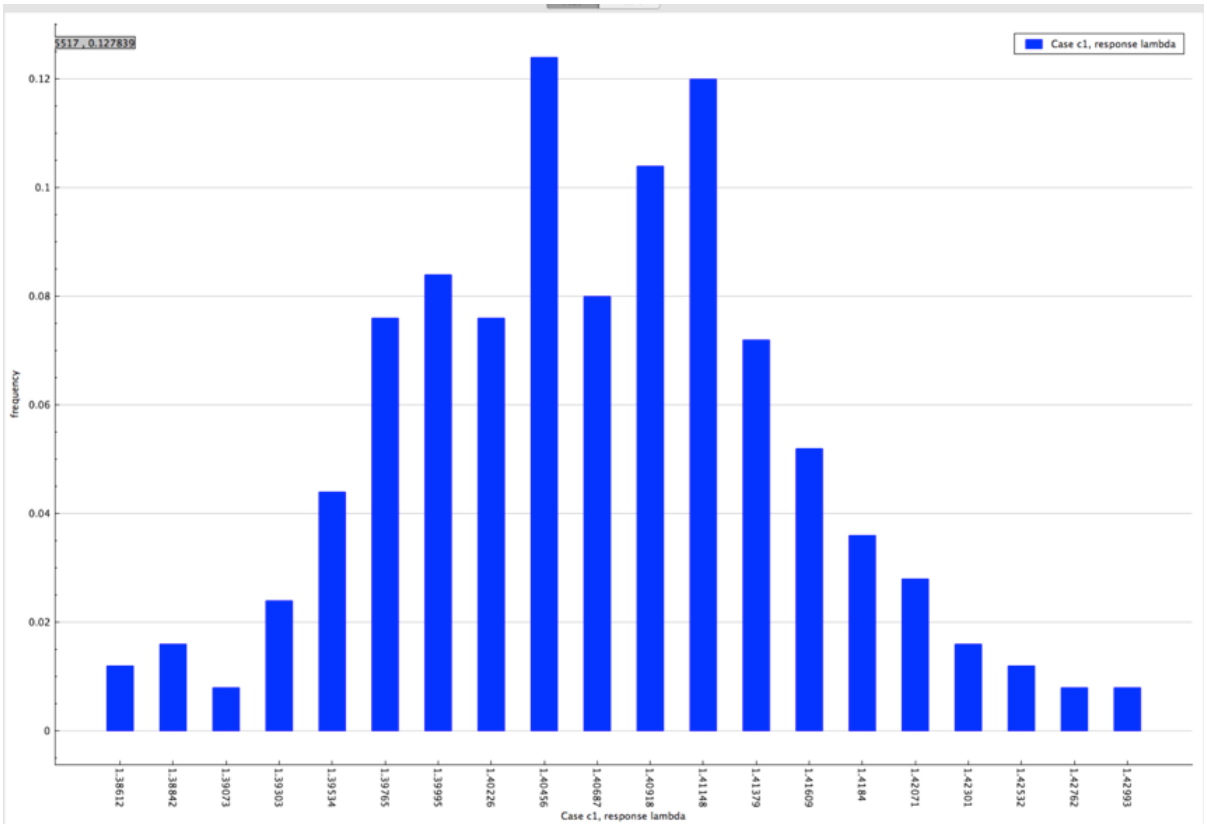

Fig. 6.4.5: Distribution of lambda (k-eff) obtained from sample problem 1.

Sample problem 2

This problem demonstrates a two-dimensional parametric study (using inline placeholders) for two pincell systems.

```
=sampler

read parametric
  variables = temp rho end
  n_samples = 3 5 end
end parametric

read case[c1]
  sequence=t-xsdrn           parm=2region
    pin-cell model with MOX
    xn252
    read comp
      uo2   1 0.95 #{temp} 92235 4.5 92238 95.5   end
      zirc2 2 1 600   end
      h2o   3 den=#{rho} 0.9991 540   end
    end comp
    read cell
      latticecell squarepitch pitch=1.8127 3 fuelr=0.45 1 cladd=0.9500 2 end
    end cell
    read model
    pin-cell model with MOX
    read parm
      sn=16
    end parm
```

(continues on next page)

(continued from previous page)

```
    read materials
      mix=1 com='fuel' end
      mix=2 com='clad' end
      mix=3 com='moderator' end
    end materials
    read geom
      geom=cylinder
      rightBC=white
      zoneIDs 1 2 3 end zoneids
      zoneDimensions 0.45 0.475 1.0006117 end zoneDimensions
      zoneIntervals 3r10 end zoneIntervals
    end geom
    end model
  end sequence
end case

read case[c2]
  sequence=t-xsdrn           parm=2region
    pin-cell model with MOX
    xn252
    read comp
      uo2   1 0.95 #{temp} 92235 4.5 92238 95.5   end
      zirc2 2 1 600   end
      h2o   3 den=#{rho} 0.9991 540   end
    end comp
    read cell
      latticecell squarepitch pitch=1.9127 3 fuelr=0.45 1 cladd=0.9500 2 end
    end cell
    read model
    pin-cell model with MOX
    read parm
      sn=16
    end parm
    read materials
      mix=1 com='fuel' end
      mix=2 com='clad' end
      mix=3 com='moderator' end
    end materials
    read geom
      geom=cylinder
      rightBC=white
      zoneIDs 1 2 3 end zoneids
      zoneDimensions 0.45 0.475 1.0406117 end zoneDimensions
      zoneIntervals 3r10 end zoneIntervals
    end geom
    end model
  end sequence
end case

read variable[rho]
  distribution=uniform
  minimum = 0.5
  value = 0.65
  maximum = 0.8
  cases = c1 c2 end
end variable

read variable[temp]
  distribution=uniform
  minimum = 700
  value = 900
  maximum = 1100
  cases = c1 c2 end
end variable
```

(continues on next page)

(continued from previous page)

```
read response[lambda]
  type = grep
  regexp = ":xsdrn.lambda:"
end response

end
```

The dependency of eigenvalue on coolant density for the two systems is printed to the output file, as shown in Fig. 6.4.6, where the first table shows the temperature and density combinations in the first two columns and the corresponding eigenvalue from case 1 and case 2 in the next two columns. Two summary tables are printed, identifying the conditions of the maximum and minimum for each response, in each case.

```

The distribution of the multiplication factor with the specified enrichment distribution is shown in Fig. 6.4.7.

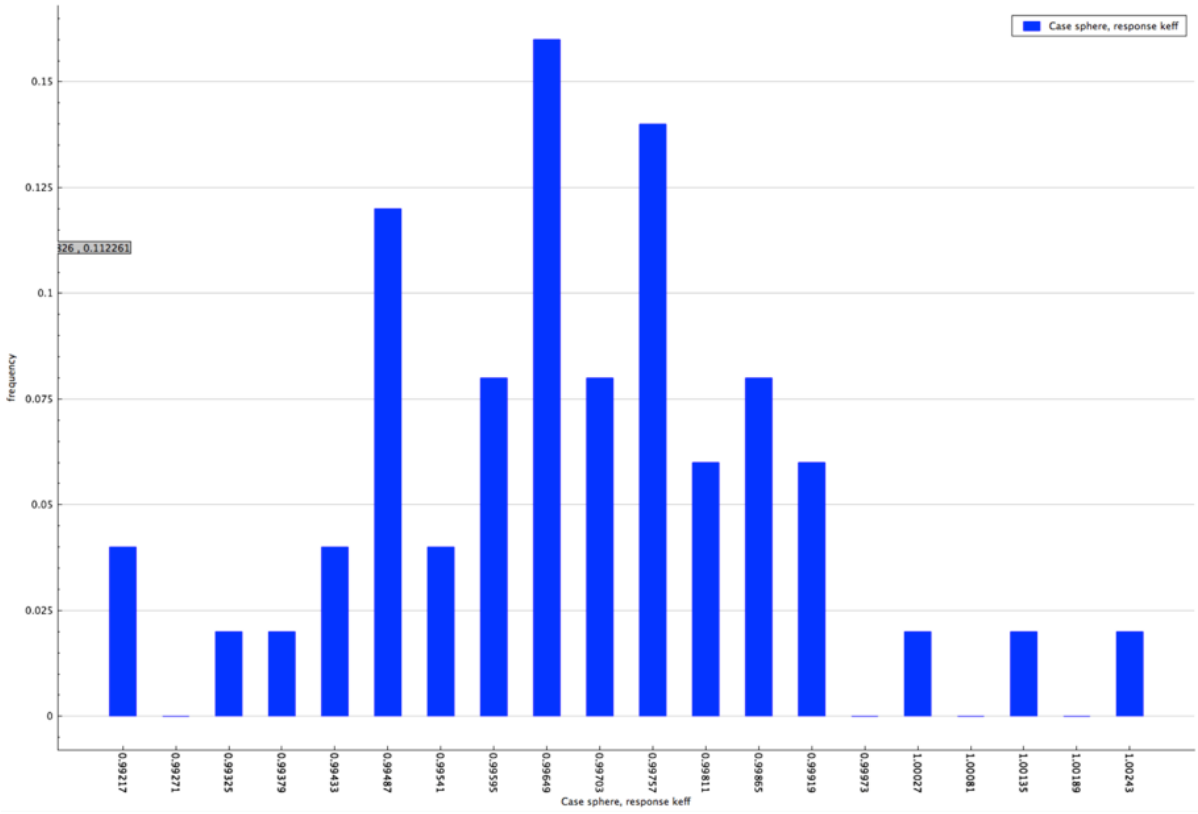

Fig. 6.4.7: Distribution of multiplication factor with sampled enrichment distribution for sample problem 3.

Sample problem 4

Sample problem 4 demonstrates sampling with covariance data for neutron cross sections and fission product yields. Note that decay sampling does not work with TRITON at this time due to not using the perturbed ORIGEN decay libraries *directly*. Additionally, it demonstrates how to extract reaction rates from a TRITON case, combining an additional OPUS run with the `opus_plt` response.

Plots of various isotopic uncertainties as a function of time are shown in Fig. 6.4.8 for ^{235}U, Fig. 6.4.9 for ^{239}Pu, Fig. 6.4.10 for ^{240}Pu, Fig. 6.4.11 for ^{241}Pu, Fig. 6.4.12 for ^{148}Nd, Fig. 6.4.13 for ^{150}Sm, and Fig. 6.4.14 for ^{151}Sm in terms of the unperturbed with error bars for the *minimum* and *maximum*, that is over the 100 samples performed, the minimum value at that time and the maximum value at that time. Note that most isotopes accumulate uncertainty over time, but this is not always the case, e.g. for ^{151}Sm. Two common burnup indicators (measured in spent fuel to infer/confirm burnup) ^{148}Nd and ^{150}Sm show linear increase with time (as expected for a burnup indicator).

The correlation matrix for concentrations at 1200 days of irradiation is shown in Fig. 6.4.15, post-processed with Excel to show high and low correlation coefficients. The bold and underline entries indicate that the each extracted isotope shows a correlation coefficient of 1.0 between the two cases. This means that the two cases are the same in terms of their isotopic response to data perturbations.

Fig. 6.4.15: Correlation matrix for concentrations in sample problem 5.

Sample problem 6

Sample problem 6 provides an example of fission yield and decay data sampling. First, COUPLE is run to assemble an ORIGEN library (on file ft33f001) from the perturbed yields and decay data libraries. Burst fission with long decay is then performed by ORIGEN and OPUS is used to extract the fission product decay heat.

6.4.6 SCALE INPUT RETRIEVAL ENGINE (SIREN)

SIREN (SCALE Input Retrieval ENgine) provides a hierarchical representation of SCALE input and enables access to individual input components or sets of related input parameters. SIREN sorts the contents of supported SCALE input sequences into a tree structure so that every component in a SCALE input can be accessed using an XPath designation. The SIREN package is used by the SCALE super-sequence Sampler to select individual components within an input file, perturb the parameter in memory, and write the perturbed input to a new file. In this way, components within an input file can be perturbed without modification to the original input file, which can be maintained as a read-only file under configuration control for quality assurance purposes.

To explore the use of SIREN expressions, two utilities are available in the SCALE bin directory. The utilities are the executables "InputViewer" and "InputSelector." The InputViewer utility accepts a SCALE input file and outputs the XPath designation for each component of that input file. The InputSelector utility accepts a SCALE input file and a SIREN select statement and then outputs the part of the input file specified by the SIREN select statement. The remainder of this section provides practical examples in the use of SIREN select statements to designate specific components of a SCALE input.

A simple CSAS6 input file, which models a sphere of HEU, is used to show how to use SIREN select statements to access specific portions of a SCALE input. The contents of the example CSAS6 input file are shown below.

```
=csas6
sample problem 6  bare 93.2% U sphere, eighth sphere w/ mirror albedo
v7-238
read comp
  uranium  1 den=18.76 1 293 92235 93.2 92238 5.6 92234 1.0 92236 0.2 end
end comp
read geometry
  global unit 1
    sphere 10  8.741  chord +x=0.0  chord  +y=0.0  chord +z=0.0
    cuboid   20  8.741 0.0 8.741 0.0 8.741 0.0
    media  1 1 10      vol=2797.5121
    media  0 1 20 -10  vol=2545.3424
    boundary 20
end geometry
read bounds
  -fc=mirror
end bounds
end data
end
```

The InputViewer utility is used to view the contents of the example input file with their respective XPath designations. The utility accepts the path to the input file as an argument so that the usage is:

```
$ InputViewer inputfile
```

A portion of the output from InputViewer is shown below; this portion corresponds to the material definition in the example input file. Notice that each component of the composition has a specific XPath designation. For instance, the "wtptPair" has several pieces of information (ids for each component and the weight percent for that component). To gain access to a specific component, the InputSelector utility is introduced below.

```
/csas6/comps
/csas6/comps/decl(read comp)
/csas6/comps/stdcomp
/csas6/comps/stdcomp/name(uranium)
/csas6/comps/stdcomp/mixture(1)
```

(continues on next page)

(continued from previous page)

```
/csas6/comps/stdcomp/roth
/csas6/comps/stdcomp/roth/decl(den)
/csas6/comps/stdcomp/roth/assign(=)
/csas6/comps/stdcomp/roth/value(18.76)
/csas6/comps/stdcomp/vf(1)
/csas6/comps/stdcomp/temp(293)
/csas6/comps/stdcomp/wtpt_pair
/csas6/comps/stdcomp/wtpt_pair/id(92235)
/csas6/comps/stdcomp/wtpt_pair/wtpt(93.2)
/csas6/comps/stdcomp/wtpt_pair
/csas6/comps/stdcomp/wtpt_pair/id(92238)
/csas6/comps/stdcomp/wtpt_pair/wtpt(5.6)
/csas6/comps/stdcomp/wtpt_pair
/csas6/comps/stdcomp/wtpt_pair/id(92234)
/csas6/comps/stdcomp/wtpt_pair/wtpt(1.0)
/csas6/comps/stdcomp/wtpt_pair
/csas6/comps/stdcomp/wtpt_pair/id(92236)
/csas6/comps/stdcomp/wtpt_pair/wtpt(0.2)
/csas6/comps/stdcomp/term(end)
/csas6/comps/term(end comp)
```

To explore how SIREN select statements are used, the InputSelector utility is used for a few cases with the example CSAS6 input file. Suppose the ^{235}U weight percent needed to be accessed for perturbation; the SIREN expression to access the ^{235}U weight percent is as follows:

Long form:

```
'/csas6/comps/stdcomp/wtpt_pair[id="92235"]/wtpt'
```

Short form:

```
'///wtpt_pair[id="92235"]/wtpt'
```

This statement tells SIREN to look for the weight percent with an ID of 92235 in the weight percent pair. A short form of the select statement (designated by the triple slash) can be used when there are unique qualities about a component; for instance, there is only a single material with an ID of 92235, so the weight percent pair must belong to that material. There are many combinations of select statements that can point to a specific input component, and the developers suggest using the InputSelector utility to familiarize oneself with this capability. The usage of InputSelector is:

```
$ InputSelector inputfile quoted_Select_Statement
```

Below is the screen output from the InputSelector with the example CSAS6 input file and the select statement for the ^{235}U weight percent.

```
---- 1 nodes selected with statement '///wtpt_pair[id='92235']/wtpt' ----
1) /csas6/comps/stdcomp/wtpt_pair/wtpt
93.2
```

The output from InputSelector shows that the select statement points to a single component in the SCALE input, which is indeed the value for the ^{235}U weight percent. There are cases where a select statement points to a portion of the input that has multiple components and the select statement may need to be refined to point to a specific component. For instance, the cuboid defined in the geometry section of the input has multiple dimensions (+x, -x, +y, -y, etc.). By using the select statement below, the dimensions of the cuboid are shown

```
'//cuboid/[id="20"]/dimensions'
```

The output from using InputSelector with this select statement is shown below.

```
---- 1 nodes selected with statement '//cuboid/[id="20"]/dimensions' ----
1) /csas6/geometry/global_unit/cuboid/dimensions

8.741 0.0 8.741 0.0 8.741 0.0
```

The output from InputSelector shows six values, which correspond to the dimensions of the cuboid (+x, x, +y, -y, +z, -z faces). To select a single dimension, the select statement should include which component is desired. For instance, to select the height of the cuboid the select statement becomes:

```
'//cuboid/[id="20"]/dimensions/plus_z'
```

In the same way, the radius of the sphere can be selected using the SIREN expression that identifies the radius of a sphere with an ID of 10:

```
'//sphere/[id="10"]/dimensions/r'
```

The output from InputSelector is shown below.

```
---- 1 nodes selected with statement '//sphere/[id="10"]/dimensions/r' ----
1) /csas6/geometry/global_unit/sphere/dimensions/r

8.741
```

There are scenarios where there is no unique or obvious identifier for a component. As an example, the media volume can utilize an array index to retrieve the volume value.

```
'//media/volume/value'
```

The output from InputSelector illustrates both media's volume value are selected below.

```
---- 2 nodes selected with statement '//media/volume/value' ----
1) /csas6/geometry/global_unit/media/volume/value
2797.5121
2) /csas6/geometry/global_unit/media/volume/value
2545.3424
```

The printed index (1) can be utilized to narrow the selection.

```
‘//media[1]/volume/value’
```

Here the first media is selected and subsequently, the media's volume value, removing the selection of the second media entirely. The output from InputSelector is shown below.

```
---- 1 nodes selected with statement '//media[1]/volume/value' ----
1) /csas6/geometry/global_unit/media/volume/value
2797.5121
```

For the sake of completeness, the following example illustrates selection of the media's volume value via the mixture's value comparator.

```
'//media[mixture="1"]/volume/value'
```

This illustrates the first media's unique mixture component can be used to select the volume for the first media. The output from InputSelector is shown below.

```
---- 1 nodes selected with statement '//media[mixture="1"]/volume/value' ----
1) /csas6/geometry/global_unit/media/volume/value

2797.5121
```

The above examples were intended to provide users with an idea of how to use SIREN select statements to access specific components within a SCALE input. The select statements are primarily used in cases where the input is to be perturbed by the Sampler super-sequence, but modification to the original input is not desirable. The recommended way to ensure that the select statements are correct is to use the InputSelector utility to check that a select statement points to the correct input component.

For viewing the input paths, an alternative to the InputViewer command line utility is available within the Fulcrum graphical user interface (GUI). By clicking on the Run Button drop-down and selecting "Input Listing" as shown in Fig. 6.4.18, the full listing of the current input file is displayed in the "Messages" box. Also, notice the path is displayed in the bottom left corner for the input component located at the cursor.

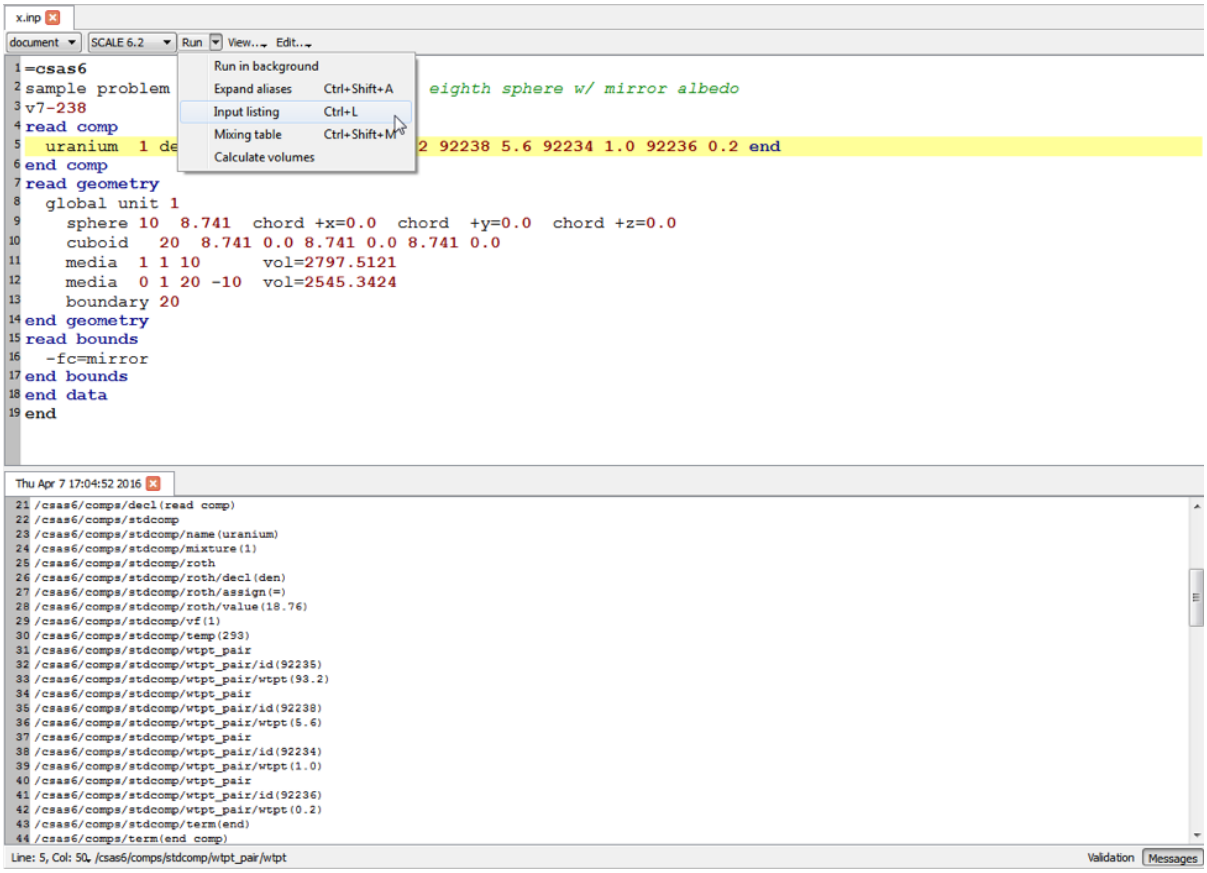

Fig. 6.4.18: Input Listing in Fulcrum.

A table of SIREN expressions is as follows.

Table 6.4.8: Expressions for SIREN.

Expressions	Description	Examples
component	Component match.	csas6
/	Component separator. When the expression begins with this, it selects the root of the document.	csas6/xslib /
//	This expression is the 'Any Child' select.	csas6//uranium //
[index]	Array index selector. When an array of objects has been selected, this expression selects the object at the given index.	csas6/ geometry/global_unit/media**[1]**
[sindex:eindex]	Subarray index selector. When an array of objects has been selected, this expression selects a subarray.	csas6/ comps/stdcomp/uranium/wtpt_pair**[2:3]**
[sindex:eindex:stride]	Subarray index selector. When an array of objects has been selected, this expression selects a subarray and subsequently components stride apart.	csas6/comps/stdcomp/uranium/wtptPair**[1:4:2]**
*	Component wild card. This can only be used in place of a component or to wild card the remainder of a component.	csas6/read comp/* csas6/read comp/ur*

6.4.7 EXPRESSION OPERATORS AND FUNCTIONS FOR SAMPLER

The expression engine utilized by Sampler supports all basic mathematical and logical operators, as well as a number of functions. Logical expressions and functions evaluate to the number 1 for true, and the number 0 for false.

Table 6.4.9: Expression operators and functions for Sampler.

Operator	Description	Example
+	Addition	3+3, x+y
+	Unary Plus	+3, +(-3), +x
-	Subtraction	3-3, x-y
-	Unary Minus	-3, -(3+3), -x
*	Multiplication	3*3, x*y
/	Division	3/3, x/y
%	Modulo	3%3, x%y
^	Power	3^3, x^y
==	Equal to	3==3, x==y
!=	Not equal to	3!=3, x!=y
<	Less than	3<3, x<y
>	Greater than	3>3, x>y
<=	Less than or equal to	3<=3, x<=y
>=	Greater than or equal to	3>=3, x>=y

continues on next page

Table 6.4.9 – continued from previous page

Operator	Description	Example
and	Left is true and right is true	1 and 1 , x==y and y==z
or	Left is true or right is true	1 or 1, x==y or y==z
nand	Not and	1 nand 1, 1 nand 0, x nand y
xor	Exclusive or	1 xor 1, 1 xor 0, x xor y
nor	Not or	1 nor 1, 1 nor 0, x nor y
abs(x)	Absolute value	abs(1),abs(-1),abs(x) ,abs(y)
min(x,. . . n)	Minimum of values	min(1),min(1,2,3,4,5, x,y),etc
max(x,. . . n)	Maximum of values	max(1),max(1,2,3,4,5, x,y),etc
avg(x,. . . n)	Average of values	avg(1),avg(1,2,3,4,5, x,y),etc
Sum(x,. . . n)	Summation of values	sum(1),sum(1,2,3,4,5, x,y),etc
mul(x,. . . n)	Multiply values	mul(1),mul(1,2,3,4,5, x,y),etc
floor(x)	Floor of the value	floor(1)=1, floor(-1.0)=-1.0, floor(-1.1)=-2.0
ceil(x)	Ceiling of the value	ceil(1)=1,ceil(-1.1)= -1
round(x)	Round the value to nearest integer	round(1.1)=1,round(1.5)=2,round(1.9)=2
roundn(x,n)	Round the value to the nth decimal position	roundn(1.15,1)= 1.2, roundn(1.519,2)= 1.52
cos(x)	Cosine of the value	cos(0.0)=1
sin(x)	Sine of the value	sin(0.0)=0
tan(x)	Tangent of the value	tan(0.0)=0
sec(x)	Secant of the value	sec(0.0)=1
csc(x)	Cosecant of the value	csc(1.0)= 1.1884
cot(x)	Cotangent of the value	cot(1.0)= 0.642093
sinh(x)	Hyperbolic sine of the value	sinh(1.0)= 1.1752
cosh(x)	Hyperbolic cosine of the value	cosh(1.0)= 1.54308
tanh(x)	Hyperbolic tangent of the value	tanh(1.0)= 0.761594
log(x)	Natural log of the value	log(2.7182818)=1
log10(x)	Common log of the value	log10(10.0)=1
exp(x)	Exponential of the value	exp(1)=2.7182818
clamp(l,x,u)	Clamp the value x between lowerbound l and upperbound u	clamp(-1,1,+1)=1,clamp(-1,-5,+1)=-1
inrange(l,x,u)	Determine if value x is greater than or equal to lowerbound l, and less than or equal to upperbound u	inrange(-1,1,+1)=1,inrange(-1,-5,+1)=0
sgn(x)	Determine the sign of x.	sgn(+1)=1,sgn(-1)=-1, sgn(0)=0,sgn(5)=1
sqrt(x)	Square Root of the value	sqrt(1)=1,sqrt(4)=2
root(x,y)	Root of x given y	root(4,2)=2,root(8,3)=2
true	Constant true value	true
false	Constant false value	False
if(condition,true,false)	If function that evaluates the condition. If true, the true value is substituted, else the false value is substituted	if(x > y, x, y) = x

6.4.8 GUIDELINES FOR RUNNING SAMPLER IN PARALLEL

Sampler calculations consist of three basic steps:

1. generate N perturbed input files and libraries,
2. run N independent SCALE jobs, and
3. analyze N results sets.

At this time, the preferred way of performing Sampler calculations is to use *run_cases=no* (in the *parameters* block) and perform step 2 above outside of Sampler, i.e. using scripting or your system's queuing system to launch the *N* SCALE jobs. The "${OUTBASENAME}.samplerfiles" directory that Sampler creates in step 1 will contain all the perturbed input files. Each of these input files should be run as a separate SCALE job. When all jobs are complete, Sampler should be run again (still with *run_cases=no*). Sampler will see that all jobs have completed, and perform the analysis in step 3. The Sampler sample problem 8 is a quick-running calculation that can be used to test and, if necessary adjust, the manual 3-step scheme described above on your system.

However, for small jobs that fit on a single node, threading can be used. To launch a Sampler calculation with 5 parallel threads, one would issue the following from the command line:

```
scalerte -r -I 5 -m sample_8.inp
```

This will perform all 3 steps of the Sampler process.

6.5 VADER: TRENDING ANALYSIS FOR CODE/DATA VALIDATION

S. Hart, J. Clarity

VADER (Validation Analysis Data Evaluation Resource) is a new module in SCALE 6.3 derived from the legacy USLSTATS program. VADER is a tool that allows the determination of bias and bias uncertainty for criticality safety computational methods. The older USLSTATS program, written in Java, existed outside of SCALE and provided tools to calculate only the confidence band with administrative margin (sometimes called USL-1) and the single-sided uniform width closed interval (USL-2). For normality testing it offered only a crude chi-squared normality test that had no user-configurable options and presented a simple pass/no-pass functionality.

VADER has been completely written in C++ using modern coding practices and standards. It has been moved to be part of the SCALE code package and is run through the normal SCALE executables. To support the VADER methods, large updates were made to the statistical capabilities of SCALE. Interfaces to known statistical distributions were added and many of the statistical calculations required for VADER were made available to all SCALE sequences. In addition to being able to process legacy USLSTATS inputs, VADER adds support for the single-sided tolerance band method (from NUREG/CR-6698) as well as two non-trending methods: the "historical" nonparametric and parametric methods, also as described in NUREG/CR-6698. VADER also includes several new tests for normality in addition to adding user control options on the original chi-squared normality test. A new t-test for the statistical significance of the trend is included.

VADER has also been integrated into the Fulcrum GUI used by SCALE. This allows VADER to benefit from the auto-complete, templating, and input validation features offered by Fulcrum. In addition, Fulcrum can plot the results given by VADER, and the plot files have been expanded to include the new methods available in VADER.

6.5.1 THEORY

The methods and theory for VADER are largely taken from NUREG/CR-6698. That document contains equations and descriptions of the methods used in VADER. It also includes working examples, some of which data was used to verify the results and create example problems for VADER.

6.5.2 INPUT

The VADER input is based on the SON input syntax common in other modernized SCALE codes such as ORIGEN and ORIGAMI. The SON input format consists of key/value pairs where the value can be either a single item, an array of items, or other SON blocks.

The VADER input generally just has one level of depth. There are no SON blocks inside of SON blocks. All input is mostly arrays at the top level of the tree. A quick look at all the top level items is given in Table 6.5.1. Each top level input will then be described in detail in the next section.

Table 6.5.1: Summary of top level options for VADER

Keyword	Required	Description
data	Yes	Data entered in triplets in the form `X, Y, std. dev`.
title	No	Title to give the case.
parameters	No	Global parameters that apply to each test or trend.
trend_values	No	User desired trend values to run the tests on.
methods	Yes	Methods that the user wishes to apply to the data.
tests	No	Statistical checks that the user wishes to apply to the data.

6.5.3 DETAILED INPUT

6.5.3.1 `data`

The `data` input array is a flat array consisting of data triplets. There is no punctuation between the triplets. The data is entered in the order $X_1\ Y_1\ \sigma_1\ X_2\ Y_2\ \sigma_2\ ...\ X_N\ Y_N\ \sigma_N$.

Where

X	The trended value, usually something like enrichment or moderator density.
Y	The y value, usually something like C/E or eigenvalue.
σ	The standard deviation of Y.

VADER will emit an error if the number of entries in this array is not divisible by three.

Example 6.5.1: Snippet of `data` input

```
data=[2.4 0.9976 0.00122 2.6 0.9978 0.00022
      ...
      1.9 1.0011 0.00213 1.99 1.013 0.00012]
```

6.5.3.2 `title`

The `title` entry allows the user to specify a title for the case. The title is cosmetic and doesn't affect any of the results. The title is echoed to the output in several places and is included on some of the graphs generated by VADER.

Example 6.5.2: `title`

```
title="My Very First VADER Case"
```

6.5.3.3 `parameters`

The `parameters` section can exist outside of any test or method. If a parameter is listed in this global section, then it will apply to any method or test that has that parameter available instead of the default value. Values in this global `parameters` section can be overridden in the specific method or test block for which the user wishes to override the global parameter. For a list of all parameters, their default values, and which tests and methods they are applied to, see Sect. 6.5.6.

Example 6.5.3: `parameters` array

```
parameters {extrapolate=yes admin_margin=0.03}
```

6.5.3.4 `trend_values`

This array allows the user to insert values at which they wish the trend Y (typically the upper subcritical limit) values to be calculated. Extrapolation outside of the data range is only available if the method supports it and extrapolation is enabled.

Example 6.5.4: `trend_values` array

```
trend_values=[-0.1 0.2 2.4 10.0]
```

6.5.3.5 `methods`

This is where the user specifies the methods to enable and, optionally, gives method-specific parameters. Each method is followed by an array of the parameters the user wishes to set. Any omitted parameters are initialized with the default value (see Table 6.5.2). If the user wishes to enable a method with all default values, then an empty array can be given.

Example 6.5.5: *methods* block with some default methods and some specific parameters

```
methods {
  USL1 {} % uses default parameters
  CR6698 {weighted=yes admin_margin=0.03 chi_p=0.97}
  Parametric {confidence=0.9}
}
```

6.5.3.6 `tests`

This block is similar to the *methods* block, but it allows the user to specify which tests they wish to enable. These tests are run on the data and generally either pass or fail and give a few statistical values as their result. Most of the tests implemented for VADER for now are normality tests.

Example 6.5.6: *tests* block

```
tests {
  chisq {} % default parameters
  t-test {confidence=0.98}
}
```

6.5.4 AVAILABLE METHODS

The sections below indicate the input name to be used to activate the available method. Details on the methods can currently be found in NUREG/CR-6698.

6.5.4.1 `USL1` - Confidence Band with Administrative Margin

6.5.4.2 `USL2` - Single-Sided Uniform Width Closed Interval Approach

6.5.4.3 `CR6698` - Single-Sided Lower Tolerance Band

6.5.4.4 `NonParametric` - Historical Non-Parametric Method

6.5.4.5 `Parametric` - Historical Parametric Method

6.5.5 AVAILABLE TESTS

The sections below indicate the input name to be used to activate the available test. Details on the tests can currently be found in NUREG/CR-6698.

6.5.5.1 `chisq` - χ^2 Normality Test

6.5.5.2 `t-test` - Trend Significance t-test

6.5.5.3 `anderson_darling` - Anderson-Darling Normality Test

6.5.6 AVAILABLE PARAMETERS

Table 6.5.2 shows all of the available parameters, their default value, and the methods and tests to which they apply. Any parameter can be put into the global `parameters` block. Only parameters that apply to a specific method or test can be put into that method or tests `parameters` block. Following the table is a more detailed description of each parameter.

Table 6.5.2: Available Parameters for VADER

Keyword	Default Value	Available In
tsunami	Off	USL1 USL2
extrapolate	Off	USL1
fit_confidence	0.95	USL1 USL2
admin_margin	0.05	USL1 USL2 CR6698 NonParametric Parametric
xrange	All X Values	USL1 USL2 CR6698 NonParametric Parametric
proportion_confidence	0.95	USL2
proportion	0.95	USL2
f_p	0.95	CR6698
normal_p	0.95	CR6698
chi_p	0.95	CR6698
weighted	No	CR6698 NonParametric Parametric
confidence	0.95	NonParametric Parametric
proportion_of_pop	0.95	NonParametric Parametric
use_npm	No	NonParametric

6.5.6.1 `tsunami`

This enables a TSUNAMI-mode calculation for VADER. It requires that all X values be between -1.0 and 1.0.

6.5.6.2 `extrapolate`

This allows extrapolation past the data values entered by the user. This is generally only applicable when the user has input values in the trend_values block.

6.5.6.3 `fit_confidence`

Confidence in the statistical result. Sometimes referred to as $1 - \gamma$. In USL1 this is used to calculated the t-statistic quantile.

6.5.6.4 `admin_margin`

Administrative margin subtracted from the result. This can be used to add an extra layer of confidence that the value reported is below criticality.

6.5.6.5 `xrange`

Allows the user to tailor X values for each method or test or change the values for all tests without having to change the *data* block. Data is entered as an array of two values. By default all of the X values are used.

Example 6.5.7: xrange

```
xrange=[-0.5 2.5]
```

6.5.6.6 proportion_confidence

In USL2 this controls the confidence on the proportion that is in the confidence band.

6.5.6.7 proportion

In USL2 this controls the proportion of the data points that will be inside the confidence band.

6.5.6.8 f_p

The percentile used for the F-distribution in the single-sided lower tolerance band method.

6.5.6.9 normal_p

The percentile used for the normal distribution in the single-sided lower tolerance band method.

6.5.6.10 chi_p

The percentile used for the χ^2 distribution in the single-sided lower tolerance band method.

6.5.6.11 weighted

Whether to use the weighted version of the mean and standard deviation equations when calculating the statistics for this method.

6.5.6.12 confidence

Statistical confidence that the proportion calculated to be above the cutoff is correct.

6.5.6.13 proportion_of_pop

Proportion of the population that will be above the cutoff value in the non-parametric method.

6.5.6.14 use_npm

Use (add) non-parametric margin to the non-parametric method.

6.6 SAMS: SENSITIVITY ANALYSIS MODULE FOR SCALE

K. B. Bekar, J. D. McDonnell, B. T. Rearden, W. A. Wieselquist

ABSTRACT

The **S**ensitivity **A**nalysis **M**odule for **S**CALE (SAMS) calculates sensitivity coefficients that predict the expected changes of the calculated value of system responses such as $k_{\text{eff}}$and reaction rate ratios due to perturbations in constituent cross-section data. Additionally, the uncertainty in each response due to cross section covariance data can be predicted. For multigroup calculations, SAMS performs sensitivity calculations using linear perturbation theory and requires the calculation of the forward and adjoint flux moments. Multigroup sensitivity coefficients computed by SAMS also include the implicit effect due to resonance self-shielding calculations. In multigroup mode, SAMS works in conjunction with XSDRNPM, NEWT, KENO V.a, or KENO-VI, which are capable of calculating the desired responses as well as associated fluxes, flux moments and/or mesh fluxes. The implicit calculations are performed with data generated by a

combination of the BONAMIST and SENLIB codes specially developed to produce resonance self-shielded cross sections and their sensitivities to input data. SAMS is also used to edit the sensitivity coefficients generated by KENO continuous energy sensitivity calculations.

SAMS automatically selects all of the sensitivity parameters that can be calculated or edited for each nuclide in each region of the system based on available cross-section data. Sensitivity parameters for a given nuclide may be generated for a number of parameters, including total, scatter, capture, and fission cross sections, as well as χ. The uncertainty information is produced for all processes available on the cross section covariance data file.

SAMS has been designed for automated operation with the TSUNAMI-1D, TSUNAMI-3D-K5 and TSUNAMI-3D-K6 SCALE control modules and produces data suitable for use with the TSUNAMI-IP, TSURFER, and TSAR modules.

The following section acknowledgements appeared in the SCALE 6.2 manual.

The author wishes to acknowledge B. L. Broadhead of the Oak Ridge National Laboratory and R. L. Childs, formerly of the Oak Ridge National Laboratory, for their assistance with this work. The support and encouragement of C. V. Parks of the Oak Ridge National Laboratory and C. M. Hopper, formerly of the Oak Ridge National Laboratory is also appreciated. The support of U.S. Department of Energy Nuclear Criticality Safety Program is greatly appreciated.

6.6.1 INTRODUCTION

SAMS is the **S**ensitivity **A**nalysis **M**odule for **S**CALE, which has been designed for automated operation with the TSUNAMI-1D, TSUNAMI-3D-K5 and TSUNAMI-3D-K6 SCALE control modules. In multigroup mode, SAMS utilizes data from forward and adjoint neutron transport analyses as well as the sensitivity of resonance self-shielded cross-section data to input data to compute sensitivity coefficients that represent the percentage effect on a system response, such as multiplication factor (k_{eff}) or reaction rate ratio, to a percentage change in the nuclear reaction probabilities or cross sections. Sensitivity coefficients computed with SAMS can be presented as an energy-integrated value, which represents a uniform change in a given cross section across all energies, or as a "profile" in which a value is calculated for each discrete energy group. When combined with the uncertainties in the cross-section data, the cross-section-covariance data, the uncertainty in k_{eff} due to uncertainties in the cross-section data can be assessed. The sensitivity data produced by SAMS are appropriate for use with the TSUNAMI-IP, TSURFER and TSAR functional modules of SCALE and may be plotted in the Fulcrum SCALE user interface.

The methodology for calculating sensitivity and uncertainty parameters in SAMS is an extension of that used in the Fantastic Oak Ridge Sensitivity System (FORSS) [SAMSLWM+81, SAMSWML+76, SAMSWOM+78]. The FORSS system was capable of calculating the sensitivity of the system k_{eff} to changes in group-wise cross-section data for any given isotope for a number of reaction types. This data could also be used in conjunction with cross-section covariance data to determine the uncertainty in the calculated k_{eff} due to uncertainties in the nuclear data library. The FORSS methodology requires the calculation of the forward and adjoint angular and scalar fluxes and flux moments. Once these flux solutions are determined, the relative change in the system response due to a change in a component cross section can be determined. These sensitivities are calculated for each material region, nuclide, reaction type, and energy group in the system model.

In multigroup transport solution mode, the generation of sensitivity coefficients with SAMS requires forward and adjoint criticality calculations to compute the system responses, required fluxes as well as the volume of each flux region. Additionally, the neutron cross-section data used in the transport solution and the sensitivity of the resonance self-shielded cross-section data to the input material number densities must be available. SAMS currently functions with neutron transport solutions from XSDRNPM, NEWT, KENO V.a and KENO-VI. The sensitivities of the resonance self-shielded cross-section data to the input material number densities is computed by routines from SENLIB and BONAMIST. SAMS reads the required data files and produces sensitivity coefficients for many reactions for all nuclides for all regions in the problem. SAMS offers several output options to provide convenient transfer of the sensitivity data for plotting and additional analysis with other modules, such as TSUNAMI-IP, TSURFER, TSAR and Fulcrum.

As is described in the SCALE TSUNAMI-3D manual section, SAMS is also used in continuous energy mode transport solution sensitivity calculations. In these calculations, sensitivities are generated by TSUNAMI-3D and SAMS is used only to provide edits of sensitivity and uncertainty results. Sensitivity coefficients generated in continuous energy mode are stored in a multigroup sensitivity data file (SDF) format that is consistent with the various SCALE tools that use SDFs. The text provided in the rest of the SAMS manual chapter is oriented toward SAMS use with multigroup transport solutions.

6.6.2 THEORY

The methodology used by SAMS to produce sensitivity coefficients is presented in this section. The explicit portion of the sensitivity coefficient represents the sensitivity of the system responses to the problem-dependent resonance self-shielded multigroup cross-section data used in the analysis. The implicit portion of the complete sensitivity coefficient is the sensitivity of the resonance self-shielded multigroup cross-section data to the data input to the resonance self-shielding calculation. Summing the implicit and explicit contributions from a particular cross-section data component produces the complete sensitivity coefficient. Uncertainty analysis involves propagating the uncertainty information from the cross-section-covariance data file to the computed value of k_{eff} via the sensitivity coefficients. Problem characterization data and system average quantities are computed, such as the energy of average lethargy causing fission. Each of these quantities is computed by SAMS and is explained in this section. When executed as part of one of the TSUNAMI sequences, the SAMS input is generated automatically by the control module for that sequence.

6.6.2.1 Explicit sensitivity coefficient generation

This methodology used to generate the explicit portion of the sensitivity coefficients is identical to that used in the FORSS [SAMSWML+76] code system for fast reactor applications, with the addition of the sensitivity of k_{eff} to the fission energy spectrum (χ). The sensitivity coefficients produced with these techniques give the sensitivity of the computed k_{eff} to a particular component of the group-wise cross-section data.

The explicit sensitivity coefficients are calculated using the well-established adjoint-based perturbation theory approach [SAMSGan67, SAMSObl76, SAMSSJ72, SAMSUsa64]. The full derivation of the general procedure is not given here; however, the specific theory for the generation of k_{eff} sensitivities is presented below. For the full derivation of the general sensitivity equations the reader is referred to [SAMSWML+76].

The Boltzmann transport equation can be written in the form

$$[A - \lambda B]\phi = 0 \tag{6.6.1}$$

where

ϕ = neutron flux,

λ = represents the eigenvalues where the largest eigenvalue is $1/k_{\text{eff}}$,

A = operator that represents all of the transport equation except for the fission term,

B = operator that represents the fission term of the transport equation.

Defining perturbed transport operators and the perturbed eigenvalues as

$$\begin{aligned} A' &= A + \delta A \\ B' &= B + \delta B, \text{ and} \\ \lambda' &= \lambda + \delta\lambda \end{aligned} \tag{6.6.2}$$

where δA and δB represent small linear perturbations in their corresponding transport operators and $\delta\lambda$ represents the resulting change in the eigenvalues. The perturbed transport equation can be written in the form

$$[A' - \lambda' B']\phi' = 0 \tag{6.6.3}$$

The equation adjoint to Eq. (6.6.1) is

$$[A^\dagger - \lambda B^\dagger]\phi^\dagger = 0, \tag{6.6.4}$$

where $\phi^\dagger$ is the adjoint flux and has a special physical significance as the "importance" of the particles within the system, and $A^\dagger$ and $B^\dagger$ are the adjoint operators corresponding to A and B.

Multiplying Eq. (6.6.3) by $\phi^\dagger$, and integrating over all phase space yields

$$\langle \phi^\dagger (A - \lambda B + \delta A - \lambda\delta B - B\delta\lambda - \delta\lambda\delta B)\phi' \rangle = 0. \tag{6.6.5}$$

Using the property of adjointness (i.e., $\langle \phi^\dagger (A - \lambda B)\phi' \rangle = \langle \phi' (A^\dagger - \lambda^\dagger B^\dagger)\, \phi^\dagger \rangle$) and Eq. (6.6.4) to reduce the number of terms yields

$$\left\langle \phi^\dagger (A - \lambda B + \delta A - \lambda\delta B - B\delta\lambda - \delta\lambda\delta B)\phi' \right\rangle = 0 \tag{6.6.6}$$

Eq. (6.6.6) is further simplified by ignoring the second-order perturbation term ($\delta\lambda\delta$B) and substituting ϕ' with ϕ, indicating that the perturbations in the transport operators do not cause significant perturbations in the flux solution. The eigenvalue perturbation becomes

$$\frac{\delta\lambda}{\lambda} = \frac{\langle \phi^\dagger (\delta A - \lambda\delta B)\phi \rangle}{\langle \phi^\dagger (\lambda B)\phi \rangle}. \tag{6.6.7}$$

Substituting the perturbation terms with partial derivatives with respect to a macroscopic cross section, Σ, of the transport operator at some point in phase space $\vec{r}$, the relative sensitivity of λ, becomes

$$\frac{\delta\lambda}{\lambda} = \frac{\left\langle \phi^\dagger(\bar{\xi}) \left(\frac{\partial A[\Sigma(\bar{\xi})]}{\partial\Sigma(\vec{r})} - \lambda \frac{\partial B[\Sigma(\bar{\xi})]}{\partial\Sigma(\vec{r})} \right) \phi(\bar{\xi}) \right\rangle}{\left\langle \phi^\dagger(\bar{\xi}) \lambda B[\Sigma(\bar{\xi})]\phi(\bar{\xi}) \right\rangle} \tag{6.6.8}$$

where ξ is the phase space vector and the brackets indicate integration over space, direction and energy variables.

Note that since $\lambda = 1/k$, then $\partial\lambda/\lambda = -\partial k/k$, where $k = k_{eff}$, the sensitivity of k due to a small perturbation in a macroscopic cross section, Σ, of the transport operator at some point in phase space $\vec{r}$ can be expressed as

$$S_{k,\Sigma(r)} \equiv \frac{\Sigma(\vec{r})}{k} \frac{\partial k}{\partial\Sigma(\vec{r})} = -\frac{\Sigma(\vec{r})}{k} \frac{\left\langle \phi^\dagger(\bar{\xi}) \left(\frac{\partial A[\Sigma(\bar{\xi})]}{\partial\Sigma(\vec{r})} - \frac{1}{k} \frac{\partial B[\Sigma(\bar{\xi})]}{\partial\Sigma(\vec{r})} \right) \phi(\bar{\xi}) \right\rangle}{\left\langle \phi^\dagger(\bar{\xi}) \frac{1}{k^2} B[\Sigma(\bar{\xi})]\phi(\bar{\xi}) \right\rangle} \tag{6.6.9}$$

The k sensitivity for individual cross sections can be obtained from Eq. (6.6.9) using the discrete ordinates form of the transport equation. In doing so, the phase space vector, $\bar{\xi}$, has been replaced by indices representing discretization in space, energy and angle. It has been demonstrated in Ref. [SAMSWML+76] that sensitivity coefficients for reaction x, isotope i, energy group g, and computational region z can be represented as

$$S_{k,\Sigma^i_{x,g,z}} = \frac{T^i_{1,x,g,z} + T^i_{2,g,z} + T^i_{3,x,g,z}}{D}. \tag{6.6.10}$$

where the denominator, D, is expressed as

$$D = \frac{1}{k} \sum_{i=1}^{I} \sum_{z=1}^{R} V_z \sum_{g=1}^{G} \left(\bar{\nu}^i_{g,z} \Sigma^i_{f,g,z} \phi_{g,z} \right) \sum_{g'=1}^{G} \left(\chi^i_{g',z} \phi^\dagger_{g',z} \right) \tag{6.6.11}$$

where

$\chi^i_{g',z}$ = average fraction of fission neutrons emitted into energy group from fission of isotope i in region z,

$\bar{\nu}^i_{g,z}$ = average number of fission neutrons emitted from fission of isotope i in region z in energy group g,

$\Sigma^i_{f,g,z}$ = macroscopic cross section for fission of isotope i in region z and energy group g,

I = number of isotopes in the system model,

R = number of computational regions in the system model,

G = number of neutron energy groups in the system model.

Energy-integrated coefficients are obtained by summing the group-wise coefficients over all energy groups. The T terms of Eq. (6.6.10) represent the transport processes for neutron loss, fission production and scattering to the group of interest in T_1, T_2 and T_3, respectively. The first term is expressed as

$$T^i_{1,x,g,z} = -\Sigma^i_{x,g,z} V_z \sum_{j=0}^{NMOM} (2\ell + 1)\, \tilde{\phi}^{\dagger j}_{g,z} \tilde{\phi}^j_{g,z} \tag{6.6.12}$$

where

$\Sigma^i_{x,g,z}$ = macroscopic cross section for some reaction x, of isotope i, energy group g, in region z,

ℓ = Legendre order that corresponds to the j^{th} real valued flux moment,

$\tilde{\phi}^{\dagger j}_{g,z}$ = j^{th} component real valued adjoint flux moment for energy group g, and region z,

$NMOM$ = the total number of real valued flux moments corresponding to the desired Legendre order of expansion.

V_z = the volume of region z

The second and third terms can be expressed as

$$T^i_{2,g,z} = \frac{1}{k} V_z \bar{\nu}^i_{g,z} \Sigma^i_{f,g,z} \phi_{g,z} \sum_{g'=1}^{G} \phi^\dagger_{g',z} \chi_{g',z} \tag{6.6.13}$$

$$T^i_{3,x,g,z} = \sum_{j=0}^{NMOM} V_z \sum_{g'=1}^{G} \tilde{\phi}^{\dagger j}_{g',z} \tilde{\phi}^j_{g,z} \Sigma^{\ell,i}_{x,g' \to g,z} \tag{6.6.14}$$

where

$\Sigma^{\ell,i}_{x,g\to g',z}$ = ℓ^{th} moment of the transfer cross section for reaction x of isotope i, from energy group to energy group g in region z.

For specific reactions, not all of the T terms defined above are needed to calculate the sensitivity coefficient. The application of Eq. (6.6.10) for each type of reaction is outlined below. The computational form of each equation is expressed with the volume integrated product of the forward and adjoint flux moments as

$$P^{\ell}_{g,g',z} = V_z \sum_j \tilde{\phi}^{\dagger j}_{g',z} \tilde{\phi}^{j}_{g,z} \tag{6.6.15}$$

For KENO calculations without mesh fluxes, the flux product is computed with Eq. (6.6.12) , where z simply represents each material region. For KENO calculations using the mesh flux generation option, the flux product for each material region is computed as

$$P^{\ell}_{g,g',z} = \sum_j \sum_m \tilde{\phi}^{\dagger j}_{g',z_m} \tilde{\phi}^{j}_{g,z_m} V_{z_m} \tag{6.6.16}$$

where m represents flux meshes that occur in region z, and the subscript z_m denotes fluxes computed in mesh m of region z. Also, V_{z_m} is the volume of mesh m in region z.

Similarly, for transport calculations using XSDRNPM and NEWT, the flux product is computed over the computational mesh using Eq. (6.6.16) where m represents the computational mesh used in the transport calculation defined for each material region, z.

Once the flux products are computed for each material region or zone, the sensitivity coefficients for each reaction type can be computed as follows.

1. Capture Reaction Sensitivity (non-fission, non-scattering)

   Only the $T^{i}_{1,x,g,z}$ term is used for this class of reactions where $\Sigma^{i}_{x,g,z}$ is the absorption cross section of interest ((n, γ), (n, α), (n, p), etc.) and can be expressed as

$$S^{i}_{x,g,z} = \frac{-\Sigma^{i}_{x,g,z} \sum\limits_{\ell=0}^{ISCT} (2\ell+1) P^{\ell}_{g,g,z}}{D} \tag{6.6.17}$$

   where $ISCT$ = the highest Legendre order of scattering used in the sensitivity calculations.

2. Fission Reaction Sensitivity

   The fission reaction requires $T^{i}_{1,x,g,z}$ and $T^{i}_{2,g,z}$, where $\Sigma^{i}_{x,g,z}$ in the definition of $T^{i}_{1,x,g,z}$ is the fission cross section and can be expressed as

$$\begin{aligned} S^{i}_{f,g,z} = \frac{1}{D} \Bigg[& \left(\tfrac{1}{k} \bar{\nu}^{i}_{g,z} \Sigma^{i}_{f,g,z} \chi^{i}_{g,z} - \Sigma^{i}_{f,g,z} \right) P^{0}_{g,g,z} + \sum\nolimits_{\substack{g'=1 \\ g\neq g'}}^{G} \tfrac{1}{k} \bar{\nu}^{i}_{g,z} \Sigma^{i}_{f,g,z} \chi^{i}_{g',z} P^{0}_{g,g',z} \\ & - \sum\nolimits^{i}_{f,g,z} \sum\nolimits_{=1}^{ISCT} (2+1) P_{g,g,z} \Bigg] \end{aligned} \tag{6.6.18}$$

3. $\bar{\nu}$ Sensitivity

   The $\bar{\nu}$ reaction only requires $T^{i}_{2,g,z}$ and can be expressed as

$$S^{i}_{\bar{\nu},g,z} = \frac{\frac{1}{k} \sum\limits_{g'=1}^{G} \bar{\nu}^{i}_{g,z} \Sigma^{i}_{f,g,z} \chi^{i}_{g',z} P^{0}_{g,g',z}}{D}. \tag{6.6.19}$$

4. χ Sensitivity

The computation of the unconstrained χ reaction sensitivity only requires $T^i_{2,g,z}$, with the χ and $\nu\Sigma_f$ terms interchanged, and is expressed as

$$S^i_{\chi,g,z} = \frac{\frac{1}{k}\sum_{g'=1}^{G} \bar{\nu}^i_{g',z}\Sigma^i_{f,g',z}\chi^i_{g,z}P^0_{g',g,z}}{D} \tag{6.6.20}$$

In Eq. (6.6.20), the sensitivities coefficients sum to 1.0 when added over all energy groups and nuclides. However, since the fission spectrum probability distribution for any nuclide must, by definition, sum to 1.0 over all energy groups, the sensitivity of k_{eff} to the fission spectrum should sum to 0.0, as any change in fission spectrum in any group must be compensated by changes in other groups to maintain the constraint that all values sum to 1.0. This methodology was first developed for the SAGEP code [SAMSHTK84] and is implemented in SAMS as

$$\tilde{S}^i_{\chi,g,z} = S^i_{\chi,g,z} - \chi^i_{g,z}\sum_{g'=1}^{G} S^i_{\chi,g',z} \tag{6.6.21}$$

The constrained χ calculation from Eq. (6.6.21) is the default for SAMS.

5. Scattering Reaction Sensitivity

All scattering reactions (elastic, inelastic, and (n, 2n) reactions) require $T^i_{1,x,g,z}$ and $T^i_{3,x,g,z}$ where $\Sigma^i_{x,g,z}$ in the definition of $T^i_{1,x,g,z}$ is the scattering cross section and $\Sigma^{\ell,i}_{x,g'\to g,k}$ in the definition of $T^i_{3,x,g,z}$ is a component of the group-to-group scattering matrix for the ℓ^{th} scattering moment of reaction x.

$$\begin{aligned} S^i_{x,g,z} = \frac{1}{D}\Bigg(&\sum_{\ell=0}^{ISCT}\left(\Sigma^{\ell,i}_{x,g\to g,z} - (2\ell+1)\Sigma^i_{x,g,z}\right)P^\ell_{g,g,z} \\ &+ \sum_{\substack{g'=1\\ g'\neq g}}^{G}\Sigma^{\ell,i}_{x,g\to g',z}P^\ell_{g,g',z}\Bigg) \end{aligned} \tag{6.6.22}$$

6. Total Reaction Sensitivity

The total reaction requires $T^i_{1,x,g,z}$, $T^i_{2,g,z}$, and $T^i_{3,x,g,z}$. Here, $\Sigma^i_{x,g,z}$ in the definition of $T^i_{1,x,g,z}$ is the total cross section and $\Sigma^{\ell,i}_{x,g'\to g,k}$ in the definition of $T^i_{3,x,g,z}$ is a component of the group-to-group scattering matrix for the ℓ^{th} scattering moment. For non-fissionable isotopes, $T^i_{2,g,z}$ will be zero. The total reaction sensitivity coefficient can be expressed as

$$\begin{aligned} S^i_{t,g,z} = \frac{1}{D}\Bigg[&\left(\sum_{s,g\to g,z}^{0,i} + \frac{1}{k}\bar{\nu}^i_{g,z}\Sigma^i_{f,g,z}\chi^i_{g,z} - \Sigma^i_{t,g,z}\right)P^0_{g,g,z} \\ &+ \sum_{\substack{g'=1\\ g\neq g'}}^{G}\left(\sum_{s,g\to g',z}^{0,i} + \frac{1}{k}\bar{\nu}^i_{g,z}\Sigma^i_{f,g,z}\chi^i_{g',z}\right)P^0_{g,g',z} \\ &+ \sum_{=1}^{ISCT}\left(\sum_{s,g\to g,z}^{,i} -(2+1)\sum_{t,g,z}^{i}\right)P^l_{g,g,z} + \sum_{\substack{g'=1\\ g'\neq g}}^{G}\sum_{s,g\to g',z}P^l_{g,g',z} \end{aligned} \tag{6.6.23}$$

6.6.2.2 Implicit sensitivity coefficient generation

The methodology to calculate the sensitivity coefficients, as presented in the previous section, was developed for fast reactor applications in which the effect of resonance self-shielding in the multigroup cross-section data is minimal. To provide an accurate estimation of the sensitivity coefficients for systems in which resonance self-shielding is important, the sensitivity coefficients as computed in Eq. (6.6.10) require additional terms to account for the first-order implicit effect of perturbations in the material number densities or nuclear data upon the shielded group-wise macroscopic cross-section data [SAMSWBP01].

The sensitivity of the cross-section data to the input data in turn affects the k_{eff} sensitivities. The implicit portion of the sensitivity coefficient, the sensitivity of the group-wise data to the input quantities, is defined as

$$S_{\Sigma_{x,g},\omega_i} = \frac{\omega_i}{\Sigma_{x,g}} \frac{\partial \Sigma_{x,g}}{\partial \omega_i} \tag{6.6.24}$$

where ω_i is some input quantity. The ω_i term could represent the number density of a particular material, a certain nuclear data component or a physical dimension of a system. For the sensitivity coefficients produced by SAMS, which are the sensitivities of k_{eff} to the group-wise cross-section data, the effect on k_{eff} of perturbing one cross section that affects the resonance-shielded values of other cross sections must be computed. If ω_i is a certain cross-section data component for process y of nuclide j in energy group h expressed as $\Sigma^j_{y,h}$, which is sensitive to perturbations in process x in energy group g for nuclide i expressed as $\Sigma^i_{x,g}$, the complete sensitivity of k_{eff} due to perturbations of $\Sigma^i_{x,g}$ can be defined using the chain rule for derivatives as

$$\begin{aligned} \left(S_{k,\Sigma^i_{x,8}}\right)_{\text{complete}} &= \frac{\Sigma^i_{x,g}}{k}\frac{dk}{d\Sigma^i_{x,g}} = \frac{\Sigma^i_{x,g}}{k}\frac{\partial k}{\partial \Sigma^i_{x,g}} + \sum_j \sum_h \frac{\Sigma^j_{y,h}}{k}\frac{\partial k}{\partial \Sigma^j_{y,h}} \times \frac{\Sigma^i_{x,g}}{\Sigma^j_{y,h}}\frac{\partial \Sigma^j_{y,h}}{\partial \Sigma^i_{x,g}} \\ &= S_{k,\Sigma^i_{x,g}} + \sum_j \sum_h S_{k,\Sigma^j_{yh}} S_{\Sigma^j_{yh},\Sigma^i_{x,g}} \end{aligned}, \tag{6.6.25}$$

where the sensitivity coefficients with respect to k_{eff} are the explicit components as computed in Eq. (6.6.10), with the region subscript, z, omitted, and j and h are varied to include all processes that are influenced by the value of $\Sigma^i_{x,g}$.

Subsequent to the computation of the explicit portion of the sensitivity coefficients, data from SENLIB and BONAMIST are used to compute the implicit portion of the sensitivity coefficients. This implementation of the implicit sensitivity coefficients is more general than that presented in the example calculation of [SAMSWBP01], as it allows for the assessment of the implicit components for all reactions due to interaction with all nuclides. Because the sensitivity of a response to a material number density is equivalent to the sensitivity of the same response to the corresponding total macroscopic cross section, the computation of the implicit sensitivity coefficients can be based on the sensitivity to the input material number densities. The implicit effect of the number densities on k_{eff} must be accounted for from several sources. One source is the effect of the number densities input to BONAMIST on the shielded cross sections in the unresolved resonance region. For this case, the implicit sensitivity of k_{eff} to the total cross section of nuclide i is

$$\begin{aligned} &\left(S_{k,\Sigma^i_{T,g}}\right)_{\text{implicit}} = \sum_j \sum_y \sum_h \frac{\Sigma^j_{y,h}}{k}\frac{\partial}{\partial \Sigma^j_{y,h}} \times \frac{\Sigma^i_T}{\Sigma^j_{y,h}}\frac{\partial \Sigma^j_{y,h}}{\partial \Sigma^i_T} \times \frac{\Sigma^i_{T,g}}{\Sigma^i_T}\frac{\partial \Sigma^i_T}{\partial \Sigma^i_{T,g}} \\ &= \sum_j \sum_y \sum_h S_{k,\Sigma^j_{yh}} S_{\Sigma^j_{y,h},\Sigma^i_T} S_{\Sigma^i_T,\Sigma^i_{T,g}} = \sum_j \sum_y \sum_h S_{k,\Sigma^j_{yh}} S_{\Sigma^j_{yh},N^i} S_{\Sigma^i_T,\Sigma^i_{T,g}} \end{aligned} \tag{6.6.26}$$

where j and y are varied to include all processes that are sensitive to N^i, the number density of the i^{th} nuclide. Additionally, the energy group for the implicit sensitivity, g, is varied over all energies. The sensitivity of the total macroscopic cross section to the group-wise macroscopic total cross section, $S_{\Sigma^i_T,\Sigma^i_{T,g}}$, is simply 1.0.

For data computed by SENLIB and input to BONAMIST, an additional term is necessary to account for the sensitivity of the SENLIB parameter, denoted ω_m. The chain rule for derivatives can again be used to propagate this sensitivity to a k_{eff} sensitivity. The implicit sensitivity of k_{eff} to the input number densities, in this case, is

$$\begin{aligned}\left(S_{k,\Sigma^i_{T,8}}\right)_{\text{implicit}} &= \sum_m \sum_j \sum_y \sum_h \frac{\Sigma^j_{y,h}}{k}\frac{\partial k}{\partial \Sigma^j_{y,h}} \times \frac{\omega_m}{\Sigma^j_{y,h}}\frac{\partial \mathcal{S}^j_{y,h}}{\partial \omega_m} \times \frac{\Sigma^i_T}{\omega_m}\frac{\partial \omega_m}{\partial \Sigma^i_T} \times \frac{\Sigma^i_{T,g}}{\Sigma^i_T}\frac{\partial \Sigma^i_T}{\partial \Sigma^i_{T,g}} \\ &= \sum_m \sum_j \sum_y \sum_h S_{k,\Sigma^j_{yh}} S_{\Sigma^j_{yh},\omega_m} S_{\omega_m,\Sigma^i_T} S_{\Sigma^i_T,\Sigma^i_{T,g}} \\ &= \sum_m \sum_j \sum_y \sum_h S_{k,\Sigma^j_{y,h}} S_{\Sigma^j_{y,h},\omega_m} S_{\omega_m,N^i} S_{\Sigma^i_T,\Sigma^i_{T,8}}\end{aligned} \tag{6.6.27}$$

where m is varied to include all SENLIB computed parameters that use the material number densities in their calculation and are input to BONAMIST.

The calculation of the implicit sensitivity of a total cross-section component in the unresolved resonance region requires the sum of the implicit quantities computed in Eq. (6.6.26) and Eq. (6.6.27) with ω_m varied to include the Dancoff factor for each zone used in the BONAMIST calculation.

To compute the implicit portion of sensitivity coefficients for reactions, x, other than total, an additional term must be employed. With the implicit sensitivity of k_{eff} to the total cross section computed, the chain rule for derivatives is again applied to propagate the sensitivity of k_{eff} to the total cross section to the sensitivity of k_{eff} to some other process. This is accomplished using the sensitivity of the total cross section to the particular processes, computed from the unshielded cross-section data as

$$\left(S_{k,\Sigma^i_{x,g}}\right)_{implicit} = \left(\frac{\Sigma^i_{T,g}}{k}\frac{\partial k}{\partial \Sigma^i_{T,g}}\right)_{implicit} \times \left(\frac{\Sigma^i_{x,g}}{\Sigma^i_{T,g}}\frac{\partial \Sigma^i_{T,g}}{\partial \Sigma^i_{x,g}}\right) \tag{6.6.28}$$

The second term on the right hand side of Eq. (6.6.28) is computed analytically using data from the short master cross-section data library.

Complete sensitivity coefficient

With the implicit sensitivities properly computed, the complete sensitivity coefficient by group can be computed as the sum of the explicit and implicit terms as

$$\left(S_{k,\Sigma^i_{x,g}}\right)_{complete} = \left(S_{k,\Sigma^i_{x,g}}\right)_{explicit} + \left(S_{k,\Sigma^i_{x,g}}\right)_{implicit} \tag{6.6.29}$$

When a Monte Carlo transport solution is used to produce sensitivity coefficients, uncertainties in the forward and adjoint flux solutions and the value of k_{eff} are propagated to the final sensitivity results using standard error propagation techniques [SAMSBev69]. The forward and adjoint fluxes are treated as uncorrelated to each other. Also, the group-wise values of each flux solution are treated as uncorrelated. The flux moments within each group are treated as fully correlated. Although this method provides an adequate assessment of the statistical uncertainty in the sensitivity coefficients, a more robust technique may be implemented in subsequent revisions.

6.6.2.3 Summary of sensitivity coefficients calculated by SAMS

Sensitivity coefficients are calculated for the sensitivity of k_{eff} to the reactions listed in Table 6.6.1, if appropriate cross-section data is available. The identifier used in the SAMS output for each of these sensitivity types is also given. The MT of 0 assigned to scattering is arbitrary, as a sum of scattering reaction does not exist in the AMPX format.

Table 6.6.1: Sensitivity types computed by SAMS.

MT	Reaction	SAMS identifier
0	Sum of scattering	scatter
1	Total	total
2	Elastic scattering	elastic
4	Inelastic scattering	n,n'
16	n,2n	n,2n
18	Fission	fission
101	Neutron disappearance	capture
102	n,γ	n,gamma
103	n,p	n,p
104	n,d	n,d
105	n,t	n,t
106	n,^{3}He	n,he-3
107	n,α	n,alpha
452	$\bar{\nu}$	nubar
1018	χ	chi

6.6.2.4 Uncertainty analysis

Given uncertainty information for the cross sections for all nuclides and reaction processes that are important to the system of interest, it is possible to estimate the uncertainty in the calculated system multiplication factor due to these data uncertainties.

The nuclear data parameters are represented by the vector α, the elements of which are $(\alpha^i_{x,g})$, where i is varied over all isotopes, x is varied over all reactions for each isotope and g is varied over all energy groups. If M is the number of nuclide-reaction pairs $\times$ the number of energy groups (i.e., the number of elements in α), the symmetric $M \times M$ matrix containing the relative variances (diagonal elements) and relative covariances (off-diagonal elements) in the nuclear data is $C_{\alpha\alpha}$. The elements of $C_{\alpha\alpha}$ are

$$\left(C_{\alpha^i_{x,g}\alpha^j_{y,g'}}\right) = \frac{COV(\alpha^i_{x,g}, \alpha^j_{y,g'})}{\alpha^i_{x,g}\alpha^j_{y,g'}}, \tag{6.6.30}$$

where i and j are varied over all isotopes, x and y are varied over all reactions for each isotope and g and g' are varied over all energy groups. Additionally,

$$COV\left(\alpha^i_{x,g}, \alpha^j_{y,g'}\right) = \left\langle \delta\alpha^i_{x,g}\delta\alpha^j_{y,g'} \right\rangle, \tag{6.6.31}$$

where $\delta\alpha^i_{x,g}$ and $\delta\alpha^j_{y,g'}$ represent the difference between the values and expectation values of the nuclear data parameters and $\langle\rangle$ represents integration over the ranges of $\alpha^i_{x,g}$ and $\alpha^j_{y,g'}$ weighted with a probability density function. A rigorous definition of the cross-section-covariance data is given in [SAMSDun00]. SAMS simply reads the covariance data from a standard COVERX data file.

The vector of length M containing sensitivities of the calculated k_{eff} to the α parameters is represented by $\mathbf{S_k}$, where each element is

$$\left(S_{k,\alpha^i_{x,g}}\right) = \frac{\alpha^i_{x,g}}{k}\frac{\partial k}{\partial \alpha^i_{x,g}}, \tag{6.6.32}$$

For the purposes of SAMS uncertainty calculations, the $\alpha^i_{x,g}$ parameters are simply the group-wise cross section data. If a particular material is present in more than one material region, the sensitivity coefficients for all regions are summed prior to creating the $\mathbf{S_k}$ vector.

The variance for the system k_{eff} value is given as

$$\sigma_k^2 = \mathbf{S_k} \mathbf{C}_{\alpha\alpha} \mathbf{S}_\mathbf{k}^T, \tag{6.6.33}$$

where T indicates a transpose.

The covariance in k_{eff} due to the energy correlations of two particular processes can be assessed by examining a subset of the elements of $\mathrm{C}_{\alpha\alpha}$, where *i, j, x* and *y* are held constant. If G is the number of energy groups, the covariance data for a particular process is represented as the $G \times G$ matrix $\mathbf{C}_{\alpha^i_x \alpha^\mathbf{j}_\mathbf{y}}$ and the group-wise sensitivity vectors, of length G, for the processes are represented as $\mathbf{S}_{\mathbf{k},\alpha^\mathbf{i}_\mathbf{x}}$ and $\mathbf{S}_{\mathbf{k},\alpha^\mathbf{j}_\mathbf{y}}$. The relative covariance in k_{eff} due to the particular process or processes is given as

$$\sigma^2_{k^{i,j}_{x,y}} = \mathbf{S}_{\mathbf{k},\alpha^\mathbf{i}_\mathbf{x}} \mathbf{C}_{\alpha^i_x \alpha^\mathbf{j}_\mathbf{y}} \mathbf{S}^T_{\mathbf{k},\alpha^\mathbf{j}_\mathbf{y}} \ . \tag{6.6.34}$$

In actuality, the COVERX data file represents the covariance data in the form of multiple $\mathbf{C}_{\alpha^i_x \alpha^\mathbf{j}_\mathbf{y}}$ matrices. Thus, although commonly used for its mathematical convenience, $\mathbf{C}_{\alpha\alpha}$ does not exist as a continuous matrix. In the COVERX format, if $\mathbf{C}_{\alpha^i_x \alpha^\mathbf{j}_\mathbf{y}}$ is present on the data file with $i \neq j$ and/or $x \neq y$, then the transpose matrix $\mathbf{C}_{\alpha^\mathbf{j}_\mathbf{y} \alpha^i_x}$ is not present. Thus, using each matrix on the COVERX file only once, an upper (or lower) triangular $\mathbf{C}_{\alpha\alpha}$ matrix could be constructed, but not a full matrix.

In SAMS, the value of σ_k^2 is calculated by first determining the values of the variances or covariance as in Eq. (6.6.35) for all processes in the system under consideration, excluding the total reaction. The total reaction is excluded because it is the sum of the other processes and its inclusion would increase the variance from its actual value. The value of is then computed as the sum of the variances (diagonal elements of $\mathbf{C}_{\alpha\alpha}$ plus twice the sum of the covariances (off-diagonal elements of $\mathbf{C}_{\alpha\alpha}$. The standard deviation of k_{eff} is simply the square root of σ_k^2.

6.6.2.5 Problem characterization

SAMS computes a number of characteristic parameters of fissile systems for the convenience of the user for multigroup sensitivity calculations. These characterization parameters are not calculated in continuous-energy mode. These include the median fission group, average fission group, average energy causing fission, and energy of average lethargy causing fission. Corresponding parameters are also computed for capture and scattering.

The median fission group is computed as the first group M that satisfies the inequality

$$\frac{\sum_{z=1}^{Z} \sum_{g=1}^{M} \phi_{g,z} \Sigma_{f,g,z}}{\sum_{z=1}^{Z} \sum_{g=1}^{G} \phi_{g,z} \Sigma_{f,g,z}} \geq \frac{1}{2} \ , \tag{6.6.35}$$

where

z = index for material regions or zones,

Z = total number of regions or zones in the system model,

G = total number of energy groups.

The average fission group (AFG) is computed as

$$AFG = \frac{\sum_{z=1}^{Z}\sum_{g=1}^{G} g\phi_{g,z}\Sigma_{f,g,z}}{\sum_{z=1}^{Z}\sum_{g=1}^{G} \phi_{g,z}\Sigma_{f,g,z}} . \tag{6.6.36}$$

The average energy causing fission (AECF) is computed as

$$AECF = \frac{\sum_{z=1}^{Z}\sum_{g=1}^{G} \bar{E}_g\phi_{g,z}\Sigma_{f,g,z}}{\sum_{z=1}^{Z}\sum_{g=1}^{G} \phi_{g,z}\Sigma_{f,g,z}} , \tag{6.6.37}$$

where

$\bar{E}_g$ = the average energy of group g, computed as $(E_g + E_{g+1})/2$.

Lethargy is defined as $u = \ln(E_0/E^*)$, where E_0 is the maximum energy considered, which is assumed for the lethargy calculation to be 10 MeV. The average lethargy causing fission is computed as

$$\bar{u} = \frac{\sum_{z=1}^{Z}\sum_{g=1}^{G} \bar{u}_g\phi_{g,z}\Sigma_{f,g,z}}{\sum_{z=1}^{Z}\sum_{g=1}^{G} \phi_{g,z}\Sigma_{f,g,z}} , \tag{6.6.38}$$

where

$\bar{u}_g$ = the average lethargy of group g, computed as $(u_g+u_{g+1})/2$.

The energy of the average lethargy causing fission (EALF) is

$$E_{\bar{u}} = \frac{E_0}{e^{\bar{u}}} = \frac{E_0}{exp\left(\frac{\sum_{z=1}^{Z}\sum_{g=1}^{G} \bar{u}_g\phi_{g,z}\Sigma_{f,g,z}}{\sum_{z=1}^{Z}\sum_{g=1}^{G} \phi_{g,z}\Sigma_{f,g,z}}\right)} . \tag{6.6.39}$$

The above definitions are applicable to determining corresponding parameters for capture and scattering reactions where the capture and 1-D scattering cross-section data are substituted for the fission cross section data.

Generalized perturbation theory

General Responses for Critical Systems

The previous sections have presented perturbation theory expressions for the explicit and implicit sensitivity coefficients relating changes in cross section data to changes in the fundamental eigenvalue of the neutron transport equation in Eq. (6.6.1). Generalized perturbation theory (GPT) can be used to extend the deterministic S/U methods in TSUNAMI-1D to address more general responses that depend on the solution of the neutron transport equation. There is currently no TSUNAMI-3D GPT capability based on MG KENO Monte Carlo calculations, but a CE capability exists, as described in the TSUNAMI-3D section of the SCALE manual. Here the basic expressions used in GPT computations are described. More details and background material on GPT can be found in [SAMSWil86].

The neutron transport equation is homogeneous because the fundamental eigenvalue effectively forces the multiplying medium to satisfy a pseudo-critical condition by scaling the fission production term to exactly balance the neutron losses. Since the solution of a homogeneous equation can only be found within an arbitrary normalization factor, the responses of interest in a critical system are generally ratios of linear functionals of the neutron flux, such as

$$R = \frac{\langle H_N \phi \rangle}{\langle H_D \phi \rangle}, \tag{6.6.40}$$

where H_N and H_D are response functions defining the response of interest. The value for a ratio response is independent of the flux normalization since it cancels from the numerator and denominator; thus the response is uniquely defined. The following are some examples of ratio responses:

(a) reaction rate ratios such as the conversion factor:

$$\begin{aligned} R &= \frac{\left\langle \Sigma_c^{(fertile)} \phi \right\rangle}{\left\langle \Sigma_a^{(fissile)} \phi \right\rangle}, \\ \Rightarrow H_N &= \Sigma_c^{(fertile)} \\ \Rightarrow H_D &= \Sigma_a^{(fissile)} \end{aligned} \tag{6.6.41}$$

(b) relative power density in fuel region V_z (e.g., fuel pin):

$$\begin{aligned} R &= \frac{\left\langle \frac{h(V_z)}{V_z} \Sigma_f \phi \right\rangle}{\left\langle \frac{1}{V_{tot}} \Sigma_f \phi \right\rangle}, \\ \Rightarrow H_N &= \frac{h(V_z)}{V_z} \Sigma_f \\ \Rightarrow H_D &= \frac{1}{V_{tot}} \Sigma_f, \\ h(V_z) &= 1, r \in V_z \\ h(V_z) &= 0, r \notin V_z \end{aligned} \tag{6.6.42}$$

(c) fast-to-thermal flux ratio:

$$\begin{aligned} R &= \frac{\langle [1 - h(E < E_{th})] \phi \rangle}{\langle (h(E < E_{th})) \phi \rangle}, \\ \Rightarrow H_N &= [1 - h(E > E_{th})] \\ \Rightarrow H_D &= h(E < E_{th}) \\ \Rightarrow E_{th} &\equiv \text{ thermal energy boundary.} \\ h(E < E_{th}) &= 1, \quad E < E_{th} \\ h(E < E_{th}) &= 0, E > E_{th} \end{aligned} \tag{6.6.43}$$

(d) collapsed/homogenized thermal absorption cross section:

$$\begin{aligned} R &= \frac{\langle h(E < E_{th}) \Sigma_a \phi \rangle}{\langle h(E < E_{th}) \phi \rangle}, \\ \Rightarrow H_N &= \Sigma_a(E) h(E < E_{th}) \\ \Rightarrow H_N &= h(E < E_{th}) \end{aligned} \tag{6.6.44}$$

Generalized Perturbation Theory for Response Ratios.

GPT is used to relate variations in input data to changes in the calculated ratio-response. Let α be an arbitrary input parameter (number density, multigroup cross section, nubar, chi, etc.) that affects the response ratio because the response functions H_N and/or H_D depend on α, or because the parameter appears in the transport equation, so that the flux is a function of α; i.e.,

$$R = R\left[H_N(\alpha), H_D(\alpha), \phi(\alpha)\right] \tag{6.6.45}$$

The response perturbation due to a sufficiently small variation in α can be approximated by the first-order term in a functional Taylor series expansion,

$$\delta R \;\cong\; \left\langle \left(\frac{\partial R}{\partial H_N}\frac{\partial H_N}{\partial \alpha} \;+\; \frac{\partial R}{\partial H_D}\frac{\partial H_D}{\partial \alpha} \;+\; \frac{\partial R}{\partial \phi}\frac{d\phi}{d\alpha}\right)\; \delta\alpha\left(\vec{\xi}\right)\right\rangle . \tag{6.6.46}$$

In GPT it is common to express the response perturbation as the sum of a "direct" and an "indirect" component. Eq. (6.6.46) is rearranged slightly to obtain:

$$\delta R = \quad \delta R^{(direct)} \;+\; \delta R^{(indirect)}, \tag{6.6.47}$$

where

$$\delta R^{(direct)} \;=\; \left\langle \left(\frac{\partial R}{\partial H_N}\frac{\partial H_N}{\partial \alpha} \;+\; \frac{\partial R}{\partial H_D}\frac{\partial H_D}{\partial \alpha} \right)\, \delta\alpha \right\rangle \;, \tag{6.6.48}$$

$$\delta R^{(indirect)} \;=\; \left\langle \left(\frac{\partial R}{\partial \phi}\frac{d\phi}{d\alpha}\right)\; \delta\alpha \right\rangle . \tag{6.6.49}$$

The direct component accounts for response changes due to perturbations in the response functions H_N and/or H_D that depend explicitly (or implicitly through self-shielding) on data parameter α. The second term, called the indirect component, accounts for the response change due to a flux perturbation in the numerator or denominator of Eq. (6.6.40), which is caused by varying α in the transport equation.

If the response functions depend explicitly on α, then the functional derivatives appearing in the direct effect component can be evaluated to give

$$\delta R^{(direct)} \equiv \frac{R}{\langle H_N\, \phi\rangle} \left\langle \frac{\partial H_N}{\partial \alpha}\, \delta\alpha \right\rangle \;-\; \frac{R}{\langle H_D\, \phi\rangle} \left\langle \frac{\partial H_D}{\partial \alpha}\, \delta\alpha \right\rangle . \tag{6.6.50}$$

In order to evaluate the indirect effect it is necessary to determine the impact of the data perturbation on the neutron balance equation. The operators A and B, as well as the flux ϕ and eigenvalue λ may all be functions of α. Taking the first-order expansion for each of these functions and neglecting higher order terms gives
