This message from subroutine RDCALC is printed if a restarted problem requests matrix information by hole when it was not requested and calculated by the original problem (parent case) that wrote the restart data. It should be verified that the correct restart data file is being used and that the restart unit (RST) is correctly specified. The request for matrix information by hole (MKH=, in the parameter data) should be eliminated if it is not necessary. The problem must be restarted with the first generation (BEG=1, in the parameter data) if matrix information by hole is required and was not calculated by the parent case. A STOP 121 is executed in conjunction with this message.

KMSG178 *** ERROR *** K?-178 FOLLOWS: PARAMETER DATA SPECIFIED MATRIX INFORMATION BY ARRAY BUT IT WAS NOT FOUND ON THE RESTART UNIT.

This message from subroutine RDCALC is printed if a restarted problem requests matrix information by array (also called array position or position index) when it was not requested and calculated by the original problem (parent case) that wrote the restart data. It should be verified that the correct restart data are being used and that the restart unit (RST) is correctly specified in the first table following the parameter tables. The request for matrix information by array (MKA=, in the parameter data) should be eliminated if it is not necessary. If matrix information by array is required and it was not calculated by the parent case, the problem must be restarted with the first generation (BEG=1, in the parameter data). A STOP 121 is executed in conjunction with this message.

KMSG179 *** ERROR *** K5-179 FOLLOWS: HOLE NUMBER ___ (UNIT NUMBER ___) INTERSECTS HOLE NUMBER ___ (UNIT NUMBER ___) IN REGION NUMBER ___.

This KENO V.a message from subroutine K5GM_HOLHOL indicates that the specified holes intersect. Check the dimensions and origins of the units being placed in the region.

KMSG180 *** ERROR *** K?-180 FOLLOWS: PROBLEM IN KENO PLOT DATA - KEYWORD ___ IS NOT VALID

This message from subroutine RDPLOT indicates that the plot data are out of order or a keyword is incorrectly spelled. See Sect. 8.1.3.11 for a list of correct keywords.

KMSG181 *** ERROR *** K?-181 FOLLOWS: LPIC IS OUT OF RANGE. LPIC=___

This message from subroutines K5GM_PRTPLT or K6GM_PRTPLT indicates that a code error has occurred or the type of plot (PIC=) was not properly specified. *lpic*=l for a mixture map, *lpic*=2 for a unit map, and *lpic*=3 for a bias ID map. Any other values of *lpic* are invalid.

KMSG182 *** ERROR *** K5-182 FOLLOWS: AN ARRAY WAS SPECIFIED IN THE GLOBAL UNIT, BUT ARRAY DATA WAS NOT ENTERED.

This KENO V.a message from subroutine K5GM_SORTA indicates that the global unit contains an array specification, but the array was not entered in the array data block. A typo may need to be corrected in the `GLOBAL UNIT` or in the `ARRAY` data block.

KMSG183 *** WARNING *** K5-183 FOLLOWS: UNIT ___ WAS NOT CHECKED FOR GEOMETRIC CONSISTENCY. IT CONTAINS ARRAY ___ BUT WAS NOT USED IN THE PROBLEM.

This KENO V.a warning message is from subroutine K5GM_JOMCHK. It indicates that a unit whose first region is an array was described in the extended geometry data, but that unit was not referenced in the unit orientation data (see Sect. 8.1.3.4 and Sect. 8.1.3.5). KENO usually checks all the geometry region data to be sure it is correct, even when the unit is not used in the problem. The code is unable to make these checks when a unit containing an array is not used in the problem. It is not necessarily an error, but the user should double check to be sure that unit was intentionally omitted from all the arrays.

KMSG184 *** ERROR *** K5-184 FOLLOWS: ALBEDOS WERE SPECIFIED FOR A PROBLEM WHOSE OUTER BOUNDARY IS NOT A CUBE OR CUBOID. THE PROBLEM WILL NOT EXECUTE.

This KENO V.a message from subroutine K5GM_JOMCHK indicates that a non-vacuum albedo boundary condition was entered for a curvilinear outer surface. This is not allowed, and the problem will not be run.

KMSG185 *** ERROR *** K?-185 FOLLOWS: ** ERROR ** THE NUMBER OF SETS OF BIASING CORRELATION DATA EXCEEDS THE NUMBER THAT WAS WRITTEN WHEN THE BIASING DATA WAS READ. ___ WERE WRITTEN, BUT AN ATTEMPT WAS MADE TO READ ___.

This message from subroutine WAITIN is accompanied by a STOP 148. It indicates a code error unless it is accompanied by error messages related to the biasing input data.

KMSG186 *** ERROR *** K?-186 FOLLOWS: THE NUMBER OF SETS OF BIASING AUXILIARY DATA EXCEEDS THE NUMBER THAT WAS WRITTEN WHEN THE BIASING DATA WAS READ. ___ WERE WRITTEN, BUT AN ATTEMPT WAS MADE TO READ ___.

This message from subroutine WAITIN is accompanied by a STOP 149. It indicates a code error unless it is accompanied by error messages related to the biasing input data.

KMSG187 *** WARNING *** K?-187 FOLLOWS: INTERVALS IN THE ABOVE RANGE WERE NOT USED. THIS COULD LEAD TO IMPROPER BIASING.

This message from subroutine LODWTS is printed to remind the user that at least one of the specified intervals was not used in the problem. This can result in improper biasing. Biasing should not be used between fissile units. When biasing is used, it should be flat or increasing as distance from the fissile material increases and flat or decreasing as a history moves toward fissile material. See Sect. 8.1.3.7 for additional assistance.

KMSG188 *** ERROR *** K?-188 FOLLOWS: HOLE NUMBER ___ REFERENCES UNDEFINED UNIT NUMBER ___

This message is printed by subroutines K5GM_HOLCHK, K5GM_HOLE, K5GM_READGM, or SGGM_HOLE if the unit number referenced by the hole is less than 1 or greater than the largest unit number in the geometry data. The message is printed by subroutine HOLE if the unit number referenced by the hole is larger than zero and not greater than the largest unit number in the geometry data but is a unit number for

which all data are missing. The message is printed by subroutine HOLCHK if the unit number referenced by the hole is undefined. Message K?-165 may accompany this message. Specify a valid unit number (*lhole* — see EXTENDED GEOMETRY DESCRIPTION, Sect. 8.1.3.4) and resubmit the problem.

KMSG189 *** ERROR *** K6-189 FOLLOWS: HOLE NUMBER ___ REFERENCES UNDEFINED UNIT NUMBER ___

This self-explanatory KENO-VI message is from subroutine SSGM_READGM.

KMSG190 *** ERROR *** K?-190 ERROR IN PLOT DATA - OPTION ___ IS NOT VALID FOR KEYWORD PIC=.

This message from subroutine RDPLOT indicates an incorrect option associated with the keyword `PIC=`. See Sect. 8.1.3.11. Acceptable options include MAT, MIX, MIXT, MEDI, UNT, UNIT, IMP, BIAS, WTS, WGT, WGTS, or WEIGH.

KMSG191 *** ERROR *** K?-191 FOLLOWS: START TYPE ___ IS INVALID FOR A PROBLEM THAT DOES NOT HAVE A GLOBAL ARRAY.

This message from subroutine DATAIN occurs if the start type (`NST=` in the start data, Sect. 8.1.3.8) is 2, 3, 4, or 5. A global array is required to use the specified start type.

KMSG192 *** WARNING *** K?-192 FOLLOWS: MATRIX INFORMATION BY ARRAY WAS SPECIFIED AS YES IN THE PARAMETER DATA (MKA=), BUT IS NOT OF USE UNLESS ARRAYS ARE SPECIFIED.

This warning message from subroutine DATAIN is self-explanatory. The code redefines the problem so matrix information will not be collected by array number.

KMSG193 *** WARNING *** K?-193 FOLLOWS: MATRIX INFORMATION BY HOLE WAS SPECIFIED AS YES IN THE PARAMETER, DATA (MKH=), BUT IS NOT OF USE UNLESS HOLES ARE SPECIFIED.

This warning message from subroutine DATAIN is self-explanatory. The code redefines the problem so matrix information will not be collected by hole number.

KMSG194 *** WARNING *** K?-194 FOLLOWS: MATRIX INFORMATION BY UNIT LOCATION WAS SPECIFIED AS YES IN THE PARAMETER DATA (MKP=), BUT IS NOT ALLOWED BECAUSE A GLOBAL ARRAY WAS NOT SPECIFIED.

This warning message from subroutine DATAIN is self-explanatory. The code redefines the problem so matrix information will not be collected by unit location.

KMSG195 *** ERROR *** K?-195 FOLLOWS: CHARACTER STRING EXCEEDS THE SPECIFIED LENGTH. CHECK FOR ENDING DELIMITER.

This error message is from subroutine RCHRS. It indicates that either the character string exceeds 132 characters or the ending delimiter was omitted for `TTL=` (plot title, Sect. 8.1.3.11) or for `COM=` (unit comment, Sect. 8.1.3.4, or array comment, Sect. 8.1.3.5). A STOP 153 is executed when this message is printed.

KMSG196 *** ERROR *** K?-196 FOLLOWS: A PROBLEM CANNOT BE RESTARTED WHEN RESTART DATA DO NOT EXIST FOR THE SPECIFIED GENERATION AND THE NEXT GENERATION FOR WHICH RESTART DATA ARE AVAILABLE IS LARGER THAN THE REQUESTED NUMBER OF GENERATIONS. ** ** EXECUTION IS TERMINATED.

This message from subroutine RDCALC indicates that a problem was to be restarted but the requested number of generations (GEN= in Sect. 8.1.3.3) was smaller than the beginning generation number (BEG= in Sect. 8.1.3.3). The beginning generation number for a restarted problem is the generation at which the calculation of k-effectives and associated information is resumed. Therefore, the number of generations to be run must be larger than the beginning generation number. The data should be corrected and the problem resubmitted. A STOP 154 is executed when this message is printed.

KMSG197 *** ERROR *** K5-197 FOLLOWS: A VALID GEOMETRY REGION MUST PRECEDE A REPLICATE REGION.

This KENO V.a message from subroutine K5GM_KENOG indicates that a replicate specification follows an invalid geometry specification (for example, REPLICATE immediately follows a UNIT specification).

KMSG198 *** ERROR *** K?-198 FOLLOWS: ARRAY ___ CONTAINS AN ERROR IN THE INPUT DATA.

This message from subroutine ARAYIN is printed as the result of an error in the FILL input data for the specified array. One or more messages from the library routine YREAD should immediately precede this message and indicate the nature of the error. The data should be corrected and the problem resubmitted. Messages K?-32, K?-33, and/or K?-85 may also print as a result of this error.

KMSG199 *** ERROR *** K?-199 FOLLOWS: THERE IS NO MIXING TABLE

This self-explanatory message comes from subroutine PREMIX-SETUP. A continuous energy problem requires a mixing table, but none was entered.

KMSG200 *** ERROR *** K?-200 FOLLOWS: START TYPE 6 WAS SPECIFIED IN THE START DATA, BUT THE STARTING POINTS WERE NOT SPECIFIED.

This message from subroutine RDSTRT indicates that start type 6 was specified but the corresponding starting points were not included in the START data block. The corresponding starting points must be entered or the start type must be changed. See Sect. 8.1.3.8.

KMSG201 *** WARNING *** K?-201 FOLLOWS: NEUTRON ___ SPECIFIED A POSITION IN THE GLOBAL ARRAY. THE GLOBAL UNIT DID NOT CONTAIN AN ARRAY SO THE POSITION WAS IGNORED ** WARNING ******** WARNING ***** WARNING ******** WARNING ******** WARNING ******** WARNING ******** WARNING ******** WARNING ******** WARNING ******** WARNING **

This warning message from subroutine K_STDATA indicates that extraneous data were specified in the start type 6 data. It should be verified that the correct global unit is specified.

KMSG202 *** ERROR *** K?-202 FOLLOWS: ONLY START TYPES 0,1,6 OR 7 ARE VALID FOR A PROBLEM WITHOUT AN ARRAY IN THE GLOBAL UNIT.

This message from subroutines K5_START or K6_START indicates that the specified start type is not valid for the problem. An appropriate start type must be chosen.

KMSG203 *** ERROR *** K?-203 FOLLOWS: UNIDENTIFIED KEYWORD ___ IN MIXING TABLE

This message from subroutine MIXING_TABLE indicates that when reading the mixing table, an unrecognized keyword was found. See Sect. 8.1.3.10 for the acceptable keywords.

KMSG204 K?-204 EXECUTION TERMINATED DUE TO ACHIEVING THE STANDARD DEVIATION SPECIFIED FOR THE PROBLEM. NOTE THAT AT LEAST 50 OR NSK*2 ACTIVE GENERATIONS ARE ALWAYS RUN.

This message from subroutines K5_GUIDE or K6_GUIDE indicates that the specified standard deviation has been achieved and the problem will therefore terminate at the current generation. If a lower standard deviation is desired the requested standard deviation (SIG=, Sect. 8.1.3.3) must be decreased.

KMSG205 *** ERROR *** K5-205 FOLLOWS: A GLOBAL UNIT MUST BE SPECIFIED FOR A SINGLE UNIT PROBLEM.

This message from subroutine K5_FLDATA is printed if a global unit is not specified for a single unit problem. A STOP 164 is executed when the message is printed. If the input data do not specify the global unit, it is defaulted to Unit 1.

KMSG206 *** ERROR *** K?-206 FOLLOWS: THE UNIT SPECIFIED FOR STARTING IS NOT USED IN THE PROBLEM OR IS UNDEFINED.

This message from subroutines K5_START or K6_START indicates that the unit in which neutrons are to be started is undefined. It should be verified that the global unit or array is correctly specified. The start data should be checked for start types 4 and 5 (Sect. 8.1.3.8) to be sure that NBX= is correctly specified.

KMSG207 *** ERROR *** K?-207 FOLLOWS: THE STARTING ARRAY POSITION IS INVALID.

This message from subroutines K5_START or K6_START indicates that the array position NXS, NYS, or NZS is not valid for start types 3 or 6. NXS, NYS, and NZS must be larger than zero and no larger than NBXMAX, NBYMAX, and NBZMAX of the global array, respectively. It should be verified that the GLOBAL UNIT or ARRAY is correctly specified. The start data (Sect. 8.1.3.8) should be corrected and the problem resubmitted.

KMSG208 *** WARNING *** K?-208 FOLLOWS: THE FRACTION OF NEUTRONS STARTED AS A SPIKE WAS LESS THAN ZERO. IT HAS BEEN RESET TO ZERO.

This message from subroutines K5_START or K6_START indicates that FCT= was incorrectly specified in the start data for start type 2. The resultant starting distribution is a cosine distribution throughout the volume of a cuboid defined by XSM, XSP, YSM, YSP, ZSM, and ZSP (see Sect. 8.1.3.8). If a spike was desired, FCT= should be set to a positive number between 0.0 and 1.0. If FCT =0.0 is specified, a cosine distribution without a spike is used as the starting distribution. If FCT=1.0 is specified, all the neutrons are started as a spike (i.e., they are started uniformly in the unit located at position NXS, NYS, NZS in the global array) as noted in Sect. 8.1.3.8

KMSG209 *** WARNING *** K?-209 FOLLOWS: THE FRACTION OF NEUTRONS STARTED AS A SPIKE WAS GREATER THAN ONE. IT HAS BEEN RESET TO ONE.

This message from subroutines K5_START or K6_START indicates that FCT= was incorrectly specified in the start type 2 data. The code reset FCT=1, so all the neutrons are started as a spike (i.e., they are started uniformly in the unit located at NXS, NYS, NZS in the global array) as noted in Sect. 8.1.3.8

KMSG210 *** ERROR *** K?-210 FOLLOWS: THE UNIT SPECIFIED FOR STARTING IS NOT IN THE GLOBAL ARRAY.

This message from subroutines K5_START or K6_START indicates that the unit specified by NBX= does not occur in the global array. It should be verified that the global array is correctly specified and that the unit specified by NBX= is correct (see Sect. 8.1.3.8).

KMSG211 *** ERROR *** K?-211 FOLLOWS: THE NUMBER OF SETS OF BIAS FACTORS FROM CARDS EXCEEDS THE NUMBER THAT WAS WRITTEN WHEN THE BIASING DATA WAS READ. ___ WERE WRITTEN, BUT AN ATTEMPT WAS MADE TO READ ___.

This message from subroutine WAITIN indicates a code error. A STOP 161 is executed when this message is printed.

KMSG212 *** ERROR *** K?-212 FOLLOWS: THE BIASING DATA SPECIFIED IBGN=___ AND IEND=___. IBGN MUST BE LARGER THAN ZERO AND IEND MUST BE AT LEAST AS LARGE AS IBGN. THE PROBLEM WILL NOT BE RUN.

This message from subroutine RDBIAS indicates an error in the biasing data. The biasing correlation data is order dependent. The order of data entry is ID=*nn ibgn iend*, where *nn* is an ID number from Table 8.1.25 and *ibgn* is the beginning BIAS ID and *iend* is the ending BIAS ID (see Sect. 8.1.3.7 and Sect. 8.1.3.7). To continue checking the input data, if *ibgn* is less than or equal to zero, it is set to 1. Similarly, if *iend* is less than *ibgn*, it is set to *ibgn*.

KMSG214 ***** ERROR ***** K6-214 FOLLOWS: THE BASE OF A TRIANGULAR FACE OF A WEDGE CANNOT BE ZERO.

This KENO-VI message is from subroutine SGGM_WEDGE. The input data for the wedge following the keyword WEDGE are incorrect. See Sect. 8.1.8.2.

KMSG215 ***** ERROR ***** K6-215 FOLLOWS: THE Y COORDINATE OF A TRIANGULAR FACE OF A WEDGE CANNOT BE ZERO.

This KENO-VI message is from subroutine SGGM_WEDGE. The input data for the wedge following the keyword WEDGE are incorrect. See Sect. 8.1.8.2.

KMSG216 ***** ERROR ***** K5-216 FOLLOWS: UNIT ___ CONTAINS ARRAY ___ WHICH WAS NOT DEFINED IN THE INPUT DATA.

This message from subroutine K5GM_JOMCHK indicates that the unit specified an array, but the array number was not entered in the array data block. The array number specified in the unit should be checked to verify that it is correct, or the unit orientation data should be entered in the array data block.

KMSG217 ***** ERROR ***** K?-217 FOLLOWS: *** ERROR *** DIFFERENTIAL ALBEDOS CANNOT BE USED IN AN ADJOINT PROBLEM.

This self-explanatory message is from subroutines MFLDATA, K5_FLDATA or K6_FLDATA. Reflector material in the mixing table and the geometry should be described instead of using differential albedos, or the problem should be run in the forward mode.

KMSG218 ***** ERROR ***** K?-218 FOLLOWS: AN INPUT DATA ERROR HAS BEEN ENCOUNTERED IN THE ___ DATA ENTERED FOR THIS PROBLEM.

This message is from subroutines INITAL, DATAIN, or KENOBUILDER. Additional error messages should be found and corrected, and the data in the named data block should be checked.

KMSG219 ***** ERROR ***** K?-219 FOLLOWS: THE START DATA SPECIFIED ___ STARTING POINTS CHOSEN FROM A COSINE DISTRIBUTION BUT NONE WERE FOUND.

This message from subroutines K5_START or K6_START is printed if start type 2 was specified and the code was unable to start any neutrons in the cuboid defined by XSM, XSP, YSM, YSP, ZSM, ZSP. It should be verified that fissile material exists within that cuboid. If it does not, the starting cuboid should be respecified to contain fissile material, or a different start type should be chosen. If message KMSG105 states that only 0 independent starting points were generated, it indicates that the code was unable to start any neutrons in the spike specified by start type 2. It should be verified that the unit specified for the spike contains fissile material. If only a very small fraction of the volume of this unit is fissile, it may be necessary to enter a larger value for the KENO parameter **TBA**= or a different start type may need to be selected. The problem will not be run if message KMSG219 is printed.

KMSG220 ***** ERROR ***** K?-220 FOLLOWS: ERROR IN PLOT DATA. IF THE COORDINATE OF THE LOWER RIGHT-HAND CORNER IS ENTERED, ONE OF THE PLOT PARAMETERS DLX, DLD, NAX OR NDN MUST BE ENTERED. CURRENT VALUES ARE LISTED BELOW. TITLE: _____ UPPER LEFT LOWER RIGHT COORDINATES COORDINATES X _____ _____ Y _____ _____ Z _____ _____ U AXIS V AXIS (DOWN) (ACROSS) X _____ _____ Y _____ _____ Z _____ _____ NDN=___ NAX=___ DLD=___ DLX=___

This message from subroutine RDPLOT indicates that the coordinates of the lower right-hand corner of the plot were specified in the input data without specifying one of the following plot parameters: (1) NDN, the number of characters down the page, (2) NAX, the number of characters across the page, (3) DLD, the vertical spacing between points, or (4) DLX, the horizontal spacing between points. The problem will not be run. To correct the error, NDN, NAX, DLD, or DLX should be specified in the plot data and the problem resubmitted. See Sect. 8.1.3.11 and Sect. 8.1.4.10 for assistance.

KMSG221 ***** ERROR ***** K6-221 FOLLOWS: THE LENGTH OF THE EDGE ALONG THE BASE OF THE X AXIS FOR A RHOMBOID MUST BE GREATER THAN 0.0. CHECK GEOMETRY WORD ___

This KENO-VI message is from subroutine SGGM_RHOMB. The data following the keyword RHOMB should be checked. See Sect. 8.1.8.2.

KMSG222 ***** WARNING ***** K?-222 FOLLOWS: ___ TRANSFERS FOR MIXTURE ___ WERE CORRECTED FOR BAD MOMENTS.

This message from subroutine MAKANG indicates moments were corrected to eliminate negative probabilities for calculated angles. If the moment was changed by more than EPS times the moment, a K?-60 or K?-64 message is printed. If EPS is very small, any change without an accompanying message is trivial. The K?-60 or K?-64 messages can be used to determine if the affected transfer and correction are significant. Most messages are caused by the cross sections being in single precision and the moments calculations being done in double precision. Generally, as the number of energy groups increase, so does the number of corrected transfers for a given mixture.

KMSG224 ***** ERROR ***** K6-224 FOLLOWS: THE HEIGHT OF A WEDGE CANNOT BE ZERO.

This KENO-VI message is from subroutine SGGM_WEDGE. The input data for the wedge following the keyword WEDGE are incorrect. See Sect. 8.1.8.2.

KMSG225 ***** ERROR ***** K6-225 FOLLOWS: TO START IN A GLOBAL PLANE GEOMETRY, IGEO =___ VALUES FOR XSM, XSP, YSM, YSP, ZSM, AND ZSP MUST BE ENTERED AS START DATA.

This error message is from subroutine K6_STRTSU. A GLOBAL PLANE GEOMETRY implies an infinite media. The boundary of the starting points must be entered. See Sect. 8.1.3.8.

KMSG226 ***** ERROR ***** K6-226 FOLLOWS: XDIST, YDIST, AND ZDIST SPECIFIED FOR A PPIPED MUST BE GREATER THAN 0.0. CHECK GEOMETRY WORD ___

This KENO-VI message is from subroutine SGGM_PPIPED. The data must be checked following the keyword PPIPED. See Sect. 8.1.8.2.

KMSG227 ***** ERROR ***** K6-227 FOLLOWS: PSI, THETA, AND PHI SPECIFIED FOR A PARALLELEPIPED MUST BE GREATER THAN OR EQUAL TO 0.0 AND LESS THAN 90.0. CHECK GEOMETRY WORD ___

This KENO-VI message is from subroutine SGGM_PPIPED. The data following the keyword PPIPED should be checked. See Sect. 8.1.8.2.

KMSG228 ***** ERROR ***** K5-228 FOLLOWS: ___ ___ IS INVALID. UNITS MUST BE GREATER THAN 0. THE PREVIOUS UNIT NUMBER IS ___. PRINTING THE GEOMETRY AS READ WILL BE TURNED ON

This message from subroutine K5GM_KENOG is printed if a unit number, *nn*, is read which is not greater than 0. This unit followed unit *mm* in the input (if *mm* is 1, the unit *nn* may be the first unit in the geometry). The geometry following this will be printed as read as an aid in locating the error. The error must be corrected, and all unit numbers must be greater than 0.

KMSG229 ***** WARNING ***** K?-229 FOLLOWS: THE NUMBER OF START TYPE 6 STARTING POINTS (LNU=___) SPECIFIED IN START DATA DOES NOT MATCH THE NUMBER OF NEUTRONS PER GENERATION (NPG=___). SPECIFIED STARTING POINTS WILL BE USED FOR FIRST ___ NEUTRONS, AND THE STARTING POINTS FOR THE REMAINING NEUTRONS WILL BE RANDOMLY SELECTED FROM THESE (LNU=___) POINTS.

This message from subroutine START6 is printed if the number of starting points specified (`LNU`) is less than the number of histories per generation (`NPG`). The remaining unspecified starting points will be randomly selected from the already specified starting points.

KMSG230 ***** ERROR ***** K?-230 FOLLOWS: MATRIX K-EFFECTIVE WAS NOT CONVERGED. K-EFFECTIVE IS ___ CONVERGENCE ERROR IS ___

This message is printed by subroutines K5_GUIDE, K6_GUIDE, or MATK if the matrix eigenvalue equation did not converge to 0.1 % after a maximum number of iterations. This is likely a code error, but it might be caused by too much variance in the matrix terms.

KMSG231 ***** ERROR ***** K6-231 FOLLOWS: THE CALCULATION WAS TERMINATED BECAUSE ARRAY ___ IS NOT PROPERLY POSITIONED IN REGION ___ OF UNIT ___. THE ARRAY BOUNDARY IS OUTSIDE POSITION ___ ___ ___ ON THE ___ ARRAY FACE.

This KENO-VI message from subroutine SGGM_PNTCHK is printed only if an array is placed in a region so that there is space in the region not occupied by the array. The array needs to be repositioned.

KMSG233 ***** ERROR ***** K?-233 FOLLOWS: MIXTURE ___ HAS A NEGATIVE CROSS SECTION FOR REACTION ___ - GROUP ___ THE VALUE IS ___

This error message from subroutine NORM1D is printed if an MT number for a specified mixture has a negative cross section value in any group. This is a library or cross section processing problem. This error should be reported to scalehelp@ornl.gov.

KMSG234 ***** ERROR ***** K?-234 FOLLOWS: MIXTURE ___ HAS NEGATIVE CROSS SECTIONS FOR REACTION ___ SET XS1=YES AND P1D=YES IN THE PARAMETERS TO SEE THE VALUE(S).

This error message from subroutine FILLSG is printed if an MT number for a specified mixture has a negative cross section value in any group. This is a library or cross section processing problem. This error should be reported to scalehelp@ornl.gov.

KMSG236 ***** ERROR ***** K?-236 FOLLOWS: EITHER NEUTRON OR GAMMA SHOULD HAVE BEEN ENTERED TO SELECT THE TYPE OF 1-D CROSS SECTIONS, BUT ___ WAS ENTERED INSTEAD.

This error message from subroutine IDX1D indicates the user specified extra 1-D cross sections but specified an invalid type. Valid types are either neutron or gamma. The data must be corrected in the `READ X1DS` data block.

KMSG237 ***** ERROR ***** K?-237 FOLLOWS: NUMBER OF SCATTERING ANGLES ASKED FOR, ___, DO NOT MATCH THE NUMBER ON THE MIXED CROSS SECTION LIBRARY ,___. UNABLE TO PROCESS FURTHER.

This error message from subroutine ICEMIX indicates the user requested a number of angles to be used in the problem, NSCT, that is inconsistent with the premixed cross section library specified for this problem. Either `SCT=` should not be specified, or it should be specified by creating a new mixed library.

KMSG238 ***** ERROR ***** K?-238 FOLLOWS: DELTA ___-COORDINATE ___ DIRECTION COSINE ACROSS ___ DIRECTION COSINE DOWN ___ ARE INCONSISTENT. IF DELTA IS ZERO, THEN BOTH DIRECTION COSINES SHOULD BE ZERO. IF DELTA IS NOT ZERO, THEN AT LEAST ONE DIRECTION COSINE SHOULD BE NONZERO, AND THE NONZERO VALUES SHOULD ALL HAVE THE SAME SIGN.

The error message from subroutine RDPLOT indicates an error in the `READ PLOT` input data. The direction cosines entered using `UAX`, `VAX`, `WAX`, `UDN`, `VDN`, and `WDN` are inconsistent with one of the following: (1) the lower right-hand corner and upper left-hand corner specified; (2) the delta across (`DLX`) and delta down (`DLD`); or (3) the number of points across (`NAX`) and the number of points down (`NDN`).

KMSG239 ***** WARNING ***** K6-239 FOLLOWS: THE VOLUMES FOR ALL REGIONS ARE NOT SET. SOME REGION VOLUMES ARE NOT SET BY INPUT, NOT IN THE SPACE FOR WHICH VOLUMES ARE CALCULATED, MISSED BY THE VOLUME CALCULATION, OR ACTUALLY 0.0. FOR THESE REGIONS, VOLUMES ARE SET TO -1.0 AND THE FLUXES AND FISSION DENSITIES ARE DIVIDED BY -1.0 INSTEAD OF THE REAL VOLUME.

This error message is from subroutine SGGM_VOLUME. If fluxes or other densities are needed, the real volumes are required. These can be calculated, with some error, or entered with as much precision as needed and the user knows.

KMSG240 ****** ERROR *****K6-240 FOLLOWS: GEOMETRY WORD UNIT IS REQUIRED BUT ___ WAS READ INSTEAD.

This error message is from subroutine SGGM_KENOG. Prior to specifying geometry or media data in the GEOMETRY DATA BLOCK, a unit must be specified.

KMSG241 ****** ERROR *****K6-241 FOLLOWS: NEUTRON ___ OF GENERATION ___ HAS LEAKED WITHOUT BEING ON THE SURFACE OF THE BOUNDARY REGION OF UNIT ___ AT X = ___ Y = ___ Z = ___ U = ___ V = ___ W = ___

This message from subroutine K6_TRACK indicates a history exited the system from somewhere internal to the geometry. The geometry of the unit at the specified point should be checked to ensure that it is correctly defined.

KMSG242 ****** ERROR *****K6-242 FOLLOWS: NEUTRON ___ IN GENERATION ___ HAS LEAKED FROM UNIT ___ AT X = ___ Y = ___ Z = ___ BUT IS STILL WITHIN THE VOLUME DEFINED BY THE UNIT BOUNDARY RECORD.

This error message from subroutines K6_TRACK or ADVANCETRACKTONEXTBOUNDARY indicates that the specified particle is inside the volume defined by the unit's boundary record but is not in any region. The media record descriptions should be checked for the specified unit. Also, specifying a screen plot of the problem may help identify the problem.

KMSG243 ***** ERROR ***** K6-243 FOLLOWS: IN UNIT ___ THE BOUNDARY RECORD CONTAINS LABEL ___ WHICH DOES NOT CORRESPOND TO A GEOMETRY RECORD.

This KENO-VI error message from subroutine SGGM_KLANGA indicates that in the specified unit the boundary record contains a geometry record label that is not linked to a geometry record in the unit.

KMSG244 ***** ERROR ***** K?-244 FOLLOWS: UNRECOGNIZABLE VOLUME CALCULATION TYPE ___ SPECIFIED

This error message from subroutine RDVOL indicates an invalid input. TYPE = parameter was encountered in the READ volume data block.

KMSG245 ***** ERROR ***** K?-245 FOLLOWS: UNIT ___ REGION ___ REFERENCES UNIT ___. AN INSTANCE OF THIS REGION HAS OCCURRED WITHOUT FINDING THE REFERENCED UNIT AT ANY NESTING LEVEL.

This error message from subroutines K5_GEOMETRY or K6_GEOMETRY indicates that the fuel center for the unit and region printed is specified with respect to the referenced unit, but the referenced unit could not be found in the geometry. A STOP 245 is executed in conjunction with this message.

KMSG246 ***** ERROR ***** K?-246 FOLLOWS: THE RESTART FILE WAS A ___ PROBLEM, BUT THE CURRENT PROBLEM IS ___. THE CURRENT PROBLEM WILL NOT BE RUN

This error message from subroutine PARAM indicates that a restart file to be read for this problem was either forward or adjoint, which conflicted with what was specified in the input. Only a forward restart file can be used for a forward problem, and only an adjoint restart file can be used for an adjoint problem.

KMSG247 ***** ERROR ***** K?-247 FOLLOWS: INVALID KEYWORD ___ IN THE VOLUME INPUT DATA ***** ERROR *****

This error message from subroutine RDVOL indicates the keyword printed is not valid in the `READ VOLUME` data block. See Sect. 8.1.3.13 for guidance on `VOLUME` inputs.

KMSG249 ***** ERROR ***** K6-249 FOLLOWS: UNDEFINED SPACE IN THE REGION CONTAINING HOLE ___.

This error message from subroutine SGGM_TRACE is caused by a unit improperly being placed in a hole, leaving a gap between crossing into a hole and entering the unit in the hole. The hole geometry must be checked.

KMSG250 K?-250 EXECUTION TERMINATED ON USER SIGNAL.

This message from subroutines K5_GUIDE or K6_GUIDE indicates that the user has set the flag to KENO so that it will not run further generations and wrap up execution. The flag is set by creating a file named stop_keno in the working directory.

KMSG251 ***** ERROR ***** K6-251 FOLLOWS: INVALID VOLUME CALCULATION TYPE ___

This error message from subroutine SGGM_VOLUME indicates that the variable VCALC has been overwritten. This indicates a code error.

KMSG253 ***** ERROR ***** K6-253 FOLLOWS: CANNOT SELECT A FACE FOR VOLUME INTEGRATION.

This error message from subroutine SGGM_PATHVOLS indicates an invalid face was selected for the volume integration. This indicates a code error.

KMSG254 ***** ERROR ***** K6-254 FOLLOWS: THE ANGLE BETWEEN THE Y AXIS AND THE Y EDGE OF THE BASE MUST BE BETWEEN 0 AND 90 DEGREES. CHECK GEOMETRY WORD ___

This KENO-VI error message from subroutine SGGM_RHOMB indicates an invalid angle has been entered. The angle must be between 0 and 90 degrees.

KMSG256 ***** ERROR ***** K6-256 FOLLOWS: RAY TRACE NUMBER ___ HAS LEAKED FROM UNIT ___ AT X= ___ Y= ___ Z= ___ BUT IS STILL WITHIN THE VOLUME DEFINED BY THE UNIT BOUNDARY RECORD.

This KENO-VI message from subroutine SGGM_TRACE occurs when volumes are calculated using ray tracing and an undefined region was encountered by a ray.

KMSG257 ***** ERROR ***** K6-257 FOLLOWS: ***** ERROR ***** KEYWORD PLACE NOT FOUND FOR ARRAY ___

This KENO-VI error message from subroutine SGGM_ARRAY means an array was improperly placed within a unit. The keyword `PLACE`, which should immediately follow the array's vector definition array, is missing from the array data. See Sect. 8.1.3.5 for more information about array placement.

KMSG258 ***** ERROR ***** K6-258 FOLLOWS: THE CALCULATION WAS TERMINATED BECAUSE A GEOMETRY WORD IN REGION ___ OF UNIT ___ PRODUCES AN IMAGINARY BOUNDARY.

This KENO-VI message from subroutine SGGM_PNTCHK should only be produced by the geometry word QUADRATIC when used as part of an array boundary. The boundary produces imaginary results. The coefficients of the geometry word should be checked.

KMSG259 ***** ERROR ***** K6-259 FOLLOWS: NEUTRON ___ FROM GENERATION ___ LOCATED IN UNIT ___ AT POSITION X = ___ Y = ___ Z = ___ IN ARRAY ___ BOUNDARY UNIT ___ GLOBAL REGION ___ AT BOUNDARY POSITION XARY = ___ YARY = ___ ZARY = ___ HAS A NEGATIVE DISTANCE TO CROSS THE ARRAY BOUNDARY THIS COULD BE DUE TO AN ARRAY BOUNDARY OVERLAPPING A HOLE.

This message from subroutines K6_TRACK, SGGM_TRACE, or NEWUNITINTERSECTIONTABLE occurs when a history computes a negative distance to cross an array boundary when it is inside the array. This can be caused by the array boundary intersecting a hole, of by round off in computing the coordinates of the point in the unit containing the array boundary for large dodecahedral arrays. For the latter case, KENO-VI will silently allow up to 5 such events per generation before giving this message and terminating.

KMSG260 ***** ERROR ***** K6-260 FOLLOWS: NEUTRON ___ FROM GENERATION ___ LOCATED IN UNIT ___ A PARTICLE AT POSITION X = ___ Y = ___ Z = ___ TRAVELING IN DIRECTION U = ___ V = ___ W = ___ TRAVELED___ CM INSIDE HOLE ___ BEFORE CROSSING THE BOUNDARY. THIS COULD BE DUE TO THE HOLE OVERLAPPING ANOTHER HOLE, UNIT, OR ARRAY BOUNDARY.

This message from subroutines K6_TRACK, SGGM_TRACE, and CROSSINTOAHOLE occurs when a history checks whether it is crossing into a hole and finds it is already inside the hole.

KMSG261 ***** ERROR ***** K6-261 FOLLOWS: NEUTRON ___ FROM GENERATION ___ LOCATED IN UNIT ___ A PARTICLE AT POSITION X = ___ Y = ___ Z = ___ TRAVELING IN DIRECTION U = ___ V = ___ W = ___ TRAVELED___ CM OUTSIDE THE UNIT BEFORE CROSSING THE BOUNDARY. THIS COULD BE DUE TO A HOLE OVERLAPPING THE UNIT BOUNDARY.

This message from subroutines K6_TRACK, SGGM_TRACE, or ADVANCETRACKTONEXTBOUNDARY occurs when a history goes to check crossing out of a unit and finds that it does not occur at the unit boundary.

KMSG262 ***** ERROR ***** K6-262 FOLLOWS: NEUTRON ___ FROM GENERATION ___ LOCATED IN UNIT ___ A PARTICLE AT POSITION X = ___ Y = ___ Z = ___ TRAVELING IN DIRECTION U = ___ V = ___ W = ___ IS OUTSIDE THE ARRAY BOUNDARY WITHOUT CROSSING OUT OF THE ARRAY THIS COULD BE DUE TO A HOLE OVERLAPPING THE ARRAY BOUNDARY.

This message from subroutine SGGM_CRSARA occurs when a history computes a negative distance to cross an array boundary when it is inside the array. This can be caused by the array boundary intersecting a hole.

KMSG263 ***** ERROR ***** K6-263 FOLLOWS: MULTIPLY DEFINED POINT - LL = ___ X = ___ Y = ___ Z = ___

This KENO-VI message from subroutine SGGM_TRACE indicates incorrect sector definitions in unit LL at point X, Y, Z.

KMSG264 ***** ERROR ***** K6-264 FOLLOWS: HOLE ___ NOT DEFINED IN REGION ___

This message from subroutine SGGM_TRACE indicates incorrect geometry specification of holes. See Sect. 8.1.4.6.1 for more information on the correction specification of `HOLE`s.

KMSG265 ***** ERROR ***** K6-265 FOLLOWS: BOUNDARY SECTOR DATA WAS NOT FOUND FOR UNIT ___

This KENO-VI message from subroutine SGGM_BNDRY indicates that the region definition vector for the unit is missing in the input.

KMSG266 ***** ERROR ***** K6-266 FOLLOWS: A VECTOR DEFINITION ARRAY IN UNIT ___ REFERENCES GEOMETRY RECORD ___ WHICH HAS NOT BEEN SPECIFIED.

This KENO-VI message from subroutine SGGM_KLANGA indicates that a region definition vector in the unit references an undefined geometry input record.

KMSG267 ***** ERROR ***** K6-267 FOLLOWS: IN UNIT ___ THE USE OF GEOMETRY LABEL ___ IN THE BOUNDARY DEFINITION VECTOR CONFLICTS WITH VECTOR DEFINITON GEOMETRY LABEL ___

This KENO-VI message from subroutine SGGM_KLANGA indicates that a geometry word referenced in a region definition vector in the unit defines the region to be on the wrong side of the unit boundary (the same geometry record is referenced with opposite signs).

KMSG268 ***** ERROR ***** K6-268 FOLLOWS: INVALID KEYWORD ___ IN THE VOLUME INPUT FILE

This self-explanatory message is from subroutine SGGM_GTVOLS, and it occurs when reading a separate volume file. See Sect. 8.1.3.13 for more information regarding the volume input file.

KMSG269 ***** ERROR ***** K6-269 FOLLOWS: FOR UNIT NUMBER ___ TOO MANY MEDIA ENTRIES WERE SPECIFIED.

This KENO-VI error message results from subroutine SGGM_GTVOLS, and it indicates that the separate volume file is inconsistent with the geometry input.

KMSG270 ***** ERROR ***** K6-270 FOLLOWS: CYLINDERS/ECYLINDERS/CONES IN THE GLOBAL UNIT BOUNDARY DEFINITION VECTOR NEED TO BE ORIENTED ALONG A MAJOR AXIS.

This KENO-VI message from subroutine SGGM_VOLCUB indicates that a bounding cuboid for the global unit cannot be calculated because one of the referenced bodies has been rotated off axis. The user can bypass this message by specifying a bounding cuboid in the input in the VOLUME data block.

KMSG271 ***** ERROR ***** K6-271 FOLLOWS: THE FIRST NON-NEGATIVE BODY SPECIFIED IN THE BOUNDARY DEFINITION VECTOR OF THE GLOBAL UNIT MUST SPECIFY FINITE VOLUME BODY.

This KENO-VI message from subroutine SGGM_VOLCUB indicates that a bounding cuboid for the global unit cannot be calculated because the first body in the boundary definition vector does not define a finite volume body. The user can bypass this message by specifying a bounding cuboid in the input in the VOLUME data block.

KMSG273 ***** ERROR ***** K?-273 FOLLOWS: THE NUMBER OF GROUPS ON THE RESTART LIBRARY DOES NOT MATCH WHAT WAS SET PREVIOUSLY. THE NUMBER OF GROUPS SET PREVIOUSLY ___ THE NUMBER OF GROUPS FROM THE RESTART UNIT ___

This self-explanatory message from subroutine READ_MIXED_XSECS indicates an inconsistency between the number of groups for cross sections on the restart unit and the number of groups specified elsewhere.

KMSG274 ***** ERROR ***** K?-274 FOLLOWS: ___ ERROR(S) OCCURED WHILE READING ___. THE MESSAGES RECEIVED FROM ___ INPUT PROCESSOR ARE AS FOLLOWS:

This error message comes from subroutines READ_DEFINITIONS_INPUT, READ_STARMESH_INPUT, or MGRID type's CHECKGRIDDATA procedure, and it indicates an error in specifying the mesh grid for the problem. See Sect. 8.1.3.14 for more information about the specification of the mesh grid geometry.

KMSG275 ***** ERROR ***** K?-275 FOLLOWS: ADJOINT SOLUTIONS ARE CURRENTLY NOT AVAILABLE IN CONTINUOUS ENERGY PROBLEMS. IF ADJOINT SOLUTION IS DESIRED, THE USER SHOULD CHOOSE THE MULTIGROUP ENERGY TREATMENT

This message from subroutine DATAIN indicates the user turned on adjoint calculation (see parameter `ADJ` in Sect. 8.1.3.3) for a continuous energy problem. The current version of KENO does not have adjoint continuous energy cross sections. If adjoint solution is desired, the user should choose the multigroup energy treatment.

KMSG276 ***** ERROR ***** K?-276 FOLLOWS: DIFFERENTIAL ALBEDOS ARE CURRENTLY NOT AVAILABLE IN CONTINUOUS ENERGY PROBLEMS.

This message from subroutine DATAIN indicates the user entered differential albedos for a continuous energy problem. The current version of KENO does not have differential albedos for continuous energy treatment. The user should replace the albedo data with appropriate materials.

KMSG277 ***** ERROR ***** K6-277 FOLLOWS: THE UNIT ___ BOUNDARY RECORD CONTAINS MORE THAN ONE POSITIVE GEOMETRY RECORD LABEL

This KENO-VI message from subroutine SGGM_JOMCHK indicates that the unit reported has multiple geometry records defining the boundary. This unit is used in an array, so it is only allowed one boundary geometry record.

KMSG278 ***** ERROR ***** K6-278 FOLLOWS: TOO MANY ERRORS TRACING THROUGH THE GEOMETRY WHILE INTEGRATING VOLUMES.

This self-explanatory message is from subroutine SGGM_PATHVOLS, and it indicates that the problem is terminated because of errors. There should be error messages before this indicating what the problems are. Errors should be corrected and the problem resubmitted.

KMSG280 ***** ERROR ***** K6-280 FOLLOWS: ERROR IN PERIODIC BOUNDARY CONDITION - DENOMINATOR 0 A = ___ B = ___ C = ___ D = ___ E = ___ F = ___ G = ___ H = ___ I = ___ J = ___ U = ___ V = ___ W = ___ X = ___ Y = ___ Z = ___

This KENO-VI error message comes from subroutine PERIOD, and it indicates the problem with periodic boundary conditions. A-J are the coefficients of the relevant quadratic equation, U-W are the direction cosines, and X-Z is the point on the boundary. The denominator is $AU^2+BV^2+CW^2+DUV+EUW+FVW$.

KMSG283 ***** ERROR ***** K?-283 FOLLOWS: USER DID NOT PROVIDE A CROSS SECTION DIRECTORY FILE (CE_XXXX). A DIRECTORY FILE THAT CONTAINS THE DATA PATH AND THE CROSS SECTION ID RECORDS MUST BE PROVIDED.

This message from subroutines NUCLIDE_SETUP or PREMIX_SETUP indicates that the filename specified in the library name record is not valid (i.e., the file does not exist in the working directory) for calculations in the continuous energy mode. Links to SCALE-provided libraries are automatically created in the working directory. If one of the default files is being used, the file may not be accessible due to network problems, or access permissions. If it is a user-supplied directory file, it should be verified to exist in the SCALE temporary working directory.

KMSG287 ***** ERROR ***** K?-287 FOLLOWS: OUTGOING ANGLE COSINE ___ IS GREATER THAN 1

This message from subroutine ROTASZ indicates a problem with the angle cosine when calculating the particle velocity in the continuous energy mode. This error usually indicates a coding error. Please contact scalehelp@ornl.gov.

KMSG288 ***** ERROR ***** K?-288 FOLLOWS: SAMPLING PROBABILITY TABLE FOR NUCLIDE:___ ENERGY (EV): ___

This message from subroutine CETRANSPORT_TOTAL_XS_FROM_PTABLE is issued if the energy of the particle that is being tracked is higher than the maximum energy of the probabilities available in the probability table that is being sampled. This error may be due to data problems. Please contact scalehelp@ornl.gov.

KMSG290 ***** WARNING ***** K?-290 FOLLOWS: COULD NOT FIND TEMP:___ ON CROSS SECTION FILE. USING CLOSEST TEMPERATURE:___

This warning message from subroutine READ_XSEC is issued to indicate that the temperature selected was not found for the current nuclide and the continuous energy cross sections that are at the closest temperature will be used. This should only be issued with `DBX=0`, so the user has disabled problem-dependent Doppler broadening. See Sect. 8.1.3.3 or Sect. 8.1.7.2.19 for more information.

KMSG292 ***** ERROR ***** K?-292 FOLLOWS: PROBLEM IN SUBROUTINE SAMPLE_COLLISION AT: NEUTRON: ___ IZA: ___ MT: ___ EIN: ___ MINIMUM ENERGY:___ MAXIMUM ENERGY:___ LOCATION:___

This message from subroutine SAMPLE_COLLISION indicates the energy of the particle being tracked is outside the energy range of the selected reaction for the selected nuclide. The code will reset the particle's energy to correspond to one of the boundaries and will continue tracking. If this message is issued, it usually indicates a problem with the continuous energy cross sections. The problem is usually not severe and may be the result of round off. Please contact scalehelp@ornl.gov.

KMSG293 ***** ERROR ***** K?-293 FOLLOWS: PROBLEM IN SUBROUTINE SAMPLE_ENERGY AT: MT: ___ EIN: ___ EOUT: ___ LOCATION:___

This message from subroutines SAMPLE_COLLISION or SAMPLE_BETA indicates the energy of the particle being tracked is outside the energy range of the selected reaction for the selected nuclide. If this message is issued, it usually indicates a problem with the continuous energy cross sections. Please contact scalehelp@ornl.gov.

KMSG294 ***** WARNING ***** K?-294 FOLLOWS: UNIT ___ REGION ___ CONTAINS FISSIONABLE MATERIAL, BUT NO FISSIONS OCCURRED IN IT. THIS MAY MEAN THE PROBLEM WAS INADEQUATELY SAMPLED.

This message from subroutine KEDIT indicates some of the fissile regions are not adequately sampled. Depending on the problem, the calculated keff value may be too small. The problem should be run again with enough histories or start data to ensure that all regions are sampled adequately.

KMSG295 ***** WARNING ***** K?-295 FOLLOWS: THERE WERE ___ COLLISIONS THAT PRODUCED A NEUTRON WITH AN ENERGY OUTSIDE THE GROUP STRUCTURE YOU SELECTED. THESE WERE TALLIED INTO THE APPROPRIATE END GROUP. IF YOU WISH TO SEPARATE THESE NEUTRONS, ADD A GROUP ON EACH END WITH LIMITS CORRESPONDING TO THE CROSS SECTIONS.

This warning message from subroutine SAMPLE_ENERGY indicates the energy boundaries of the groups specified for tallying in the continuous energy mode does not cover the possible energy ranges of all reactions for all nuclides in the problem. Group energy boundaries must be adjusted.

KMSG296 ***** ERROR ***** K?-296 FOLLOWS: IT IS NOT POSSIBLE TO TURN OFF WRITING ARRAYS TO DIRECT ACCESS IN WRTICE.

This error message from subroutine WRITE_ICE indicates that the arrays must be saved in the direct access file.

KMSG297 ***** ERROR ***** K?-297 FOLLOWS: ENERGY BOUNDARIES MUST BE IN DESCENDING ORDER (EV). EB (___) = ___ IS GREATER THAN EB (___) = ___.

This error message from subroutine RDENER indicates the upper energy boundaries specified in the ENERGY data block are not in descending order. The upper energy boundary of the highest energy group (i.e., group 1) must be specified first and then successive energy groups with descending upper energy group boundaries must be specified until all groups are specified.

KMSG298 ***** ERROR ***** K?-298 FOLLOWS: CROSS SECTION FILE FOR NUCLIDE ___ HAS NO 2-D KINEMATICS DATA FOR THERMAL RANGE. THIS IS OK IF FREEGAS TREATMENT IS NOT TURNED OFF. FOR THIS PROBLEM, FREEGAS TREATMENT HAS BEEN TURNED OFF (FRE=NO IN PARAMETER DATA BLOCK). EITHER PROVIDE DATA THAT CONTAINS 2-D KINEMATICS FOR THERMAL RANGE OR TURN ON FREEGAS TREATMENT.

This message from subroutine READ_KINEMATICS indicates that no thermal scattering has been specified for the given nuclide. Data must be provided or free-gas scattering must be allowed.

KMSG299 ***** ERROR ***** K?-299 FOLLOWS: INVALID KEYWORD ___ IN THE ENERGY BOUNDARIES INPUT DATA.

This message from subroutine RDENER says that an invalid keyword was read while reading the energy boundaries for a continuous energy problem. The energy data block must be checked to correct the error. See Sect. 8.1.3.12 for more information.

KMSG300 ***** ERROR ***** K?-300 FOLLOWS: INVALID THERMAL CUTOFF VALUE ___ IN THE PARAMETERS BLOCK. THE CUTOFF VALUE MUST BE GREATER THAN ZERO.

The thermal cutoff value for a continuous energy problem must be greater than zero. The data must be corrected, and the problem rerun.

KMSG304 K?-304 ALTHOUGH THE STANDARD DEVIATION SPECIFIED FOR THE PROBLEM IS ACHIEVED, AT LEAST 50 OR NSK*2=___ ACTIVE GENERATIONS HAVE NOT BEEN RUN. EXECUTION WILL CONTINUE.

This message from GUIDE indicates that although the standard deviation asked for in the input has been achieved, too few generations have been run to get a fair value for the standard deviation, and more generations will be run.

KMSG305 ***** ERROR ***** K6-305 FOLLOWS: MESH FLUXES HAVE BEEN SPECIFIED, BUT THE MESH DOES NOT COMPLETELY COVER THE GEOMETRY. THE POINT X=___ Y=___ Z=___ LIES OUTSIDE THE MESH. THE PROBLEM WILL NOT BE RUN. FIX THE MESH AND RESUBMIT THE CASE.

This self-explanatory message comes from subroutines ACCUMULATETEMPVOLUMES and from PNTVOLS.

KMSG306 ***** ERROR ***** K?-306 FOLLOWS: UNIT ___ HAS BEEN DEFINED ___ TIMES. THIS BEHAVIOR IS NO LONGER ALLOWED AS IT COULD POTENTIALLY MISLEAD THE USERS. NOTE THAT DEFINING UNITS THAT ARE NOT USED IN THE PROBLEM IS STILL ALLOWED. IF DUPLICATE UNITS ARE KEPT FOR CONVENIENCE (E.G., SCOPING CALCULATIONS), THEN SIMPLY USE A UNIT NUMBER THAT IS UNIQUE AND IS NOT UTILIZED IN THE PROBLEM. THE PROBLEM WILL NOT BE RUN. REMOVE DUPLICATE DEFINITIONS AND RESUBMIT.

This self-explanatory message comes from subroutines K5GM_READGM and SGGM_READGM.

KMSG307 ***** ERROR ***** K?-307 FOLLOWS: INVALID KEYWORD ___ IN THE REACTIONS INPUT DATA.

This message comes from subroutine READ_REACTIONS_INPUT, and indicates that an invalid keyword was entered in the input. See Sect. 8.1.3.15 for valid reaction block input. The data must be corrected, and the problem resubmitted.

KMSG308 ***** ERROR ***** K?-308 FOLLOWS: THE USER ENTERED ___ FOR THE ___ NUMBER. ONLY LEGAL NUMBERS (>0) AND * (WILDCARD) ARE ALLOWED. THE PROBLEM WILL NOT BE RUN.

This message results from subroutine READENTRY, and it indicates invalid reaction input. See Sect. 8.1.3.15 for valid reaction block input; data must be corrected and resubmitted.

KMSG309 ***** ERROR ***** K?-309 FOLLOWS: REACTION TALLY CALCULATIONS ARE CURRENTLY ALLOWED FOR ONLY CE TRANSPORT.

This self-explanatory message printed by subroutine READ_REACTIONS_INPUT indicates that reaction tally calculations were requested when running KENO with multigroup transport mode. Currently, this capability is only available with continuous-energy transport mode.

KMSG312 ***** ERROR ***** K?-312 FOLLOWS: OBSOLETE PARAMETER (CXM). USE REACTION DATA BLOCK TO SPECIFY PARAMETERS FOR REACTION TALLY CALCULATIONS.

This self-explanatory message printed by subroutine PARAM indicates that `CXM` is no longer supported as a *user parameter*.

KMSG313 ***** ERROR ***** K?-313 FOLLOWS: INVALID COMPUTATIONAL MODE (CXM=___) FOR TALLYING REACTION CROSS SECTIONS FOR CE-DEPLETION. AVAILABLE MODES ARE: (1) ALL REACITONS, NGP GROUP, (2) TRANSMUATION REACTIONS, NGP GROUP, (3) ALL REACTIONS, 1 GROUP, (4) TRANSMUTATION REACTIONS, 1 GROUP.

This self-explanatory message printed by subroutine TESTREACTIONFLAGS indicates that invalid `CXM` parameter was provided by the sequence that runs KENO. This rare case might be encountered if the KENO restart file is corrupted. This error should be reported to scalehelp@ornl.gov.

KMSG314 ***** ERROR ***** K?-314 FOLLOWS: NO MESH FOUND FOR ___. A MESH GRID MUST BE DEFINED EITHER WITH THE PARAMETER MSH IN PARAMETER INPUT OR WITH A GRID SPECIFIED IN GRIDGEOMETRY DATA INPUT.

This self-explanatory message printed by subroutine ASSIGNGRIDTOMESHQUANTITY indicates that no mesh was entered with any input methods. The mesh quantity was activated with either `CDS=yes`, `GFX=yes`, `FIS=yes`, or `MFX=yes` parameters, but a mesh was not defined either with parameter `MSH` in the `parameter data` block or in the `gridgeometry data` block. The user should define a mesh using either input method for the tally requested and rerun the calculation.

KMSG315 ***** ERROR ***** K?-315 FOLLOWS: MESH < ___ > SPECIFIED FOR ___ IS NOT FOUND IN INPUT.

This self-explanatory message is printed by subroutine ASSIGNGRIDTOMESHQUANTITY. It indicates that the mesh assigned to the mesh quantity activated with either `CDS`, `GFX`, `FIS`, or `MFX` parameters was not entered in the `gridgeometry data` block. The user should either correct the mesh assignment or define a mesh for the tally requested, and then rerun the calculation.

KMSG316 ***** WARNING ***** K?-316 FOLLOWS: NO MESH PROVIDED FOR SOURCE CONVERGENCE DIAGNOSTICS (SCD). CONTINUE WITH DEFAULT MESH.

This self-explanatory message is printed by subroutine SETUPMESHPOINTERS if no mesh was assigned to Shannon entropy tally used for fission source convergence diagnostics tests with parameter `SCD` in the `parameter data` input block. KENO constructs a DEFAULT mesh and tally fission points on this mesh for Shannon entropy calculations.

KMSG319 ***** WARNING ***** K?-319 FOLLOWS: CFP WAS EITHER NOT SPECIFIED OR A NON-POSITIVE VALUE WAS ENTERED! THE CE TSUNAMI IFP METHOD REQUIRES A POSITIVE NUMBER OF LATENT GENERATIONS. CFP=5 WILL BE USED FOR THIS CALCULATION.

KMSG320 ***** WARNING ***** K?-320 FOLLOWS: CFP>10 DETECTED! THIS CE TSUNAMI IFP RUN MAY PRODUCE A LARGE MEMORY FOOTPRINT!

KMSG321 ***** WARNING ***** K?-321 FOLLOWS: CFP<0 DETECTED! AN F*(R) MESH WILL NOT BE USED FOR THIS CALCULATION. THIS CE TSUNAMI CLUTCH CALCULATION MAY NOT PRODUCE ACCURATE SENSITIVITIES.

KMSG322 ***** ERROR ***** K?-322 FOLLOWS: CFP IS GREATER THAN THE NUMBER OF ACTIVE GENERATIONS! CE TSUNAMI IFP SENSITIVITY TALLIES WILL NOT BE PERFORMED. CFP SHOULD BE << THE NUMBER OF ACTIVE GENERATIONS.

KMSG323 ***** ERROR ***** K?-323 FOLLOWS: CFP IS GREATER THAN THE NUMBER OF INACTIVE GENERATIONS! CE TSUNAMI F*(R) TALLIES CANNOT BE PERFORMED. CFP SHOULD BE << THE NUMBER OF INACTIVE GENERATIONS.

KMSG324 ***** ERROR ***** K?-324 FOLLOWS: NO F*(R) MESH GRID WAS SPECIFIED!

KMSG325 ***** WARNING ***** K?-325 FOLLOWS: ONLY ___ PARTICLE HISTORIES ARE BEING USED TO POPULATE F*(R) TALLIES PER F*(R) MESH INTERVAL. THIS MAY LEAD TO POORLY-CONVERGED F*(R) ESTIMATES AND INACCURATE SENSITIVITY COEFFICIENTS! AT LEAST 10-100 INACTIVE PARTICLE HISTORIES SHOULD BE SIMULATED PER MESH INTERVAL TO OBTAIN ACCURATE F*(R) SCORES.

KMSG326 ***** ERROR ***** K?-326 FOLLOWS: THE CE TSUNAMI IFP METHOD CANNOT BE EXECUTED IN PARALLEL.

This self-explanatory message is printed by subroutine INITIALIZE_SENSITIVITIES if CE TSUNAMI calculation with IFP sensitivity method was run in parallel. Execution is immediately terminated since MPI parallelism is not available with IFP sensitivity method.

KMSG327 ***** WARNING ***** K?-327 FOLLOWS: USER SET MAP-TO-UNION (M2U) TO ON. DOPPLER BROADENING IS ON BY DEFAULT (DBX=2), BUT CANNOT FUNCTION WITH MAP-TO-UNION. DOPPLER BROADENING HAS BEEN DISABLED.

This self-explanatory message is printed by subroutine PARAM if `M2U=yes` and `DBX=2` were set together. Note that `DBX` parameter is defaulted to 2; therefore, entering only `M2U=yes` also satisfies the condition that controls emitting this message. For such a case, KENO disables the Doppler Broadening temperature correction calculations when loading the nuclide cross section data in continuous-energy mode and continues the calculation. If data at the actual problem temperature are required in the calculations for a more realistic modeling, then it is recommended that the map-to-union capability be disabled by entering `M2U=no`.

KMSG328 ***** ERROR ***** K?-328 FOLLOWS: NO SOURCE ENTROPY CALCULATIONS! ALL FISSION SOURCE POINTS ARE OUTSIDE THE USER-DEFINED MESH.

This self-explanatory message is printed by subroutine MESHSRCTEST if no fission points were tallied on the user-defined mesh for three consecutive generations. This results in 0.0 entropy values for these generations. These results indicate that user-defined mesh covers only a part of geometry; i.e., the fissile regions are not covered properly with the user-defined mesh. Therefore, execution is terminated with this error message. To obtain better diagnostics information for the fission source convergence, it is highly recommended to define a mesh grid for Shannon entropy tally, and to be sure that defined mesh grid covers all fissile regions.

KMSG329 ***** ERROR ***** K?-329 FOLLOWS: NO SOURCE ENTROPY CALCULATIONS! ALL FISSION SOURCE POINTS ARE SCORED IN THE SAME MESH VOXEL. USER-DEFINED MESH FOR SOURCE CONVERGENCE DIAGNOSTICS DOES NOT ENCLOSE THE FISSILE REGIONS PROPERLY.

This self-explanatory message is printed by subroutine MESHSRCTEST if all fission points were tallied in a single mesh voxel for three consecutive generations. This results in 0.0 entropy values for these generations. These results indicate that the user-defined mesh does not enclose the fissile regions properly. Therefore, execution is terminated with this error message. To obtain better diagnostics information for the fission source convergence, it is highly recommended to define a mesh grid for Shannon entropy tally, and to be sure that defined mesh grid covers all fissile regions.

KMSG330 ***** WARNING ***** K?-330 FOLLOWS: DISABLING SOURCE ENTROPY CALCULATIONS. ALL FISSION SOURCE POINTS ARE SCORED IN THE SAME MESH VOXEL. THE DEFAULT MESH FOR SOURCE CONVERGENCE DIAGNOSTICS DOES NOT ENCLOSE THE FISSILE REGIONS PROPERLY.

This self-explanatory message from subroutine MESHSRCTEST indicates that for three consecutive generations, all fission points were tallied in a single mesh voxel; therefore, entropy for these three generations was calculated as 0.0. For such a case, KENO disables the Shannon entropy calculations and source convergence diagnostics tests and continues calculation.

The default mesh constructed by KENO ideally covers the geometry completely. This result implies that either all fissile regions are confined in a single mesh voxel (i.e., fissile regions are relatively small compared with the entire problem geometry), or fissile regions are weakly coupled, and source neutrons have been started in one side. To obtain better diagnostics information for the fission source convergence, it is highly recommended to define a mesh grid for Shannon entropy tally, and to be sure that defined mesh grid covers the entire fissile regions.

KMSG331 ***** WARNING ***** K?-331 FOLLOWS: ALL FISSION SOURCE POINTS ARE OUTSIDE OF THE USER-DEFINED MESH.

This self-explanatory message is printed by subroutine MESHSRCTEST if none of the fission points have been tallied on the user-defined mesh for the current generation. This indicates that user-defined mesh does not cover the problem geometry completely (especially all fissile regions), and Shannon entropy for the current generation is calculated as 0.0. Although the same message may not be printed for other generations if there are some fission points scored on this mesh, this does not change the fact that the mesh was not defined properly for Shannon entropy calculations. This will result in incorrect interpretation of the fission source convergence tests.

KMSG332 ***** WARNING ***** K?-332 FOLLOWS: MESH FLUXES HAVE BEEN SPECIFIED, BUT CE TSUNAMI DOES NOT ALLOW MESH FLUX USAGE. CONTINUE CALCULATIONS WITH DISABLING MESH FLUXES.

KMSG333 ***** ERROR ***** K?-333 FOLLOWS: THE NUMBER OF GENERATIONS SKIPPED MUST BE LESS THAN THE NUMBER OF GENERATIONS TO BE RUN. NSK=___ - GEN=___. THE CASE WILL NOT BE RUN.

This self-explanatory message from subroutine PARAM indicates that the number of generations to be run (`GEN`) is always greater than the number of generations skipped (`NSK`). If only `GEN` is entered in the parameter data block, then its value must be greater than the default `NSK` value, which is 3. If only `NSK` is entered in the parameter data block, then its value must be less than the default `GEN` value, which is 203.

KMSG334 ***** ERROR ***** K?-334 FOLLOWS: UNABLE TO CREATE A WEIGHTED LIBRARY. CODE COULD NOT INITIALIZE AMPX WORKING LIBRARY TO WRITE REACTION CROSS SECTIONS IN CE DEPLETION CALCULATIONS. CE DEPLETION CALCULATIONS WILL BE TERMINATED.

Internal code error when running KENO as part of TRITON sequence. This error should be reported to scalehelp@ornl.gov.

KMSG335 ***** ERROR ***** K?-335 FOLLOWS: UNABLE TO ADD NUCLIDE ___ TO THE WEIGHTED LIBRARY. CE DEPLETION CALCULATIONS WILL BE TERMINATED.

Internal code error when running KENO as part of TRITON sequence. This error should be reported to scalehelp@ornl.gov.

KMSG336 ***** ERROR ***** K?-336 FOLLOWS: UNABLE TO GET NEUTRON 1D CROSS SECTION FOR THE REACTION, MT=___. CE DEPLETION CALCULATIONS WILL BE TERMINATED.

Internal code error when running KENO as part of TRITON sequence. This error should be reported to scalehelp@ornl.gov.

KMSG337 ***** ERROR ***** K?-337 FOLLOWS: UNABLE TO CREATE A NEUTRON 1D CROSS SECTION FOR THE WEIGHTING LIBRARY. CE DEPLETION CALCULATIONS WILL BE TERMINATED.

Internal code error when running KENO as part of TRITON sequence. This error should be reported to scalehelp@ornl.gov.

KMSG338 ***** ERROR ***** K?-338 FOLLOWS: ERROR OCCURED WHILE WRITING WEIGHTED LIBRARY, RETURN CODE=___. CE DEPLETION CALCULATIONS WILL BE TERMINATED.

Internal code error when running KENO as part of TRITON sequence. This error should be reported to scalehelp@ornl.gov.

KMSG339 ***** ERROR ***** K?-339 FOLLOWS: UNABLE TO INITIALIZE OBJECT FOR ENERGY BOUNDS FOR THE WEIGHTING LIBRARY. CE DEPLETION CALCULATIONS WILL BE TERMINATED.

Internal code error when running KENO as part of TRITON sequence. This error should be reported to scalehelp@ornl.gov.

KMSG340 ***** ERROR ***** K?-340 FOLLOWS: UNABLE TO INITIALIZE HEADER OBJECT FOR THE WEIGHTING LIBRARY. CE DEPLETION CALCULATIONS WILL BE TERMINATED.

Internal code error when running KENO as part of TRITON sequence. This error should be reported to scalehelp@ornl.gov.

KMSG341 ***** ERROR ***** K?-341 FOLLOWS: DATA ENTERED TO THE REACTION BLOCK WITHOUT CALCULATION MODE. CALCULATION MODE SHOULD BE ENTERED IN REACTION BLOCK WITH ONE OF THE FOLLOWING KEYWORDS: (1) XS/XSTALLY=YES, (2) RX/RRTALLY=YES, (3) CEDEPL=YES, AND/OR, (4) MIXFLX=YES.

This continuous-energy–specific self-explanatory message is printed by subroutine READ_REACTIOS_INPUT if the data entered in `reaction data` block do not include any information for the calculation mode. The valid keywords to set the calculations modes are `XS` or `XSTALLY` for micro reaction cross section calculations, `RX` or `RRTALLY` for reaction tally calculations, `CEDEPL` for both mixture flux and reaction cross section calculations, and `MIXFLX` for mixture flux calculations. At least one of the listed calculation modes above must be entered for a successful calculation.

KMSG342 ***** WARNING ***** K?-342 FOLLOWS: REACTION BLOCK IS CURRENTLY ALLOWED FOR ONLY CE TRANSPORT. SKIP READING DATA FROM REACTION BLOCK.

This self-explanatory message is printed by subroutine READ_REACTIOS_INPUT if a `reaction data` block was entered in a multigroup problem. The `reaction data` block will not function when KENO is run in multigroup mode. Use KMART5 or KMART6 to generate reaction rates when running KENO in multigroup mode.

KMSG346 ***** ERROR ***** K?-346 FOLLOWS: ERROR IN MIXTURE ENTRY IN REACTION BLOCK. MIXTURE NUMBER (MIX=___) SPECIFIED IN REACTION BLOCK IS NOT USED IN THE PROBLEM.

This self-explanatory message is printed by CHECKDATA procedure of REACTIONFILTERS type if the user set up a reaction filter for a non-existing MIXTURE in the problem.

KMSG347 ***** ERROR ***** K?-347 FOLLOWS: ERROR IN NUCLIDE ENTRY IN REACTION BLOCK. NUCLIDE ___[MIXTURE = ___] SPECIFIED IN REACTION BLOCK IS NOT FOUND IN THE MIXING TABLE.

This self-explanatory message is printed by CHECKDATA procedure of REACTIONFILTERS if the user set up a reaction filter with a NUCLIDE and MIXTURE pair where the MIXTURE does not contain this NUCLIDE. Defining a reaction filter with non-existing nuclide results in a code termination.

KMSG348 ***** WARNING ***** K?-348 FOLLOWS: SPECIFIED REACTION IS NOT AVAILABLE IN CE DATA LIBRARY FOR THE GIVEN NUCLIDE. PERFORM REACTION TALLY CALCULATIONS BY SKIPPING THIS REACTION MT=___ FOR THE GIVEN NUCLIDE, ___.

This message is printed by CHECKDATA procedure of REACTIONFILTERS if the nuclide reaction data requested by the NUCLIDE and MT pairs have not been found in the continuous-energy data library. Note that KENO loads 1D neutron reaction data for all nuclides defined in the problem (MT < 150). This message implies that these reaction data are not a valid reaction for the given nuclide; therefore, it is not provided as part of ENDF data, and it is also not included in the AMPX processed continuous-energy data libraries. If data for this nuclide reaction exist in ENDF and the nuclide cross section file being used is a standard file that is part of an official and current SCALE system, then potentially please contact scalehelp@ornl.gov.

KMSG349 ***** WARNING ***** K?-349 FOLLOWS: A CE TSUNAMI F*(R) MESH PRINT (FST=YES) WAS REQUESTED BUT AN F*(R) MESH IS NOT BEING USED.

KMSG350 ***** ERROR ***** K?-350 FOLLOWS: A FISSION NEUTRON WAS BORN OUTSIDE OF THE F*(R) MESH AT POSITION: X =___ Y =___ Z =___ THE F*(R) MESH MUST ENCOMPASS ALL FISSILE MATERIAL IN THE SYSTEM.

KMSG351 ***** ERROR ***** K?-351 FOLLOWS: MISSING REACTION MT SPECIFICATION IN REACTION BLOCK (MT).

This message is printed by subroutine READ_REACTIONS_INPUT for only continuous-energy calculations. It indicates that reaction MT was not defined in one of the reactions filter entries. See Sect. 8.1.3.15 for valid reaction block input. The data must be corrected, and the problem resubmitted.

KMSG352 ***** ERROR ***** K?-352 FOLLOWS: MISSING NUCLIDE SPECIFICATION IN REACTION BLOCK (NUC).

This message is printed by subroutine READ_REACTIONS_INPUT for only continuous-energy calculations. It indicates that nuclide(s) were not defined in one of the reactions filter entries. See Sect. 8.1.3.15 for valid reaction block input. The data must be corrected, and the problem resubmitted.

KMSG353 ***** ERROR ***** K?-353 FOLLOWS: MISSING MIXTURE SPECIFICATION IN REACTION BLOCK (MIX).

This message is printed by subroutine READ_REACTIONS_INPUT for only continuous-energy calculations. It indicates that mixture(s) were not defined in one of the reactions filter entries. See Sect. 8.1.3.15 for valid reaction block input. The data must be corrected, and the problem resubmitted.

KMSG354 ***** ERROR ***** K?-354 FOLLOWS: ERROR IN REACTION BLOCK. NUMBER OF ENERGY GROUPS (___) AND ENERGY BOUNDS (___) DO NOT AGREE. NUMBER OF ENERGY GROUPS ____ = ___, NUMBER OF ENERGY INTERVAL = ___.

This continuous-energy mode–specific message from subroutine READ_REACTIONS_INPUT indicates that either `ngp_xs` and entries in `ener_xs`, or `ngp_flx` and entries in `ener_flx` are not consistent.

KMSG355 ***** ERROR ***** K?-355 FOLLOWS: CE TSUNAMI GPT SYSTEMRESPONSES MAY ONLY CONTAIN ONE NUMERATOR RESPONSE.

KMSG356 ***** ERROR ***** K?-356 FOLLOWS: CE TSUNAMI GPT SYSTEMRESPONSES MAY ONLY CONTAIN ONE DENOMINATOR RESPONSE.

KMSG357 ***** ERROR ***** K?-357 FOLLOWS: DEFINITION NUMBER ___ IN SYSTEMRESPONSE ___ WAS NOT FOUND.

KMSG358 ***** ERROR ***** K?-358 FOLLOWS: NO GPT DEFINITIONS WERE READ FOR THIS CE TSUNAMI GPT CALCULATION.

KMSG359 ***** ERROR ***** K?-359 FOLLOWS: NO GPT SYSTEMRESPONSES WERE READ FOR THIS CE TSUNAMI GPT CALCULATION.

KMSG360 ***** ERROR ***** K?-360 FOLLOWS: DEFINITION NUMBER ___ CONTAINS AN EHIGH THAT IS NOT LESS THAN ITS ELOW.

KMSG361 ***** WARNING ***** K?-361 FOLLOWS: CFP WAS NOT SPECIFIED! FOR THE BEST RESULTS, THE CE TSUNAMI CLUTCH F*(R) METHOD REQUIRES A POSITIVE NUMBER OF LATENT GENERATIONS. CFP=5 WILL BE USED FOR THIS CALCULATION.

KMSG362 ***** WARNING ***** K?-362 FOLLOWS: TEMPERATURE:___ IS WITHIN 4 K OF CLOSEST LIBRARY TEMPERATURE. USING REFERENCE TEMPERATURE: ___.

This message from subroutine READ_XSEC indicates that when Doppler Broadening temperature correction is applied, the nuclide cross section data are loaded at the library reference temperature, which is within 4 K of the given temperature.

KMSG363 ***** WARNING ***** K?-363 FOLLOWS: TEMPERATURE:___ IS ___ REFERENCE LIBRARY TEMPERATURE. USING REFERENCE TEMPERATURE:___.

This message from subroutine READ_XSEC indicates that when Doppler Broadening temperature correction is applied, (1) minimum library temperature is always used if the given temperature is less than this minimum, or (2) maximum library temperature is used if the given temperature is greater than this maximum.

KMSG364 ***** WARNING ***** K?-364 FOLLOWS: AN ENERGY GRID WAS ENTERED THAT DOES NOT COVER ALL POSSIBLE NEUTRON ENERGIES, AS IS REQUIRED BY CE TSUNAMI-3D. THE MIN AND MAX BOUNDS OF THIS ENERGY GRID WERE AUTOMATICALLY EXTENDED TO ___ EV AND ___ EV.

KMSG365 ***** WARNING ***** K?-365 FOLLOWS: DEFINITION NUMBER ___ REFERENCES A REACTION THAT IS NOT SUPPORTED BY EHIGHTRANSFER OR ELOWTRANSFER.

KMSG366 ***** ERROR ***** K?-366 FOLLOWS: DEFINITION NUMBER ___ CONTAINS AN EHIGHTRANSFER THAT IS NOT LESS THAN ITS ELOWTRANSFER.

KMSG367 ***** ERROR ***** K?-367 FOLLOWS: DBRC PARAMETER (DBR=___) IS NONZERO BUT COULD NOT FIND DBRC DATA IN CE DATA LIBRARY FOR ANY NUCLIDE.

This message is printed by subroutine NUCLIDE_SETUP if no DBRC data are available in the given continuous-energy data library. Access permissions, network problems, and typographical errors in the input file should be verified. If the nuclide cross section file being used is a standard file that is part of an official and current SCALE system, then please contact scalehelp@ornl.gov.

KMSG368 ***** ERROR ***** K?-368 FOLLOWS: PARAMETER, THC, IS NO LONGER SUPPORTED IN THE ENERGY DATA BLOCK. PLEASE MOVE THIS PARAMETER TO THE PARAMETERS BLOCK.

This self-explanatory message is printed by subroutine RDENER if `THC` parameter was entered in the energy data block. This parameter is no longer supported as part of the energy data block. This issue must be corrected by defining `THC` parameter in the parameter block rather than in the energy block, and then rerun the problem.

KMSG369 ***** WARNING ***** K?-369 FOLLOWS: PARAMETER THC SPECIFIED BUT WILL BE IGNORED SINCE THIS IS NOT A CE CALCULATION.

This self-explanatory message is from subroutine KENOBUILDER, and it notifies that the defined `THC` parameter is not a valid multigroup parameter; therefore, it will be ignored in the multigroup calculations.

KMSG370 ***** WARNING ***** K?-370 FOLLOWS: MESH VOLUME CALCULATION TYPE=___ IS NOT YET AVAILABLE. THE TYPE IS CHANGED TO RANDOM. BE SURE TO VERIFY THAT THE VOLUMES HAVE BEEN CALCULATED ADEQUATELY.

This self-explanatory message is from subroutine RDVOL, and it indicates that mesh volume calculation is always performed with `RANDOM` estimates. Methods other than `RANDOM` estimates defined in input are always ignored by KENO codes, and the volume calculation method is defaulted to `RANDOM` estimates.

KMSG371 ***** ERROR ***** K6-371 FOLLOWS: KENO-VI GEOMETRY PROCESSOR ALLOWS MAXIMUM SIX CHORD MODIFIER OF ANY TYPE WHEN TRUNCATING A PRE-DEFINED SHAPE. THERE ARE MORE THAN SIX CHORD MODIFIERS ON THE SHAPE, ___ ___, IN UNIT ___.

This self-explanatory KENO-VI message is printed by subroutine SGGM_KENOG if more than the supported number of `CHORD` modifiers were defined on the given shape in the specified unit.

KMSG372 ***** WARNING ***** K?-372 FOLLOWS: ___ POSITIONS HAVE F*(R) MESH TALLIES OF 0.0; A VALUE OF 1.0 WILL BE USED IN THE SENSITIVITY CALCULATIONS.

KMSG373 ***** ERROR ***** K?-373 FOLLOWS: INVALID NGP PARAMETER, (NGP=___). NGP MUST BE A POSITIVE INTEGER.

This self-explanatory continuous-energy mode–specific message from subroutine DATAIN is caused by an invalid **NGP** entry in the parameter data block. The number of energy groups is always a positive integer number.

KMSG374 ***** WARNING ***** K?-374 FOLLOWS: NO ENERGY BOUNDARIES SPECIFIED. DEFAULT ENERGY GROUP BOUNDARIES USED FOR TALLYING WILL BE OBTAINED FROM ___-GROUP SCALE MULTI GROUP LIBRARY.

This self-explanatory message from subroutine DATAIN indicates no energy boundaries were specified with any input method in the continuous-energy calculations. KENO codes always need a set of energy boundaries for tallying. For such a case, KENO codes acquire the energy group boundaries from the 252-group SCALE multigroup library and continue calculation.

KMSG375 ***** WARNING ***** K?-375 FOLLOWS: NGP PARAMETER WILL BE IGNORED SINCE THE ENERGY GROUP BOUNDARIES HAS ALREADY BEEN READ FROM ENERGY DATA BLOCK. NGP VALUE PRINTED IN NUMERIC PARAMETERS EDIT IN THE OUTPUT REFLECTS THIS UPDATE.

This self-explanatory message from subroutine DATAIN indicates that data provided by another input method (energy data block) will override the number of energy group value entered by `NGP` parameter.

KMSG376 ***** WARNING ***** K?-376 FOLLOWS: NGP PARAMETER WILL BE IGNORED SINCE IT IS NOT A VALID PARAMETER FOR MULTI GROUP TRANSPORT.

This self-explanatory message coming from subroutine DATAIN indicates that the multigroup calculation does not process `NGP` parameter that is dedicated for continuous-energy calculations.

KMSG377 ***** WARNING ***** K?-377 FOLLOWS: ENERGY DATA BLOCK IS CURRENTLY ALLOWED FOR ONLY CONTINUOUS ENERGY TRANSPORT. SKIP READING DATA FROM ENERGY DATA BLOCK.

This self-explanatory message from RDENER indicates that the multigroup calculation does not process data in the energy data input block since it is dedicated for continuous-energy calculations.

KMSG378 ***** WARNING ***** K?-378 FOLLOWS: IN MULTI GROUP MODE, DEFAULT ENERGY BOUNDARIES USED FOR TALLYING ARE ALWAYS OBTAINED FROM THE MULTI GROUP LIBRARY USED BY TRANSPORT.

This self-explanatory message from subroutine UPDATE_EBOUNDS_MG_MODE reminds that multigroup mode acquires the energy group structure from the multigroup library used by transport process, and it uses these energy boundaries in all tallies if not otherwise requested.

KMSG379 ***** WARNING ***** K?-379 FOLLOWS: NGP PARAMETER WILL BE IGNORED SINCE ENERGY GROUP BOUNDARIES HAS ALREADY BEEN READ FROM ENERGY DATA BLOCK. NGP VALUE PRINTED IN NUMERIC PARAMETERS EDIT IN THE OUTPUT MAY NOT REFLECT THIS UPDATE. FINAL NGP VALUE IS CORRECTLY PRINTED IN ADDITIONAL INFORMATION EDIT (SHOWN AS NUMBER OF ENERGY GROUPS).

This self-explanatory message from subroutine DATAIN reminds that energy boundaries were read from the energy data block and **NGP** value printed in different output edits might not be updated accordingly. Update methods for data used in the output edits, and/or order of output editing might show some minor differences depending on how KENO is run (e.g., running KENO as stand-alone, running KENO through a SCALE sequence, running KENO through a SCALE sequence with parm=check).

KMSG380 ***** WARNING ***** K6-380 FOLLOWS: CALCULATED VOLUME FRACTION OF FISSILE MATERIAL IN THE SYSTEM REPORTED BELOW MAY NOT REFLECT THE ACTUAL VALUE SINCE SOME REGION VOLUMES WERE NEITHER SPECIFIED NOR CALCULATED. EVEN NEGATIVE VOLUME FRACTION FOR FISSILE MATERIAL MAY BE REPORTED SINCE ALL UNDEFINED VOLUMES WERE SET TO -1.0.

This self-explanatory KENO-VI message is printed by subroutine K6_VOLFIS. It notifies that the fraction of the fissile material might be calculated as negative numbers if there is a missing region volume data. When volumes are not entered, not calculated, or calculated as zero, KENO resets their values to -1.0. Therefore, missing volumes might result in incorrect volume fraction calculation for the fissile materials.

KMSG381 ***** WARNING ***** K?-381 FOLLOWS: IN MULTI GROUP MODE, DEFAULT ENERGY BOUNDARIES USED FOR TALLYING ARE ALWAYS OBTAINED FROM THE MULTI GROUP LIBRARY USED BY TRANSPORT. NGP VALUE PRINTED IN NUMERIC PARAMETERS EDIT IN THE OUTPUT MAY NOT REFLECT THIS. FINAL NGP VALUE IS CORRECTLY PRINTED IN ADDITIONAL INFORMATION EDIT (SHOWN AS NUMBER OF ENERGY GROUPS).

This self-explanatory message is multigroup mode–specific and comes from subroutine DATAIN. It indicates that the default energy group structure used for all tallies are always acquired from the library used by transport process in multigroup calculations. The `NGP` value printed in different output edits might not be updated accordingly. Update methods for data used in the output edits, and/or order of output editing, might show some minor differences depending on how KENO is run (e.g., running KENO as standalone, running KENO through a SCALE sequence, running KENO through a SCALE sequence with parm=check).

KMSG383 ***** WARNING ***** K?-383 FOLLOWS: ENERGY GROUP BOUNDARIES READ FROM ENERGY DATA BLOCK OVERRIDE THE DEFAULT NGP VALUE (252). NGP VALUE PRINTED IN NUMERIC PARAMETERS EDIT IN THE OUTPUT MAY NOT REFLECT THIS UPDATE. THE FINAL NGP VALUE IS CORRECTLY PRINTED IN ADDITIONAL INFORMATION EDIT (SHOWN AS NUMBER OF ENERGY GROUPS).

This self-explanatory message is specific to continuous-energy mode, and it is printed by subroutine DATAIN when running KENO standalone or through a sequence with PARM=CHECK. The `NGP` value printed in different output edits might not be updated accordingly.

KMSG384 ***** ERROR ***** K?-384 FOLLOWS: SPECIFICATION OF ENERGY BOUNDARIES WITH BOTH ENERGY DATA BLOCK AND DEFINITIONS DATA BLOCK IS NOT ALLOWED.

This self-explanatory message is printed by subroutine READ_DEFINITIONS_INPUT when running KENO as part of a SCALE sequence (CSAS, TRITON). It indicates that energy boundaries were specified with both `CSAS definitions data` and `KENO energy data` blocks, and this is illegal.

KMSG385 ***** ERROR ***** K?-385 FOLLOWS: ___ IS NOT ALLOWED TO BE USED TOGETHER WITH THE DATA SPECIFIED IN ___ BLOCK.

This message from subroutine READ_DEFINITIONS_INPUT is caused by using both old and new input definition methods when running KENO as part of either CSAS or TRITON sequence to activate some of the KENO capabilities. For example, specifying the fission rate mesh tally with `FIS` parameter in KENO parameter data block (old method, activate

capability with a single parameter) together with specifying fission source accumulation in `CSAS tallies data` block is not allowed.

KMSG386 ***** ERROR ***** K?-386 FOLLOWS: INCONSISTENT ENERGY BOUNDARIES. THE SIZE OF ENERGY BOUNDARIES SPECIFIED IN DEFINITIONS DATA WITH THE IDENTIFICATION NUMBER, ___, MUST BE LESS THAN THE SIZE OF THE DEFAULT ENERGY BOUNDARIES ACQUIRED FROM THE MULTI GROUP LIBRARY USED BY TRANSPORT, (___ > ___).

This message is specific to multigroup mode and emitted from subroutine VALIDATE_ENERGY_INTERVALS to explain that energy boundaries specified in `CSAS definitions data` block are not consistent with the DEFAULT energy group structure (or energy boundaries) obtained from the library used by transport process. Multiple energy group structures for tallying are supported in KENO, even for multigroup mode. However, in multigroup mode, each group structure must be a subset of the DEAFAULT energy boundaries acquired from the multigroup library used in the neutron transport. Therefore, the size of a group structure defined in `CSAS definition data` block cannot be larger than the DEFAULT energy boundaries.

KMSG387 ***** ERROR ***** K?-387 FOLLOWS: INCONSISTENT ENERGY INTERVALS. ALTHOUGH THEIR SIZE MATCH, ENERGY BOUNDARIES SPECIFIED IN DEFINITIONS DATA WITH IDENTIFICATION NUMBER, ___, DEFINE DIFFERENT ENERGY INTERVALS COMPARED TO THE DEFAULT ENERGY BOUNDARIES ACQUIRED FROM MULTI GROUP LIBRARY USED BY TRANSPORT.

This message is specific to multigroup mode and emitted from subroutine VALIDATE_ENERGY_INTERVALS to explain that energy boundaries specified in `CSAS definitions data` block are not consistent with the DEFAULT energy group structure (or energy boundaries) obtained from the library used by transport process. Multiple energy group structures for tallying are supported in KENO, even for multigroup mode. However, in multigroup mode, each group structure must be a subset of the DEFAULT energy boundaries acquired from the multigroup library used in the neutron transport. Therefore, the energy intervals defined in `CSAS definition data` block must be the same as the DEFAULT energy boundaries if their sizes are equal.

KMSG388 ***** ERROR ***** K?-388 FOLLOWS: INCONSISTENT ENERGY INTERVALS. ENERGY BOUNDARIES SPECIFIED IN DEFINITIONS DATA WITH THE IDENTIFICATION NUMBER ___ MUST BE A SUBSET OF THE DEFAULT ENERGY BOUNDARIES ACQUIRED FROM THE MULTI GROUP LIBRARY USED BY TRANSPORT.

This message is specific to multigroup mode and emitted from subroutine VALIDATE_ENERGY_INTERVALS to indicate that energy boundaries specified in `CSAS definitions data` block are not consistent with the DEFAULT energy group structure (or energy boundaries) obtained from the library used by transport process. Multiple energy group structures for tallying are supported in KENO. However, in multigroup mode, each group structure must be a subset of the DEFAULT energy boundaries acquired from the multigroup library used in the neutron transport.

KMSG389 ***** ERROR ***** K?-389 FOLLOWS: ENERGY BOUNDARIES SPECIFIED IN DEFINITIONS DATA WITH THE IDENTIFICATION NUMBER ___ MUST BE IN DESCENDING ORDER (EV). EB (___) = ___ IS GREATER THAN OR EQUAL TO EB(___) = ___.

This message is emitted from subroutine VALIDATE_ENERGY_INTERVALS to indicate that energy boundaries defined either with **KENO energy data** or **CSAS definitions data** blocks were not in descending order. KENO always expects the energy points entered in descending order.

KMSG390 ***** ERROR ***** K?-390 FOLLOWS: IDENTIFICATION NUMBER ___ WAS USED MORE THAN ONCE WHEN SPECIFYING ENERGY BOUNDARIES IN DEFINITIONS DATA.

This self-explanatory message is printed by eBounds_type's ADD procedure when running KENO as part of CSAS or TRITON sequences. It indicates that identification numbers must be unique entries, and using the same identification number multiple times for different energy boundaries definitions is an illegal operation.

KMSG391 ***** ERROR ***** K?-391 FOLLOWS: MESH TALLY IDENTIFICATION NUMBER ___ WAS USED MORE THAN ONCE WHEN SPECIFYING MESH TALLY IN TALLIES BLOCK.

This self-explanatory message is printed by subroutine TALLIES_TYPE_ADD_MESH_TALLY when running KENO as part of CSAS or TRITON sequences. It indicates that identification numbers must be unique entries and using the same identification number multiple times for different mesh tallies is an illegal operation.

KMSG392 ***** ERROR ***** K?-392 FOLLOWS: MESH TALLIES ___ AND ___ SPECIFIED IN TALLIES BLOCK HAVE IDENTICAL DEFINITIONS.

This self-explanatory message is printed by subroutine TALLIES_TYPE_ADD_MESH_TALLY when running KENO as part of CSAS or TRITON sequences. It indicates that the same mesh tally was defined two times in the tallies data block. This is considered a potential user error: therefore, calculation is terminated.

KMSG393 ***** ERROR ***** K?-393 FOLLOWS: BAD VALUE FOR KEYWORD MESH TALLY, NEEDS AN IDENTIFICATION NUMBER.

This message from subroutine READ_MESH_TALLY_INPUT when running KENO as part of CSAS or TRITON sequences indicates that the mesh tally identification number either was not entered or was defined as a non-integer number.

KMSG394 ***** ERROR ***** K?-394 FOLLOWS: INVALID MESHTALLY IDENTIFIER, ___, IN TALLIES BLOCK. IDENTIFICATION NUMBER MUST BE A POSITIVE INTEGER.

This message from subroutine READ_MESH_TALLY_INPUT when running KENO as part of CSAS or TRITON sequences indicates that mesh tally identification number is not a positive integer number.

KMSG395 ***** ERROR ***** K?-395 FOLLOWS: ___ – ENDED WITH – END ___ –.

This message is printed by subroutine READ_MESH_TALLY_INPUT when running KENO as part of CSAS or TRITON sequences if `READ TALLIES` is not ended with `END TALLIES`, or `READ MESH` is not ended with `END MESH`.

KMSG396 ***** ERROR ***** K?-396 FOLLOWS: INVALID RESPONSE TYPE, ___. ONLY [FLUX, FISSION_DENSITY, FISSION_SOURCE] ARE THE VALID RESPONSE TYPES.

This message printed by subroutine READ_MESH_TALLY_INPUT when running KENO as part of CSAS or TRITON sequences if the mesh tally calculation was requested with an invalid response type.

KMSG397 ***** ERROR ***** K?-397 FOLLOWS: INVALID ENERGY IDENTIFICATION NUMBER (ENERGY= ___) IN MESH TALLY ___ IN TALLIES BLOCK. IDENTIFICATION NUMBER MUST BE A POSITIVE INTEGER OR DEFAULT.

This message printed by subroutine READ_MESH_TALLY_INPUT when running KENO as part of CSAS or TRITON sequences is caused by an invalid identification number that was entered as the energy identifier in tallies data block.

KMSG398 ***** ERROR ***** K?-398 FOLLOWS: SPECIFICATION OF ENERGY BOUNDARIES WITH BOTH NGP PARAMETER AND DEFINITIONS DATA IS NOT ALLOWED.

This self-explanatory message printed by subroutine READ_DEFINITIONS_INPUT when running KENO as part of CSAS or TRITON sequences indicates that energy boundaries cannot be specified by using the old input specification method (`NGP` parameter) and new input specification methods (`energybounds` in CSAS definition data block) together.

KMSG399 ***** ERROR ***** K?-399 FOLLOWS: INVALID ENERGY BOUNDS SPECIFICATIONS WITH IDENTIFICATION NUMBER ___; ALL ENERGY POINTS ARE IDENTICAL.

This self-explanatory message is printed by eBounds_type's ADD procedure when running KENO as part of CSAS or TRITON sequences. It indicates that defined energy boundaries cannot be used for tallying since all energy points were entered as the same.

KMSG400 ***** WARNING ***** K?-400 FOLLOWS: IGNORE READING ENERGY GROUP BOUNDARIES FROM DEFINITIONS DATA THAT ARE MARKED AS DEFAULT SINCE THIS IS A MULTI GROUP CALCULATION.

This self-explanatory message is printed by eBounds_type's ADD procedure when running KENO as part of CSAS or TRITON sequences. It notifies that DEFAULT energy group structure acquired from the library used in the neutron transport cannot be overridden by the energy boundaries data in **CSAS definitions data** block.

KMSG401 ***** WARNING ***** K?-401 FOLLOWS: IDENTICAL ENERGY BOUNDARIES WERE SPECIFIED IN DEFINITIONS DATA WITH IDENTIFICATION NUMBERS ___ AND ___. ONLY ONE OF THEM WILL BE PROCESSED AND STORED FOR THE CALCULATIONS.

This self-explanatory message is printed by eBounds_type's ADD procedure when running KENO as part of CSAS or TRITON sequences. It notifies that two sets of energy boundaries defined in **CSAS definitions data** block have the identical specifications. KENO only processes one of them and stores it in energy data container for tallying. It updates energy bound pointers for the tallies if they are defined to use the energy bounds not stored.

KMSG403 ***** ERROR ***** K?-403 FOLLOWS: ENERGY BOUNDARIES (ENERGY=___) SPECIFIED IN ___ ___ IN TALLIES BLOCK IS NOT FOUND IN THE DEFINITIONS DATA INPUT BLOCK.

This self-explanatory message is printed by VALIDATE_ENERGY_BOUNDS_ID procedure when running KENO as part of CSAS or TRITON sequences. It indicates that the energy boundaries were not entered in **CSAS definitions data** block even though it was intended to be used with a mesh tally calculation defined in **CSAS tallies data** block.

KMSG404 ***** ERROR ***** K?-404 FOLLOWS: SPECIFICATION OF MESH GRIDS WITH BOTH GRIDGEOMETRY DATA INPUT AND GRIDGEOMETRY IN DEFINITIONS DATA IS NOT ALLOWED.

This self-explanatory message is emitted by subroutine READ_DEFINITIONS_INPUT when running KENO as part of a SCALE sequence (CSAS, TRITON). It indicates that mesh grids were specified with both **CSAS definitions data** and **KENO gridgeometry data** blocks, and this is not allowed.

KMSG405 ***** WARNING ***** K?-405 FOLLOWS: WARNING MESSAGES EMITTED BY ___ INPUT PROCESSOR ARE AS FOLLOWS:

KENO and MONACO use the same legacy input parser to process the data entered in **definitions data** block. This common utility has its own messaging method, which accumulates all user error and warning messages encountered while processing data, then forwards them to the caller who runs this utility. Warning messages from this utility are filtered and printed with this message by READ_DEFINITIONS_INPUT to notify user about the possible issues in the input. Note that this message is only emitted when running KENO as part of a SCALE sequence (CSAS, TRITON).

KMSG406 ***** ERROR ***** K?-406 FOLLOWS: GRID IDENTIFICATION NUMBER ___ WAS USED MORE THAN ONCE WHEN SPECIFYING GRIDGEOMETRY.

This self-explanatory message is printed by CHECKGRIDDATA procedure of MGRID type procedure, and it indicates that identification numbers must be unique entries and using the same identification number multiple times for different mesh grid definitions is an illegal operation.

KMSG407 ***** WARNING ***** K?-407 FOLLOWS: IDENTICAL GRIDGEOMETRIES WERE SPECIFIED WITH IDENTIFICATION NUMBERS ___ AND ___. ONLY ONE OF THEM WILL BE PROCESSED AND STORED FOR THE CALCULATIONS.

This self-explanatory message is printed by REMOVEDUPLICATES procedure of MGRID type, and it notifies that two sets of grid geometry either defined in **CSAS definitions data** or in **KENO gridgeometry data** blocks have the identical specifications. KENO only processes one of them and stores it in grid data container for tallying. It updates the grid data pointers for the tallies if they are defined to use the mesh grids not stored.

KMSG408 ***** ERROR ***** K?-408 FOLLOWS: GRIDGEOMETRY (GRID=___) SPECIFIED IN ___, ___ IN TALLIES BLOCK IS NOT FOUND IN THE DEFINITIONS DATA INPUT BLOCK.

This self-explanatory message is printed by VALIDATE_GRID_ID procedure when running KENO as part of CSAS or TRITON sequences. It indicates that the mesh grid was not entered in **CSAS definitions data** block even though it was intended to be used with a mesh tally calculation defined in **CSAS tallies data** block.

KMSG409 ***** ERROR ***** K?-409 FOLLOWS: INVALID GRID IDENTIFICATION NUMBER (GRID= ___) IN MESH TALLY ___ IN TALLIES BLOCK. IDENTIFICATION NUMBER MUST BE A POSITIVE INTEGER.

This message comes from subroutine READ_MESH_TALLY_INPUT when running KENO as part of CSAS or TRITON sequences. It indicates that the mesh grid identification number defined in **CSAS tallies data** block is not a positive integer number.

KMSG410 ***** WARNING ***** K?-410 FOLLOWS: ENERGY BOUNDARIES MARKED AS DEFAULT WILL BE USED IN ALL TALLY CALCULATIONS IF OTHERWISE NOT REQUESTED.

This message is printed immediately after the energy boundaries output edit to indicate that the DEFAULT energy boundaries listed in this edit will be used in all tally calculations, unless otherwise requested. Note that the default energy boundaries can be defined with different input data or can be read by the code from the relevant SCALE library depending on the computation mode.

KMSG411 ***** WARNING ***** K?-411 FOLLOWS: ENERGY GROUP BOUNDARIES READ FROM ENERGY BLOCK OVERRIDE THE DEFAULT NGP VALUE.

This self-explanatory message printed by subroutine DATAIN indicates that data read from energy data block will override the default `NGP` value.

KMSG412 ***** WARNING ***** K?-412 FOLLOWS: NO ENERGY BOUNDARIES SPECIFIED AS DEFAULT IN DEFINITIONS DATA. THE DEFAULT ENERGY GROUP BOUNDARIES USED FOR TALLYING ARE OBTAINED FROM ___-GROUP SCALE MULTI GROUP LIBRARY.

This self-explanatory message printed by subroutine DATAIN when running KENO as part of CSAS or TRITON sequences indicates that **CSAS definition data** block does not have a definition for the DEFAULT energy boundaries. For this continuous-energy–specific case, KENO obtains the DEFAULT energy boundaries from the SCALE 252-group multigroup library and utilizes it for tallying.

KMSG413 ***** WARNING ***** K?-413 FOLLOWS: DEFAULT ENERGY GROUP BOUNDARIES READ FROM DEFINITIONS DATA OVERRIDE THE DEFAULT NGP VALUE. NGP VALUE PRINTED IN NUMERIC PARAMETERS EDIT IN THE OUTPUT MAY NOT REFLECT THIS UPDATE. THE FINAL NGP VALUE IS CORRECTLY PRINTED IN ADDITIONAL INFORMATION EDIT (SHOWN AS NUMBER OF ENERGY GROUPS).

This self-explanatory message is specific to continuous-energy mode, and it is printed by subroutine DATAIN when running KENO through a sequence with PARM=CHECK. This message reminds that the DEFAULT NGP value will be overridden by this data read from the definitions data block, and the updated NGP value can be shown in Additional information output edit.

KMSG414 ***** WARNING ***** K?-414 FOLLOWS: DEFAULT ENERGY GROUP BOUNDARIES READ FROM DEFINITIONS DATA OVERRIDE THE DEFAULT NGP VALUE. NGP VALUE PRINTED IN NUMERIC PARAMETERS EDIT IN THIS OUTPUT REFLECTS THIS UPDATE.

This self-explanatory message is specific to continuous-energy mode, and it is printed by subroutine DATAIN when running KENO through a sequence. This message indicates that the DEFAULT NGP value printed in numeric parameters output edit was also updated accordingly.

KMSG415 ***** WARNING ***** K?-415 FOLLOWS: SPECIFIED NGP VALUE (NGP=___) DOES NOT CORRESPOND TO ONE OF THE STANDARD ENERGY GROUP STRUCTURES AVAILABLE. CONSTRUCT ___ EQUAL LETHARGY BINS AND SET THEM AS DEFAULT ENERGY GROUP BOUNDARIES WHICH WILL BE USED FOR TALLYING.

This self-explanatory message is specific to continuous-energy mode, and it is printed by subroutine SETUP_DEFAULT_EBOUNDS_CE_MODE. It indicates that specified `NGP` parameter does not match any SCALE group structure; therefore, KENO constructs the DEFAULT energy boundaries with `NGP` equal lethargy bins and stores this in the ebounds data container. The DEFAULT energy boundaries will be used for all tallies.

KMSG416 ***** ERROR ***** K6-416 FOLLOWS: BOUNDARY CONDITIONS OTHER THAN VACUUM IS NOT ALLOWED ON THE BOUNDARIES WHEN THE BOUNDARY DEFINITION VECTOR OF THE GLOBAL UNIT HAS NEGATIVE BODY LABEL(S).

This self-explanatory KENO-VI message from subroutine K6_RDBNDS indicates that a non-vacuum albedo boundary condition was defined illegally. KENO-VI allows constructing global unit with combinations of multiple bodies whose labels listed in the boundary definition vector of the global unit. However, only VACUUM albedo boundary condition is to be applied to the global boundaries if the boundary definition vector of the global unit has negative body label(s). Therefore, execution is terminated with this error message. See Sect. 8.1.3.6 for specific examples for albedo boundary condition specifications for KENO-VI geometry.

KMSG417 ***** ERROR ***** K6-417 FOLLOWS: BOUNDARY CONDITION SPECIFICATION WITH SURFACE AND FACE CODES WITHOUT CORRESPONDING BODY IS NOT ALLOWED WHEN MULTIPLE BODIES USED TO DEFINE THE GLOBAL UNIT BOUNDARY.

This self-explanatory KENO-VI message from subroutine K6_RDBNDS is caused by a missing `BODY` parameter in the boundary condition specification. When multiple bodies define the global boundaries, boundary conditions of each body should be defined with `BODY` parameter following by the corresponding face codes. Therefore, the execution is terminated with this error message. See Sect. 8.1.3.6 for specific examples for albedo boundary condition specifications for KENO-VI geometry.

KMSG418 ***** ERROR ***** K?-418 FOLLOWS: FACE CODES AND SURFACE KEYWORDS ARE NOT ALLOWED TO BE USED TOGETHER IN BOUNDARY DATA SPECIFICATION FOR THE SAME BODY (BODY=___).

This self-explanatory message from subroutines K6_RDBNDS or K5_RBNDS indicate that there is illegal input data in bounds data block. KENO does not allow using `SURFACE` and cuboidal `FACE CODE` s together for albedo boundary condition specifications.

KMSG419 ***** ERROR ***** K5-419 FOLLOWS: FACE CODES ARE NOT ALLOWED TO BE USED WITH NON-CUBOIDAL BOUNDING SHAPE WHICH IS A ___.

This self-explanatory message from subroutine K5_JOMCHK indicates that `FACE CODE` s were used illegally when specifying albedo boundary conditions. Cuboidal `FACE CODE` s cannot be used for non-cuboidal boundary shape when defining boundary conditions.

KMSG420 ***** ERROR ***** K5-420 FOLLOWS: ___ BOUNDARY CONDITION IS NOT ALLOWED ON HEMISPHERES AND HEMICYLINDERS.

This message from subroutine K5GM_JOMCHK indicates that non-vacuum boundary conditions were applied to the outermost geometry region, which is a hemisphere or a hemicylinder. KENO V.a geometry does not allow boundary conditions other than VACUUM on these boundary shapes. Execution is terminated.

KMSG421 ***** ERROR ***** K5-421 FOLLOWS: BODY IS AN INVALID PARAMETER NAME IN BOUNDARY CONDITION DATA SPECIFICATION.

This message emitted from subroutine K5GM_RDBNS indicates that an invalid bounds data parameter was used when defining albedo boundary conditions. `BODY` parameter is a KENO-VI specific parameter used to define albedo boundary conditions to the boundary shape(s) which constructs the global unit. Therefore, execution is terminated.

KMSG422 ***** ERROR ***** K6-422 FOLLOWS: FACE CODES ARE NOT ALLOWED TO BE USED WITH NON-CUBOIDAL BOUNDING SHAPE (BOUNDARY BODY ___ IN THE GLOBAL UNIT BOUNDARY IS A ___).

This self-explanatory message emitted from subroutine K6_RDBNDS indicates that FACE CODEs were used illegally when specifying albedo boundary conditions on the non-cuboidal boundary shape(s). Cuboidal FACE CODE s cannot be used with non-cuboidal boundary shape(s) when defining the boundary conditions. Therefore, execution is terminated.

KMSG430 ***** ERROR ***** K?-430 FOLLOWS: ILLEGAL PARAMETER VALUE (___ , ___), IT MUST BE A POSITIVE NUMBER.

This message printed by subroutine RDSTRT is caused by an illegal parameter value in START data block. START data parameters LNU, NXS, NYS, and NZS must be a positive integer value; otherwise, execution is terminated with this error message.

KMSG431 ***** ERROR ***** K?-431 FOLLOWS: LNU IN EACH SUCCESSIVE DATA SET SHOULD BE LARGER THAN THE PREVIOUS VALUE OF LNU (CURRENT LNU=___, PREVIOUS LNU=___).

This message printed by subroutine RDSTRT if an illegal LNU parameter value is in START data block. LNU parameter is used in START type 6 data. This start type allows neutrons to be started at the arbitrary starting points defined by a set of data. The last entry for each start 6 data set must be LNU, and the LNU value of each successive set of data must be larger than the last. Otherwise, execution is terminated with this error message.

KMSG432 ***** WARNING ***** K?-432 FOLLOWS: ONLY ___ STARTING POINT WILL BE READ FROM THE ASCII START DATA FILE (RDU=___).

This message emitted by subroutine RDSTRT indicates that starting points read from the ASCII start data file is less than the number of neutrons per generations. If there are no other start data sets defined in the START data block, KENO uniformly samples the remaining starting points from the set of these arbitrary starting points already read from the ascii start data file. See Sect. 8.1.4.8 for specific examples for start type 6.

KMSG433 ***** ERROR ***** K?-433 FOLLOWS: START TYPE 6 PARAMETER ___ HAS BEEN USED MORE THAN ONCE IN THE SAME DATA SET.

This self-explanatory message from subroutine RDSTRT indicates that one of the START type 6 parameter was defined more than once in the same start type 6 data set. Starting parameters NXS, NYS, NZS, TFX, TFY, and TFZ should be used once in the same start type 6 data set ended by LNU parameter.

KMSG434 ***** ERROR ***** K?-434 FOLLOWS: NO LNU HAS BEEN SPECIFIED WITH THE ___ SET IN START TYPE 6.

This self-explanatory message printed by subroutine RDSTRT is caused by a missing LNU parameter in one of the start type 6 data set which may include either NXS, NYS, and NZS, or TFX, TFY, and TFZ parameters.

KMSG435 ***** ERROR ***** K?-435 FOLLOWS: RDU (RDU=___) CANNOT BE USED TOGETHER WITH ___ IN THE SAME START TYPE 6 DATA SET ENDED WITH (___ , ___).

This self-explanatory message from subroutine RDSTRT is caused by using RDU parameter together with any NXS, NYS, NZS, TFX, TFY, and TFZ options in the same start type 6 data set. RDU cannot be used together with these start type 6 options in the same data set; therefore, execution is terminated.

KMSG436 ***** ERROR ***** K?-436 FOLLOWS: SPECIFIED ASCII START DATA FILE (RDU=___) DOES NOT EXIST.

This self-explanatory message is printed by subroutine RDSTRT if the defined ASCII start data file could not be found. Execution is terminated with this error message for such a case.

KMSG437 ***** ERROR ***** K?-437 FOLLOWS: INSUFFICIENT NUMBER OF START DATA POINTS (SPECIFIED LNU=___ >> MAX. LNU READ FROM RDU FILE, LNU=___) FOUND IN SPECIFIED ASCII START DATA FILE (RDU=___).

This self-explanatory message is printed by subroutine RDSTRT if the ASCII start data file contains starting points less than the defined LNU value. There must be at least LNU number of starting points in the ASCII start data file for a successful operation. See Sect. 8.1.4.8 for specific examples for start type 6.

KMSG438 ***** WARNING ***** K?-438 FOLLOWS: ___ SEQUENCE DOES NOT SUPPORT PARAMETER (___) SPECIFIED IN THE PARAMETER DATA. THIS PARAMETER WILL BE IGNORED IN THIS CALCULATION.

This self-explanatory message is printed by subroutine PARAM if an unsupported parameter is entered in the **parameter data** input block. KENO by design has several parameters, some of them dedicated to the sequence running KENO. For example, parameters CET, CFP, etc. are allocated for sensitivity calculations performed by KENO when running KENO as part of a TSUNAMI sequence. These parameters are not valid for other sequences running KENO such as CSAS and TRITON. If there is an inconsistency between such sequence-specific parameters and the sequence, which is running KENO, then execution is terminated with this error message to prevent excess resource allocation for the sequence-specific capabilities activated by these parameters.

KMSG439 ***** ERROR ***** K?-439 FOLLOWS: ILLEGAL VALUE FOR START TYPE 6 PARAMETER (___=___). ___ CANNOT BE GREATER THAN THE NUMBER OF UNITS IN THE ___-DIRECTION OF THE GLOBAL ARRAY (___=___).

This message from subroutine K_STDATA indicates that the values entered with the NXS, NYS, and NZS start type 6 parameters are not consistent with the definition of the global array. Valid NXS, NYS, and NZS values must be less than or equal to the NUX, NUY, and NUZ entries in the global array definitions in the `array data` block. Otherwise, execution is terminated with this error message.

KMSG440 ***** WARNING ***** K?-440 FOLLOWS: ___ IS NOT A VALID DATA FOR START TYPE ___. THIS PARAMETER WILL BE IGNORED IN THIS CALCULATION.

This self-explanatory message is printed by subroutine RDSTRT if a start type parameter is defined with another start type which does not support this parameter. For example, LNU parameter is a start type 6-specific parameter, and it is not allowed with start type 0. For such a case, execution is terminated with this error message.

KMSG441 ***** WARNING ***** K?-441 FOLLOWS: ___ IS NO LONGER SUPPORTED BY START DATA (OBSOLETE PARAMETER). THIS PARAMETER WILL BE IGNORED IN THIS CALCULATION.

This self-explanatory message from subroutine RDSTRT indicates that an obsolete parameter was used in the **start data** input block. KENO development is an evolving process; sometimes due to new limitations as part of modernization or other needs, some legacy parameters are no longer supported. KENO ignores processing this parameter and continues the calculation by emitting this warning message.

KMSG442 ***** INFORMATION WARNING ***** K6-442 FOLLOWS: POSIT WARNING — POINT MAY NOT BE IN GEOMETRY X = ___ Y = ___ Z = ___

This message from subroutine K6_START indicates that starting point sampled/entered might be outside the geometry. Usually, this warning message is followed by an error message if the starting point is verified that it is not located inside the geometry by subroutine SGGM_POSIT. If the number of points outside the geometry is less than 5, then calculation will continue by resampling these points from the set of successful starting points (which are inside the geometry). Otherwise, execution is terminated. For such a case, the user should ensure that all starting points are located inside the geometry that are either defined with start type 6 data or defined in ASCII start data file(s).

8.1.7 THEORY AND TECHNIQUES

8.1.7.1 The transport equation

The equation KENO solves may be derived in the following manner, starting with the Boltzmann neutron transport equation which may be written as

$$\begin{aligned}\frac{1}{\mathrm{v}}\frac{\partial\Phi}{\partial t}(X,E,\Omega,t)+\Omega\bullet\nabla\Phi(X,E,\Omega,t)+\Sigma_t(X,E,\Omega,t)\,\Phi(X,E,\Omega,t)\\ =S(X,E,\Omega,t)\\ +\int_{E'}\int_{\Omega'}\Sigma_s\left(X,E'\rightarrow E,\Omega'\rightarrow\Omega,t\right)\Phi\left(X,E',\Omega',t\right)d\Omega'dE'\,,\end{aligned}\tag{8.1.3}$$

where

$\Phi(\mathrm{X},\mathrm{E},\Omega,\mathrm{t})$ = neutron flux (neutrons/cm^2/s) per unit energy at energy E per steradian about direction Ω at position X at time t moving at speed v corresponding to E;

$\Sigma_t(\mathrm{X},\mathrm{E},\Omega,\mathrm{t})$ = macroscopic total cross section of the media (cm^{-1}) at position X, energy E, direction Ω and time t;

$\Sigma_s(\mathrm{X},\mathrm{E}'\rightarrow\mathrm{E},\Omega'\rightarrow\Omega,\mathrm{t})$ = macroscopic differential cross section of the media (cm^{-1}) per unit energy at energy E' per steradian about direction Ω' at position X, and time t, for scattering to energy E and direction Ω;

$\mathrm{S}(\mathrm{X},\mathrm{E},\Omega,\mathrm{t})$ = neutrons/cm^3/s born at position X and time t per unit energy at energy E per steradian about direction Ω (excludes scatter source).

Defining $\mathrm{q}(\mathrm{X},\mathrm{E},\Omega,\mathrm{t})$ as the total source resulting from the external source, scattering, fission, and all other contributions, the following relationship can be written.

$$\begin{aligned}q(X,E,\Omega,t)=\\ S(X,E,\Omega,t)+\int_{E'}\int_{\Omega'}\Sigma_s\left(X,E'\rightarrow E,\Omega'\rightarrow\Omega,t\right)\Phi\left(X,E',\Omega',t\right)d\Omega'dE'\,.\end{aligned}\tag{8.1.4}$$

Combining Eq. (8.1.3) and Eq. (8.1.4), assuming media to be stationary and ignoring time-dependence, yields

$$\Omega\bullet\nabla\Phi(X,E,\Omega)+\Sigma_t(X,E,\Omega)\,\Phi(X,E,\Omega)=q(X,E,\Omega)\tag{8.1.5}$$

8.1.7.2 Continuous energy mode solution procedure

Using the relationship $X' = X - R\Omega$, using an integrating factor on both sides of Eq. (8.1.5), and defining

$$T(R) = \int_0^R \Sigma_t(X - R^{'}\Omega, E)dR, \tag{8.1.6}$$

the following equation can be written.

At this point, the problem becomes an eigenvalue problem. If there is no external source, the source may be defined as

$$\Phi(X, E, \Omega) = \int_O^\infty q(X - R\Omega, E, \Omega)e^{-T(R)}dR \tag{8.1.7}$$

At this point, the problem becomes an eigenvalue problem. If there is no external source, the source may be defined as

$$\begin{aligned} q\,(X, E, \Omega) = \int \int dE^{'} d\Omega^{'}\ \Phi\left(X, E^{'}, \Omega^{'}\right)\ \Sigma_{s}\left(X, E^{'} \rightarrow E, \Omega^{'} \cdot \Omega\right) \\ +\ \frac{1}{k} Q^{'}(X, E, \Omega), \end{aligned} \tag{8.1.8}$$

where

k is the largest eigenvalue of the integral equation,

$Q'(X, E, \Omega)$ is the fission source at position X for energy E and direction Ω (all fission contributions to point E from all energy points in the previous generation),

$\Sigma_s\,(X, E' \rightarrow E, \Omega' \bullet \Omega)$ is the scattering cross section for scattering at position X from energy point E' and direction Ω' to energy point E and direction Ω.

Assuming the fission neutrons to be isotropic, the fission source $Q'(X, E, \Omega)$ can be written as

$$Q^{'}(X, E, \Omega) = \frac{1}{4\pi} \int_{E'} \int_{\Omega'} dE^{'} d\Omega^{'} \Phi(X, E^{'}, \Omega^{'}) \chi(X, E^{'} \rightarrow E) \nu(X, E^{'}) \Sigma_f(X, E^{'}), \tag{8.1.9}$$

where

- $\chi\,(X, E' \rightarrow E)$ **is the fraction of neutrons born at energy point E from** fission at energy point E' in the media at position X,
- $\nu\,(X, E')$ **is the number of neutrons resulting from a fission at energy** point E' at position X,
- $\Sigma_f\,(X, E')$ **is the macroscopic fission cross section of the** material at position X for a neutron at energy point E'.

Substituting Eq. (8.1.8) into Eq. (8.1.7) yields the following equation:

$$\begin{aligned} \Phi\,(X, E, \Omega) = \int_0^\infty \mathrm{dR}\ e^{-T(R)} \left\{ \frac{1}{k} Q^{'}\,(X - R\Omega, E, \Omega) \right. \\ \left. +\ \int_{E'} \int_{\Omega'} dE^{'} d\Omega^{'} \Phi\left(X - R\Omega, E^{'}, \Omega^{'}\right) \Sigma_{s}\left(X - R\Omega, E^{'} \rightarrow E, \Omega^{'} \cdot \Omega\right) \right\} \end{aligned} \tag{8.1.10}$$

The definition of k may be given as the ratio of the number of neutrons produced in the (n + 1)*th* generation to the number of neutrons produced in the n*th* generation or the largest eigenvalue of the integral equation. Using Eq. (8.1.9), Eq. (8.1.7) can be written as

$$\Phi(X,E,\Omega)=\int_0^\infty dRe^{-T(R)}\left\{\frac{1}{k}\int_{E'}\int_{\Omega'}\nu\left(X-R\Omega,E'\right)\Sigma_f\left(X-R\Omega,E'\right)\chi\left(X-R\Omega,E'\rightarrow E\right)\Phi\left(X-R\Omega,E',\Omega'\right)d\mathrm{E}'\frac{d\Omega'}{4\pi}\right.$$
$$\left.+\int_{E'}\int_{\Omega'}d\mathrm{E}'d\Omega'\Phi\left(X-R\Omega,E',\Omega'\right)\Sigma_s\left(X-R\Omega,E'\rightarrow E,\Omega'\cdot\Omega\right)\right\} \tag{8.1.11}$$

Writing Eq. (8.1.11) in generation notation, multiplying and dividing certain terms by $\Sigma_t(X,E)$ and multiplying both sides of the equation by $\nu(X,E)\Sigma_f(X,E)$, yields the following equation, which is solved by KENO V in the continuous energy mode:

$$\frac{\nu(X,E)\Sigma_f(X,E)}{\Sigma_t(X,E)}\Sigma_t(X,E)\Phi_n(X,E,\Omega)=\frac{\nu(X,E)\Sigma_f(X,E)}{\Sigma_t(X,E)}\Sigma_t(X,E)\int_0^\infty dRe^{-T(R)}$$
$$\left\{\frac{1}{k}\int_{E'}\int_{\Omega'}\frac{\nu\left(X-R\Omega,E'\right)\Sigma_f\left(X-R\Omega,E'\right)}{\Sigma_t\left(X-R\Omega,E'\right)}\chi\left(X-R\Omega,E'\rightarrow E\right)\Sigma_t\left(X-R\Omega,E'\right)\Phi_{n-1}\left(X-R\Omega,E',\Omega'\right)d\mathrm{E}'\frac{d\Omega'}{4\pi}\right.$$
$$\left.+\int_{E'}\int_{\Omega}\frac{\Sigma_S\left(X-R\Omega,E'\rightarrow E,\Omega'\cdot\Omega\right)}{\Sigma_t\left(X-R\Omega,E'\right)}\Sigma_t\left(X-R\Omega,E'\right)\Phi_n\left(X-R\Omega,E',\Omega'\right)dE'd\Omega'\right\} \tag{8.1.12}$$

where n indicates the n*th* generation and n - 1 is the (n - 1)*th* generation. Note that the left-hand side of the equation, $\nu(X,E)\Sigma_f(X,E)\phi_n(X,E,\Omega)$ is the fission production for the n*th* generation.

The solution strategy used by KENO solves Eq. (8.1.12) by using an iterative procedure. The fission production at point X at energy point E due to neutrons in the (n - 1)*th* generation, normalized to the system multiplication, is

$$\frac{1}{k}\int_{E'}\int_{\Omega'}\frac{\nu(X,E')\Sigma_f(X,E')}{\Sigma_t(X,E')}\chi(X,E'\rightarrow E)\Sigma_t(X,E)\Phi_{n-1}(X,E'\Omega')dE'\frac{d\Omega'}{4\pi} \tag{8.1.13}$$

The collision points used in KENO are chosen by selecting path lengths from the distribution

$e^{-T(R)}$,

which is the probability of transport from any position $X-R\Omega$ to position X.

The first collision density of neutrons at energy E per unit solid angle about Ω resulting from the fission source produced by the (n - 1) generation, normalized to the system multiplication, is

$$\Sigma_t(X,E)\int_0^\infty dRe^{-T(R)}\frac{1}{k}\int_{\Omega'}\int_{E'}\frac{\nu(X-R\Omega,E')\Sigma_f(X-R\Omega,E')}{\Sigma_t(X-R\Omega,E')}$$
$$\chi(X-R\Omega,E'\rightarrow E)\Sigma_t(X-R\Omega,E')\Phi_{n-1}(X-R\Omega,E',\Omega')dE'\frac{d\Omega'}{4\pi} \tag{8.1.14}$$

The scattering source at position X emerging at energy E and direction Ω resulting from previous collisions in the same generation, is

$$\int_{E'}\int_{\Omega'}\frac{\Sigma_s\left(X,E'\rightarrow E,\Omega'\cdot\Omega\right)}{\Sigma_t\left(X,E'\right)}\Sigma_t\left(X,E'\right)\Phi_n\left(X,E',\Omega'\right)d\Omega'dE' \tag{8.1.15}$$

The collision density at energy E, per solid angle about Ω is

$$\Sigma_t(X,E)\int_0^{\infty} \mathrm{dR}\; e^{-T(R)} \int_{E'}\int_{\Omega'} \frac{\Sigma_s\left(X-R\Omega, E' \rightarrow E, \Omega'\cdot\Omega\right)}{\Sigma_t\left(X-R\Omega,E'\right)} \Sigma_t\left(X-R\Omega,E'\right)\Phi_n\left(X-R\Omega,E',\Omega'\right)d\Omega' dE' \tag{8.1.16}$$

The total collision density times $\frac{\nu_g(X)\Sigma_{fg}(X)}{\Sigma_{tg}(X)}$ is the relationship from which KENO picks the source points for the next generation.

Problem initialization

In order to use continuous energy cross sections in the random walk, various initialization tasks must be addressed for each problem. Based on the mixture specifications for a problem, KENO reads the microscopic cross section data for each nuclide and dynamically allocates storage for the particular problem. For continuous energy problems, if **UUM=**no then KENO will not allocate macroscopic cross sections for each material, and will instead use the master set of microscopic cross section data (on a non-unionized energy grid). This is the default behavior. Storing cross sections on a material-based unionized energy grid (**UUM=**yes) results in smaller cross section lookup times and faster KENO runtimes; however, storing unionized cross section data for every material can require a prohibitively large amount of memory for problems with a large number of materials. Users should therefore only set **UUM**=yes for relatively small models; experience is the best guide as to what "small" means with respect to available system resources. After finishing the cross section processing, KENO reads the user-specified KENO data (See Sect. 8.1.5) and stores the problem-dependent data for retrieval during the random walk. After the data initialization tasks are complete, the Monte Carlo random walk can be performed according to the procedures that are documented in the subsequent sections.

Initial source distribution

Before the Monte Carlo simulation can be performed, the initial source distribution of neutrons must be sampled. Typically, each mixture in a problem is composed of multiple isotopes, and each mixture must be checked for the presence of fissionable material. For each fissionable mixture, the volume fraction of fissionable material must be calculated on a per isotope basis.

The first source distribution is comprised of the initial spatial coordinates, direction cosines and energy for each neutron within the problem. Regarding the coordinate values, both continuous energy and multigroup KENO use the same start types, and the initial angular distribution is sampled from an isotropic distribution. For the initial energy distribution, the energy of each neutron must be sampled from the continuous energy fission spectrum, $\chi(E)$, of a fissionable isotope within the mixture. If more than one fissionable isotope is present, the i^{th} isotope can be selected using the following relation:

$$\sum_{j=1}^{i-1}\Sigma_f^j < R\sum_{j=1}^{N}\Sigma_f^j \le \sum_{j=1}^{i}\Sigma_f^j \tag{8.1.17}$$

where

$\sum_f^j$ = macroscopic fission cross section for the j^{th} isotope,

R = random number [0, 1),

N = total number of fissionable isotopes in the mixture.

Note that the relation in Eq. (8.1.17) requires the knowledge of the fission cross section at a particular energy. Therefore, an initial energy of 0.025 eV is assumed for selecting the appropriate isotope to sample. Once the i^{th} isotope is selected, the initial energy is sampled from the corresponding $\chi_{\text{i}}(E)$.

Collision site selection

Each neutron must be tracked until the history is terminated via leakage from the system or the particle is "killed" via roulette. The selection of the next collision site is governed by the following probability density function (PDF):

$$f(x)dx = \Sigma_t^m(E)e^{-\Sigma_t^m(E)x}dx, \tag{8.1.18}$$

where

$\Sigma_t^m(E)$ = macroscopic total cross section for mixture m at energy E,

x = spatial variable.

The PDF in Eq. (8.1.18) describes the probability that a neutron will have an interaction between x and $x + dx$ along its flight path. Integrating Eq. (8.1.18) over the spatial variable yields the following cumulative distribution function (CDF):

$$F(x) = \int_0^x \Sigma_t^m(E)e^{-\Sigma_t^m(E)x'}dx' = 1 - e^{-\Sigma_t^m(E)x}, \tag{8.1.19}$$

and the next collision site is determined by setting the CDF in Eq. (8.1.19) equal to a random number on the interval [0, 1) and solving for x.

Note that Eq. (8.1.19) requires the total cross section for mixture m at energy E in order to calculate the next collision site. As mentioned in the Sect. 8.1.7.2.1, KENO has two approaches to calculate the macroscopic total cross section for each mixture; (1) use a unionized energy grid (**UUM=**yes) — once KENO reads the microscopic data for each isotope/nuclide in a mixture, KENO calculates and stores the macroscopic total cross sections for the nuclides in each mixture (2) on-the-fly mixture macroscopic cross section calculation (**UUM=**no) — KENO does not store macroscopic cross sections and instead calculates mixture cross sections upon request during particle tracking. Selecting **UUM**=yes results in substantially increased memory usage for problems with a large number of materials, making it impossible to perform CE calculations for some detailed problems. Thus, it is highly recommended to use **UUM**=no, the default setting, for the large problems with multiple mixture definitions. For most cases selecting **UUM**=no increases the runtime for KENO CE calculations by approximately 17 %, but this feature also expands the code's capability to simulate very large problems with multiple mixture configurations.

Just as the `UUM` option allows the user to prevent KENO from storing mixture cross sections on a unionized energy grid, the `M2U` option toggles whether or not KENO stores cross sections on a unionized energy grid for each individual nuclide. The default for this option is `M2U=no`, which prevents the storage of all the transport cross sections (i.e. inelastic scattering levels) for each nuclide in addition to the major reactions that are already on the unionized energy grid (i.e. total, fission, capture, and scatter) on an energy grid that is unionized for that nuclide, and setting `M2U`=yes activates this unionization and storage. `M2U`=no reduces the nuclear data memory footprint of large models by several gigabytes, but it also increases the runtime of these problems by several percent. It is encouraged to investigate both `UUM` and `M2U` options in continuous energy problems to optimize the runtime and memory depending on the user's models and applications. In the continuous energy depletion calculations, `UUM` parameter is intentionally forced to "no" to minimize the memory requirement of internal data storage. The cross section storage and treatment options should be used consistently in both validation and analysis calculations.

If any of the isotopes in the mixture have unresolved-resonance data and corresponding probability-table data, KENO must determine if the neutron energy is in the unresolved resonance range (URR) for each isotope

during the random walk. If the neutron energy is in the URR for an isotope, the appropriate probability table must be sampled to obtain the total cross section for each isotope (refer to Sect. 8.1.7.2.1 for sampling probability tables). Subsequently, the macroscopic total cross section for mixture m is adjusted to account for sampling the probability tables. Once the revised $\Sigma_t^m(E)$ is determined, Eq. (8.1.19) can be used to select the next collision site within mixture m at energy E.

Collision treatment

Once the collision site is determined, the collision can be modeled, and the post collision parameters can be calculated. In the continuous energy approach, each collision is modeled with an individual isotope/nuclide. If a mixture is defined by multiple isotopes and/or nuclides, the target must be selected at each collision site. If there are N different isotopes/nuclides present in a mixture, the following equation can be used to select the i^{th} target for interaction:

$$\sum_{j=1}^{i-1} \Sigma_t^j < R \sum_{j=1}^{N} \Sigma_t^j \leq \sum_{j=1}^{i} \Sigma_t^j, \tag{8.1.20}$$

where,

Σ_t^j = macroscopic total cross section for the j^{th} isotope/nuclide.

As noted in Sect. 8.1.7.2.2 and Sect. 8.1.7.2.3, the collision energy may be in the URR of one or more isotopes within the mixture. Consequently, the total cross section for each isotope that has unresolved-resonance data is sampled from the probability table information prior to selecting the next collision site (see discussion in Sect. 8.1.7.2.1). Subsequently, the sampled values for the total and partial reactions are stored for retrieval. Therefore, the macroscopic total cross section values that are used in Eq. (8.1.20) are adjusted to account for sampling the probability table data by retrieving the appropriate microscopic total cross section value at energy E. Once the corrected values for $\Sigma_t^j(E)$ are determined, Eq. (8.1.20) can be used to select the target for interaction.

After selecting the collision target, the neutron's weight is reduced by the nonabsorption probability:

$$w = \frac{\sigma_s^i(E)}{\sigma_t^i(E)} w_b = P_{nabs}(E) w_b, \tag{8.1.21}$$

where

$\sigma_s^i(E)$ = microscopic scattering cross section for the i^{th} isotope/nuclide at energy E,

$\sigma_t^i(E)$ = microscopic total cross section for the i^{th} isotope/nuclide at energy E,

wb = weight before collision.

The absorption and fission weights are calculated using the following relations, respectively:

$$w_a = \frac{\sigma_a^i(E)}{\sigma_t^i(E)} w_b, \tag{8.1.22}$$

where

$\sigma_a^i(E)$ = microscopic absorption cross section for the i^{th} isotope/nuclide at energy E,

and

$$w_f = \frac{\bar{\nu}^i(E)\sigma_f^i(E)}{\sigma_t^i(E)} w_b, \tag{8.1.23}$$

$\bar{\nu}^i$ = average number of neutrons released per fission at energy E,

$\sigma_f^i(E)$ = microscopic fission cross section for the i^{th} isotope/nuclide at energy E.

If the collision isotope is in the URR at energy E and probability table data are available, the collision probabilities must be adjusted for sampling the partial reactions from the appropriate probability table. In particular, the revised or sampled values for scattering, absorption and fission must be used to calculate the collision weights as defined by Eq. (8.1.21) through Eq. (8.1.23). Depending on the neutron's weight, splitting and/or Roulette are performed as necessary. Once the appropriate weights are calculated, the collision can be processed to determine the type of interaction and the corresponding exiting energy and angle if secondary neutrons are generated.

Because an explicit collision treatment is dictated by the point cross section data, the type of reaction must be modeled explicitly in the continuous energy version of KENO. Fig. 8.1.204 summarizes the cross section hierarchy and can be used as an aide to understanding the collision treatment in KENO in continuous energy mode. After selecting the isotope/nuclide for interaction according to Eq. (8.1.20) and calculating the weights using Eq. (8.1.21) through Eq. (8.1.23), the collision is modeled using the following procedures:

1. At each collision site, ensure that the type of collision is selected based on the cross section data. Moreover, the k^{th} reaction can be randomly selected using the following relation:

$$\sum_{j=1}^{k-1} \sigma_j < R \sum_{j=1}^{NI} \sigma_j < \sum_{j=1}^{k} \sigma_j \tag{8.1.24}$$

   where

   $\sigma_j(E)$ = cross section for the j^{th} reaction,

   NI = number of elastic and nonelastic reactions (i.e., excludes neutron disappearance reactions).

   Note that the fission reactions (e.g., first chance fission, second chance fission, etc.) are excluded from Eq. (8.1.24) because an implicit approach is used to treat fission. The details of the fission treatment are provided in Sect. 8.1.7.2.5. If a neutron production reaction with multiple exit neutrons such as (n, 2n), (n, 3n) is selected and the reaction is not a fission reaction, then the weight of the neutron is adjusted by the multiplicity to account for the additional neutrons, such as $w = 2w$ for (n, 2n), $w = 3w$ for (n, 3n).

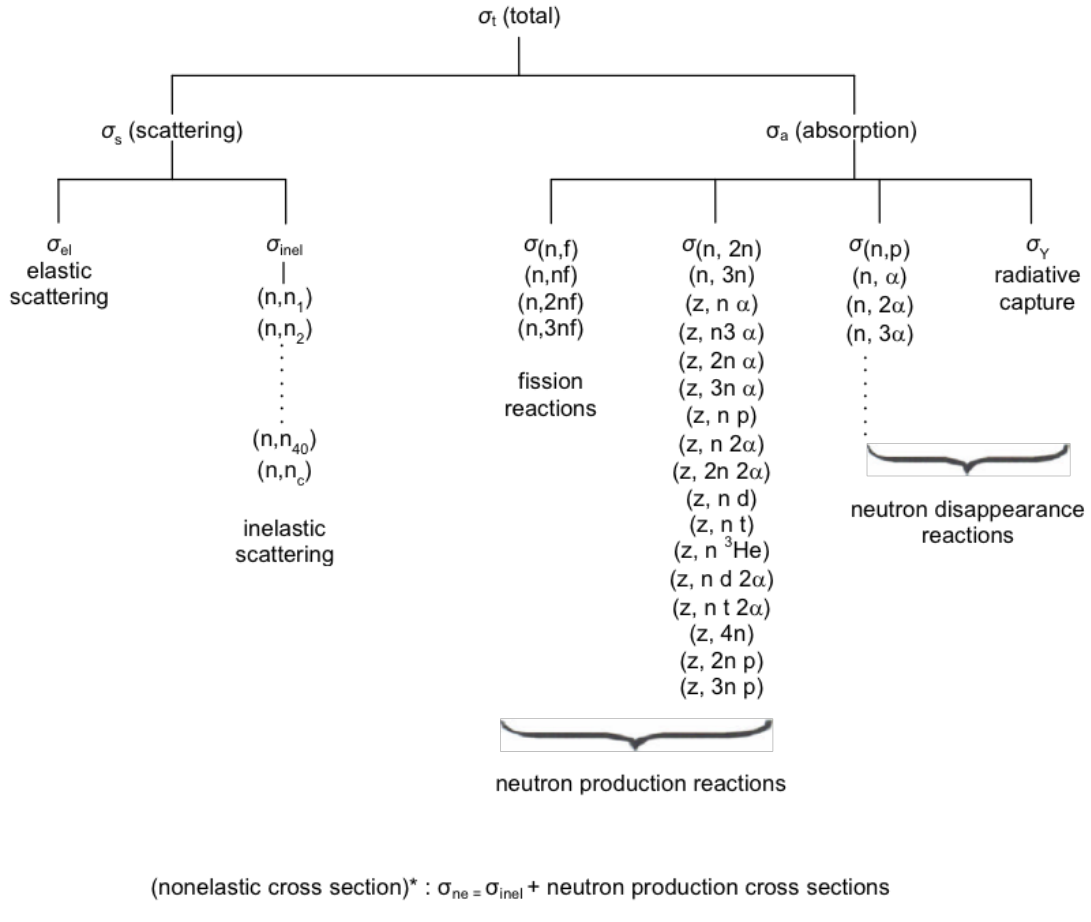

Fig. 8.1.204: Cross section hierarchy for particle interactions.

2. Select the exiting angle for the collision. The cross section library provides a kinematics data block that provides the angle and energy distributions of secondary particles for a specified reaction. Each record for each section of a reaction provides a flag (NPU) indicating the number of secondary angles for that energy. If the NPU flag is 1 and the corresponding cosine value is -2 (set as a programming flag), then the reaction is isotropic. The exiting angle for the collision can be obtained as follows:

   i. Isotropic Emission

   If the LAND flag is 0 for the secondary angular distribution, the exiting angle cosine is sampled uniformly between -1 and +1:

$$\mu = 2R - 1 \tag{8.1.25}$$

   If the LAND flag is 1 for the secondary angular distribution, the exiting angle cosine must be sampled from an anisotropic distribution provided in the cross section library for the specified reaction. Details for sampling the exiting angle from the angular distribution data are provided in Sect. 8.1.7.2.6.

   The secondary angular distribution data are provided as a function of incident energy. The initial record of each section for a reaction provides the number of incident energies (*NE*) for the secondary angular

and energy distributions. Corresponding to each incident energy is a secondary angular distribution. Therefore, there will be *NE* records used to describe the secondary angular data for each section.

For each angular distribution record, there is an *LMU* flag and a *NPU* flag that describes the format of the data. The *LMU* flag designates whether the secondary distribution is provided in equiprobable cosine bins or in nonequiprobable cosine bins. The procedures for sampling the two types of data are provided in Sect. 8.1.7.2.10. The *LMU* flag must be the same for all *NE* records within a section. The *NPU* flag specifies the number of cosine values in the distribution.

Based on the incident energy of the neutron, the angular distribution data are sampled according to the procedures of Sect. 8.1.7.2.10 to obtain the exiting angle cosine, μ, in the lab system.

3. Select the exiting energy for the collision. In addition to the angular distributions of the kinematics data, the cross section library provides the energy distributions of secondary particles for a specified reaction.

   The secondary energy distributions are provided as a function of incident energy and secondary angle cosine in each section. Once the exiting angle cosine is selected, the exiting energy is selected from the energy distribution that corresponds to the (E, μ) pair. The exit energy is determined using the procedures of Sect. 8.1.7.2.10.

   For each energy distribution record, there is an *LE* flag and an *NPE* flag describing the format of the data. The *LE* flag designates whether the secondary distribution is provided in equiprobable energy bins or in nonequiprobable energy bins. The procedures for sampling the two types of data are provided in Sect. 8.1.7.2.10. Note that the *LE* flag must be the same for all *NE* records within a section for the secondary energy distribution data. The *NPE* flag specifies the number of secondary energy values in the distribution. For elastic scattering and discrete-level inelastic scattering, the *NPE* flag will equal the *NPU* flag due to the one-to-one correspondence between angle and energy.

4. Select the azimuthal angle η uniformly between 0. and 2π (i.e., $\eta = 2R\pi$.

5. Calculate the new direction cosines in the lab system using the following equations:

$$u' = u\mu - \sqrt{v^2 + w^2}\sqrt{1-\mu^2}\cos(\eta) \tag{8.1.26}$$

$$v' = v\mu + \frac{uv}{\sqrt{v^2 + w^2}}\cos(\eta)\sqrt{1-\mu^2} - \frac{w}{\sqrt{v^2 + w^2}}\sqrt{1-\mu^2}\sin(\eta) \tag{8.1.27}$$

$$w' = w\mu + \frac{uw}{\sqrt{v^2 + w^2}}\cos(\eta)\sqrt{1-\mu^2} + \frac{v}{\sqrt{v^2 + w^2}}\sqrt{1-\mu^2}\sin(\eta) \tag{8.1.28}$$

where

u, v, and w = initial direction cosines,

$u', v',$ and w' = exiting direction cosines,

μ = cosine of the scattering angle, and

η = cosine of the azimuthal angle.

Fission treatment

As noted in the previous section, an implicit approach is used to treat a fission event. During the collision treatment, the fission weight is calculated using Eq. (8.1.23). After processing the collision, the fission weight is evaluated to determine if the fission treatment should be applied. If the fission weight is greater than zero, the collision occurred in fissile material. During the random walk, several fission source points must be generated to provide an adequate representation of the true source distribution. A minimum production factor is defined at the beginning of each generation to ensure that enough fission points are generated:

$$mpf = \frac{3.0\bar{k}}{\sqrt{FG}}, \tag{8.1.29}$$

where

$\bar{k}$ = running average of k_{eff} through the current generation, and

FG = number of histories per generation.

Eq. (8.1.29) represents an estimate of the 99% lower confidence interval for the distribution of the generation k-effective.

If the fission weight is greater than zero, a pseudo-fission weight is calculated as follows:

$$pfw = \frac{w_f}{R} = \frac{\nu^{-i}(E)\sigma^i_f(E)}{R\sigma^i_t(E)} w_b. \tag{8.1.30}$$

If the pseudo-fission weight is less than the minimum production factor given by Eq. (8.1.29) fission points are not generated and tracking of the particle continues. However, if the pseudo-fission weight is greater than the minimum production factor, *pfw* is redefined to be the minimum production factor divided by a random number:

$$pfw = \frac{mpf}{R} \tag{8.1.31}$$

Once the pseudo-fission weight is redefined, a fission point can be generated. Each time a fission point is generated, the pseudo-fission weight is stored with the point in the fission bank. When a new point is stored in the fission bank, the energy and angular cosine must be selected from the kinematics data. Once the kinematics data are sampled for the new fission point, the fission weight of the history is decremented by the minimum production factor. If the remaining fission weight is greater than zero, the fission treatment procedures are repeated until the fission weight of the history has been exhausted (i.e., $w_f \leq 0$).

Sampling details

The preceding sections describe the procedures for the continuous energy random walk for KENO. During the random walk, KENO must sample various tables of data that may include probability tables and angle-energy distributions for secondary particles.

Probability tables

For each isotope with unresolved resonance data, multiple probability tables may be used to describe the URR. The header block for each isotope has an LPTAB flag that provides the number of probability tables for an isotope. Each table is defined for a range of incident energies between E_i and E_{i+1}, and the energy range for a table should not overlap with another table for the isotope. For a particle with energy E, a search must be performed to find the probability table with energy bounds that bracket the particle energy, $E_i \leq E < E_{i+1}$.

Once the appropriate table is identified, the table can be sampled to obtain the total, elastic scattering, fission and capture cross section values in the URR.

The probability table block provides four separate records that correspond to each reaction within a table; however, the probability table construction is based on the total cross section. Therefore, the probabilities in each table refer to the total cross section band values, and the bands should be sampled based on the total cross section. Once the band is sampled, the corresponding partial reaction cross section values are selected from the same band as the total cross section. The cross section format permits the probability table to be expressed in equiprobable or nonequiprobable cross section bands (i.e., LBND = 0 or 1, respectively). The procedures for sampling both types of tables are provided in the subsequent subsections.

Equiprobable cross section bands

Each probability record has an NB parameter that designates the number of cross section bands for a table. If the table is constructed with equiprobable cross section bands, the k^{th} band can be selected as follows:

$$k = NB\ ^{*}R + 1 \tag{8.1.32}$$

where

R = random number [0., 1).

Based on the sampled cross section band, the total cross section corresponding to k^{th} band is extracted from the table. Likewise, the elastic scattering, fission and capture cross section values that correspond to the k^{th} band are also extracted from their respective records in the probability-table block.

Nonequiprobable cross section bands

If the LBND flag is 1, the cross section bands in the table are not equiprobable, and a different procedure must be used to sample the appropriate cross section band. For this case, the probability values in the table must be constructed as a cumulative distribution function. As noted previously, each probability record has an NB parameter that designates the number of cross section bands for a table, and the k^{th} band can be selected as follows:

$$\sum_{j=1}^{k-1} P_j < R \sum_{j=1}^{NB} P_j \leq \sum_{j=1}^{k} P_j, \tag{8.1.33}$$

where

Pj = probability corresponding to the j^{th} cross section band.

Based on the sampled cross section band, the total cross section corresponding to the k^{th} band is extracted from the table. Likewise, the elastic scattering, fission and capture cross section values that correspond to the k^{th} band are also extracted from their respective records in the probability-table block.

Kinematics data

The kinematics data in the KENO library are provided in the lab or target-at-rest system as opposed to the center-of-mass system. By adhering to the lab coordinate system, KENO does not have to transform between different coordinate systems during the random walk; however, the energy and angle representations for elastic and discrete-level inelastic scattering become more complex in the lab system. For example, an angular distribution that is isotropic in the center-of-mass system is anisotropic in the lab system. Moreover, the secondary energy distribution as a function of exit angle in the lab system can be double valued (i.e.,

two possible exit energies with respect to a single angle) for energies above the threshold for the reaction. Likewise, a similar double valued distribution is observed for elastic scattering with hydrogen in the lab system if the actual mass ratio is used (i.e., $A = 0.99928$ as opposed to $A = 1.0$). Consequently, special care must be exercised in the construction of the secondary angle and energy distributions in the lab system.

The subsequent sections address the general procedures for sampling the kinematics data with emphasis on the special cases that must be addressed during the random walk. In Sect. 8.1.7.2.11, the general procedures for sampling the kinematics data are provided, Sect. 8.1.7.2.14 discusses isotropic angular data with energy coupling, while Sect. 8.1.7.2.15 discusses coherent and incoherent elastic scattering. A discussion is also provided in Sect. 8.1.7.2.16 to describe the elastic and discrete-level inelastic treatment.

General procedures

The kinematics data format is designed to accommodate coupled angle energy distributions of secondary particles. The following discussion provides the procedures for sampling the coupled distributions. Special cases such as elastic and discrete level inelastic scattering are discussed after the "General Procedures" section.

The sampling procedures in the following sections assume that the angle and energy distributions are continuous in nature. As a result, interpolation procedures can be used to obtain intermediate angle or energy values between the tabulated angle or energy values. During the course of KENO development, there may be a need to provide an average angle or energy value for a bin. The kinematics format can be modified as needed to accommodate additional angle and energy representations. Therefore, the following procedures represent the anticipated approach for sampling the current form of the kinematics data.

Exit angle cosine

The first record for each reaction provides the number of sections (NSECT) used to describe the kinematics for the reaction. Within each section, the first record defines the incident energy range for the section. After the first record for a section, the first block of data provides the secondary angular distributions for *NE* different incident energies within the energy range of the section. Consequently, there will be *NE* different angular distribution records in the secondary angle cosine block. The kinematics format permits the anisotropic angular distributions to be expressed in either equiprobable or nonequiprobable cosine bins (i.e., LMU = 0 or 1, respectively). Moreover, the formats permit the number of cosine bins to vary as a function of incident energy. In particular, each cosine distribution record can have *NPU* secondary angles that correspond to *NPU* - 1 cosine bins.

Equiprobable Cosine Bins. If the incident energy, E, is between E_{i} and $E_{\mathrm{i+1}}$, the angle cosine is sampled in both tables, and the exit angle cosine is obtained by interpolating between the two tables. If the angular distribution is provided in equiprobable cosine bins, the a^{th} bin is selected from the i^{th} table as follows:

$$a = (NPU_i - 1)\ {}^{*}R_1 + 1 = NA_i * R_1 + 1. \tag{8.1.34}$$

In Eq. (8.1.34) a denotes an integer quantity, and NA_{i} is the number of cosine bins for the i^{th} table. Using a similar procedure, the b^{th} bin is selected from the i+1$^{\mathrm{st}}$ table:

$$b = NA_{i+1}\ {}^{*}R_1 + 1 \tag{8.1.35}$$

As noted for the i^{th} table, b is an integer quantity in Eq. Eq. (8.1.35) and $NA_{\mathrm{i+1}}$ is the number of cosine bins for the i+1$^{\mathrm{st}}$ table. Once the cosine bins are selected, the cosine of the exiting angle from the i^{th} and i+1$^{\mathrm{st}}$ tables is calculated with Eq. (8.1.36) and Eq. (8.1.37), respectively:

$$\dot{\mu}_i = \mu_{ia} + (a - NA_i * R_1)\,(\mu_{ia+1} - \mu_{ia})\,, \tag{8.1.36}$$

$$\dot{\mu}_{i+1} = \mu_{i+1b} + (b - NA_{i+1} * R_1)\,(\mu_{i+1b+1} - \mu_{i+1b})\,. \tag{8.1.37}$$

The exiting angle cosine is obtained by interpolating between i and i+1 based on the incident energy grid:

$$\mu = \dot{\mu}_i + \left(\frac{E - E_i}{E_{i+1} - E_i}\right)(\dot{\mu}_{i+1} - \dot{\mu}_i)\,. \tag{8.1.38}$$

Nonequiprobable Cosine Bins. If the angular distribution is in the form of nonequiprobable cosine bins, the a^{th} bin is selected from the cumulative distribution function for the i^{th} table:

$$C_{ia-1} < R_1 \leq C_{ia}\ , \tag{8.1.39}$$

where

C_{ia-1} = cumulative probability corresponding to the $a - 1^{st}$ cosine bin,

C_{ia} = cumulative probability corresponding to the a^{th} cosine bin,

Using a similar procedure, the b^{th} bin is selected from the i+1$^{\text{st}}$ table:

$$C_{i+1b-1} < R_1 \leq C_{i+1b}\ , \tag{8.1.40}$$

where

C_{ib-1} = cumulative probability corresponding to the $b - 1^{st}$ cosine bin,

C_{ib} = cumulative probability corresponding to the b^{th} cosine bin.

If the cosine bins are not equiprobable and the PDF is represented by a continuous distribution, the bins are selected so that linear interpolation can be performed in the PDF. Because the CDF is obtained by integrating the PDF, the interpolation procedure for the CDF has a quadratic form. The value for $\dot{\mu}_i$ is obtained with the following equation:

$$\dot{\mu}_i = \mu_{ia} + \frac{\sqrt{P_{ia}^2 + 2s_i(R_1 - C_{ia-1})} - P_{ia}}{s_i}\ , \tag{8.1.41}$$

and

$$s_i = \frac{P_{ia+1} - P_{ia}}{\mu_{ia+1} - \mu_{ia}}\ , \tag{8.1.42}$$

where

P_{ia} = value of the PDF corresponding to the lower boundary of the a^{th} cosine bin in the distribution for E_i, and

P_{ia+1} = value of the PDF corresponding to the upper boundary of the a^{th} cosine bin in the distribution for E_i.

Likewise, the equation for $\dot{\mu}_{i+1}$ is obtained using an equation that is similar to Eq. (8.1.41)

$$\dot{\mu}_{i+1} = \mu_{i+1b} + \frac{\sqrt{P_{i+1b}^2 + 2s_{i+1}(R_1 - C_{i+1b-1})} - P_{i+1b}}{s_{i+1}}, \tag{8.1.43}$$

and

$$s_{i+1} = \frac{P_{i+1b+1} - P_{i+1b}}{\mu_{i+1b+1} - \mu_{i+1b}}, \tag{8.1.44}$$

where

P_{i+1b} = value of the PDF corresponding to the lower value of the b^{th} cosine bin in the distribution for E_{i+1}, and

P_{i+1b+1} = value of the PDF corresponding to the upper value of the b^{th} cosine bin in the distribution for E_{i+1}.

The exiting angle cosine is obtained by interpolating between $\dot{\mu}_i$ and $\dot{\mu}_{i+1}$ based on the incident energy using Eq. (8.1.38).

Exit energy

In the kinematics data block, each incident energy has a secondary distribution of *NPU* angle cosines. Therefore, there are *NPU* (E, μ) pairs associated with each incident energy. For each (E, μ) pair, there is a corresponding exit energy distribution that can have *NPE* exit energies. Because the kinematics data are tabulated in a coupled angle-energy format, the exit energy is obtained by a 2-D interpolation as shown in Fig. 8.1.205.

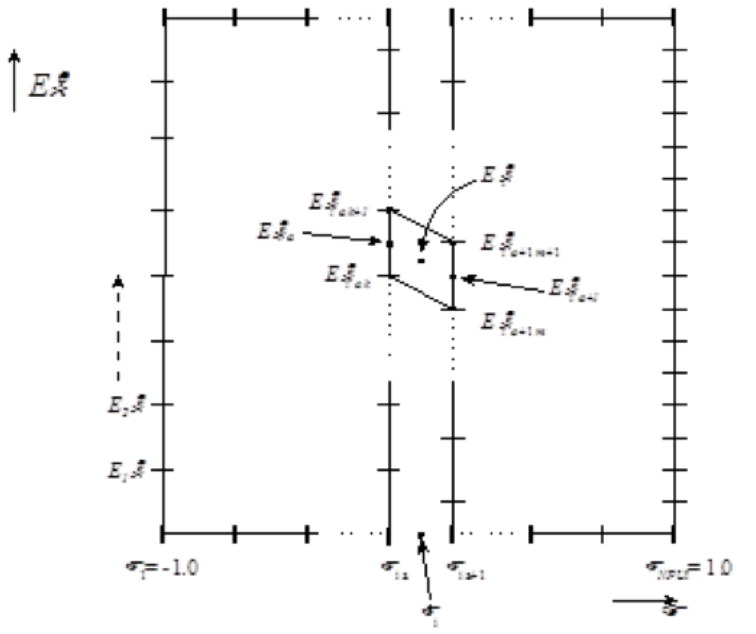
The objective of the sampling procedure is to sample the exit energy *E'* in conjunction with the sampled angle cosine. Therefore, the interpolation for the exit energy is performed with an equation that is analogous to Eq. (8.1.38):

$$E' = E'_i + \left(\frac{E - E_i}{E_{i+1} - E_i}\right)(E'_{i+1} - E'_i) \tag{8.1.45}$$

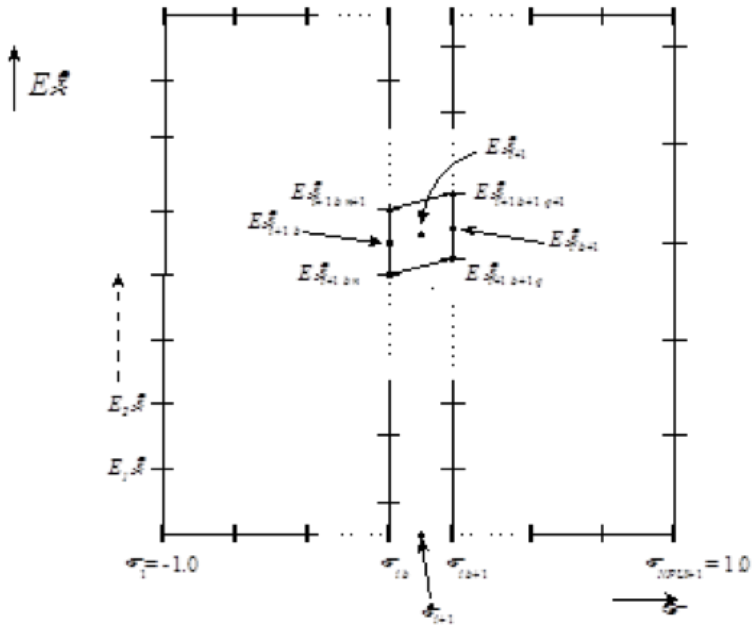
Based on Eq. (8.1.45), the values of E'_i and E'_{i+1} must be obtained in order to calculate the exit energy for the collision. The a^{th} and b^{th} cosine bins are selected according to the procedures in Sect. 8.1.7.2.11 from tables i and i+1, respectively. As a result, the secondary energy distributions corresponding to the a^{th} and b^{th} cosine bins must be used to sample the exit energies from tables i and i+1. The details for sampling the energy bins are deferred for the moment. Once the appropriate energy bins are sampled from the two tables, the interpolation for E'_i and E_{i+1} is obtained with the following equations:

$$E'_i = E'_{ia} + \left(\frac{\dot{\mu}_i - \mu_{ia}}{\mu_{ia+1} - \mu_{ia}}\right)\left(E'_{ia+1} - E'_{ia}\right) , \tag{8.1.46}$$

$$E'_{i+1} = E'_{i+1b} + \left(\frac{\dot{\mu}_{i+1} - \mu_{i+1b}}{\mu_{i+1b+1} - \mu_{i+1b}}\right)\left(E'_{i+1b+1} - E'_{i+1b}\right). \tag{8.1.47}$$



Secondary Angle-Energy Table i for E_i



Secondary Angle-Energy Table $i+1$ for E_{i+1}

Fig. 8.1.205: Interpolation diagram for secondary angle-energy data.

Based on Eq. (8.1.46) and Eq. (8.1.47) the values for E'_{ia}, E'_{ia+1}, and $E'_{ia+1b+1}$ and E'_{i+1}. The values for E'_{ia} and E'_{ia+1} correspond to secondary energies that are coupled with the a^{th} and $a + 1^{st}$ angle cosines in Table i. Likewise, the values for E'_{i+1b} E'_{i+1b+1} correspond to the secondary energies that are coupled with the b^{th} and $b + 1^{st}$ angle cosines in Table i+1. Therefore, the exit energies from Table i are sampled from the secondary energy distributions that correspond to (E, μ_{ia}) and (E, μ_{ia+1}), and the energies from Table i+1 are sampled from the energy distributions for $(E, \mu_{i+1}b)$ and (E, μ_{i+1b+1}).

As with the angular data, the secondary energy distributions may be provided in equiprobable or nonequiprobable energy bins. The following discussion provides the procedures for sampling the different distributions.

Equiprobable Energy Bins. In Table i, the k^{th} and m^{th} energy bins are sampled from the energy distributions for $(E, \mu_{i\,a})$ and $(E, \mu_{i\,a+1})$, respectively. The number of energy bins in a distribution is one less than the number of energies in the table (i.e., *NPE* - 1). If the energy distributions are provided in equiprobable bins, the k^{th} and m^{th} bins are selected as follows:

$$k = (NPE_{ia} - 1) * R_2 + 1, \tag{8.1.48}$$

$$m = (NPE_{ia+1} - 1) * R_2 + 1. \tag{8.1.49}$$

The exiting energy values for $E'_{i\,a}$ $E'_{i\,a+1}$ are interpolated as follows:

$$E'_{ia} = E'_{iak} + \Big[k - (NPE_{ia} - 1) * R_2\Big]\Big(E'_{iak+1} - E'_{iak}\Big), \tag{8.1.50}$$

$$E'_{ia+1} = E'_{ia+1m} + \Big[m - (NPE_{ia+1} - 1) * R_2\Big]\Big(E'_{ia+1m+1} - E'_{ia+1m}\Big). \tag{8.1.51}$$

In Table i+1, the n^{th} and q^{th} energy bins are sampled from the energy distributions for $(E, \mu_i b)$ and (E, μ_{ib+1}), respectively. As presented for the i^{th} table, the n^{th} and q^{th} bins are selected from an equiprobable distribution in a manner analogous with Eq. (8.1.48) and Eq. (8.1.49):

$$n = (NPE_{i+1b} - 1) * R_2 + 1, \tag{8.1.52}$$

$$q = (NPE_{i+1b+1} - 1) * R_2 + 1. \tag{8.1.53}$$

The exiting energy values for $E_{i+1\ b}$ and E_{i+1b+1} are interpolated as follows:

$$E'_{i+1b} = E'_{i+1bn} + \Big[n - (NPE_{i+1b} - 1) * R_2\Big]\Big(E'_{i+1bn+1} - E'_{i+1bn}\Big), \tag{8.1.54}$$

$$E'_{i+1b+1} = E'_{i+1b+1q} + \Big[q - (NPE_{i+1b+1} - 1) * R_2\Big]\Big(E'_{i+1b+1q+1} - E'_{i+1b+1q}\Big). \tag{8.1.55}$$

The exit energy from the i^{th} table (i.e., E') is obtained by substituting the values for E'_{ia} and E'_{ia+1} into Eq. (8.1.46), and the exit energy from the i+1$^{\text{st}}$ table (i.e., E'_{i+1}) is calculated by substituting the values for E'_{ib} and E'_{ib+1} into Eq. (8.1.47). Finally, the exit energy for the collision is obtained by inserting the calculated values for E'_i and E'_{i+1} into Eq. (8.1.45).

Nonequiprobable Energy Bins. If the energy distributions are provided in nonequiprobable bins, the k^{th} and m^{th} bins are sampled according to the cumulative distribution values:

$$C_{iak-1} < R_2 \leq C_{iak}, \tag{8.1.56}$$

$$C_{ia+1m-1} < R_2 \leq C_{ia+1m}, \tag{8.1.57}$$

where

C_{iak-1} = cumulative probability corresponding to the k-1st energy bin in the (E, μ_{ia}) distribution,

C_{iak} = cumulative probability corresponding to the k^{th} energy bin in the (E, μ_{ia}) distribution,

$C_{ia+1m-1}$ = cumulative probability corresponding to the m-1st energy bin in the $(E, \mu_i a + 1)$ distribution, and

C_{ia+1m} = cumulative probability corresponding to the m$^{\text{th}}$ energy bin in the (E, μ_{ia+1}) distribution.

For the nonequiprobable bins, the bins for the secondary energy are selected so that linear interpolation can be performed in the PDF. Since the CDF is obtained by integrating the PDF, the interpolation procedure for the CDF is quadratic in form. As a result, the value for $E'_{i\ a}$ is obtained with the following equation:

$$E'_{ia} = E'_{iak} + \frac{\sqrt{P^2_{iak} + 2s_{ia}(R_2 - C_{iak-1})} - P_{iak}}{s_{ia}}, \tag{8.1.58}$$

and

$$s_{ia} = \frac{\sqrt{P_{iak+1} - P_{iak}}}{E'_{iak+1} - E'_{iak}}, \tag{8.1.59}$$

where

P_{iak} = value of the PDF corresponding to the lower boundary of the k^{th} energy bin in the (E, $\mu_{i\ a}$) distribution, and

P_{iak+1} = value of the PDF corresponding to the upper boundary of the k^{th} energy bin in the (E, $\mu_{i\ a}$) distribution.

Likewise, the value for $E_{i\ a+1}$ is obtained with the following equation:

$$E'_{ia+1} = E'_{ia+1m} + \frac{\sqrt{P^2_{ia+1m} + 2s_{ia+1}(R_2 - C_{ia+1m-1})} - P_{ia+1m}}{s_{ia+1}}, \tag{8.1.60}$$

and

$$s_{ia+1} = \frac{P_{ia+1m+1} - P_{ia+1m}}{E'_{ia+1m+1} - E'_{ia+1m}} \tag{8.1.61}$$

where

P_{ia+1m} = value of the PDF corresponding to the lower boundary of the m^{th} energy bin in the (E, μ_{ia+1}) distribution, and

$P_{ia+1m+1}$ = value of the PDF corresponding to the upper boundary of the m^{th} energy bin in the (E, μ_{ia+1}) distribution.

For nonequiprobable distributions in the i+1st table, the n^{th} and q^{th} bins are sampled according to the cumulative distribution values:

$$C_{i+1bn-1} < R_2 \leq C_{i+1bn}, \tag{8.1.62}$$

$$C_{i+1b+1q-1} < R_2 \leq C_{i+1b+1q}, \tag{8.1.63}$$

where

$C_{i+1bn-1}$ = cumulative probability corresponding to the n-1st energy bin in the (E, $\mu_{i+1\ b}$) distribution,

C_{i+1bn} = cumulative probability corresponding to the n^{th} energy bin in the (E, $\mu_{i+1\ b}$) distribution,

$C_{i+1b+1q-1}$ = cumulative probability corresponding to the q-1st energy bin in the (E, $\mu_{i+1\ b+1}$) distribution, and

$C_{i+1b+1q}$ = cumulative probability corresponding to the q^{th} energy bin in the (E, $\mu_{i+1\ b+1}$) distribution.

As observed for the ith table, the interpolation procedure for the CDF is quadratic in form, and the value for $E'_{i+1\ b}$ is obtained as follows:

$$E'_{i+1b} = E'_{i+1bn} + \frac{\sqrt{P^2_{i+1bn} + 2s_{i+1b}(R_2 - C_{i+1bn-1})} - P_{i+1bn}}{s_{i+1b}}, \tag{8.1.64}$$

and

$$s_{i+1b} = \frac{P_{i+1bn+1} - P_{i+1bn}}{E'_{i+1bn+1} - E'_{i+1bn}}, \tag{8.1.65}$$

where

P_{i+1bn} = value of the PDF corresponding to the lower boundary of the n^{th} energy bin in the (E, μ_{i+1b}) distribution, and

$P_{i+1bn+1}$ = value of the PDF corresponding to the upper boundary of the n^{th} energy bin in the (E, μ_{i+1b}) distribution.

Likewise, the value for E'_{i+1b+1} is obtained with the following equation:

$$E'_{i+1b+1} = E'_{i+1b+1q} + \frac{\sqrt{P^2_{i+1b+1q} + 2s_{i+1b+1}(R_2 - C_{i+1b+1q-1})} - P_{i+1b+1q}}{s_{i+1b+1}}, \tag{8.1.66}$$

and

$$s_{i+1b+1} = \frac{P_{i+1b+1q+1} - P_{i+1b+1q}}{E'_{i+1b+1q+1} - E'_{i+1b+1q}}, \tag{8.1.67}$$

where

$P_{i+1b+1q}$ = value of the PDF corresponding to the lower boundary of the q^{th} energy bin in the (E, μ_{i+1b+1}) distribution, and

$P_{i+1b+1q+1}$ = value of the PDF corresponding to the upper boundary of the q^{th} energy bin in the (E, μ_{i+1b+1}) distribution.

To obtain the exit energy for the collision, the energy from the ith table (i.e., E'_i) is calculated by substituting the values for E'_{ia} and E'_{ia+1} into Eq. (8.1.46), and the exit energy from the i+1st table (i.e., E'_{i+1}) is calculated by substituting the values for E'_{ib} and E'_{ib+1} into Eq. (8.1.47). Finally, the exit energy for the collision is obtained by inserting the calculated values for E'_i and E'_{i+1} into Eq. (8.1.45).

Isotropic Angular Distributions With Energy Coupling

The kinematics format can accommodate isotropic angular distributions in the coupled angle energy format. The following discussion describes the special case with the appropriate sampling procedures. If the secondary angular distribution is isotropic at an incident energy E, a single exit cosine with a value of -2.0 is specified in the (E, μ) block. Therefore, the exit angle cosine is sampled uniformly between -1.0 and 1.0:

$$\mu = 2R_1 - 1. \tag{8.1.68}$$

Because there is only one exit cosine specified in the (E, μ) block, there is a single energy distribution record specified for the (E, μ) pair. The general structure (i.e., material identifiers and data flags are omitted for clarity) of the kinematics data within a section for a reaction is presented in Table 8.1.31. As a result, the sampling procedure for the exit energy is based on the incident energy.

Table 8.1.31: Kinematics data structure for isotropic angular distributions

(E, μ) Data Block					
E	C_2	μ	C_μ	P_μ	
E_1	0	-2.0	1.0	1.0	
E_2	0	-2.0	1.0	1.0	
.	.	.	.	.	
.	.	.	.	.	
.	.	.	.	.	
E_{NE}	0	-2.0	1.0	1.0	
(E, μ, $E¢$) Data Block					
E	μ	$E¢$(j)	$C_{E¢}$(j)	$P_{E¢}$(j)	j=1, NPE
E_1	-2.0	$E¢$(j)	$C_{E¢}$(j)	$P_{E¢}$(j)	j=1, NPE
E_2	-2.0	$E¢$(j)	$C_{E¢}$(j)	$P_{E¢}$(j)	j=1, NPE
.	.	.	.	.	.
.	.	.	.	.	.
.	.	.	.	.	.
E_{NE}	-2.0	$E¢$(j)	$C_{E¢}$(j)	$P_{E¢}$(j)	j=1, NPE

Once the angle is sampled according to Eq. (8.1.68), the exit energy is sampled in a manner that is analogous to the procedures of Sect. 8.1.7.2.13. If the incident energy, E, is between E_i and $E_{\mathrm{i}+1}$, the k^{th} energy bin is sampled from the distribution corresponding to E_i using Eq. (8.1.69) or Eq. (8.1.70) for equiprobable or nonequiprobable distributions, respectively.

$$k = (NPE_i - 1) * R_2 + 1, \tag{8.1.69}$$

or

$$C_{ik-1} < R_2 \leq C_{ik}, \tag{8.1.70}$$

where

NPE_i = number of exit energies corresponding to E_i,

C_{ik-1} = cumulative probability corresponding to the k-1$^{\mathrm{st}}$ energy bin in the distribution for E_i, and

C_{ik} = cumulative probability corresponding to the k$^{\mathrm{th}}$ energy bin in the distribution for E_i.

For equiprobable energy bins, the exit energy corresponding to E_i is calculated as follows:

$$E_i^{'} = E_{ik}^{'} + \left[k - (NPE_i - 1) * R_2\right]\left(E_{ik+1}^{'} - E_{ik}^{'}\right). \tag{8.1.71}$$

If the secondary energy distributions are provided in nonequiprobable bins the exit energy is calculated using the following equation:

$$E_i^{'} = E_{ik}^{'} + \frac{P_{ik}^2 + 2s_i(R_2 - C_{ik-1}) - P_{ik}}{s_i}, \tag{8.1.72}$$

and

$$s_i = \frac{P_{ik+1} - P_{ik}}{E_{ik+1}^{'} - E_{ik}^{'}}, \tag{8.1.73}$$

where

P_{ik} = value of the PDF corresponding to the lower boundary of the k^{th} energy bin in the distribution for E_i, and

P_{ik+1} = value of the PDF corresponding to the upper boundary of the k^{th} energy bin in the distribution for E_i.

By replacing i with i+1 in Eq. (8.1.69) through Eq. (8.1.73), the exit energy $E_{i+1}^{'}$ can be calculated from the secondary energy distribution corresponding to the incident energy E_{i+1}. Subsequently, Eq. (8.1.45) can be used to calculate the exit energy.

Coherent and incoherent elastic scattering

If thermal scattering law data are available for a material, the elastic scattering mechanism may be specified as either coherent or incoherent elastic scattering. Consequently, there is no change in energy resulting from either collision. The secondary energy distribution block for each (E, μ) pair only has one exit energy with a value equal to the incident energy E. Therefore, the procedure for coherent or incoherent elastic scattering reduces to sampling the exit angle cosine. The procedures detailed in Sect. 8.1.7.2.12 are used to sample the exit angle cosine. The general structure of the kinematics data within a section for coherent or incoherent elastic scattering is presented in Table 8.1.32 with the material identifiers and data flags omitted for clarity. Once the angle cosine is selected, the exit energy is set equal to the incident energy.

Table 8.1.32: Kinematics data structure for coherent and incoherent elastic scattering

Elastic and discrete-level inelastic scattering

There is a one-to-one correspondence between the exiting angle and energy for elastic and discrete level inelastic scattering . Once the exiting angle is selected, the exiting energy is already determined based on the kinematics equations documented in most conventional reactor theory text books. However, an obscure fact is that the exiting energy distributions for discrete-level inelastic reactions and hydrogen elastic scattering can be double valued in the lab system. For discrete level inelastic scattering in the lab system, the range of incident energies that can have a double valued exit energy is given by the following expression:

$$\Delta E_{double} = \frac{Q}{A(1-A)}, \tag{8.1.74}$$

where

Q = the excess of the kinetic energy of the product particles over that of the original particles, and

A = atomic mass ratio of the target mass to the mass of a neutron.

Eq. (8.1.74) provides the size in energy of the double valued region above the threshold energy for the reaction. As indicated by Eq. (8.1.74), the range of energies for a double valued region is inversely proportional to the target mass. Using Eq. (8.1.74) and ENDF/B data, the values of ΔE_{double} can be calculated for all discrete level inelastic scattering reactions for all isotopes. A plot of ΔE_{double} as a function of atomic mass ratio is provided in Fig. 8.1.206 for all possible discrete level inelastic scattering collisions for all isotopes. As shown in Fig. Fig. 8.1.206, the size of the double valued region approaches 1 MeV as the mass ratio decreases. Because ΔE_{double} can be relatively large, the double valued anomaly cannot be ignored in the collision

treatment. The following discussion outlines the properties of the kinematics data and the procedures for treating elastic and discrete level inelastic scattering.

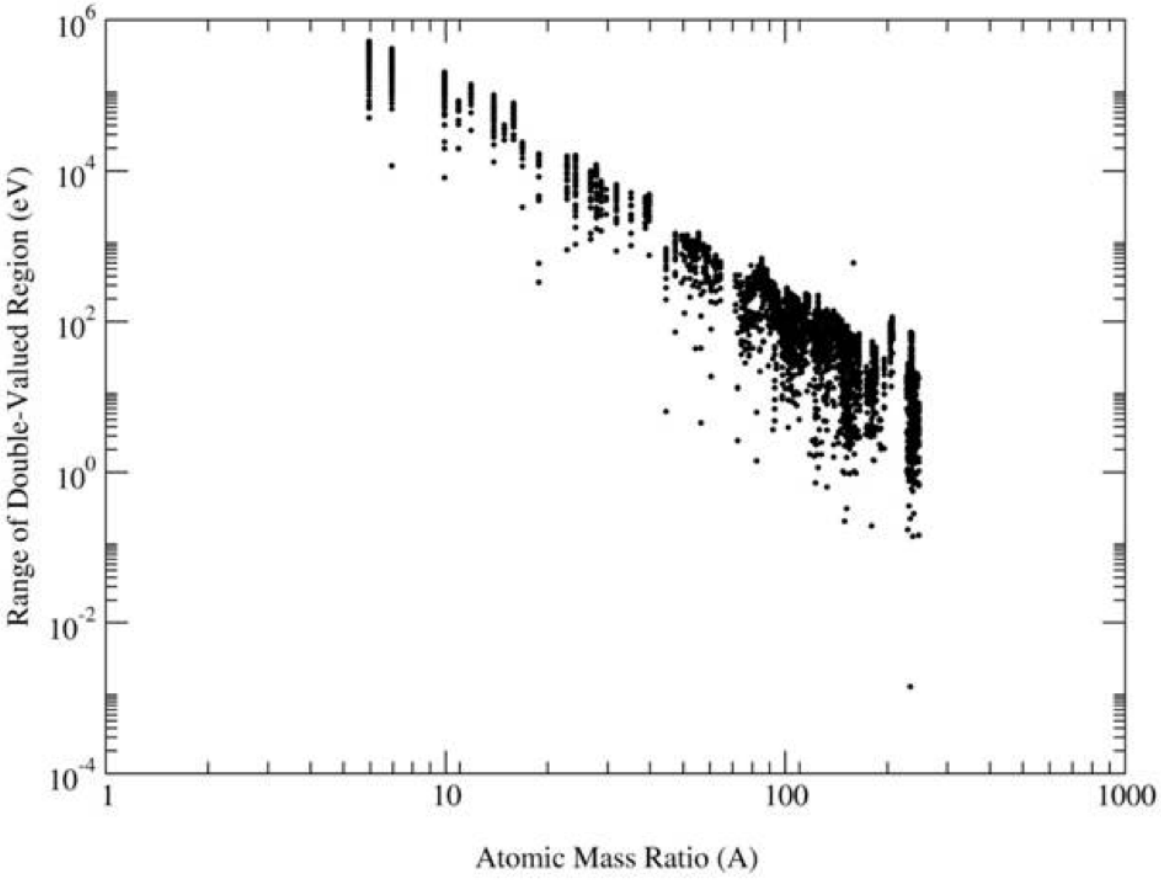

Fig. 8.1.206: Range of incident energies (ΔE_{double}) for double valued region as a function of mass ratio.

As noted previously, *NPU* secondary angle cosines are provided for each incident energy for a reaction, and the cosine distribution can be represented with either equiprobable or nonequiprobable distributions. Depending on the type of distribution, procedures similar to those of Sect. 8.1.7.2.13 are used to sample an equiprobable or nonequiprobable angular distribution for the exit cosine in the lab system.

The angular data blocks for discrete level inelastic scattering and hydrogen elastic scattering are similar in form to other reactions; however, the exit lab cosines for discrete level inelastic scattering are greater than zero in the double-valued region, and an exit lab cosine may appear twice in the distribution with different probabilities. As an example, discrete level inelastic scattering for ^{7}Li is characterized by a double valued exit energy distribution as a function of exit cosine in the lab system. Fig. 8.1.200 provides the exit energy distribution for an inelastic collision that leaves the ^{7}Li nucleus in the first excited state (i.e., MT = 51) in the lab system. For ^{7}Li, the threshold for MT = 51 is 5.4672×10^5 eV, and the double valued region extends from the threshold energy up to 5.58259×10^5 eV; therefore, the incident energy range of the double valued region is ~1.15×10^4 eV. As shown in Fig. 8.1.200, the exit energy distributions are provided for different incident energies within the double valued region and an incident energy above the double valued region. As the incident energy exceeds the maximum energy for which two exiting energies can be produced, the secondary energy distribution becomes single valued (i.e., one exit energy for an exit cosine).

Note that the double valued anomaly does not occur in the center-of-mass system. Therefore, the two exit energies possible for the lab system actually correspond to two different center-of-mass exit cosines. During the preparation of the KENO library, the angular distribution tables for discrete level inelastic scattering and elastic scattering for hydrogen can be constructed in the center-of-mass system and subsequently converted to the lab system. In order to properly construct the angular distribution tables in the lab system, the minimum lab cosine, $\mu^{\min}_{\text{lab}}$, must be determined because exit angles below the minimum lab cosine are not possible.

For discrete level inelastic scattering and elastic scattering, the exit cosine in the lab system can be expressed as a function of the center-of-mass scattering angle, μ_{cm}:

$$\mu = \frac{\gamma + \mu_{cm}}{(1 + 2\gamma\mu_{cm} + \gamma^2)^{1/2}}, \tag{8.1.75}$$

where

$$\frac{1}{\gamma} = \left[A^2 + \frac{A(A+1)Q}{E}\right]^{1/2} \tag{8.1.76}$$

Physically, the quantity $1/\gamma$ represents the ratio of the exit velocity of the neutron in the lab system to the center-of-mass velocity. Moreover, the quantity $1/\gamma$ reduces to A for elastic scattering (i.e., $Q = 0$). The minimum value for μ can be obtained by taking the derivative of Eq. (8.1.77) with respect to μ_{cm} which yields the following expression:

$$\frac{d\mu}{d\mu_{cm}} = \frac{1 + \gamma\mu_{cm}}{(1 + 2\gamma\mu_{cm} + \gamma^2)^{3/2}}. \tag{8.1.77}$$

Setting Eq. (8.1.77) equal to 0 reveals that the minimum lab cosine ($\mu^{\min}_{\text{lab}}$) occurs when $\mu_{\text{cm}} = -1/\gamma$. For elastic scattering, the minimum lab cosine occurs when $\mu_{\text{cm}} = -A$. Because hydrogen is the only nuclide with a mass ratio below 1, hydrogen is the only nuclide that has a double valued exit energy distribution in the lab system for elastic scattering.

During the preparation of the KENO library, the lab distributions for discrete level inelastic scattering and hydrogen elastic scattering will be constructed so that $\mu^{\min}_{\text{lab}}$ is a boundary for an angular bin, and no angular cosines in the lab system will be permitted below $\mu^{\min}_{\text{lab}}$. As shown in Fig. 8.1.207 for ^{7}Li, the exit cosines greater than $\mu^{\min}_{\text{lab}}$ will have two possible exit energies in the double valued region. As a result, the angular distribution table in the library will have angles that appear twice with different probabilities. For example, an angle cosine μ may be present in the table with probabilities P_{m} and P_{n}. Although the value of the angle cosine is the same for both probabilities, the corresponding exit energy will be different for each (μ, *P)* pair. In other words, the probability for an exit cosine determines the location in the exit energy distribution table for selecting the outgoing energy.

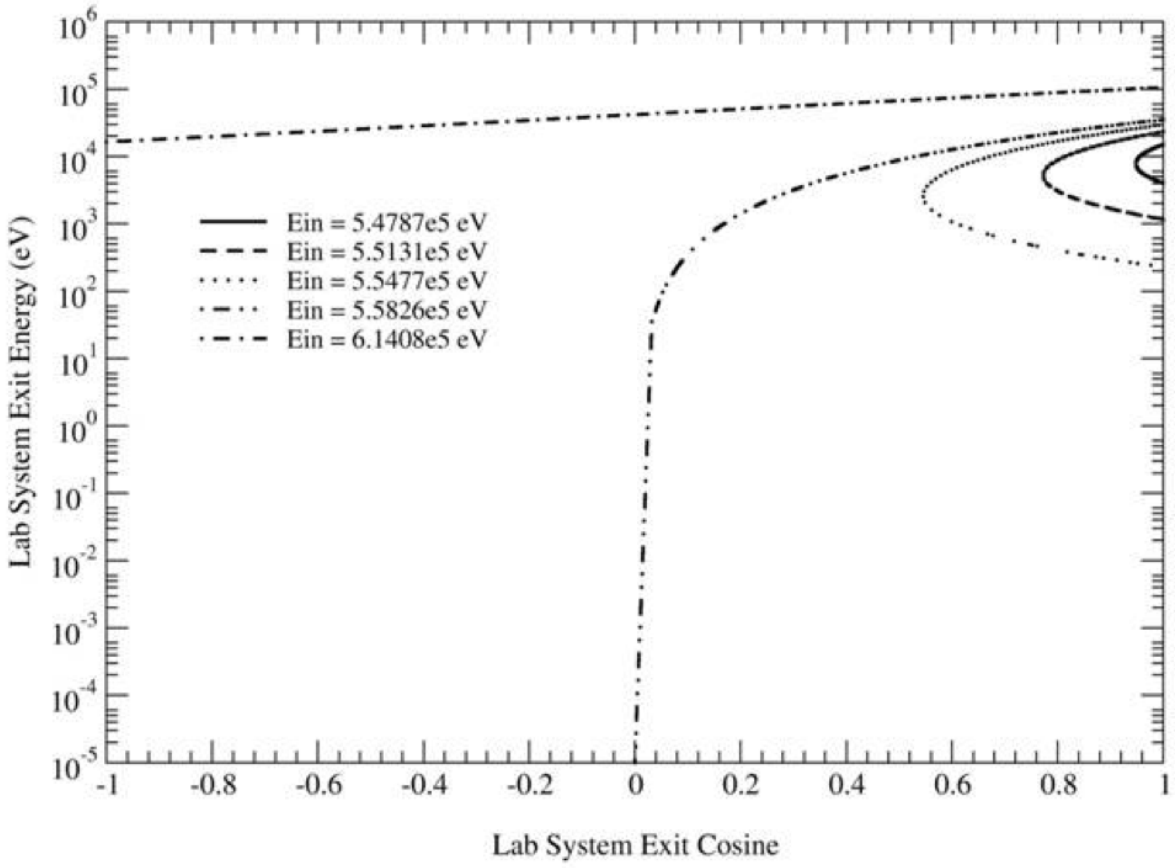

Fig. 8.1.207: ^{7}Li exit energy distribution for the first discrete level inelastic scattering reaction (MT=51). $E_{\text{threshold}} = 5.4672 \times 10^5$ eV; $\Delta E_{\text{double}} = 1.1539 \times 10^4$ eV.

Based on the format of the kinematics data, angle cosine distributions are provided as a function of incident energy. If the incident energy, E, is between E_{i} and $E_{\text{i+1}}$, then the i^{th} table is selected with probability P_{i} and the i+1 table is selected with probability $P_{\text{i+1}}$:

$$P_i = \frac{E_{i+1} - E}{E_{i+1} - E_i}, \tag{8.1.78}$$

$$P_{i+1} = \frac{E - E_i}{E_{i+1} - E_i}. \tag{8.1.79}$$

Once the angular distribution corresponding to the incident energy is selected, the exit angle cosine can be selected using procedures like those in Sect. 8.1.7.2.12 For example, if the i^{th} incident energy is selected, either Eq. (8.1.34) is used to select the a^{th} cosine bin for equiprobable bins, or Eq. (8.1.39) is used for nonequiprobable bins. Subsequently, either Eq. (8.1.36) or Eq. (8.1.41) is used to calculate the exit angle cosine, depending on the type of angular distribution provided.

The coupled secondary angle-energy data blocks (E, μ, E') follow the angular data block in the kinematics data. For elastic scattering and discrete level inelastic scattering, there is one possible exit energy. Therefore, in the exit energy distribution block, a single exit energy ($NPE = 1$) is provided for each (E, μ) pair, and the general structure (i.e., material identifiers and data flags are omitted for clarity) of the secondary energy distribution data block is presented in Table 8.1.33. Because only one exit energy is provided for each (E, μ)

pair, the probability for the exit energy is 1.0. As indicated in Table 8.1.33, a cumulative probability of 1.0 is stored for each exit energy; however, the parameters stored in the PDF location are the power-interpolation parameters needed to interpolate the exit energy.

Table 8.1.33: Secondary energy distribution format for elastic and discrete-level inelastic scattering

E	μ	E'	$C_{E'}$	$p_{E'}$
E_1	μ_1	E'_1	1.0	p_1
E_1	μ_2	E'_2	1.0	p_2
.	.	.	.	.
.	.	.	.	.
.	.	.	.	.
E_1	μ_{NPU}	E'_{NPU}	1.0	p_{NPU}
		.		
		.		
		.		
E_{NE}	μ_1	E'_1	1.0	p_1
E_{NE}	μ_2	E'_2	1.0	p_2
.	.	.	.	.
.	.	.	.	.
.	.	.	.	.
E_{NE}	μ_{NPU}	E'_{NPU}	1.0	p_{NPU}

When an exiting angle $\dot{\mu}_i$ is sampled between μ_{a} and $\mu_{\text{a+1}}$, the exiting energy values that correspond to μ_{a} and $\mu_{\text{a+1}}$ for the incident energy E_{i} can be used to interpolate the exiting energy E' that corresponds to$\dot{\mu}_i$. Physically, the interpolation procedures correspond to an interpolation along one of the incident energy curves as depicted in Fig. 8.1.205. In order to perform the interpolation, the a^{th} and a+1$^{\text{st}}$ (E, μ) pairs are located in the secondary energy distribution block corresponding to E_{i}. Subsequently, the corresponding a^{th} and a+1 exit energy values (i.e., E'_a and E'_{a+1}) are read from the secondary energy distribution record.

The exiting energy is interpolated with the following relation:

$$E'(\dot{\mu}_i) = E'_a + \left(\frac{\dot{\mu}_i^{P_a} - \mu_a^{P_a}}{\mu_{a+1}^{P_a} - \mu_a^{P_a}} \right) \left(E'_{a+1} - E'_a \right) , \tag{8.1.80}$$

where

P = is a "power-interpolation" factor for the a^{th} cosine bin that is obtained from a fit to the E' distribution as a function of μ.

The interpolation procedure in Eq. (8.1.80) is analogous to the interpolation scheme that has been used successfully to interpolate Bondarenko factors as a function of temperature in the BONAMI module. If the curve is monotonic in nature, the power-interpolation scheme can be used to represent the curvature with a minimum number of points. For elastic and discrete level inelastic scattering, the $E'(\mu)$ distribution is monotonic and is suited for the power interpolation scheme. Note that if p is 1, Eq. (8.1.80) reduces to a linear interpolation in μ-E' space.

Thermal scattering effects

A collision between a neutron and nucleus can be affected by the thermal motion of the target nucleus. Moreover, ENDF provides thermal scattering law data to account for the thermal effects of scattering with a material below 10 eV; however, the scattering law data are only available for a select number materials as shown in Table 8.1.34. If thermal scattering law data are not available, elastic scattering is treated with the free gas approximation in the KENO library. For heavy nuclides with 0 K scattering libraries available, the Doppler Broadening Rejection Correction (DBRC) method is used instead. For DBRC-enabled nuclides, thermal scattering effects are taken into account up to 210 eV (although this parameter can be controlled by the user). More information on DBRC is given in Sect. 8.1.7.2.18.

Table 8.1.34: ENDF/B thermal scattering law data.

The continuous energy cross section library is processed to account for the appropriate scattering effects. As a result, the KENO cross section library inherently accounts for thermal scattering using either the thermal scattering law data or the free gas approximation. In other words, the kinematics data based on thermal effects are combined with the fast data to represent the collision kinematics for the material. As noted previously, the kinematics data block for a reaction is divided into sections that describe the collision kinematics for a range of incident energies. As a result, the kinematics data structure has a modular format that is beneficial for data library production. Because of the kinematics data structure, the thermal scattering law data, which are typically applied up to 10 eV, can be processed independently with AMPX to obtain the angle energy probability distributions. Subsequently, one or more sections in the kinematics data block can be used to represent the thermal angle -energy distributions for energies up to 10 eV. Moreover, the fast kinematics data can be represented with one or more sections for energies above 10 eV. As part of the library preparation,

the thermal kinematics data are combined with the fast kinematics data block to complete the collision representation for the entire range of incident energies. Because the thermal scattering effects are treated during the processing of the cross section data for a material, the thermal effects are inherently treated in KENO. The 10 eV cutoff energy for thermal scattering can be input by the parameter **THC** in the parameter input. Using a cutoff value above 10 eV increases the energy range of free gas approximation because AMPX processed thermal scattering law data are available up to 10 eV, and this may increase the runtime in the sampling process while improving the accuracy in the results for some casees. During the Monte Carlo random walk, the procedures provided in Sect. 8.1.7.2.12 and Sect. 8.1.7.2.13 are used to sample the exit angle and energy for the collision.

Doppler broadening rejection correction method

When colliding with a heavy nuclide, the thermal motion of the target nuclide can significantly affect the exit angle and energy of the neutron. The thermal motion of the target nuclide was previously ignored, but this assumption has been proven inadequate by Dagan and Becker [BDL09].

A new sampling equation has been implemented to allow for Doppler broadening of the scattering kernel. Removing this approximation can have a significant impact on the critical eigenvalue of systems by allowing neutrons to be upscattered into absorption resonances. Currently, DBRC is enabled in KENO only for ^{238}U, and this feature can be activated by setting the parameter **DBR**=1.

Doppler broadening methods

CE KENO calculations will perform temperature adjustment of neutron cross sections by default. The cross sections provided with SCALE are typically supplied in 300 K intervals, and additional cross section temperature resolution may be desired to model non-room temperature systems or systems with significant temperature effects.

The capability to perform problem-dependent Doppler broadening of nuclear cross sections has been implemented in KENO. This feature is controlled by the **DBX** parameter, which causes KENO to perform Doppler broadening on the cross sections in all compositions in a problem before simulating particle histories. When this occurs, the cross sections for each material are broadened to the temperature assigned to that material in the `READ COMP` block, as long as the requested temperature is more than 4 K from the library temperature. Within this ± 4 K band, the library temperature is used to avoid difficulties with numerical instabilities in small cross section adjustments. The default for this feature is `DBX=2`, which performs Doppler broadening for both the 1-D and 2-D cross sections. Current options available are as follows:

- `DBX` = 0 – Doppler broadening is not performed. KENO selects the library at the closest temperature. If desired, the user can use the `TTL` parameter to force a job abort if the library temperature is too far from the requested temperature. By default, `TTL=-1`, so the closest library will be used regardless of the temperature difference.
- `DBX=1` – Doppler broadening is performed using a finite difference method on the one-dimensional cross sections that are temperature dependent. Logarithmic interpolation is also used to broaden the probability table data. When this option is used, the collision probabilities are recalculated after the Doppler broadening is complete to ensure consistency.
- `DBX=2` – The same actions as `DBX=1` are performed, and Doppler broadening is also performed on the thermal moderator data by conducting interpolation on the double differential probability data present on the cross section library.

Nuclide level energy unionization is automatically disabled (`M2U=NO`) when Doppler broadening is enabled in order to reduce the memory usage. At this writing, research is in progress to allow KENO to perform on-the-fly cross section Doppler broadening as particle histories are being simulated.

8.1.7.3 Multigroup mode solution procedure

$$\frac{1}{v_g}\frac{\partial \Phi_g}{\partial t}(X,\Omega,t) + \Omega \bullet \nabla \Phi_g(X,\Omega,t) + \Sigma_{\mathrm{tg}}(X)\ \Phi_g(X,\Omega,t) = \mathrm{q_g}(X,\Omega,t), \tag{8.1.81}$$

where

- g is the energy group of interest,
- v_g is the average velocity of the neutrons in group g,
- $\Phi_g(X,\Omega,t)$ is the angular flux of neutrons having their energies in group g, at position X and time t, and
- $\Sigma_{tg}(X)$ is the macroscopic total cross section of the media at position X for group g, corresponding to

$$\Sigma_{tg}(X) = \frac{\int_{\Delta E_g} \Sigma_t(X,E)\Phi(X,E,\Omega,t)dE}{\int_{\Delta E_g} \Phi(X,E,\Omega,t)dE}, \tag{8.1.82}$$

where

- ΔE_g defines group g, and
- $q_g(X,\Omega,t)$ is the total source contributing to energy group g at position X, and time t in direction Ω.

Using the relationship $X' = X - R\Omega$, defining the problem to be time independent using an integrating factor on both sides of Eq. (8.1.81), and defining

$$T(R) = \int_0^R \Sigma_{tg}(X - R'\Omega)dR', \tag{8.1.83}$$

the following equation can be written:

$$\Phi_g(X,\Omega) = \int_O^\infty q_g(X - R\Omega,\Omega)e^{-T(R)}dR. \tag{8.1.84}$$

At this point, the problem becomes an eigenvalue problem. If there is no external source, the source may be defined as

$$q_g(X,\Omega) = \sum_{g'} \int d\Omega' \Phi_{g'}\left(X,\Omega'\right)\ \Sigma_s\left(X, g' \to g, \Omega' \cdot \Omega\right) + \frac{1}{k} Q'_g(X,\Omega), \tag{8.1.85}$$

where

- k is the largest eigenvalue of the integral equation,
- $Q'_g(X,\Omega)$ is the fission source at position X for energy group g and direction Ω (all fission contributions to group g from all energy groups in the previous generation), and
- $\Sigma_s(X, g' \to g, \Omega' \to \Omega)$ is the scattering cross section for scattering at position X from group g' and direction Ω' to group g and direction Ω.

In terms of energy, the scatter can be defined as

$$\Sigma_s\left(X, g' \to g, \Omega' \cdot \Omega\right) = \frac{\int_{\Delta E_g}\int_{\Delta E_{g'}} \Sigma_s\left(X, E' \to E, \Omega' \cdot \Omega\right)\ \Phi\left(X, E', \Omega'\right) \mathrm{d}E' \mathrm{d}E}{\int_{\Delta E_{g'}} \Phi\left(X, E', \Omega'\right) \mathrm{d}E'}\ , \tag{8.1.86}$$

where

ΔE_g is the energy-range-defining energy group g, and

$\Delta E'_g$ is the energy-range-defining energy group g'.

Assuming the fission neutrons to be isotropic, the fission source $Q_{g'}(X, \Omega)$ can be written as

$$Q'_g(X, \Omega) = \frac{1}{4\pi} \sum_{g'} \int_{\Omega'} d\Omega' \Phi_{g'}(X, \Omega') \chi(X, g' \rightarrow g) \nu_{g'}(X) \Sigma_{fg'}(X), \tag{8.1.87}$$

where

- $\chi(X, g' \rightarrow g)$ is the fraction of neutrons born in energy group g from fission in energy group g in the media at position X,
- $\nu_{g'}(X)$ is the number of neutrons resulting from a fission in group g' at position X, and
- $\Sigma_{fg'}(X)$ is the macroscopic fission cross section of the material at position X for a neutron in energy group g'.

Substituting Eq. (8.1.85) into Eq. (8.1.84) yields the following equation:

$$\Phi_g(X, \Omega) = \int_0^\infty dR e^{-T(R)} \left\{ \frac{1}{k} Q'_g(X - R\Omega, \Omega) + \sum_{g'} \left[\int_{\Omega'} d\Omega' \Phi_{g'}(X - R\Omega, \Omega') \Sigma_s(X - R\Omega, g' \rightarrow g, \Omega' \cdot \Omega) \right] \right\} \tag{8.1.88}$$

The definition of k may be given as the ratio of the number of neutrons in the (n + 1)*th* generation to the number of neutrons in the n*th* generation or the largest eigenvalue of the integral equation. Using Eq. (8.1.87), Eq. (8.1.88) can be written as

$$\Phi_g(X, \Omega) = \int_0^\infty dR e^{-T(R)} \left\{ \sum_{g'} \frac{1}{k} \int_{\Omega'} \nu_{g'}(X - R\Omega) \Sigma_{fg'}(X - R\Omega) \chi(X - R\Omega, g' \rightarrow g) \Phi_g(X - R\Omega, \Omega') \frac{d\Omega'}{4\pi} + \sum_{g'} \left[\int_{\Omega'} d\Omega' \Sigma_{tg'}(X - R\Omega, \Omega') \Sigma_s(X - R\Omega, g' \rightarrow g, \Omega' \cdot \Omega) \right] \right\} \tag{8.1.89}$$

Writing Eq. (8.1.89) in generation notation, multiplying and dividing certain terms by $\Sigma_t(X)$, and multiplying both sides of the equation by $\nu_g(X)\Sigma_{fg}(X)$ yields the following equation, which is solved by KENO:

$$\frac{\nu_g(X)\Sigma_{fg}(X)}{\Sigma_{tg}(X)} \Sigma_{tg}(X) \Phi_{g,n}(X, \Omega) = \frac{\nu_g(X)\Sigma_{fg}(X)}{\Sigma_{tg}(X)} \Sigma_{tg}(X) \int_0^\infty dR e^{-T(R)} \left\{ \frac{1}{k} \sum_{g'} \left[\int_{\Omega'} \frac{\nu_{g'}(X - R\Omega)\Sigma_{fs'}(X - R\Omega)}{\Sigma_{tg'}(X - R\Omega)} \chi(X - R\Omega, g' \rightarrow g) \Sigma_{tg'}(X - R\Omega) \Phi_{g',n-1}(X - R\Omega, \Omega') \frac{d\Omega'}{4\pi} \right] + \sum_{g'} \left[\int_{\Omega'} \frac{\Sigma_s(X - R\Omega, g' \rightarrow g, \Omega' \cdot \Omega)}{\Sigma_{tg'}(X - R\Omega)} \Sigma_{tg'}(X - R\Omega) \Phi_{g',n}(X - R\Omega, \Omega') d\Omega' \right] \right\} \tag{8.1.90}$$

where n indicates the n*th* generation and n - 1 is the (n - 1)*th* generation. Note that the left-hand side of the equation — $\nu_g(X) \sum_{fg}(X) \Phi_{g,n}(X, \Omega)$ — is the fission production for the n*th* generation.

The solution strategy used by KENO solves Eq. (8.1.90) by using an iterative procedure. The fission production at point X in energy group g due to neutrons in the (n - 1)*th* generation, normalized to the system multiplication, is

$$\frac{1}{k}\sum_{g'}\int_{\Omega'}\frac{\nu_{g'}(X)\Sigma_{fg'}(X)}{\Sigma_{tg'}(X)}\chi(X,g'\rightarrow g)\Sigma_{tg'}(X)\Phi_{g',n-1}(X,\Omega')\frac{d\Omega'}{4\pi}. \tag{8.1.91}$$

The collision points used in KENO are chosen by selecting path lengths from the distribution

$$e^{-T(R)},$$

which is the probability of transport from any position X - RΩ to position X.

The first collision density of neutrons in group g per unit solid angle about Ω resulting from the fission source produced by the (n - 1) generation, normalized to the system multiplication, is

$$\frac{\Sigma_{tg}(X)\int_0^\infty dRe^{-T(R)}\frac{1}{k}\int_{\Omega'}\sum_{g'}\frac{\nu_{g'}(X-R\Omega)\Sigma_{fg'}(X-R\Omega)}{E_{tg'}(X-R\Omega)}}{\chi(X-R\Omega,g'\rightarrow g)\Sigma_{tg'}(X-R\Omega)\Phi_{g',n-1}(X-R\Omega,\Omega')\frac{d\Omega'}{4\pi}}. \tag{8.1.92}$$

The scattering source at position X emerging in group g and direction Ω resulting from previous collisions in the same generation, is

$$\sum_{g'}\int_{\Omega'}\frac{\Sigma_s(X,g'\rightarrow g,\Omega'\cdot\Omega)}{\Sigma_{tg'}(X)}\Sigma'_{tg}(X)\Phi_{g',n}(X,\Omega)d\Omega' \tag{8.1.93}$$

The collision density in group g, per solid angle about Ω is

$$\Sigma_{tg}\int_0^\infty dRe^{-T(R)}\sum_{g'}\int_{\Omega'}\frac{\Sigma_s(X-R\Omega,g'\rightarrow g,\Omega'\cdot\Omega)}{\Sigma_{tg'}(X-R\Omega)}\Sigma_{tg'}(X-R\Omega)\Phi_{g',n}(X-R\Omega,\Omega')\,d\Omega' \tag{8.1.94}$$

The total collision density times $\frac{\nu_g(X)\Sigma_{fg}(X)}{\Sigma_{tg}(X)}$ is the relationship from which KENO picks the source points for the next generation.

Collision treatment in KENO

A collision occurs in a geometrical region when a history exhausts its mean-free-path length within the boundaries of the region. For each collision, the absorbed weight and the fission weight are tabulated, then the weight is modified by the nonabsorption probability. This new weight is checked for splitting and Russian roulette, and if it survives, the history is scattered. A new energy group is selected from the cumulative transfer probability distribution. This group-to-group transfer determines an angular scattering distribution, usually expressed as a Legendre expansion of the cross section transfer array. A set of discrete angles and probabilities are generated by a generalized Gaussian quadrature procedure, preserving the moments of the Legendre expansion of the angular scattering distribution. KENO treats P_0 and P_1 Legendre expansions as special cases. If the scattering distribution is isotropic, a flag is set to randomly select new direction cosines from an isotropic distribution, instead of using discrete scattering angles. If the distribution is a P_1 expansion, KENO randomly selects the cosine of the scattering angle according to

(1) $|\bar{\mu}| < \frac{10^{-10}}{3}$: scattering distribution is isotropic,

(2) $|\bar{\mu}| \leq 1/3 : \mu = \left(\sqrt{1+6\zeta\bar{\mu}+(3\bar{\mu})^2}-1\right)/3\bar{\mu}$,

or

(3) $|\bar{\mu}| > 1/3 : \mu = \zeta(1 - |\bar{\mu}|) + \bar{\mu}$

where ζ is a uniform random variable between -1 and +1 and

$\bar{\mu}$ is the mean cosine of the scattering angle.

Otherwise, KENO randomly selects one of the discrete scattering angles (μ). New direction cosines are then calculated according to the following relationships where u, v, and w are the initial direction cosines and u', v', and w' are the direction cosines after the collision:

$$u' = u\cos\Psi - \sqrt{v^2 + w^2}\sin\Psi\cos\eta$$

$$v' = v\cos\Psi + \frac{uv}{\sqrt{v^2+w^2}}\cos\eta\sin\Psi - \frac{w}{\sqrt{v^2+w^2}}\sin\Psi\sin\eta$$

$$w' = w\cos\Psi + \frac{uw}{\sqrt{v^2+w^2}}\cos\eta\sin\Psi + \frac{v}{\sqrt{v^2+w^2}}\sin\Psi\sin\eta$$

where

$\sin\psi = \sqrt{1-\mu^2}$,

$\cos\psi = \mu$ = cosine of the scattering angle,

η = a random azimuthal angle between 0 and 2π.

Fission point selection

In order for a fission to occur, a neutron must first have a collision. The fission weight, fisw, is defined as the neutron weight, wt, times the ν-fission probability, fnfp:

$$fisw = wt \times fnfp \tag{8.1.95}$$

Two important variables used in the processing of fission points are (1) FWR, which is defined as the fission weight, fisw, divided by a random number, and (2) RAKBAR, which is defined as a factor times the running average value of k-effective, AKBAR. This factor is a function of the square root of the number of neutrons per generation and was chosen because it usually produces an adequate number of independent fission points and does not produce so many that an excessive amount of time is spent choosing from the fission points produced.

The following procedure for generating fission points is repeated until FWR is less than RAKBAR. A fission point is generated only if FWR is greater than RAKBAR. Multiple fissions at the same point are allowed only if fisw is greater than RAKBAR. If fisw is greater than RAKBAR, a fission point is stored with FWR set equal to RAKBAR divided by a random number and fisw is decremented by RAKBAR. Then the energy group of fission is chosen randomly from the fission spectrum of the mixture in which the fission occurred. The energy group of fission, the X, Y, and Z position, the location of the unit within the array, the region number, the value of FWR, the region number of the array boundary, and the nesting data for holes and/or arrays are stored in the fission bank. The quantity of fission points kept to be used as fission positions for the next generation is limited to the number of positions in the fission bank (input parameter `NFB=`). Typically `NFB` is equal to the input parameter `NPG`, the number of neutrons per generation. If a fission occurs and the fission counter is less than `NFB`, the fission point information is stored in the fission bank. If a fission occurs and the fission counter is greater than or equal to the number per generation, a search is made to find the smallest stored value of FWR. If FWR of the newly fissioned neutron is less than the smallest FWR in the table, it is discarded. Otherwise, the information from the newly fissioned neutron replaces that associated with the smallest value of FWR found in the table.

When the next generation is ready to be processed, data are transferred from the fission bank into the neutron bank to be used as starting positions for the fission neutrons. If more than NPG neutrons are saved in the fission bank, `NPG` of those having the highest values of FWR will be used. If too few fission positions were stored (less than the number per generation), a warning message to that effect (K?-132) is printed, and additional fission points are randomly chosen from those that were stored until the number of fission points available to start the next generation is equal to the number of neutrons per generation.

Biasing or weighting

In order to minimize the statistical deviation of k-effective per unit computer time, KENO uses weighted tracking rather than analog tracking. Weighted tracking accounts for absorption by reducing the neutron weight rather than allowing the neutron history to be terminated by absorption. To prevent expending excessive computer time tracking low-weight neutrons, Russian roulette is played when the weight of the neutron drops below a preset weight, WTLOW. Neutrons that survive Russian roulette are assigned a weight, WTAVG. The value of WTLOW and WTAVG can be assigned as a function of position and energy. The values used by KENO are

DWTAV = 0.5, the default value of WTAVG,

WTAVG = DWTAV, the weight given a neutron that survives Russian roulette, and

WTLOW = WTAVG/3.0, the value of weight at which Russian roulette is played.

A study [Hof82] by Hoffman shows these default values to be reasonable for bare critical assemblies. Fig. 8.1.208 from this study shows the analytic relationship between the variance and WTLOW when WTAVG is 0.5. Note that the default value of 0.167 for WTLOW is very close to the minimum point on the curve. Experimental results of actual Monte Carlo calculations[7] provide further assurance that 0.167 is an optimum choice for WTLOW when WTAVG is 0.5.

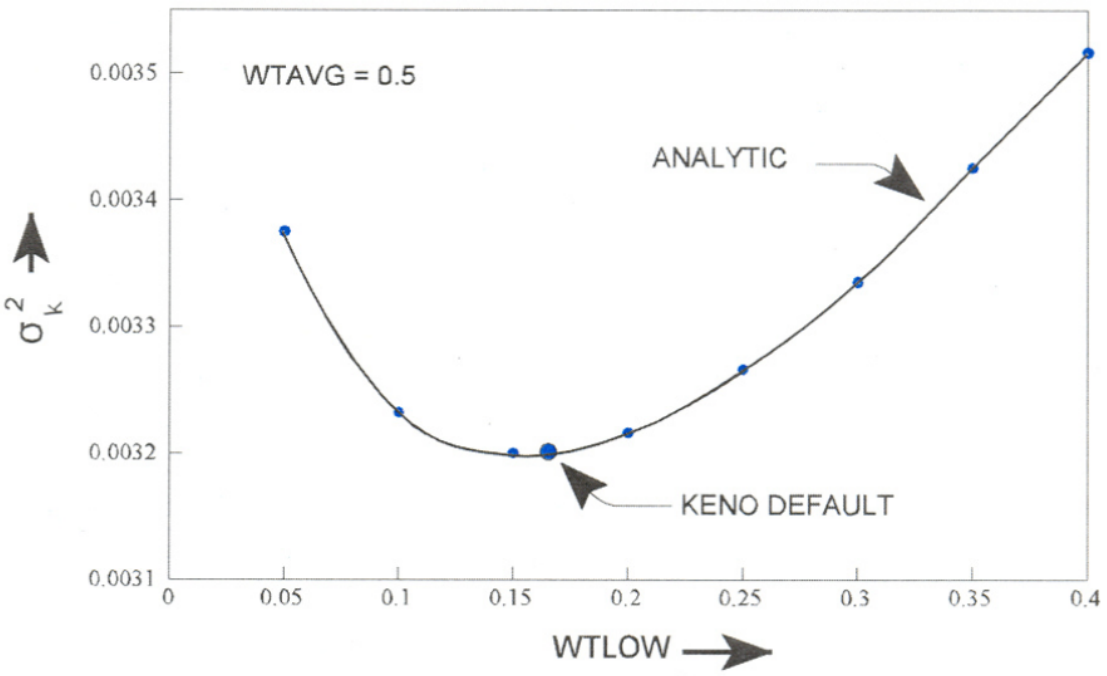

Fig. 8.1.208: Analytic estimate of the relationship between WTLOW and the variance, σ_k^2, when WTAVG is 0.5.

Fig. 8.1.209, also from the Hoffman study, shows the analytic relationship between the variance and the value chosen for WTAVG for a value of WTLOW = 0.167. Although the KENO default value for WTAVG is not the optimum, a close examination of the data shows that the variance was changing relatively slowly as a function of WTAVG. Even though this study shows a value near 0.26 to be optimum for this system, further studies of other systems are needed before changing the default value of WTAVG from 0.5 as it has been used in previous versions of KENO.

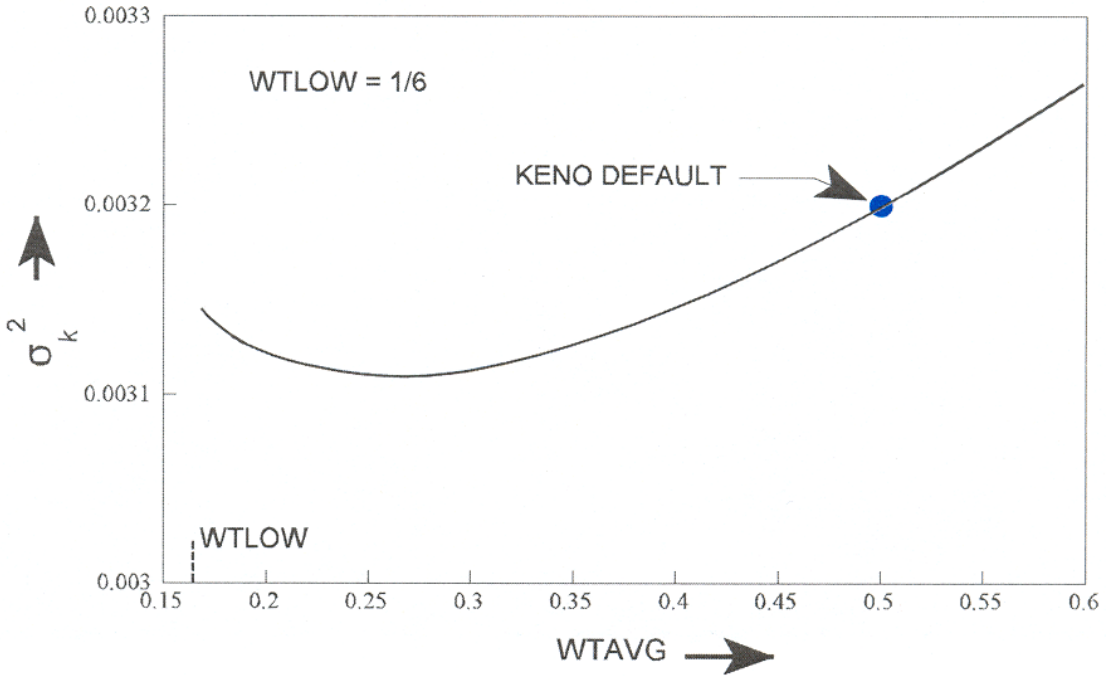

Fig. 8.1.209: Analytic estimate of the relationship between WTAVG and the variance, σ_k^2, when WTLOW is $^1/_6$.

Inside a fissile core, the importance of a neutron is a slowly varying function in terms of energy and position. Hence, for many systems, the standard defaults for WTLOW and WTAVG are good values to use. For reflectors, however, the worth of a neutron varies as a function of distance from the fissile material and as a function of energy. As a neutron in the reflector becomes less important relative to a neutron in the fissile region, it becomes desirable to spend less time tracking it. Therefore a space- and energy-dependent weighting or biasing function is used in KENO to allow the user to minimize the variance in k-effective per unit of tracking time. When a biasing function is used in a reflector, it becomes possible for a neutron to move from one importance region into another in which the WTLOW is greater than the weight of the neutron. When this occurs, Russian roulette is played to reduce the number of neutrons tracked. When the reverse occurs, that is, when the neutron moves to a region of higher importance, its weight may be much higher than WTAVG for that region. When the weight of the neutron is greater than a preset value, WTHI, the neutron is split into two neutrons, each having a weight equal to one-half the weight of the original neutron. This procedure is repeated until the weight of the split neutron is less than WTHI. The default value for WTHI is WTAVG*3.0. WTHI is the weight at which splitting occurs.

The weighting or biasing function for a given core material and reflector material can be obtained by using the adjoint solution from S_n type programs for a similar (usually simplified) problem. This adjoint flux gives the relative contribution of a neutron at a given energy and position to the total fissions in the system. The weighting function for KENO is thus proportional to the reciprocal of the adjoint flux. Although such a function can be difficult to obtain, the savings gained makes the effort worthwhile for many of the materials that are frequently used as reflectors. Biasing functions [ODellA87] have been prepared for several reflector materials commonly used in KENO calculations. The use of biasing to minimize the variance in k-effective per unit of computer time will usually increase the variance in other parameters such as leakage or absorption

in the reflector.

Differential albedos

Arrays reflected by thick layers of material having a small absorption to the scattering ratio may require large amounts of computer time to determine k-effective[Dem99a] because of the relatively long time a history may spend in the reflector. A differential albedo technique was developed for use with the KENO codes to eliminate tracking in the reflector. This involves returning a history at the point it impinges on the reflector and selecting an emergent energy and polar angle from a joint density function dependent upon the incident energy and polar angle. The weight of the history is adjusted by the functional return from the reflector, which is also based on the incident energy and angle.

The characteristics of a differential albedo emulate the attributes of the reflector material and are independent of the material or materials adjacent to the reflector. Thus, a differential albedo that is generated for a given reflector material can be used with any array, regardless of the type of fuel or fissile material contained within the array.

For many calculations involving reflected arrays of fissile material, the differential albedo treatment is a powerful tool that can significantly reduce the computing time required to determine k-effective. The savings will vary depending on the importance of the reflector to the system. A substantial effort is required to generate a differential albedo, but the savings gained were well worth the effort for commonly used reflector materials. The savings are not worth the applicability questions on modern computing platforms; the differential albedo capability is maintained only for backwards compatibility.

To generate the differential albedo information for a material, a fixed-source calculation must be made for each incident energy and angle. The data presently available for use with KENO were generated by 1-D discrete ordinates calculations for slab geometry representing infinite slabs. Consequently, for a finite reflector, these data will not correctly treat histories that enter the reflector near an edge. Past experience with differential albedo reflectors indicates that k-effective appears to be conservative for small faces and will tend toward the correct result as the face becomes large relative to the area near the corners. Care must be taken to ensure that any surface to which a differential albedo is applied is large enough that the errors at the edges can be ignored.

Because differential albedos are expensive and time consuming to generate, those corresponding to the Hansen-Roach 16-energy-group structure are the only differential albedos available for use with KENO at this writing. In the past, their use was limited to problems using cross sections having the Hansen–Roach 16-energy-group structure. KENO extends the use of differential albedos to other energy-group structures by allowing appropriate energy transfers. This is accomplished by creating lethargy boundary tables for the albedo group structure and the cross section group structure and determining the lethargy interval corresponding to the desired transfer (cross section group structure to albedo group structure or vice versa) based on a uniform lethargy distribution over the interval. When the energy-group boundaries of the cross sections and albedos are different, the results should be scrutinized by the user to evaluate the effects of the approximations.

8.1.7.4 KENO Geometries

KENO V.a geometry is restricted to the use of specific shapes. These shapes are called geometry regions or regions. Allowed shapes in KENO V.a are cubes, cuboids (rectangular parallelepipeds), spheres, cylinders, hemispheres, and hemicylinders. These shapes must be oriented along orthogonal axes and cannot be rotated in KENO V.a. They can be translated. Hemispheres and hemicylinders are not limited to half spheres and half cylinders; the definitive plane can be positioned by entering a chord. The value of this chord can range from the positive magnitude of the radius (giving a complete sphere or cylinder) to the negative magnitude of the radius (giving a zero volume, nonexistent sphere or cylinder).

KENO-VI geometry can model any geometric shape that can be described using quadratic equations. These geometric shapes are stacked together forming regions. The set of regions is then used to build units. A set of predefined shapes that include cones, cuboids (rectangular parallelepipeds), cylinders, dodecahedrons, ecylinders (extruded elliptical cylinders), ellipsoids, hexprisms, hoppers, parallelepipeds, planes, rhombohedrons, spheres, wedges (triangular prisms), as well as others is used to construct regions. In addition, the keyword `QUADRATIC` is provided which allows additional shapes to be constructed by specifying the quadratic equations that describe the shape. These shapes can be rotated and translated to any orientation and position within their respective units. Hemispheres and hemicylinders can be constructed using spheres and cylinders with a chord. Regions are rotated by providing the nonzero angles associated with the Euler X-convention.

A major restriction applied to KENO V.a geometry is that intersections are not allowed. Furthermore, each successive geometry region must completely enclose the preceding region. Tangency and shared faces are allowed. The volume of a region is the volume of the specified shape minus the volume of the preceding region shape and any holes contained in the region. To alleviate the complete enclosure restriction, KENO V.a allows multiple sets of geometry regions, with each set independently governed by this restriction. Each set of these multiple geometry regions is called a *unit*. Units can be stacked together in a 3-D rectangular parallelepiped called an *array* or *lattice*, just as children's blocks can be stacked. Units that are to be stacked together in this manner must have a rectangular parallelepiped outer region, and the adjacent faces of adjacent units must be the same size and shape. An array can be treated as a building block and used as a unit within another array.

A major improvement in KENO-VI is the ability to intersect regions. Region volumes are no longer calculated due to the complexity involved with intersecting regions. Each set of multiple geometry regions is called a unit. KENO-VI allows multiple sets of geometry regions (i.e., units), and each set has an independent coordinate system. A global unit must be specified for every problem, including single-unit problems. Units with cuboidal outer boundaries where the adjoining faces have the same dimensions can be stacked together in a 3-D rectangular parallelepiped called an *array* or *lattice*, just as children's blocks can be stacked. Unlike KENO V.a, units having hexagonal or dodecahedral outer boundaries where the adjoining faces have the same dimensions can also be stacked together in an array. An array boundary must be specified that either coexists with the outermost edge of the array or that is entirely within the array. The array boundary can be any shape that is definable using quadratic equations. An array can be treated as a building block and used as a unit within another array.

The use of holes in KENO allows a unit to be emplaced within another unit. This feature allows the addition of a complex structure, previously defined as a unit, to be directly placed within another unit. In KENO V.a a hole is not allowed to intersect other holes or regions, but holes may intersect multiple regions in KENO-VI.

Multiple arrays can be described in KENO. The global array in an unreflected problem is the outermost array in the problem geometry description. The global array in a reflected problem is the array referenced by surrounding geometry regions following the last array placement description that does not immediately follow a unit number description. In KENO-VI, the outermost boundary is always specified as the global unit boundary. If the outermost boundary is to be the array boundary, a global unit must still be specified with the global unit boundary coinciding with the array boundary. Unlike past versions of KENO, KENO-VI cannot run a single unit problem without specifying a global unit.

8.1.7.5 Fluxes

Fluxes are computed in KENO with a track length estimator. The scalar flux in region z for energy group g for a single generation is computed as

$$\Phi_{g,z} = \frac{\sum_{k=1}^{K} W_{k,z} l_{k,z}}{V_z \sum_{k=1}^{K} W_{k,0}}, \tag{8.1.96}$$

where

$l_{k,z}$ = distance traversed by particle k while within region z and energy group g,

$W_{k,z}$ = weight of particle k while traversing region z,

V_z = volume of region z,

$W_{k,0}$ = initial weight of particle k, and

K = total number of histories in the generation.

The average fluxes for all active generations and the standard deviation in the averages are also computed. Scalar fluxes computed by KENO are reported in units of neutrons per cm^2 per initial source neutron.

KENO is also capable of computing the angular flux for a level symmetric quadrature set. The angular flux for energy group g in region z for quadrature direction n is computed as

$$\Phi_{g,z}^{n} = \frac{\sum_{k=1}^{K} W_{k,z} l_{k,z,n}}{V_z \sum_{k=1}^{K} W_{k,0}}, \tag{8.1.97}$$

where

$l_{\mathrm{k,z,n}}$ = the distance traversed by particle k while within region z and energy group g within the quadrature direction n.

The angular flux can be expanded to flux moments using an appropriate spherical harmonics expansion. KENO has even number symmetric level quadrature sets S_2-S_{16}.

Flux moments can also be computed directly in KENO. The *jth* moment, which corresponds to real valued spherical harmonics functions [Dem99b] for a single generation for energy group g in region z, is computed as

$$\phi_{g,z}^{j} = \frac{\sum_{k=1}^{K} R_k^j W_{k,z} l_{k,z}}{V_z \sum_{k=1}^{K} W_{k,0}}, \tag{8.1.98}$$

where

R_k^j = real valued spherical harmonics function for moment index j corresponding to the direction of particle k.

KENO offers the option of computing the angular fluxes and flux moments using a transformed coordinate system so that the moments are based on a polar rather than a Cartesian position vector. This is a 3-D extension of the 1-D method for calculating the flux moments in terms of Legendre polynomials based only on the direction cosine with respect to the spatial coordinate.

Here, $\hat{i}$, $\hat{j}$, and $\hat{k}$ represent the directional coordinate system axes, μ, η, ξ represent the direction cosines, and θ and *rho*represent the polar and azimuthal angles of the "normal" coordinate system. The same symbols

primed represent the transformed coordinate system. The transformed polar or $\hat{k}'$ axis is co-linear, with the position vector $\vec{r}$ directed from the center of the region for which moments are desired to the point at which the flux tally occurs. By using the center of the region as a reference point, consistency of the moment calculation is assured with differing models of the same system. The $\tilde{i}'$ and $\tilde{j}'$ axes are chosen to form an orthogonal coordinate system, with $\tilde{i}'$ held in the plane formed by $\hat{i}$ and $\hat{j}$. The use of constraints other than the restriction of $\tilde{i}'$ to this plane may be explored in future studies. If an additional constraint is not placed on either $\tilde{i}'$ or $\tilde{j}'$, the transform would be able to rotate about $\hat{k}'$, and the consistency of consecutive transformations of the same direction could not be assured. With the transform computed, the position and direction of travel of the particle remain unchanged, but the quadrature directions and/or spherical harmonics terms are calculated using the transformed coordinate system. With the direction cosines consistently transformed for each history, the new polar and azimuthal angles can be computed and the spherical harmonics functions can be calculated for each history.

KENO offers a mesh flux tally in which the fluxes are computed in a user-defined cubic mesh superimposed on the geometry model. The mesh is defined from the origin of the global unit and is oriented with the Cartesian axes. At the end of each particle track, appropriate track lengths are assigned to the mesh intervals that were crossed for the region in which the track occurred. The length of the actual particle track is equal to the sum of the lengths assigned to the meshes encountered by the particle track. Because the coordinates of the mesh are defined in terms of the global unit, fluxes for regions in repeated units (i.e., units in arrays or holes) may be stored separately for each occurrence of the unit. The volumes of each region in each mesh interval are computed so that the fluxes are appropriately normalized on a per unit volume basis, consistent with Eq. (8.1.96). When the mesh flux option is activated, all requested fluxes, scalar, angular and/or moment, are computed for each mesh interval.

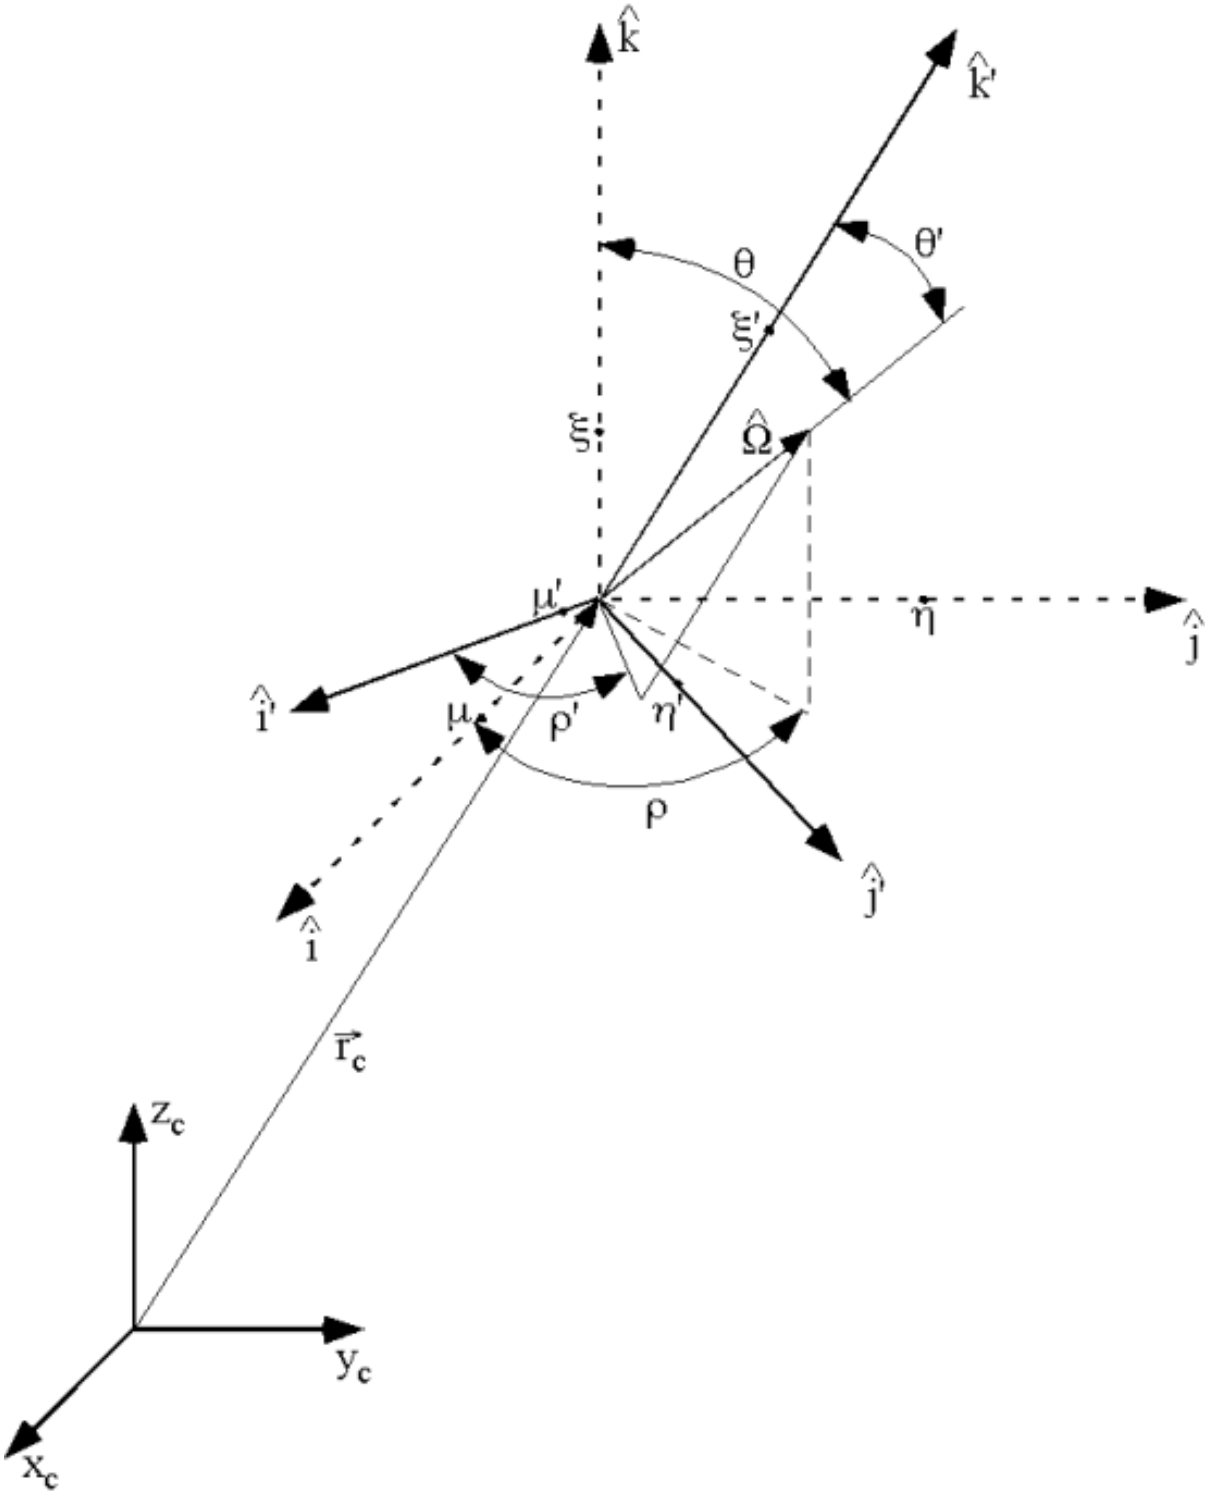

Fig. 8.1.210: Coordinate transform used for quadrature direction and spherical harmonics terms.

8.1.7.6 Reaction Rate and Few Group Micro Cross Section Calculations

A few-group microscopic reaction cross section calculation capability is included in the KENO codes to provide this data especially for the CE depletion calculations in SCALE. This new method produces multigroup cross sections and reaction rates directly in CE mode calculations rather than using a post-processing approach. In each generation, KENO uses track length estimators for the reaction rate tallies for all isotopes in each specified regions. At the end of each generation, a subsequent calculation is performed to compute few group microscopic reaction cross sections for all isotopes in a region as the ratio of the computed reaction rates to the flux averaged over this cell. Finally, KENO computes mean values and statistical uncertainties for all these quantities, and saves them in a file, which could be used by the depletion modules in SCALE.

Reaction tally calculations can be enabled by entering the required data in the **reaction data** block described in Sect. 8.1.3.15.

8.1.7.7 Source Convergence Diagnostics

Fission source convergence detection techniques are implemented in KENO to provide improved confidence in the computed k_{eff} and tally results. The dominance ratio of a system is equal to the ratio of the eigenvalue of the first nonfundamental mode to that of the fundamental mode, k_1/k_0. The dominance ratio is strongly related to the convergence rate of the fission source for systems, and problems with larger dominance ratios will require more inactive generations to produce reliable k_{eff} and reaction rate estimates. A converged k_{eff} estimate does not necessarily guarantee a converged fission source distribution, and the fission source and flux distribution may continue to evolve well after k_{eff} convergence is reached. Convergence of the fission source distribution is necessary to ensure that all regions containing fissile material in a model are adequately represented in the final k_{eff} estimate. Typically, the k_{eff} estimate converges much faster than the fission source and neutron flux distributions, and simulations may undersample important regions and produce inaccurate flux and reaction rate estimates if the user includes only enough inactive generations for the eigenvalue to converge. This is particularly important in models where one region is physically small but substantially more reactive than others (i.e. the k-effective of the World problem [Whi71]). The highly reactive region may not be adequately sampled, which may result in an underprediction of k_{eff}. Thus, it is essential to monitor the convergence of both the fission source distribution and k_{eff}; versions of KENO included in SCALE versions prior to SCALE 6.2 only monitored the convergence of k_{eff}, but diagnostic tools to identify unconverged fission source distributions are included in SCALE 6.2 and beyond.

Note: Due to limited experience with these tests in KENO, the Shannon entropy test results should be used as a supplement to guarantee that a problem's fission source is converged. Failure of Shannon entropy tests typically indicates insufficient convergence of fission site source distributions. Whenever Shannon entropy tests report failure, users should review the plots of k_{eff} as a function of generation skipped and k_{eff} as a function of generation completed (Sect. 8.1.5.29 and Sect. 8.1.5.30) to ensure that the k_{eff} value is adequately converged. If it is not clear that the k_{eff} value is converged, users should rerun the calculation using a different number of neutrons per generation (using the `NPG` parameter) or using a different random number seed value (using the `RND` parameter) or a different starting source term distribution (using the `READ START` block).

It may also be possible to pass the Shannon entropy tests by changing the source convergence mesh (using the `SCD` parameter and the `READ GRID` block) or changing the number skipped generations (using the `NSK` parameter).

For KENO calculations that are used for other purposes (such as producing neutron flux and reaction rate distributions, fuel depletion calculations, or fission distributions for radiation transport calculations) in which

the spatial dependence of the neutron flux and fission source may be more important, KENO calculations with failed Shannon entropy tests should be rerun because these spatially dependent distributions may not be adequately converged.

Shannon Entropy Statistics

The fission source distribution, S, is measured at the beginning of each generation using given spatial meshes. The state of source distribution at the j^{th} generation can then be characterized by Shannon entropy:

$$H(S^j) = -\sum_i^M [S_i^j \log_2(S_i^j)], \tag{8.1.99}$$

where S_i^j is the fraction of the fission source distribution from the j^{th}' generation tallied in the spatial bin i, and M is the total number of spatial bins (typically represented using a spatial mesh). The value of H ranges from a maximum value of $\log_2 M$ when the source distribution is uniform, and to a minimum value of zero when the whole source is located in a single bin. By computing H for each generation, the distribution of the fission source is used to generate a score for H for each generation, and the convergence of the fission source can be assessed by tracking the convergence and randomness of the values of H over each successive generation. Random fluctuations in the generation-to-generation Shannon entropy tallies make it difficult to determine if and when the Shannon entropy of a system has converged, so several metrics and tests are typically applied to examine the Shannon entropy and identify convergence in a system [Uek05].

The first test for fission source convergence is a comparison between the mean square of posterior relative entropy, and the centered mean square Shannon entropy. The posterior relative entropy, $D(S^j \parallel T)$, is defined as the statistical distance between the binned fission source $S_i^j$and the average fission source over the second half of the active generations, T, and is given by

$$D(S^j \parallel T) = \sum_i^M [S_i^j \log_2(S_i^j / T_i)], \tag{8.1.100}$$

where T is defined by

$$T_i = \frac{2}{N} \sum_{j=N/2+1}^{N} S_i^j, \tag{8.1.101}$$

where N is the number of active generations. The posterior relative entropy is non-negative and becomes zero only when $S^j = T$ and achieves its maximum value when S^j is uniform.

The mean square posterior relative entropy is defined as

$$msq(D) = \frac{2}{N} \sum_{j=N/2+1}^{N} D(S_i^j \parallel T_i)^2, \tag{8.1.102}$$

and the centered mean square Shannon entropy is defined as

$$cmsq(H) = \frac{2}{N-2} \sum_{j=N/2+1}^{N} [H(S_i^j) - \bar{H}]^2, \tag{8.1.103}$$

where $\bar{H}$ is defined as

$$\bar{H} = \frac{2}{N} \sum_{j=N/2+1}^{N} H(S_i^j). \tag{8.1.104}$$

This test compares the measure of fluctuations of Shannon entropy (*cmsq(H)*) with the measure of the magnitude of the penalty incurred by assuming T (*msq(D)*) and states that the fission source is converged if *msq(D) < cmsq(H)*. This test is useful to determine whether the source is converged by the end of the calculation. Failure of this test indicates that the fission source was still moving during the active generations, which indicates that the number of skipped generations was not sufficient to converge the fission source.

The second test is given by

$$D(S^j \parallel T) - [H(T - H(S^j))] \leq \varepsilon \tag{8.1.105}$$

where $\mathcal{E}$ has been set to 0.1. This test verifies that the Shannon entropy of each active generation does not vary significantly from the average Shannon entropy of the system and should be valid over all active generations. For example, this test could detect an unconverged fission source for a problem with an undersampled, highly fissile fuel region, as any neutrons that reached this region would produce an outlier in the Shannon entropy tally for that generation. This test is especially useful for reporting the generation at which the source converged. Once the converged generation is determined, the user can repeat the calculation with the number of inactive generations (skipped generations) set to be the identified generation or greater to ensure that only contributions from generations with a converged source contribute to flux and reaction rate tallies. This test complements the first test since it will not be affected by whether or not the binned source is uniform.

The last test calculates whether

$$H_\eta = H(S^j) - H_b \leq \eta, \tag{8.1.106}$$

where H_b is the average Shannon Entropy over the second half of active generations, and η has been set to 0.1. This test verifies that the average Shannon entropy of all active generations does not differ significantly from the Shannon entropy of the last half of the active generations. This test is useful for detecting fission source convergence in problems where an inadequate number of inactive generations was sampled, as the Shannon entropy would continue to change during the active generations until it eventually converges.

Source Convergence Diagnostic Input

Because the processing of the source tallies for fission source convergence calculations is quite fast and produces small memory requirements, these source convergence diagnostics have been permanently enabled in KENO and require no additional input parameters. However, the KENO input specifications were updated to allow users to specify the spatial mesh data for the source convergence tests via the `SCD` parameter and `READ GRID` data block.

8.1.8 APPENDICES

8.1.8.1 KENO V.a Shape Descriptions

The geometry **shape**s allowed in KENO V.a geometry description are:

CUBE, CUBOID, SPHERE, CYLINDER, ZCYLINDER, XCYLINDER, YCYLINDER, HEMISPHERE, HEMISPHE+X, HEMISPHE-X, HEMISPHE+Y,

HEMISPHE-Y, HEMISPHE+Z, HEMISPHE-Z, XHEMICYL+Y, XHEMICYL-Y, XHEMICYL+Z, XHEMICYL-Z, YHEMICYL+X, YHEMICYL-X, YHEMICYL+Z, YHEMICYL-Z, ZHEMICYL+X, ZHEMICYL-X, ZHEMICYL+Y, ZHEMICYL-Y

CUBE specifies a cube. It sets +X = +Y = +Z and -X = -Y = -Z. Note that the +X dimension need not equal the -X dimension of the cube (i.e., the origin need not be at the center of the cube).

CUBOID is a rectangular parallelepiped and may be described anywhere relative to the origin.

SPHERE specifies a sphere that is centered about the origin, unless otherwise specified by the optional region origin data.

CYLINDER specifies a cylinder that has its length described along the Z axis. Its centerline must lie on the Z axis, unless otherwise specified by the optional region origin data.

ZCYLINDER specifies a cylinder that has its length described along the Z axis. Its centerline must lie on the Z axis, unless otherwise specified by the optional region origin data.

XCYLINDER specifies a cylinder that has its length described along the X axis. Its centerline must lie on the X axis, unless otherwise specified by the optional region origin data.

YCYLINDER specifies a cylinder that has its length described along the Y axis. Its centerline must lie on the Y axis, unless otherwise specified by the optional region origin data.

HEMISPHERE is used to specify a spherical segment of one base whose spherical surface exists in the positive Z direction. The base or flat portion of the spherical segment is centered about a point that may be specified in the optional region origin data. By default, the center of the spherical surface is the origin and the distance to the base from the center of the spherical surface is zero.

HEMISPHE*bc* is used to specify a spherical segment of one base whose spherical surface exists in the *bc* direction (b = + or -, c = x, y, or z). The base or flat portion of the spherical segment is located a distance ρ from the center of the spherical surface, and the center may be specified in the optional region origin data. **HEMISPHE+Z** is the same as the previously described **HEMISPHERE** and **HEMISPHE-Z** is the mirror image of **HEMISPHE+Z**, therefore existing only in the negative Z direction. By default the center of the spherical surface is the origin and the distance of the base from the center of the spherical surface is zero.

b*HEMICYL*cd is used to specify a cylindrical segment whose axis is in the *b* direction (b = x, y, or z) and whose cylindrical surface exists only in the *c* direction from a plane perpendicular to the *d* axis (c = + or -, d = x, y, or z). The position of the plane (cut surface) can be specified in the optional region chord data. This plane cuts the cylinder parallel to the axis at some distance, ρ, from the axis. By default, the axis passes through the origin and ρ is zero. (Examples: **ZHEMICYL+X, YHEMICYL-Z, XHEMICYL+Y**)

Up to 6 dimensions follow the shape keyword [*xx(1)* through *xx(6)*]. These entries are separated by one or more blanks and define the size of the region. Dimensions must be given in cm.

xx(1): Radius for a sphere, cylinder, hemisphere or hemicylinder,

+X dimension for a cube or cuboid.

xx(2): -X dimension for cube or cuboid,

+Z for cylinder or Z cylinder,

+X for X cylinder,

+Y for Y cylinder,

+length for hemicylinder,

omit *xx(2)* for a sphere or hemisphere.

xx(3): +Y dimension for cuboid,

-Z for cylinder or Z cylinder,

-X for X cylinder,

-Y for Y cylinder,

-length for hemicylinder,

omit *xx(3)* for a sphere, hemisphere, or cube.

xx(4): -Y dimension for cuboid,

omit for all other geometry types.

xx(5): +Z dimension for cuboid,

omit for all other geometry types.

xx(6): -Z dimension for cuboid,

omit for all other geometry types.

8.1.8.2 KENO VI Shape Descriptions

The geometry **shape**s allowed in KENO-VI geometry description are:

CONE, **CUBOID**, **CYLINDER**, **DODECAHEDRON**, **ECYLINDER**, **ELLIPSOID**, **HEXPRISM**, **HOPPER**, **PARALLELEPIPED**, **PPIPED**, **PENTAGON**, **PLANE**, **QUADRATIC**, **RHEXPRISM**, **RHOMBOID**, **SPHERE**, **WEDGE**, **XCYLINDER**, **XPPLANE**, **YCYLINDER**, **YPPLANE**, **ZCYLINDER**, **ZPPLANE**

CONE specifies a body consisting of one nappe of a right circular cone. It is defined by specifying the top radius of the cone, R_t, the Z coordinate of the top face, Z_t, the bottom radius of the cone, R_b, and the Z coordinate of the bottom face, Z_b. Fig. 8.1.211 shows the correct input sequence for a cone.

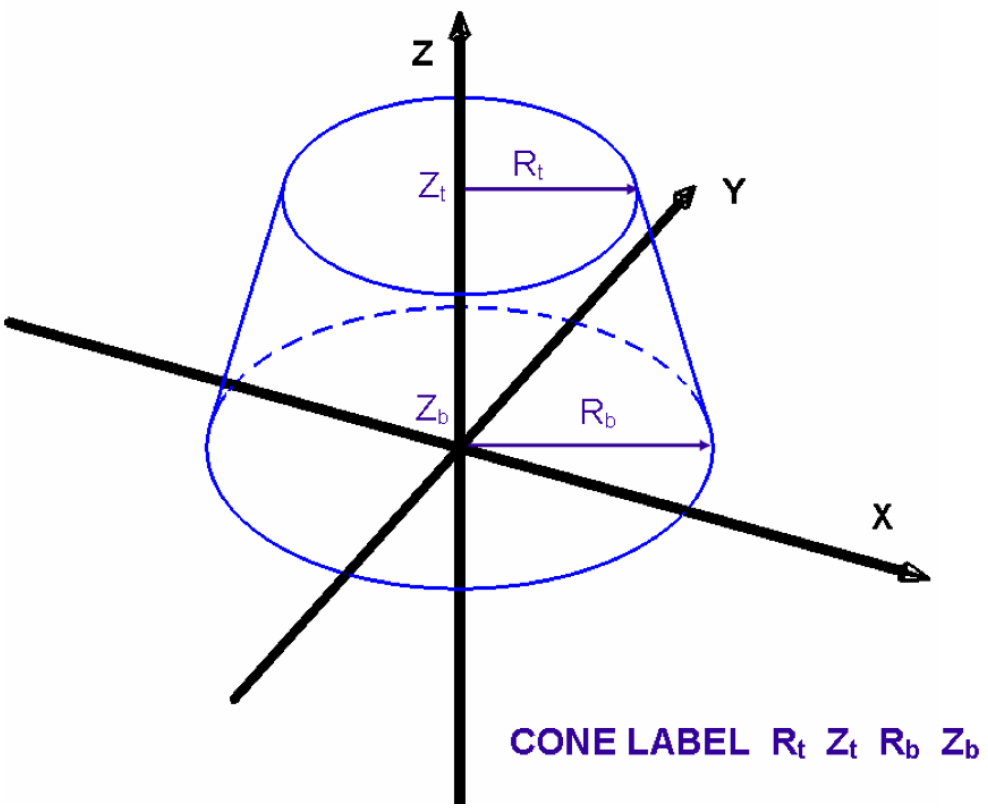

Fig. 8.1.211: Example of cone construction.

CUBOID specifies a rectangular parallelepiped. It is defined by specifying the +X dimension, -X dimension, +Y dimension, -Y dimension, +Z dimension, -Z dimension. It is perpendicular to the X, Y, and Z axes unless otherwise specified by the option geometry modification data. Fig. 8.1.212 shows the correct input sequence for a cuboid.

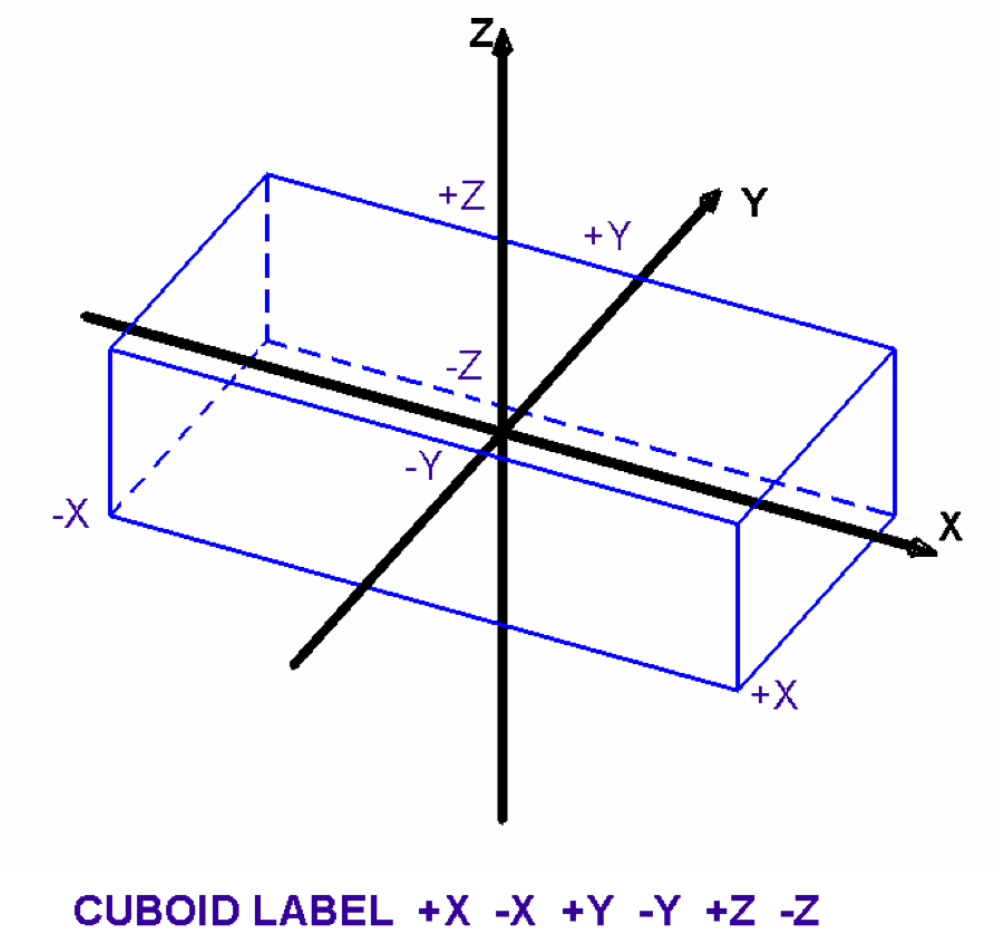

Fig. 8.1.212: Example of cuboid construction.

CYLINDER specifies a right circular cylinder. It is defined by specifying the radius of the cylinder, R, the Z coordinate of the top face, Z_t, and the Z coordinate of the bottom face, Z_b. Its centerline must lie on the Z axis, unless otherwise specified by the optional geometry modification data. Fig. 8.1.213 shows the correct input sequence for a cylinder.

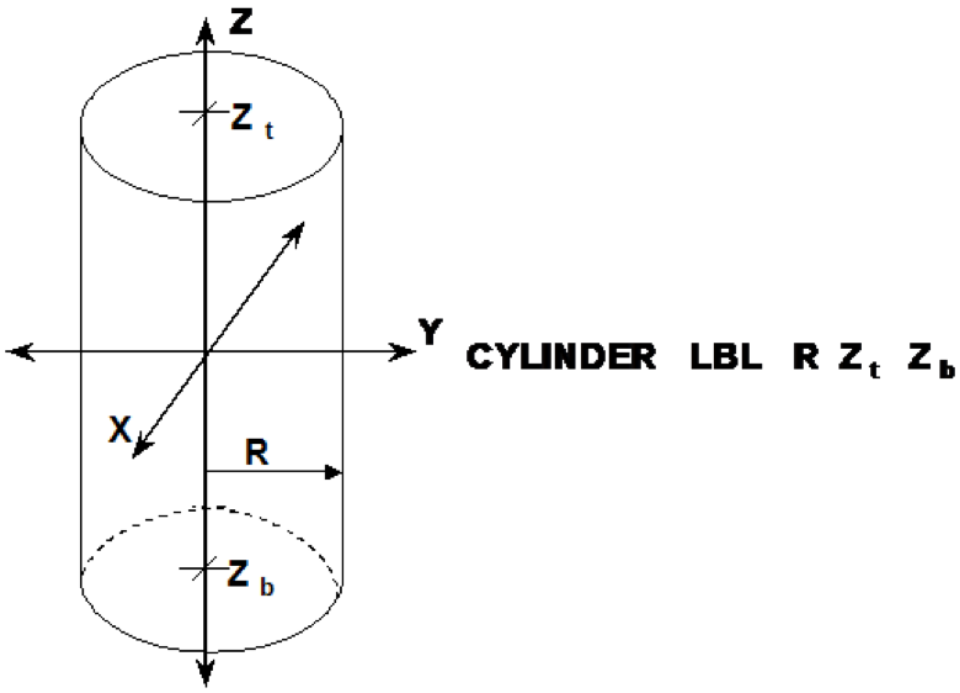

Fig. 8.1.213: Example of cylinder construction.

DODECAHEDRON specifies a body whose surface consists of 12 rhombuses of the same size and shape. It is defined by specifying the radius of the inscribed sphere, R. It is centered on the origin in a fixed orientation unless otherwise specified by the optional geometry modification data. Fig. 8.1.214 shows the correct input sequence for a dodecahedron.

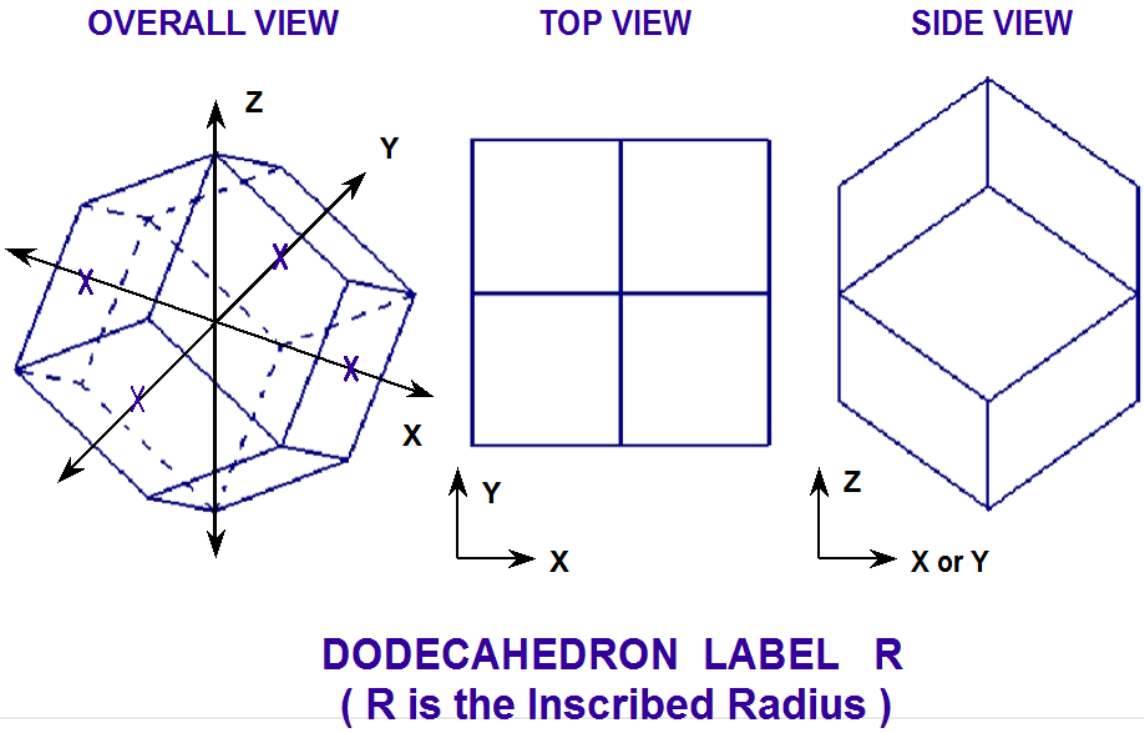

Fig. 8.1.214: Example of dodecahedron construction.

ECYLINDER specifies a right cylinder with an elliptical cross section. It is defined by specifying the semiradius along the X-axis, R_x, the semiradius along the Y-axis, R_y, the Z coordinate of the top face, Z_t, and the Z coordinate of the bottom face, Z_b. Its centerline must lie on the Z axis, unless otherwise specified by the optional geometry modification data. Fig. 8.1.215 shows the correct input sequence for an elliptical cylinder.

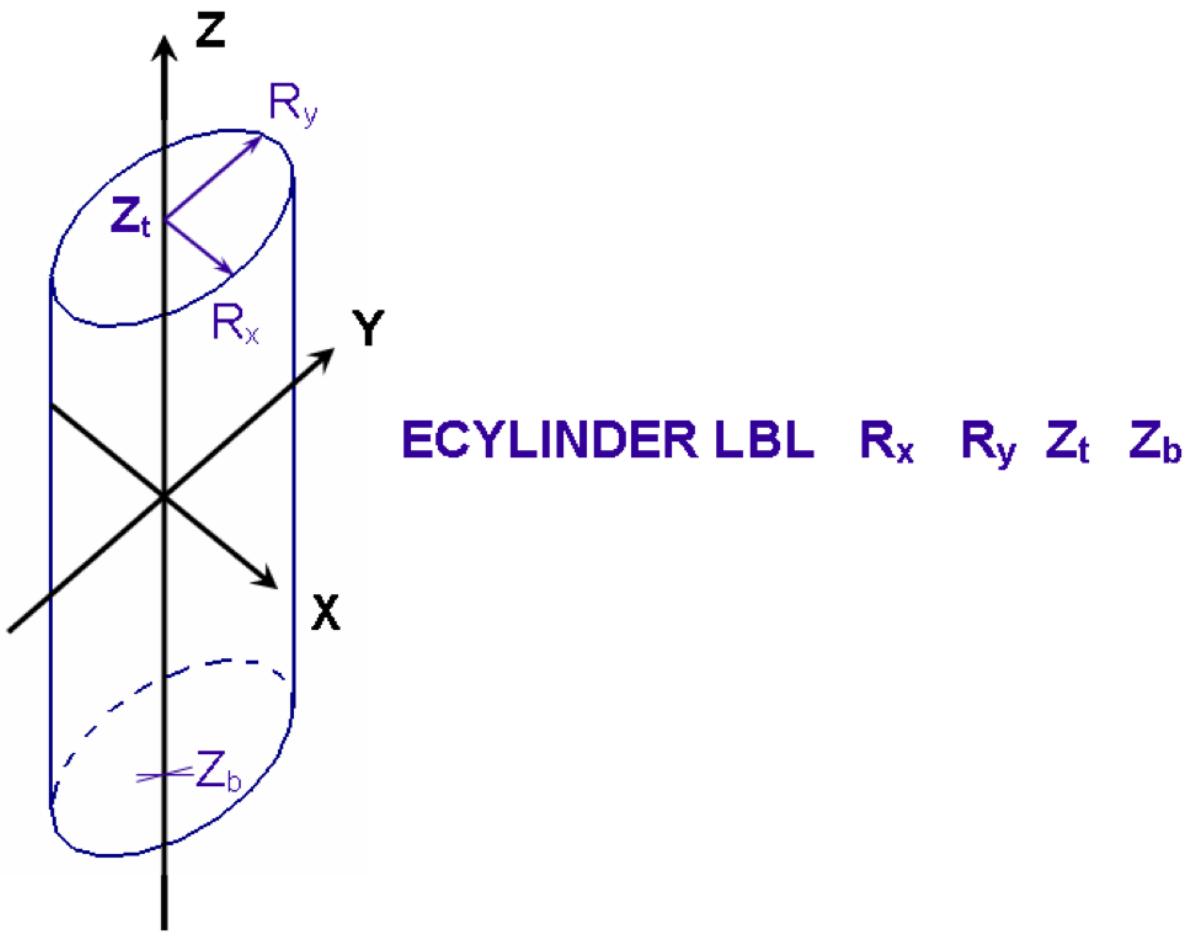

Fig. 8.1.215: Example of elliptical cylinder construction.

ELLIPSOID specifies a body whose cross-section slices parallel to each of the coordinate axes are ellipses. It is defined by specifying the semiradius along the X-axis, R_x, the semiradius along the Y-axis, R_y, and the semiradius along the Z-axis, R_z. It is centered about the origin, unless otherwise specified by the optional geometry modification data. Fig. 8.1.216 shows the correct input sequence for an ellipsoid.

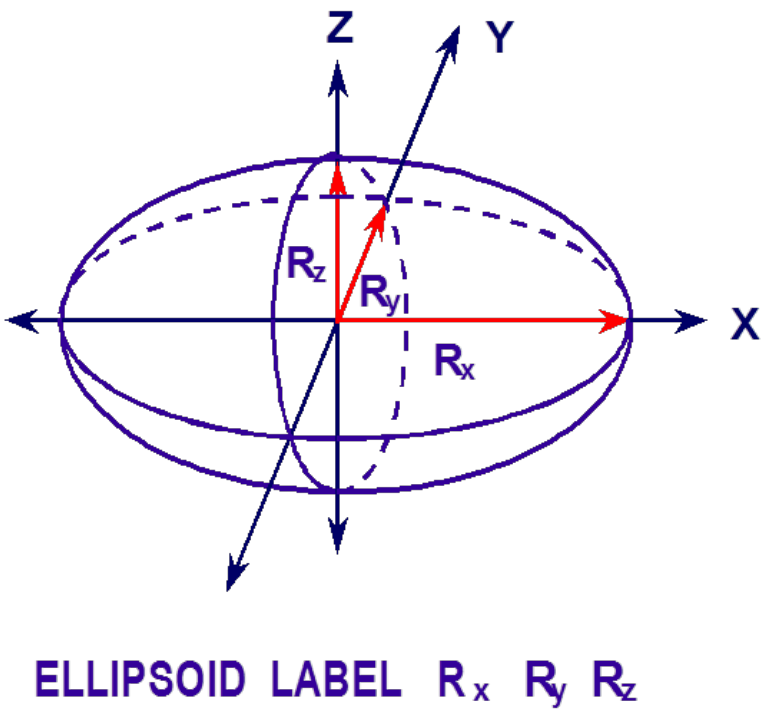

Fig. 8.1.216: Example of ellipsoid construction.

HEXPRISM specifies a body whose top and bottom faces are hexagons that have the same orientation and are perpendicular to the Z axis. It is defined by specifying the inscribed radius, R, the Z coordinate of the top face, Z_t, and the Z coordinate of the bottom face, Z_b. Fig. 8.1.217 is an example input for a hexprism.

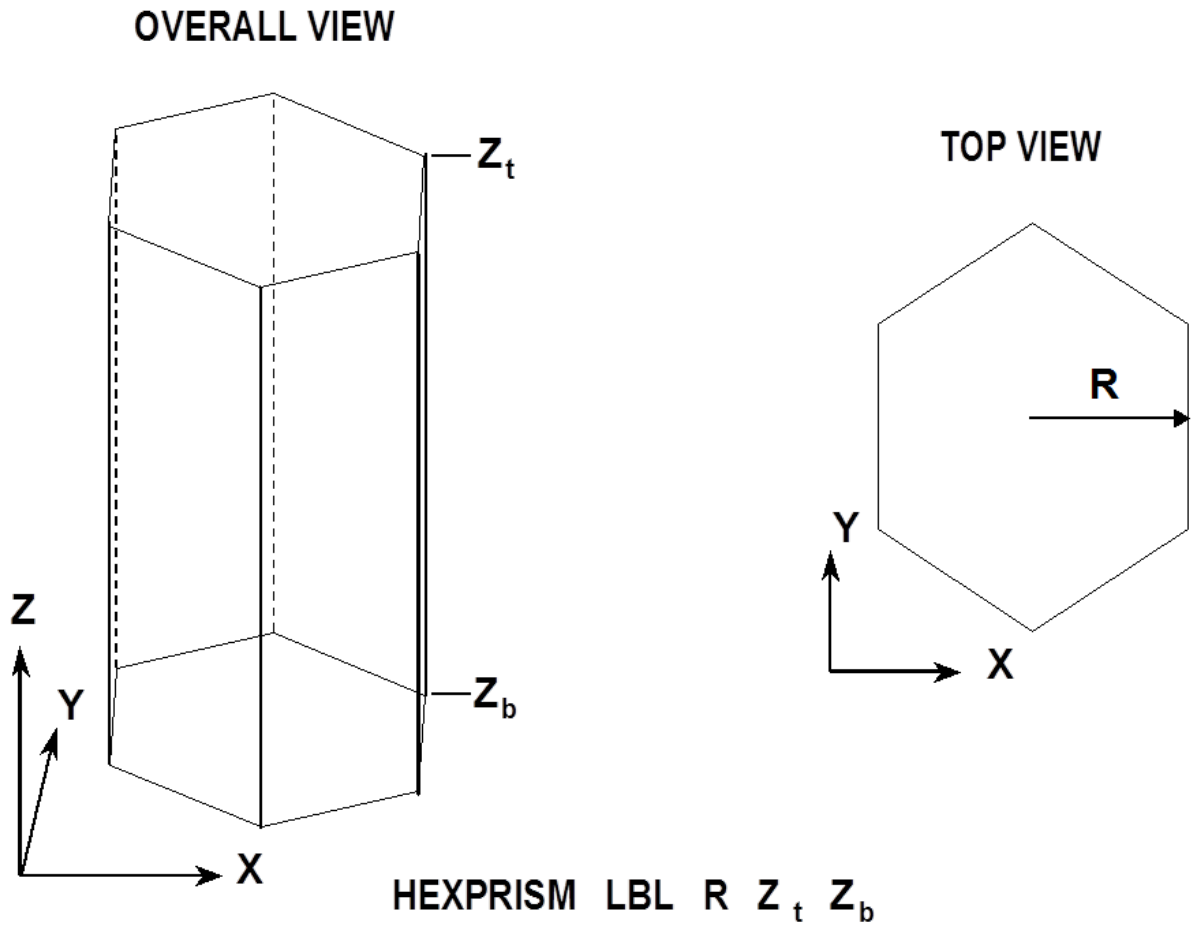

Fig. 8.1.217: Example of hexprism construction.

HOPPER specifies a body whose top and bottom faces are rectangular parallelepipeds centered about the Z-axis and parallel to the X and Y axes. It is defined by specifying the half-length of the top face along the X-axis, X_t, the half-length of the top face along the Y-axis, Y_t, the Z coordinate of the top face, Z_t, the half-length of the bottom face along the X-axis, X_b, the half-length of the bottom face along the Y-axis, Y_b, and the Z coordinate of the bottom face, Z_b. Its centerline must lie on the Z axis unless otherwise specified by the optional geometry modification data. Fig. 8.1.218 shows the correct input sequence for a hopper.

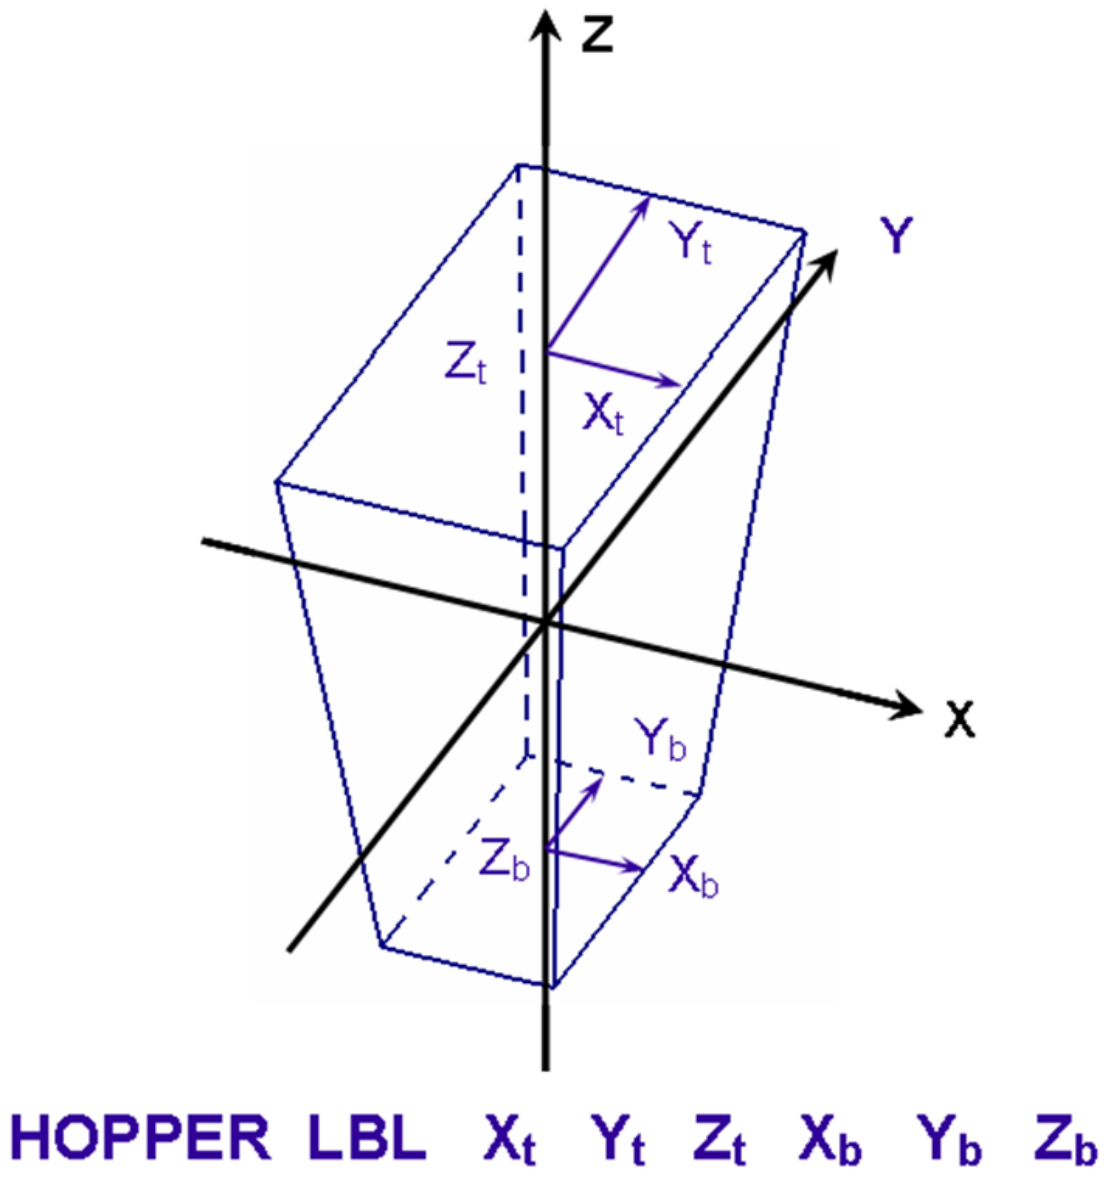

Fig. 8.1.218: Example of hopper construction.

PARALLELEPIPED or PPIPED is a body with six faces composed of parallelograms, whose opposing faces are parallel. It is defined by specifying the length of the faces in the X direction, XDIST, the length of the faces in the Y direction, YDIST, the length of the faces in the Z direction, ZDIST, the angle between the X-face and the Y-axis, PSI, the angle between the Y-face and the Z-axis, THETA, and the angle between the projection of the top corner nearest the Z-axis onto the X-Y plane and the X-axis, PHI. The bottom face must lie on the X-Y plane at Z = 0 with a corner at the origin unless otherwise specified by the optional geometry modification data. Fig. 8.1.219 shows the correct input sequence for a parallelepiped. The angles psi, theta, and phi must be in the range 0 to 90°.

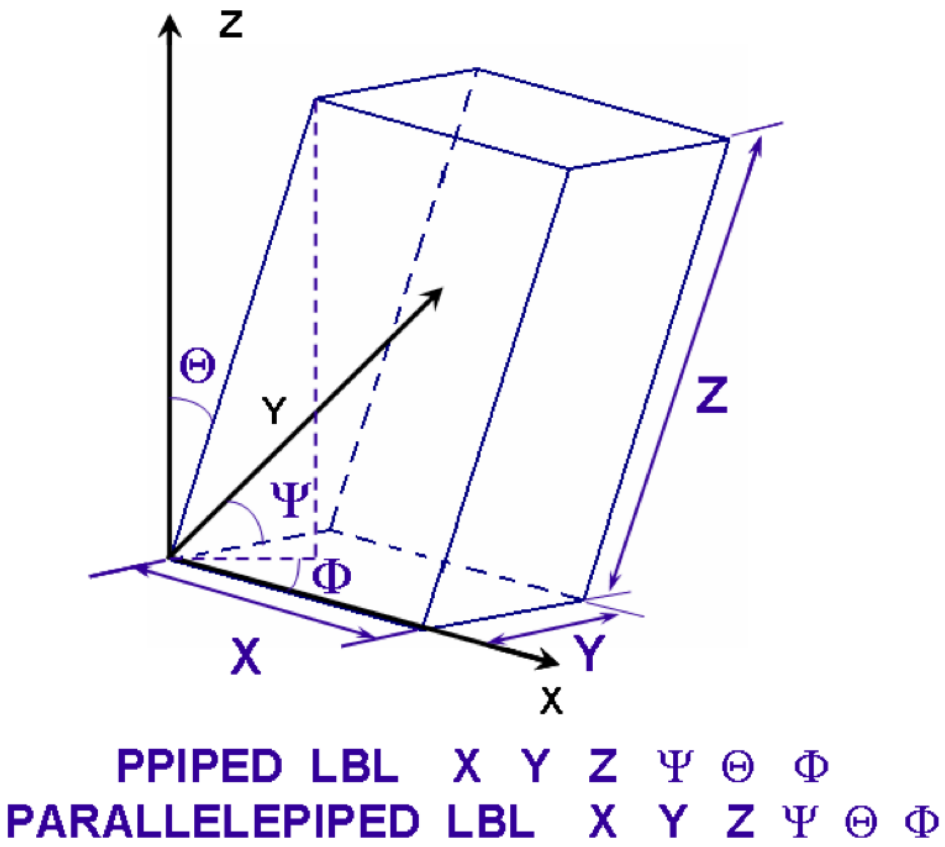

Fig. 8.1.219: Example of parallelepiped construction.

PENTAGON specifies a body whose top and bottom faces are pentagons that have the same orientation and are perpendicular to the Z axis. It is defined by specifying the inscribed radius, R, the Z coordinate of the top face, Z_t, and the Z coordinate of the bottom face, Z_b. Fig. 8.1.220 is an example input for a pentagon.

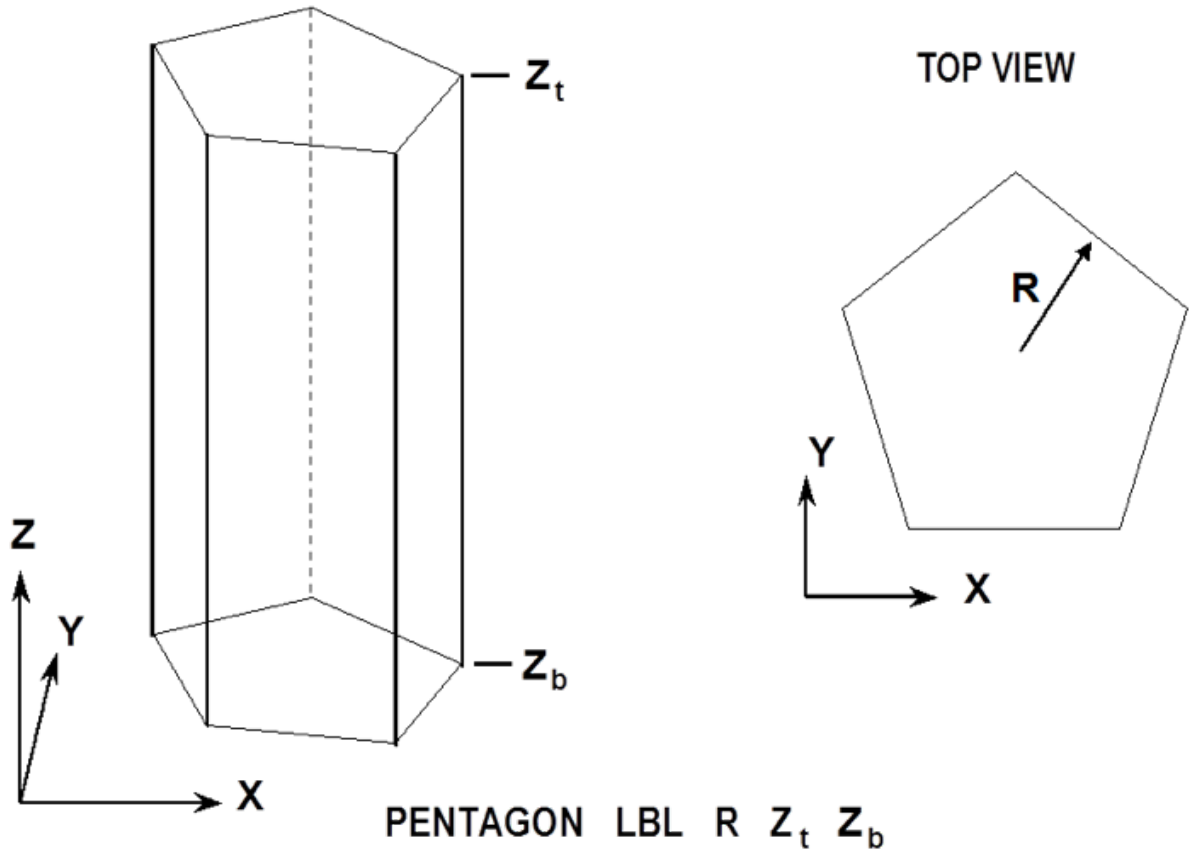

Fig. 8.1.220: Example of pentagon construction.

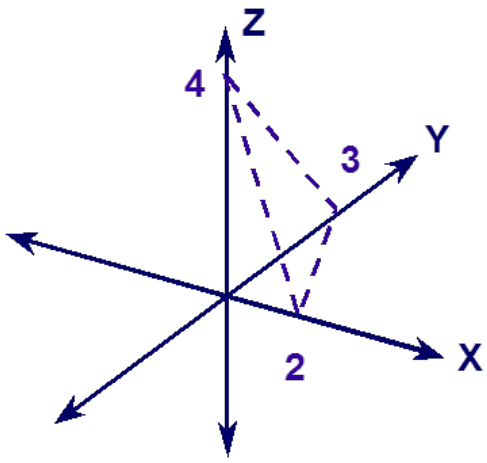
PLANE is a surface where any two points can be connected by a straight line entirely contained within a plane that divides all space into two regions. The positive side of the plane is the side the normal points to or where the equation $aX + bY + cZ + d > 0$. It is defined by specifying the coefficients of the equation $aX + bY + cZ + d = 0$ using the keywords XPL=a, YPL=b, ZPL=c, and CON=d. Only the nonzero coefficients of the equation need to be specified. Fig. 8.1.221 shows the correct input sequence for a plane.



PLANE Label XPL=a YPL=b ZPL=c CON=d

aX + bY + cZ + d = 0

6X + 4Y + 3Z - 12 = 0

Fig. 8.1.221: Example of plane construction.

QUADRATIC specifies a surface using a quadratic equation of the form:

$$aX^2 + bY^2 + cZ^2 + dXY + eXZ + fYZ + gX + hY + iZ + j = 0.$$

It is defined by specifying the coefficients of the above equation using the keywords AQU=a, BQU=b, CQU=c, DQU=d, EQU=e, FQU=f, GQU=g, HQU=h, IQU=i, and JQU=j. Only the nonzero coefficients of the equation need to be specified.

RHEXPRISM specifies a body whose top and bottom faces are rotated hexagons that have the same orientation and are perpendicular to the Z axis. It is defined by specifying the inscribed radius, R, the Z coordinate of the top face, Z_t, and the Z coordinate of the bottom face, Z_b. Fig. 8.1.222 is an example input for a rotated hexprism.

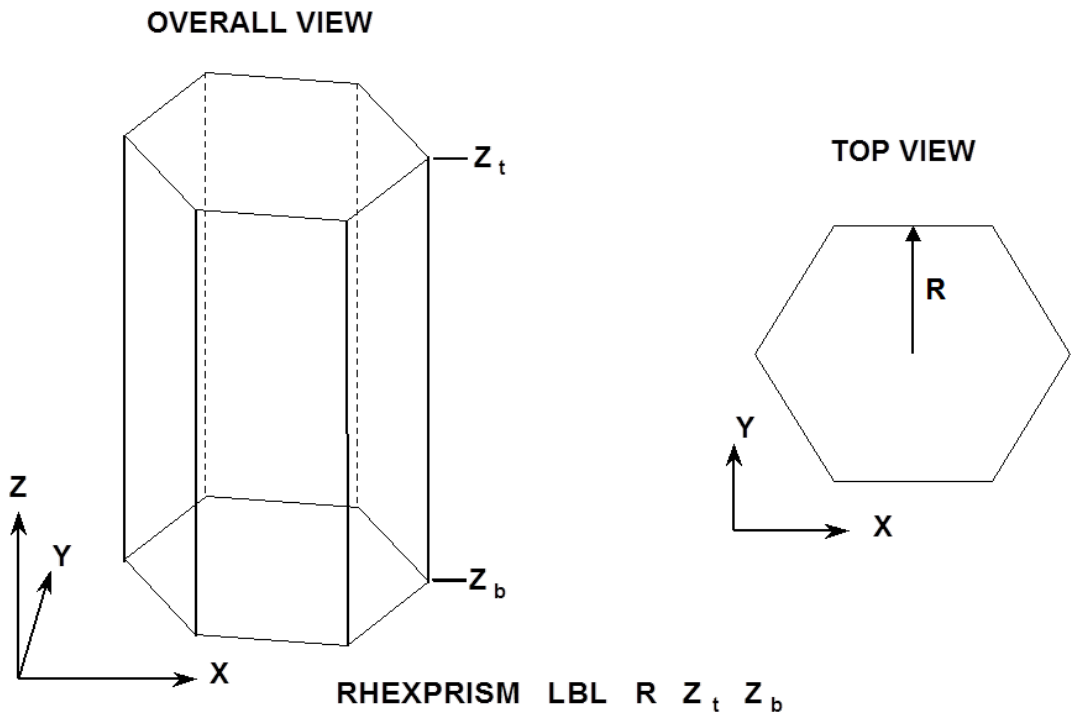


Fig. 8.1.222: Example of rotated hexprism construction.

RING is a body composed of the space between 2 concentric cylinders. It is defined by specifying the radius Rin of the inner cylinder and Rout of the outer cylinder, and the coordinate Zt of the top and Zb of the bottom of the annulus. Its center line lies on the Z axis unless specified by the optional geometry modification data. Fig. 8.1.223 shows the correct input sequence for a ring.

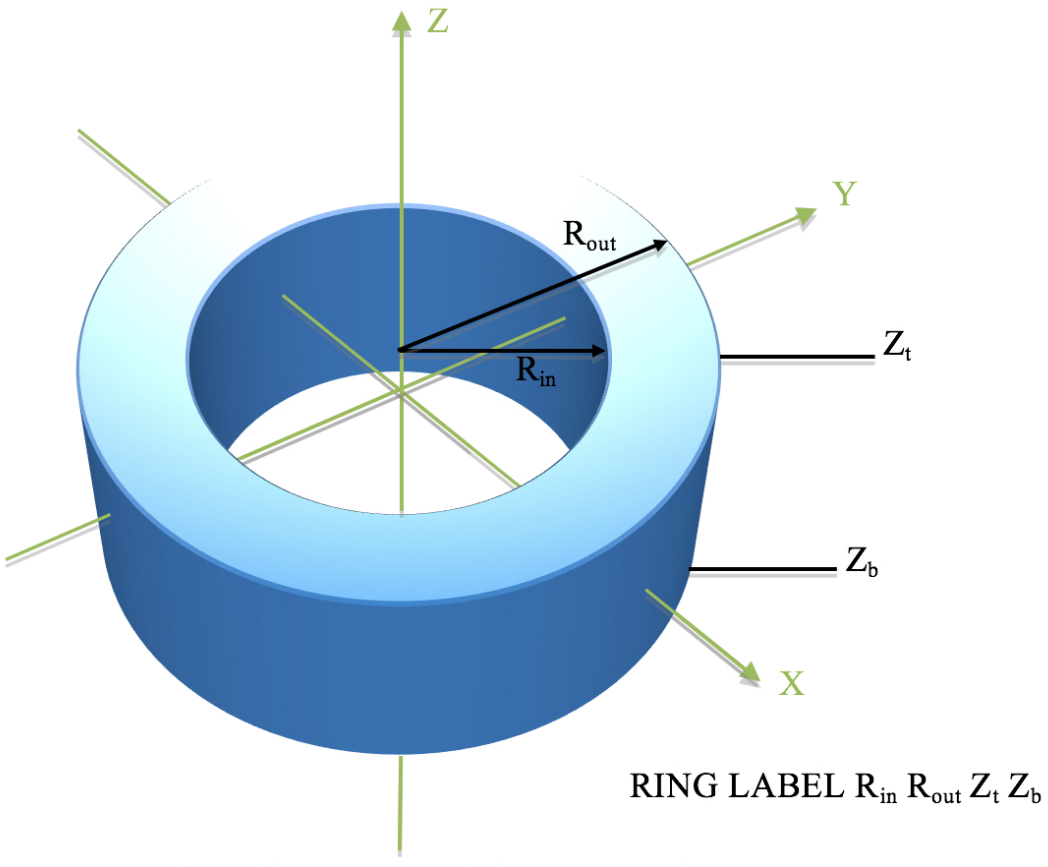

Fig. 8.1.223: Example of ring construction.

RHOMBOID is a body composed of six identical faces, each one a rhombus. It is defined by specifying the length of the edge of the base along the X-axis, DX and the angle between Y edge of the base and the Y-axis, Ψ. Its base is in the XY plane at Z = 0, with a corner at the origin unless otherwise specified by the optional geometry modification data. Fig. 8.1.224 shows the correct input sequence for a rhomboid.

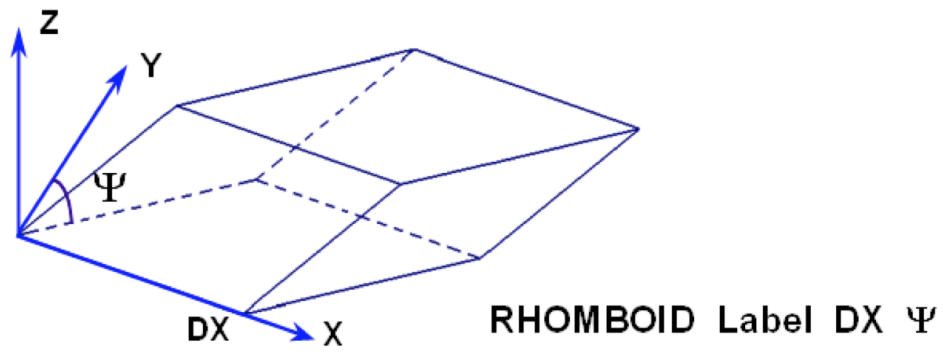

Fig. 8.1.224: Example of rhomboid construction.

SPHERE specifies a sphere. It is defined by specifying the radius, R. It is centered about the origin, unless otherwise specified by the optional geometry modification data. Fig. 8.1.225 shows the correct input

sequence for a sphere.

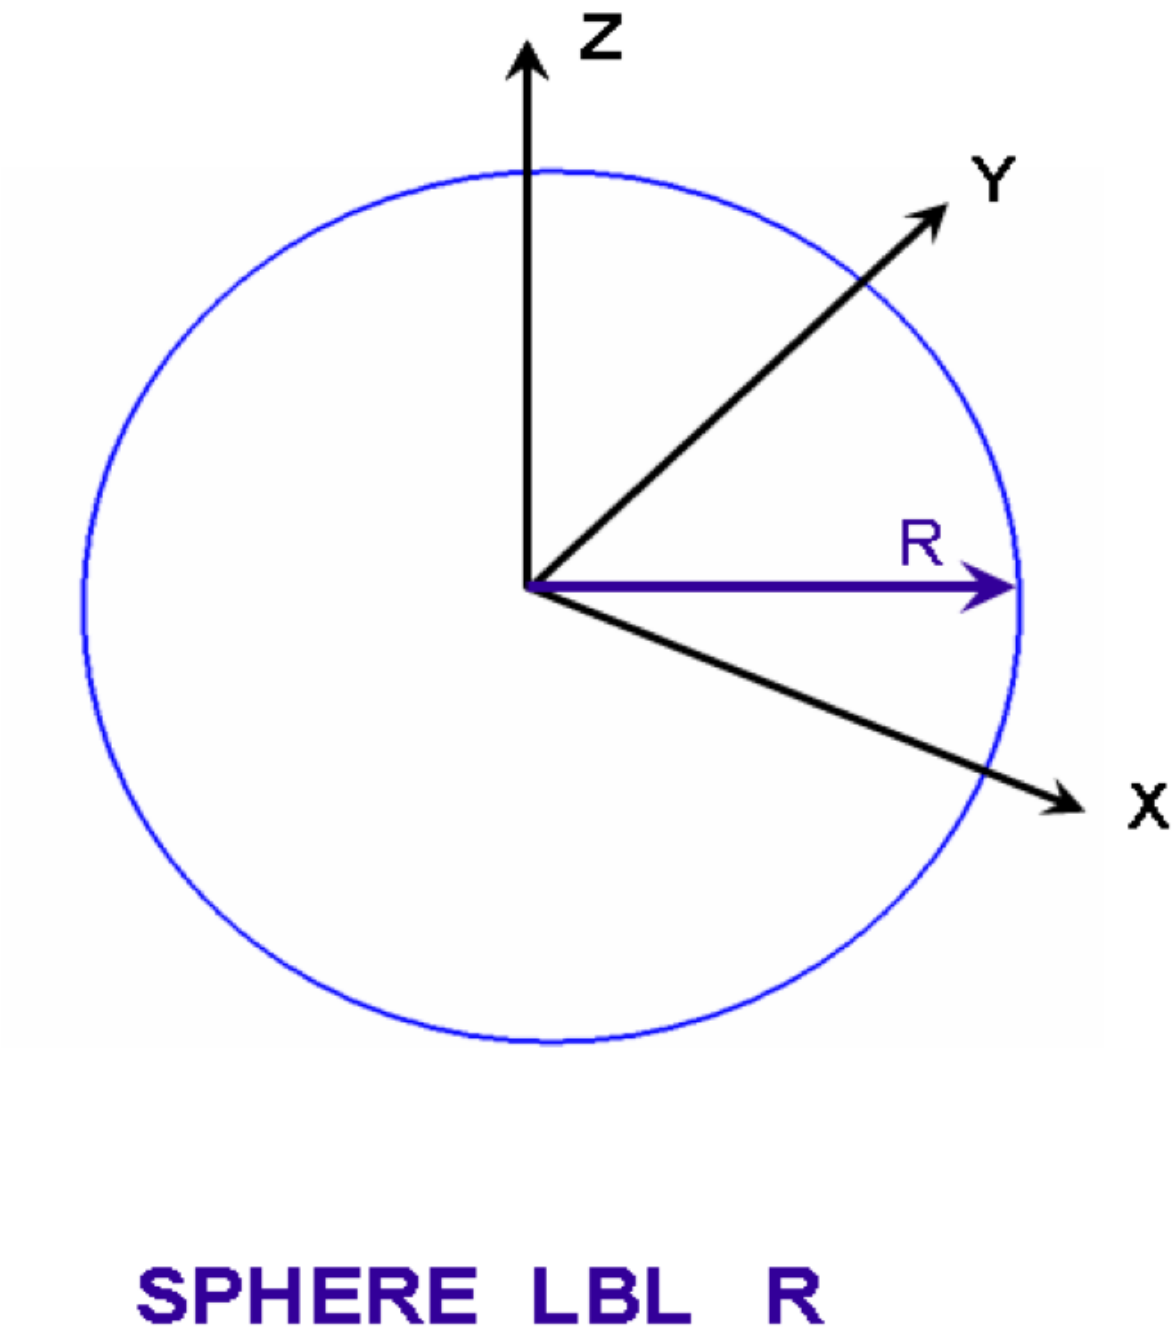

Fig. 8.1.225: Example of sphere construction.

WEDGE is a right-triangular prism having five faces. The two ends are triangles, and the three sides are rectangles. It is defined by specifying the length of the base along the X-axis, XBASE, the X and Y coordinate where the other two sides meet, Xpt and Ypt, and the length along the Z-axis, ZLNG. One side is in the XZ plane at Y = 0, and the bottom face is in the XY plane at Z = 0, with a corner at the origin unless otherwise specified by the optional geometry modification data. Fig. 8.1.226 shows

the correct input sequence for a wedge.

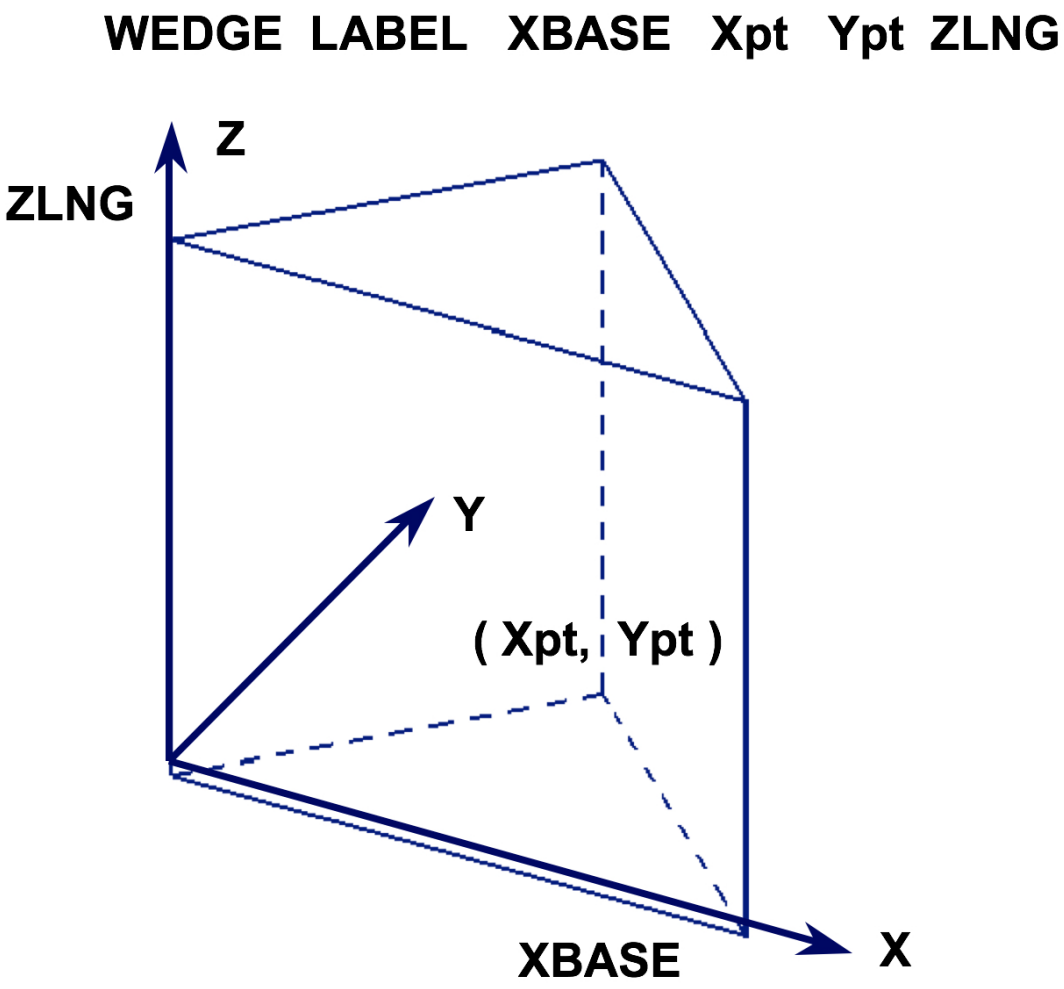

Fig. 8.1.226: Example of wedge construction.

XCYLINDER specifies a right circular cylinder oriented about the X-axis. It is defined by specifying the radius of the cylinder, R, the X coordinate of the top face, X_t, and the X coordinate of the bottom face, X_b. Its centerline must lie on the X axis, unless otherwise specified by the optional geometry modification data. Fig. 8.1.227 shows the correct input sequence for a cylinder.

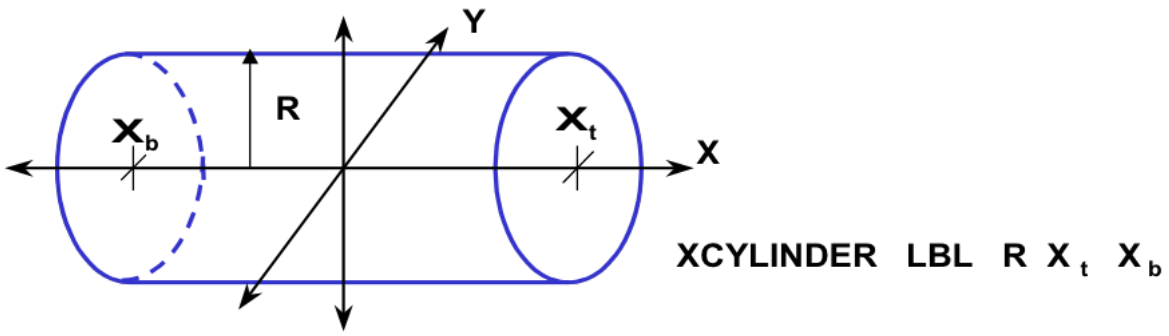

Fig. 8.1.227: Example of xcylinder construction.

XPPLANE is a set of flat parallel surfaces where any two points in one of the surfaces can be connected by a straight line entirely contained within that surface. These surface planes divide space into three sections; one section between the two planes which is considered inside the surfaces, one section on the negative side of the negative plane which is considered outside the surfaces, and one section on the positive side of the positive plane which is considered outside the surfaces. The set of parallel planes are defined by the keyword XPPLANE, which places the planes perpendicular to the X-axis, the X-intercept between the more positive plane and the X-axis (X_+) and the X-intercept between the more negative plane and the X-axis (X_-). Fig. 8.1.228 shows the correct input sequence for the set of paired planes.

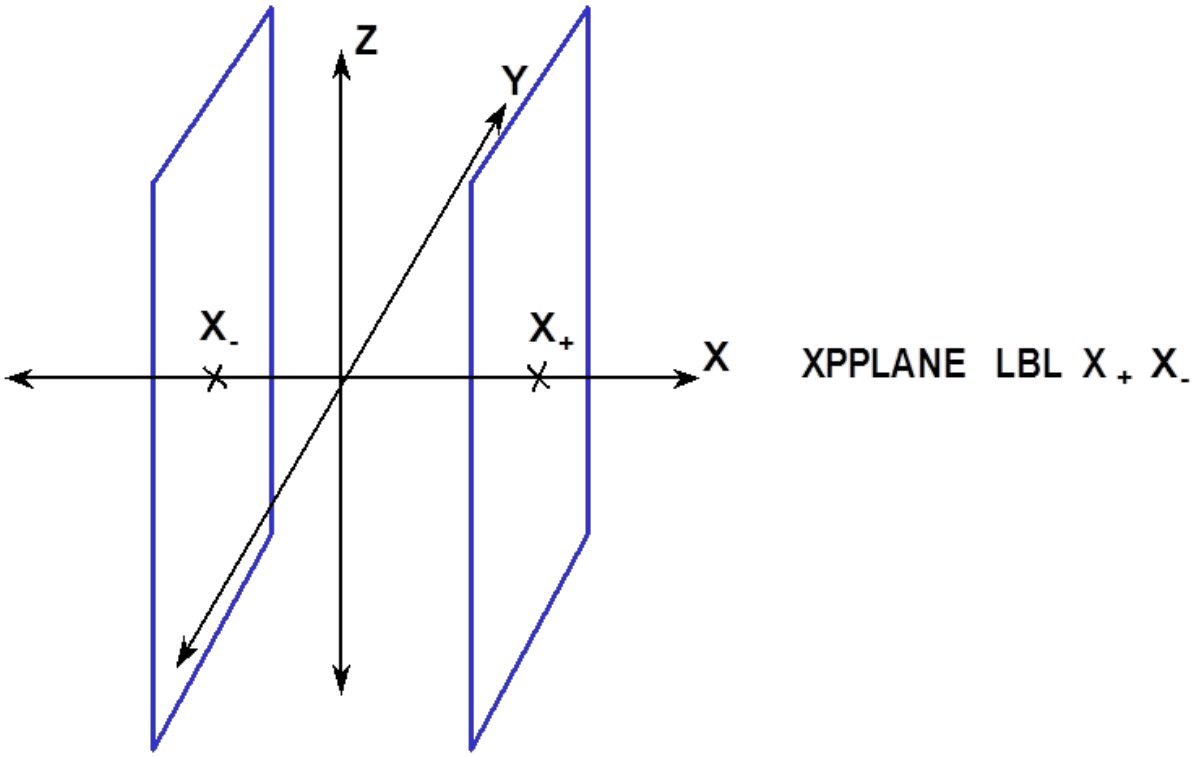

Fig. 8.1.228: Example of x-paired plane construction.

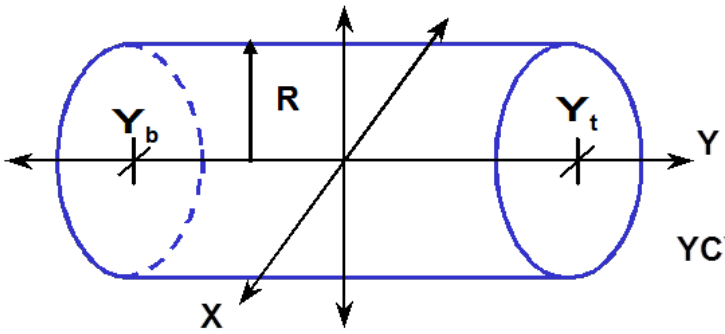
YCYLINDER specifies a right circular cylinder oriented about the Y-axis. It is defined by specifying the radius of the cylinder, R, the Y coordinate of the top face, Y_t, and the Y coordinate of the bottom

face, Y_b. Its centerline must lie on the Y axis, unless otherwise specified by the optional geometry modification data. Fig. 8.1.229 shows the correct input sequence for a cylinder.



YCYLINDER LBL R Y $_t$ Y $_b$

Fig. 8.1.229: Example of ycylinder construction.

YPPLANE is a set of flat parallel surfaces where any two points in one of the surfaces can be connected by a straight line entirely contained within that surface. These surface planes divide space into three sections; one section between the two planes which is considered inside the surfaces, one section on the negative side of the negative plane which is considered outside the surfaces, and one section on the positive side of the positive plane which is considered outside the surfaces. The set of parallel planes are defined by the keyword YPPLANE, which places the planes perpendicular to the Y-axis, the Y-intercept between the more positive plane and the Y-axis (Y_+) and the Y-intercept between the more negative plane and the Y-axis (Y_-). Fig. 8.1.230 shows the correct input sequence for the set of paired planes.

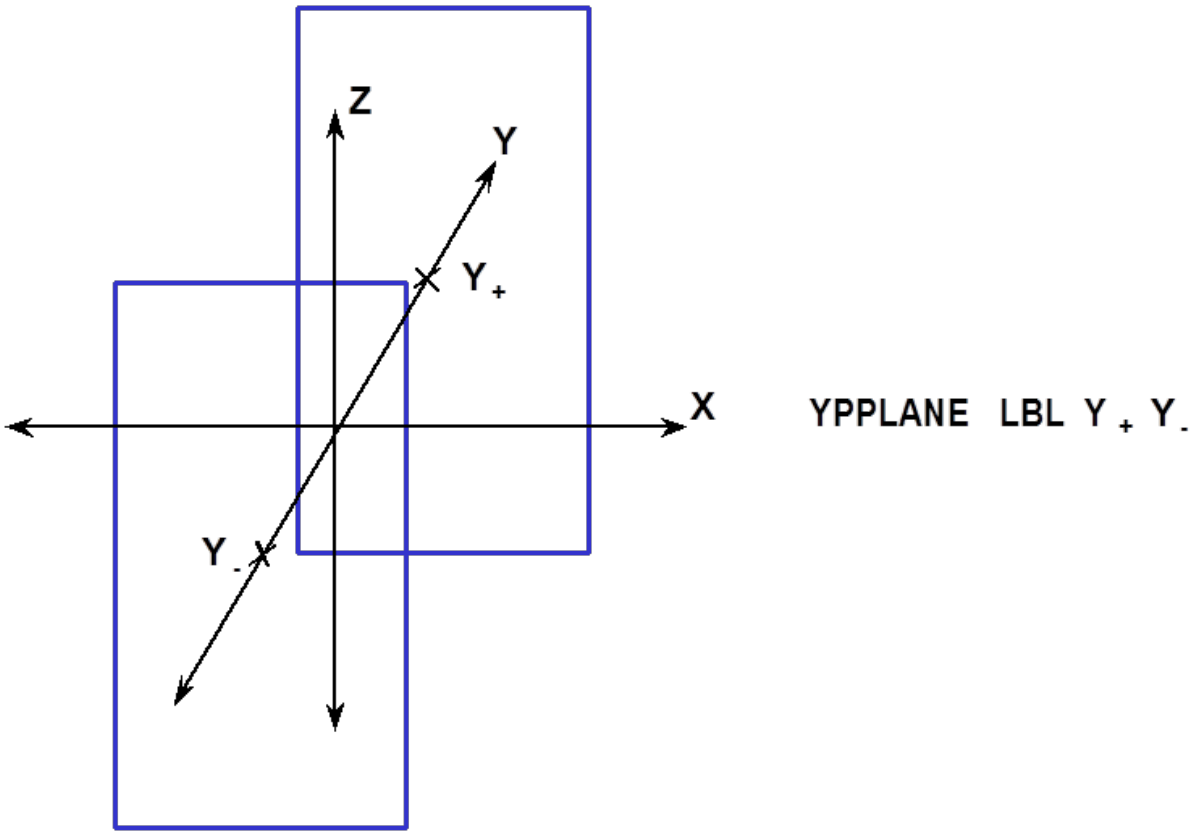


Fig. 8.1.230: Example of y-paired plane construction.

ZCYLINDER specifies a right circular cylinder oriented about the Z-axis. It is defined by specifying the radius of the cylinder, R, the Z coordinate of the top face, Z_t, and the Z coordinate of the bottom face, Z_b. Its centerline must lie on the Z-axis, unless otherwise specified by the optional geometry modification data. The keyword ZCYLINDER is the same as CYLINDER. It is included to be consistent with the XCYLINDER and YCYLINDER keywords. Fig. 8.1.231 shows the correct input sequence for a zcylinder.

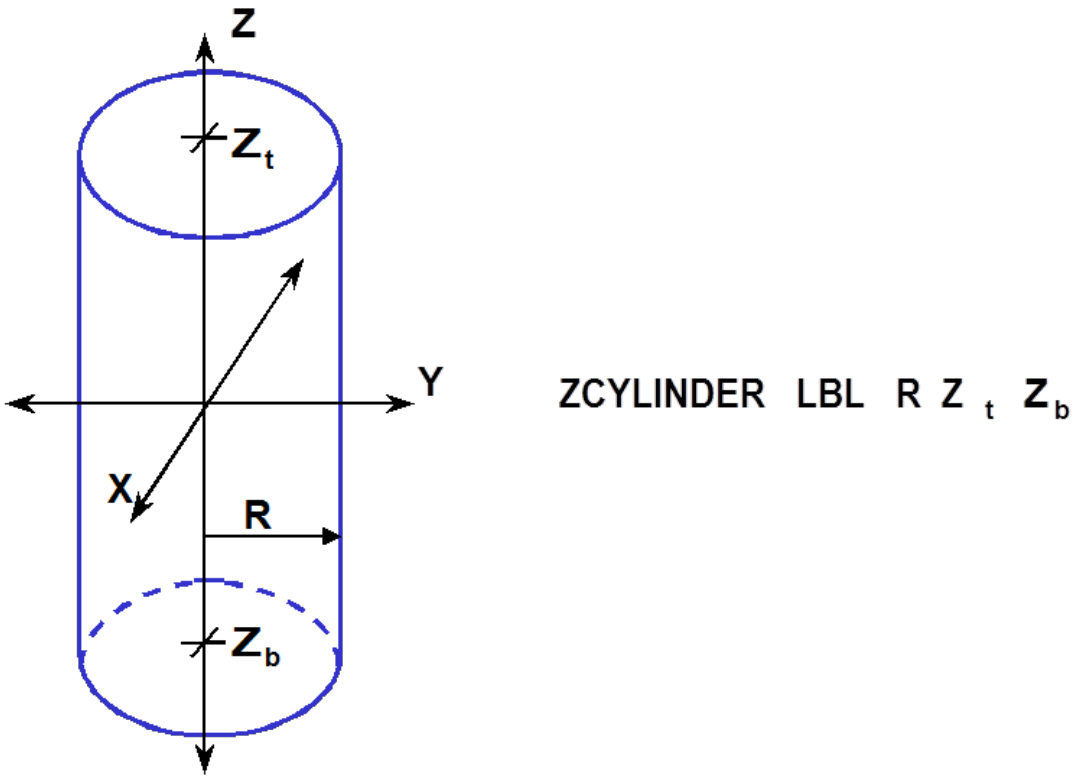

Fig. 8.1.231: Example of zcylinder construction.

ZPPLANE is a set of flat parallel surfaces where any two points in one of the surfaces can be connected by a straight line entirely contained within that surface. These surface planes divide space into three sections; one section between the two planes which is considered inside the surfaces, one section on the negative side of the negative plane which is considered outside the surfaces, and one section on the positive side of the positive plane which is considered outside the surfaces. The set of parallel planes are defined by the keyword ZPPLANE, which places the planes perpendicular to the Z-axis, the Z-intercept between the more positive plane and the Z-axis (Z_+) and the Z-intercept between the more negative plane and the Z-axis (Z_-). Fig. 8.1.232 shows the correct input sequence for the set of paired planes.

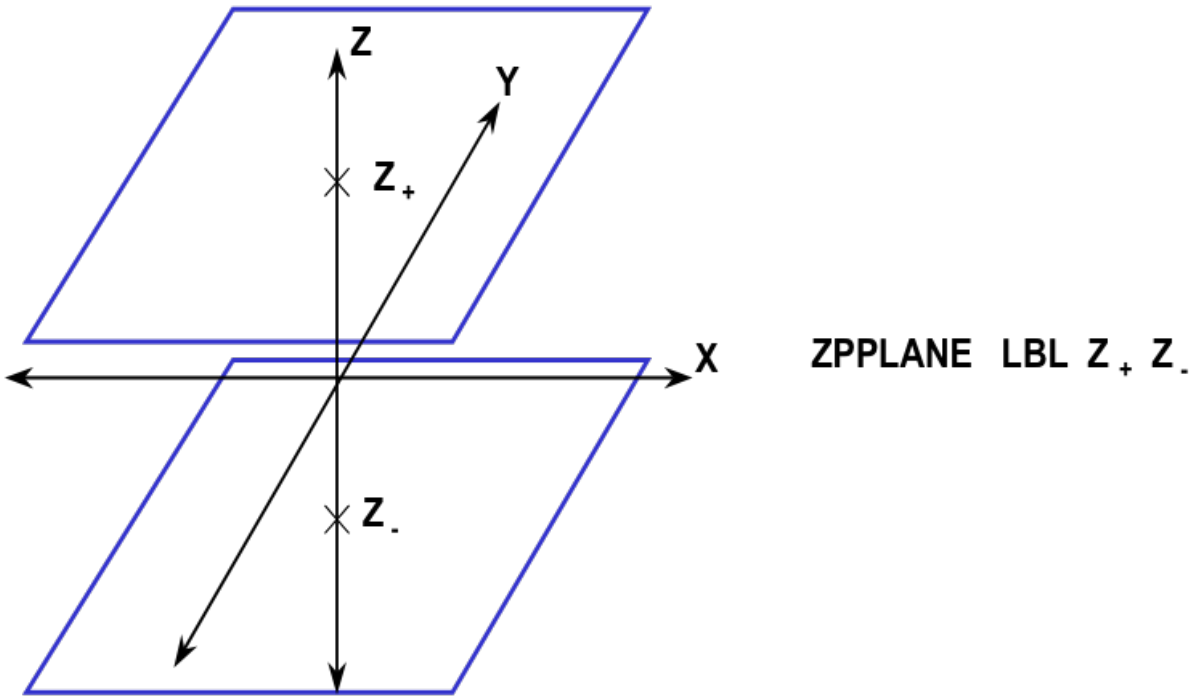

Fig. 8.1.232: Example of z-paired plane construction.

8.1.8.3 KENO Sample Problems

This section contains sample problems to demonstrate some of the options available in KENO in stand-alone mode. Because stand-alone KENO has no means to read standard composition information and process for use, the problem-dependent cross section library must be prepared before executing KENO in the multigroup mode. The **MIXTURE** data block (See Sect. 8.1.3.1) is used to provide the mixing table. In the continuous energy mode, the cross sections are directly used and therefore no problem-dependent library is needed. The mixing table is required in the continuous energy mode as well. If KENO is executed as part of CSAS5 or CSAS6 sequence, generation of the problem-dependent library (for the multigroup mode) and the mixing table is automatically performed by the sequence.

A total of 33 KENO V.a different case inputs and 27 KENO-VI inputs are provided as multigroup mode KENO sample problems in a single input file "kenova.inp" and "kenovi.inp" for KENO V.a and KENO-VI, respectively. This input file contains an initial CSAS-MG input to create the problem-dependent cross section library to be used in the sample problems in the input file. Although KENO does not run stacked cases, when KENO is run as part of SCALE, the driver allows KENO to be executed each time it encounters an **=KENOVA**, respectively **=KENOVI**. The ".inp" file contains all 33/27 problems one after the other. A similar input file "cekenova.inp", respectively "cekenovi.inp" is also provided for continuous energy mode of calculations. The changes required to create the continuous energy mode input file from the multigroup mode input file are simple. The continuous energy mode file does not have (or need) the CSAS-MG input at the beginning. In addition, all "lib=4" entries in the PARAMETER data block are changed to **cep=ce_v7.1_endf** to indicate the mode of calculation is continuous energy and the continuous energy cross section directory file is "ce_v7.1_endf" indicating ENDF/B-VII.1-based cross sections. The mixing table entry SCT is not applicable in the continuous energy mode, so it has been deleted from the continuous energy input file. Finally, material-specific albedos have also been removed from the continuous-energy input because they are not supported with continuous-energy mode.

The same 33/27 problems are also executed as individual cases with filenames “k5smp??.inp”, respectively “k6smp??.inp”, where ?? stands for sample problem number (01 through 33 or 27). Since each one of these sample problems needs a problem-dependent cross section library (multigroup mode only) and a mixing table, these problems have been converted to run as CSAS5/6 problems. Similar input files are also provided to be run in the continuous energy mode and the files are named “cek5smp??.inp”, respectively “cek6smp??.inp”, where ?? again stands for sample problem number (01 through 33 or 27). The change required to create the continuous energy mode inputs from the multigroup mode inputs is very simple: the cross-section library name is changed from “v7.1-252” to “ce_v7.1”.

In the following section the input for each case is listed assuming the multigroup mode of calculation in KENO. The KENO input is also listed in the file corresponding “.inp” file. The CSAS-MG input file for these cases is in the next section.

Warning: Some input might show differences in **NPG**, **NSK** and **GEN** parameters between multigroup and continuous energy input files.

CSAS-MG data

CSAS-MG can (1) be run alone with problem-dependent working library on logical Unit 4 saved for later use with the KENO sample problems, or (2) be placed in front of the KENO sample problems.

The CSAS-MG SCALE control module calculates the necessary resonance data required to create the problem-dependent AMPX working format library using SCALE standard composition input.

The multigroup mode KENO sample problem input data are independent of energy group structure. To use a different energy group structure, simply supply the desired master cross-section library name in the CSAS-MG or CSAS5/6 data. See XSProc, Standard Composition and CSAS5/6 chapters for additional information and examples. See the XSLib chapter for information about the master format cross-section libraries that are available in SCALE.

Data for CSAS-MG are provided to create a problem-dependent AMPX working format cross-section library suitable for use with the multigroup mode KENO sample problems. These data include all of the mixtures used in the KENO sample problems and will create an AMPX working format cross-section library with nuclide IDs matching those in the KENO sample problem mixing tables. This cross-section library is problem-specific and is not appropriate for use with other problems.

The CSAS-MG input data to produce an AMPX working format cross-section library for the multigroup mode KENO V.a sample problems are given below. Note that “kenovi.inp” also has its own CSAS-MG data which is identical to the below input with some minor updates in the comment lines.

KENO V.a sample problem data

A brief problem description and the associated input data are included for each multigroup mode KENO sample problems. Different options may be easily activated by making changes in the data. These problems are set up using an AMPX working format library which was created by a CSAS-MG case just prior to the KENO V.a/KENO-VI cases. The nuclide identifiers for this library are consistent with the SCALE identifiers created by CSAS-MG. Input data to create this library are given in Sect. 8.1.8.3.1. The unit number is defined by the parameter **LIB=** in the parameter data.

Sample Problem 1 2C8 BARE

This is a simple 2 × 2 × 2 array of uranium metal cylinders as described in the article "Critical Three-Dimensional Arrays of U(93.2)-Metal Cylinders," [KENO-Appendix-CTho73] by J. T. Thomas. This critical experiment is designated in Table II of that article as cylinder index 11 and reflector index 1. Fig. 8.1.233 shows the critical experiment.

Sample Problem 2 CASE 2C8 BARE WITH 8 UNIT TYPES MATRIX CALCULATION

This problem is the same as sample problem 1 except it is set up as a mixed unit problem with each unit of the array defined as a different unit type. Matrix k-effectives will be calculated for this problem by both unit type and array position. The print flags are set to print all matrix data.

Sample Problem 3 2C8 15.24-CM PARAFFIN REFL

A 2 × 2 × 2 array of uranium metal cylinders is reflected by 6 in. of paraffin on all faces (Fig. 8.1.233). This critical experiment[1] is designated as cylinder index 11 and reflector index 5 in Table II of Ref. 1. Fig. 8.1.234 shows half of the critical experiment, which consisted of the half shown and the mirror image of it. These two assemblies were moved together to achieve criticality. The top reflector is missing in Fig. 8.1.234, but was present when criticality was achieved.

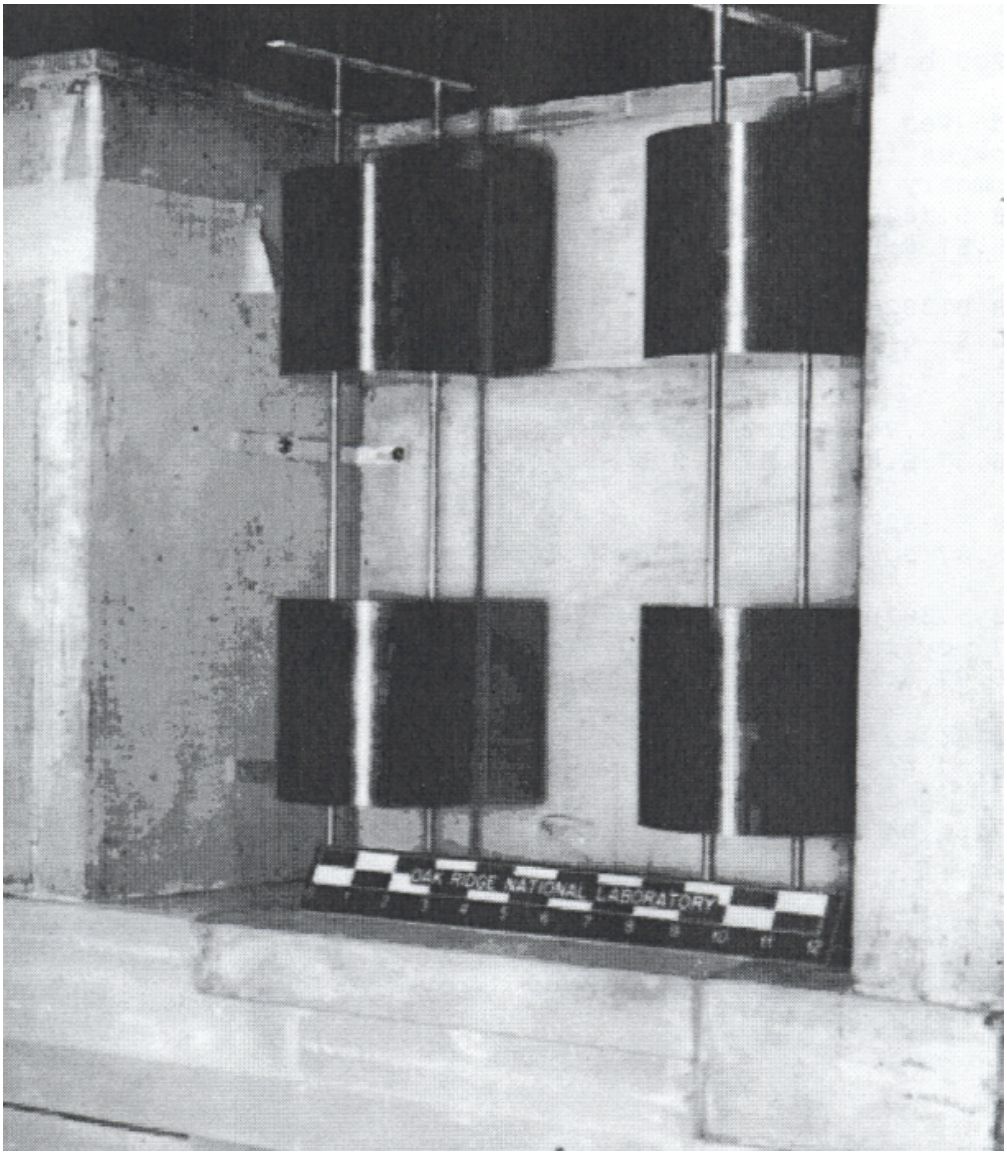

Fig. 8.1.234: Half of the paraffin reflected 2C8 assembly before the top reflector was added.

Sample Problem 5 2C8 12-INCH PARAFFIN ALBEDO REFLECTOR

This problem is the same as samples problems 3 and 4 except the reflector is represented by a 12 in. paraffin albedo. Note the decrease in execution time when using an albedo reflector instead of doing actual tracking. Note also that k-effective is somewhat higher for this system, probably due to the small edge size of the system [KENO-Appendix-CWT69].

Input Data

KENO V.a

Sample Problem 12 4 AQUEOUS 4 METAL

This problem is a critical experiment consisting of a composite array[1] of four highly enriched uranium metal cylinders and four cylindrical Plexiglas containers filled with uranyl nitrate solution. The metal units in this experiment are designated in Table II of Ref. 1 as cylinder index 11 and reflector index 1. A photograph of the experiment is given in Fig. 8.1.235.

Fig. 8.1.235: Critical assembly of 4 solution units and 4 metal units.

Sample Problem 13 TWO CUBOIDS IN A CYLINDRICAL ANNULUS

This critical experiment [KENO-Appendix-CIM64] consists of two assemblies of 93.2% ^{235}U-enriched uranium metal (ρ = 18.69^{g}/cc) stacked vertically. The bottom assembly contains a uranium metal cuboid offset to the left within a uranium metal cylindrical annulus. The top assembly contains a uranium metal cuboid offset to the right within a uranium metal cylindrical annulus. The cuboid extends above the annulus. A drawing of the two sections and the total assembly is given in Fig. 8.1.236.

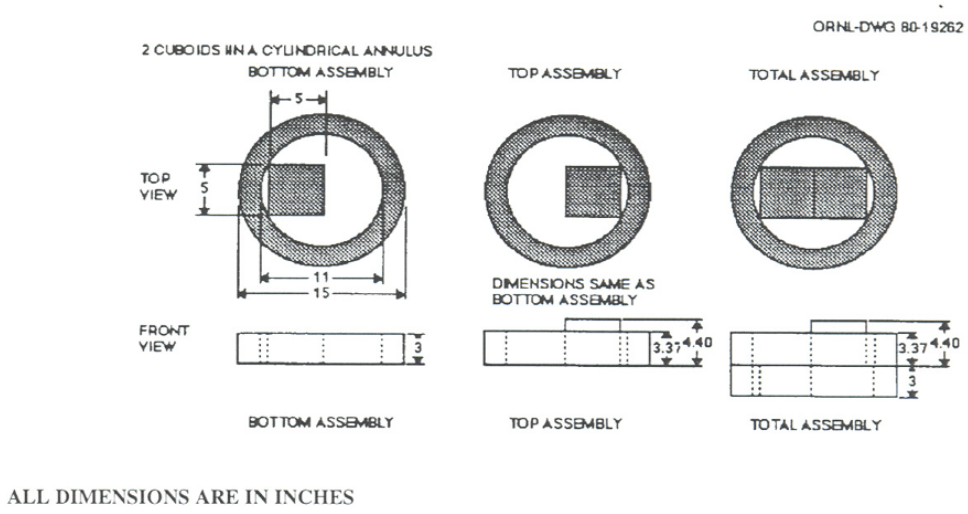

Fig. 8.1.236: Drawing of two cuboids in an annulus critical assembly.

Sample Problem 14 U METAL CYLINDER IN AN ANNULUS

This critical experiment[3] consists of a 93.2 ^{235}U-enriched uranium metal cylinder within a cylindrical annulus of the same material as shown in Fig. 8.1.237. The uranium metal specification is identical to that used in sample problem 13.

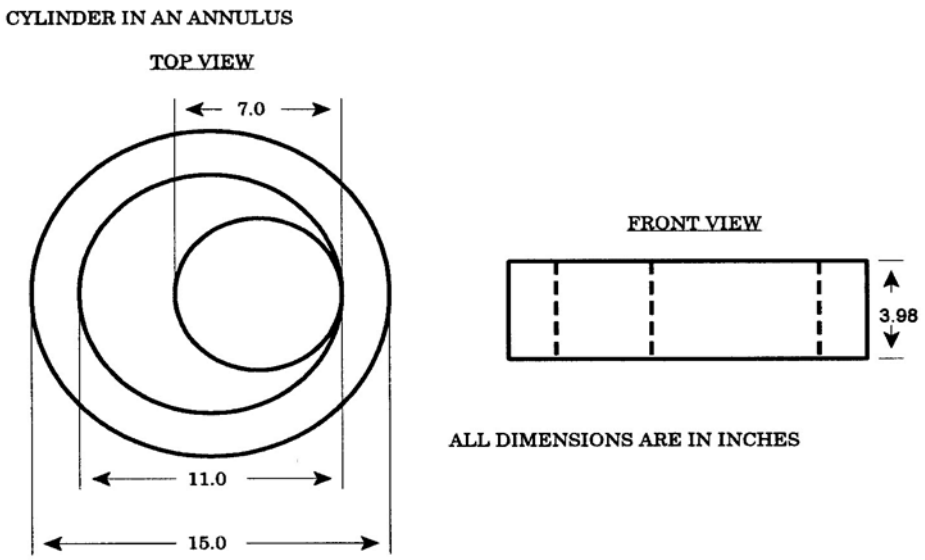

Fig. 8.1.237: Drawing of the cylinder in an annulus critical assembly.

Sample Problem 15 SMALL WATER REFLECTED SPHERE ON PLEXIGLAS COLLAR

This critical experiment [KENO-Appendix-CBKH+77] is a small highly enriched uranium sphere supported by a Plexiglas doughnut in a tank of water. The sphere extends down through the hole of the doughnut. However, the KENO geometry package cannot rigorously describe a doughnut (torus) with either KENO V.a or KENO-VI. Therefore, the KENO mockup of this problem describes the doughnut as an annular cylindrical plate and the sphere is supported by it. Both are contained in a cylindrical tank of water. A drawing of the experiment is given in Fig. 8.1.238. This drawing shows the sphere above the cylindrical collar for the sake of clarity. The sphere is actually supported by the collar and extends into the opening in its center. The actual experiment utilized a torus or doughnut instead of a cylindrical collar.

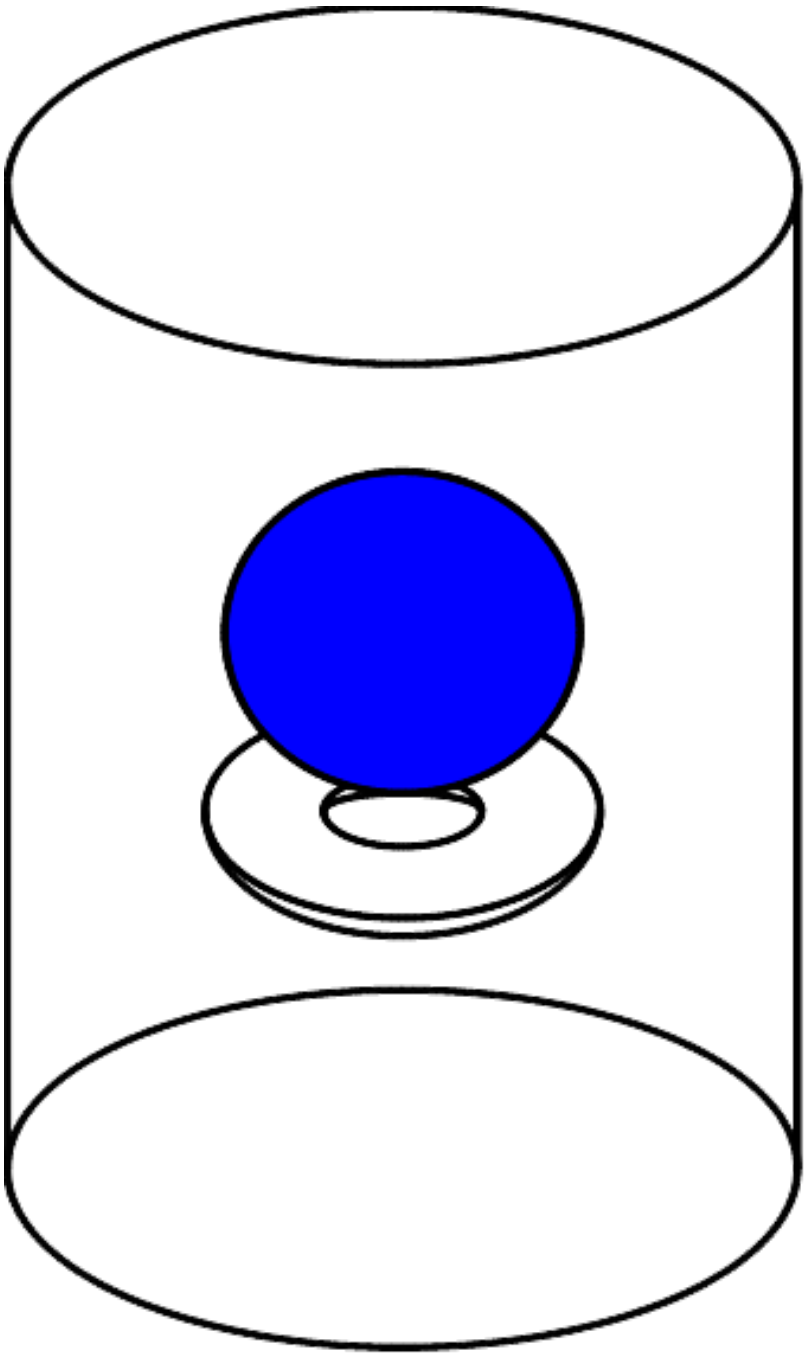

Fig. 8.1.238: Drawing of a critical assembly consisting of a uranium sphere on a Plexiglas collar with a cylindrical water reflector.

Sample Problem 16 UO2F2 INFINITE SLAB K-INFINITY

This problem solves for the k-infinity of an infinite number of slabs of uranyl fluoride solution contained in Pyrex glass and separated by borated uranyl fluoride solution. The uranyl fluoride slab is 4.958 cm thick, 93.2% enriched, and has a density of 578.7 g U/l. The Pyrex glass is 1.27 cm thick and is present on both faces of the uranyl fluoride solution. A total of 27.46 cm of borated solution separates the Pyrex glass of adjacent slabs of solution. 1.482×10^{-27} atoms of boron per milliliter are present in the borated solution.

Sample Problem 18 1F27 DEMONSTRATION OF OPTIONS

A reflected cubic array of 27 cylinders of aqueous uranyl nitrate in Plexiglas bottles [KENO-Appendix-CTho64]. The walls of the bottles were 0.64-cm thick, and each bottle was filled with 5 liters of 92.6% enriched solution at a concentration of 415 g/L, a specific gravity of 1.555 and 0.39 mg excess nitrate/g soln (From experimental facility documents. Not reported in ORNL/TM-719.) The $3 \times 3 \times 3$ array was surrounded by a 6-in. paraffin reflector. Most of the print options available in KENO are exercised in this problem. A perspective of this critical experiment is shown in Fig. 8.1.239. A photograph of one of the experiments utilized 27 of the Plexiglas bottles is shown in Fig. 8.1.240. Sample problem 18 has 15.24 cm of paraffin on all six faces rather than the 2.54-cm Plexiglas shown on five faces.

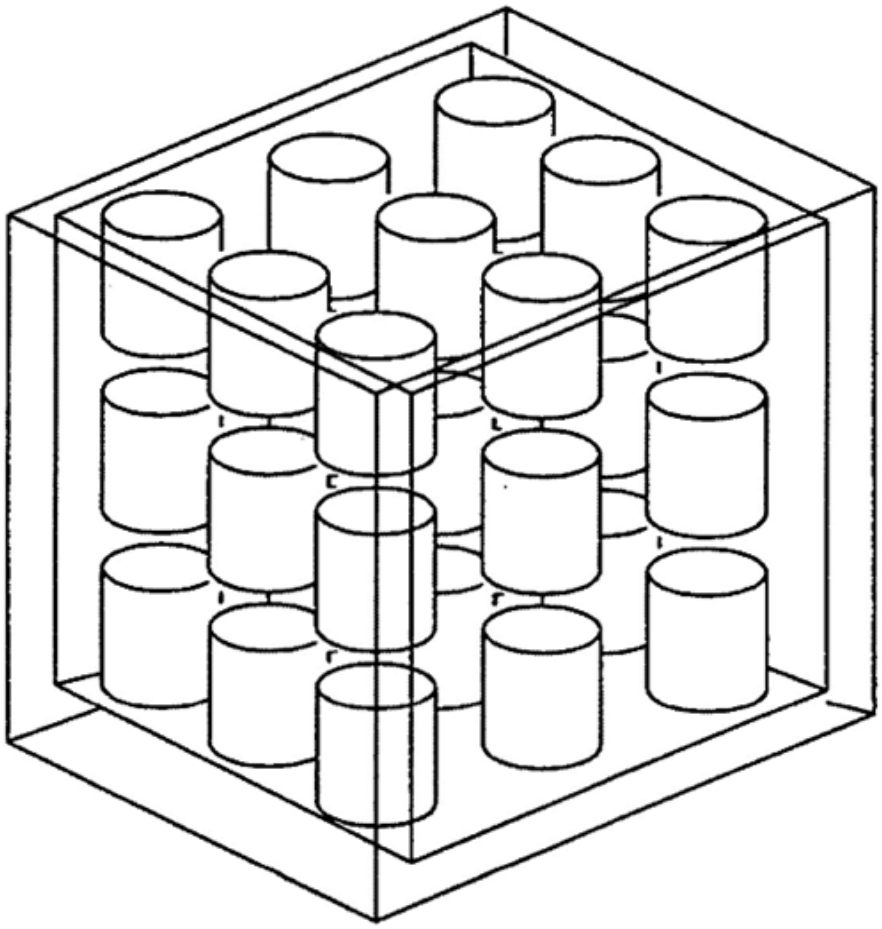

Fig. 8.1.239: Perspective of critical 1F27 experiment.

Fig. 8.1.240: View of a 27-unit array with 2.54-cm. thick Plexiglas reflector on five sides and a 15.24-cm. thick paraffin base.

Sample Problem 20 TRIANGULAR PITCHED ARRAY

This problem is a critical experiment14 consisting of seven cylinders in a triangular-pitched unreflected array. The central cylinder has six cylinders arranged around it. The surface-to-surface separation between the units is 0.15 in. Each unit consists of a 60-mil-thick aluminum can with an 8-in. inside diameter, filled with a solution of 93.2% enriched uranyl fluoride with a H/235U atomic ratio of 44.3 and a density of 576.87 g U/L. The apparatus for conducting this experiment is shown in Fig. 8.1.241.

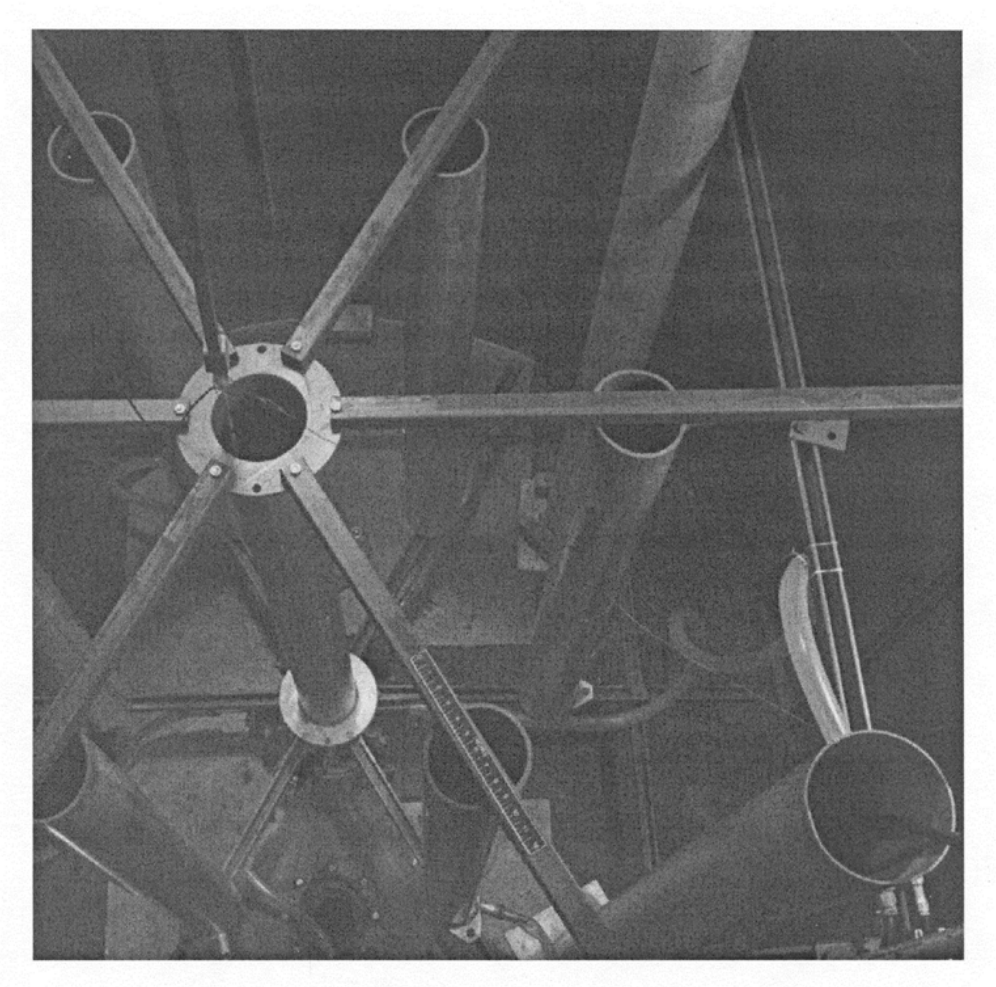

Fig. 8.1.241: Typical arrangement for critical experiments with interacting arrays of aluminum cylinders containing enriched ^{235}U solutions.

Sample Problem 21 PARTIALLY FILLED SPHERE

This critical experiment consisted of a partially filled, unreflected spherical container. This aluminum container had an inside diameter of 27.244 in. and a wall thickness of 1/16 in. It is referred to in the report as the 27.3-in.-diameter vessel. The sphere was 98% filled with uranyl fluoride at an enrichment of 4.89% with an $H/^{235}U$ atomic ratio of 1099. The height of the solution in the sphere was 64.6 cm above the bottom of the sphere. A schematic diagram of the apparatus used in the experiment is given in Fig. 8.1.242. The steel tank was ignored.

Sample Problem 22 CASE 2C8 BARE WITH 3 NESTED HOLES, EACH IS EQUAL VOLUME

The physical representation of this sample problem is the critical experiment described in sample problem 1. It is a simple $2 \times 2 \times 2$ array of 93.2% wt enriched uranium metal cylinders. This sample problem defines a uranium cylinder in a void spacing cuboid using nested holes. Eight of these units are stacked together in a $2 \times 2 \times 2$ array.

Sample Problem 24 CASE 2C8 BARE AS STACKED ROTATED CYLINDERS

The physical representation of this sample problem is the critical experiment described in sample problem 1. This sample problem describes each of the eight units in the critical $2 \times 2 \times 2$ array using hemicylinders whose axes are in the x direction. In KENO V.a this is realized using xhemicylinders, while in KENO-VI the hemycylinders with different chord sizes are rotated in the X-direction.

Sample Problem 25 CASE 2C8 BARE AS MIXED YHEMICYLINDERS

The physical representation of this sample problem is the critical experiment described in sample problem 1. This sample problem describes each of the eight units in the critical $2 \times 2 \times 2$ array using hemicylinders whose axes are in the y direction. This is realized in KENO V.a by using yhemicylinders, while in KENO-VI it is realized using hemicylinders with different chord sizes and directions whose long axes are rotated in the Y-direction.

Sample Problem 27 (KENO V.a oONLY) CASE 2C8 BARE AS MIXED XHEMICYLINDERS WITH ORIGINS

The physical representation of this sample problem is the critical experiment described in sample problem 1. This sample problem describes each of the eight units in the critical $2 \times 2 \times 2$ array using hemicylinders whose axes are in the x direction. Origins are specified for each hemicylinder.

Sample Problem 29 BARE CRITICAL SPHERE 3.4420-IN. RADIUS

This problem is a critical experiment [KENO-Appendix-CMLTH93] consisting of a critical Oralloy sphere. The density of the Oralloy is 18.747 g/cc, and the isotopic enrichment (wt %) is 93.21% ^{235}U, 5.7697% ^{238}U, 0.9844% ^{234}U, and 0.0359% ^{236}U. The critical radius was 8.74268 cm. A photograph of the experiment is given in Fig. 8.1.243. The support structure was ignored in the input data.

Sample Problem 33 CRITICAL TRIANGULAR PITCHED ARRAY OF ANNULAR RODS

This sample problem represents a critical experiment [KENO-Appendix-CJoh66] that consists of a partially flooded array of 19 low enriched uranium metal cylindrical annuli billets arranged in a triangular pitched array. The density of the uranium metal was 19.0 g/cc, and the isotopic enrichment in weight percent was 1.95% ^{235}U, 98.02% ^{238}U, 0.006% ^{236}U, and 0.002% ^{234}U. The cylindrical annuli had an inside diameter of 6.604 cm, an outside diameter of 18.288 cm, and were placed with a pitch of 20.828 cm. Each billet was 101.6 cm long. The array was positioned in a very large tank. This configuration was critical when the tank was filled to a height of 47.7 cm on a scale whose zero point was 0.6 cm below the bottom of the billets. The bottom of the billets was 21.6 cm above the bottom of the tank. The tank and all support structures have been ignored in this model. The model utilizes only 15.24 cm of water reflector on all sides of the array. Fig. 8.1.244 and Fig. 8.1.245 provide a representation of the model. A photograph of a single annular billet is shown in Fig. 8.1.246.

8.2 MONACO: A FIXED-SOURCE MONTE CARLO TRANSPORT CODE FOR SHIELDING APPLICATIONS

D. E. Peplow and C. Celik

Monaco is a general-purpose, fixed-source, Monte Carlo shielding code for the SCALE package. It is a functional module that uses either AMPX cross sections or continuous energy libraries to calculate neutron and photon fluxes and responses to specific geometry regions, to point detectors and to mesh tallies. Basic multigroup transport methods are inherited from Monaco's predecessor, MORSE. Continuous energy physics has been incorporated into the code with a new physics package that uses the same CE data as CE-KENO-VI, with extensions for simulating photons. Variance reduction capabilities include source biasing and weight windows, either by geometry region or by using a mesh-based importance map. User input includes the cross section file unit number; the geometry description using the SCALE General Geometry Package; source description as a function of position, energy, and direction; tally descriptions (fluxes in which regions, at what point detectors, or over what mesh grids); and response functions (functions of energy). Output consists of tables detailing the region and point detector fluxes (and their responses), as well as files for mesh tallies.

8.2.1 INTRODUCTION

Monaco is a neutron/photon, fixed-source Monte Carlo shielding code for the SCALE code package. Monaco uses the SCALE General Geometry Package (SGGP)—the same geometry description as KENO-VI. Monaco has many options available to the user for specifying source distributions, many tally options, and many variance reduction capabilities. Monaco was originally based on the MORSE Monte Carlo code but has been extensively modified to modernize the coding, increase the number of capabilities in terms of sources and tallies, and allow for either multigroup or continuous energy (CE) transport through the use of the new SCALE CE Modular Physics Package (SCEMPP).

Monaco was developed to address a number of long-term goals for the Monte Carlo shielding capabilities in SCALE. The principal goals for this project included (1) unification of geometric descriptions between the SCALE shielding and criticality Monte Carlo codes, (2) implementation of a mesh-based importance map and mesh-based biased source distribution so that automated variance reduction could be used, and (3) establishment of a code using modern programming practices from which to continue future development. The addition of a continuous-energy transport capability is a significant change as well.

Monaco is the key component of the MAVRIC sequence, which also uses Denovo to create the mesh-based importance map and mesh-based biased source distribution for general 3-D automated variance reduction. See the MAVRIC chapter for more information.

8.2.2 MONACO CAPABILITIES

Monaco has a wide range of source descriptions and tallies for performing general radiation transport calculations. Note that Monaco can work with either the AMPX-based multigroup libraries or the newer AMPX-based CE libraries. Note that for CE calculations, tallies still employ a multigroup energy structure to store and report results.

8.2.2.1 Source Descriptions

Multiple sources can be defined for a Monaco calculation. Sampling of the different sources can be biased by the user. Each source is specified by its spatial distribution, its energy distribution, its directional distribution, and its strength. Distributions defined by the user can also be biased and can be used multiple times by different sources. The Monaco tallies assume that the sources all have units of particles/second. If the source strengths are given in other units, the user will have to incorporate the proper conversion to the tally results and remember to interpret the results accordingly.

Distributions

Two types of basic distributions are used by Monaco — binned histograms and a set of value/function pairs. The binned histogram type is defined by $n + 1$ bin boundaries and n values, representing the integrated amount in each bin. For the true distribution $f(x)$, the bin boundaries $[x_0,\ x_1,\ \ldots,\ x_n]$ and the integrated amounts $F_i = \int_{x_{i-1}}^{x_i} f(x)\,\mathrm{dx}$ are given. The distribution will be normalized by Monaco after reading. The user can optionally bias a binned histogram distribution by supplying one of the following: the biased sampling distribution amounts, $G_i = \int_{x_{i-1}}^{x_i} g(x)\,\mathrm{dx}$; the importance of each bin, I_i; or the suggested weight for each bin, w_i.

Based on what type of input is given, Monaco will compute a properly normalized probability distribution function for sampling. If the importances are given, the sampling distribution is computed as

$$G_i = \frac{I_i F_i}{\sum_i I_i F_i} \tag{8.2.1}$$

If suggested weights are given, then the sampling distribution is computed as

$$G_i = \frac{\frac{F_i}{w_i}}{\sum_i \frac{F_i}{w_i}} \tag{8.2.2}$$

for bins with non-zero weight. The sampling distribution for bins with a suggested weight of zero are set to $G_i = 0$. When sampled, particles are assigned a weight of $\frac{F_i}{G_i}$.

The second type of distribution that a user can define is for a series of point values of a function. For a set of $n + 1$ point pairs, (x_i, f_i) for $i \in [0 \ldots n]$, defining n intervals, a distribution can be made by linearly interpolating between adjacent point pairs. This type of distribution can also be biased by supplying one of the following: the biased sampling distribution function value g_i at each point, the importance of each point, I_i; or the suggested weight for each point, w_i. Similar to above, if importances or weights are given, Monaco computes the biased distribution for sampling. For the value/function point pairs type of distribution, the weight assigned to the sampled particle is a continuous function.

Some commonly used distributions are built into Monaco and can be used by simple keywords. Monaco can produce a graph of any distribution so that the user can verify that the input was entered correctly.

Spatial energy and directional attributes

Each Monaco source is described by three separable components: spatial, energy and directional.

The spatial component of a source in Monaco is simple but very flexible. First, the general shape of the source region is defined in global coordinates. The basic solid shapes and their allowed degenerate cases are listed in Table 8.2.1. The user can reference any of the defined distributions to describe the source distribution in any coordinate (x, y, and z for cuboids, r and z for cylinders and r for spheres) to use for sampling or leave the source distribution as uniform over each dimension for the solid shape. The source region can be limited by the underlying SGGP geometry variables of unit, media, and mixture. This way, source volumes (or planes, lines, or points) can be defined that are independent or dependent on the model geometry. A cylinder or cylindrical shell region can be oriented with its axis in any direction.

Table 8.2.1: Available source shapes and their allowed degenerate cases

Shape	**Allowable degenerate cases**
cuboid	rectangular plane, line, point
cylinder	circular plane, line, point
cylindrical shell	cylinder, planar annulus, circular plane, cylindrical surface, line, ring, point
sphere	point
spherical shell	sphere, spherical surface, point

Monaco samples the source position using either the given distributions or uniformly over the basic solid shape and then uses rejection if any of the optional SGGP geometry limiters have been specified. For sources that are confined to a particular unit, media, or mixture, users should make sure the basic solid shape tightly bounds the desired region for efficient sampling.

For the energy component of each source, either type of distribution described above can be used. Biasing can be used in the energy component of the source as well. The Watt spectrum is a built-in distribution which uses the Froehner and Spencer [MONACO-FS81] method for sampling. If the defined energy distribution has point(s) that are out of the problem's energy range for a CE problem, these points will be rejected in

the source energy sampling and an error message will be generated. The warnings will be suppressed if the number of rejected source points exceeds a pre-defined threshold (1000).

Distributions can be used to define the directional component of the source. A function of the cosine of the polar angle, with respect to some reference direction in global coordinates, can be used by Monaco. If no directional distribution is specified, the default is an isotropic distribution (one directional bin from $\mu = -1$ to $\mu = 1$). The default reference direction is the positive z-axis (<0,0,1>).

Monaco mesh source map files

An alternative to specifying the separate spatial and energy distributions, a Monaco mesh source file can be used. A mesh source consists of a 3D Cartesian mesh that overlay the geometry. Each mesh cell has some probability of emitting a source particle, and within each mesh cell, a different energy distribution can be sampled. Position within each mesh cell is sampled uniformly, and the emission direction is sampled from the standard directional distribution. Monaco mesh source files are typically produced by the MAVRIC sequence or by other Monaco calculations (see the mesh source saver option in the source input). For a source constructed from the separable spatial and energy distributions, Monaco can create a mesh source file which can then be visualized using the Mesh File Viewer. This is a convenient way to ensure that the source being used is what was intended.

8.2.2.2 Tallies

Monaco offers three tally types: point detectors, region tallies, and mesh tallies. Each is useful in determining quantities of interest in the simulation. Any number of each can be used, up to the limit of machine memory. The tallies will compute flux for each group, the total neutron and total photon fluxes, and any number of dose-like responses. A typical dose-like response, R, is the integral over energy of the product of a response function, $f(E)$, and the flux, $\phi(E)$.

$$R = \int f(E)\,\phi(E)\,dE \tag{8.2.3}$$

In multigroup calculations, the total response would be expressed as the sum over all groups $R = \sum f_g \phi_g$. For CE calculations, tallies can be segmented into energy and time bins which can be thought of as "groups". All three of the tally types can be scaled with a constant — for example, to account for units conversions.

Tally statistics

The three Monaco tallies are really just collections of simple and extended tallies for each group, each total, and each group contribution to a response or total response. The simple tally works in the following way: a history score h_i is zeroed out at the start of history i. During the course of the history, when an event occurs during substep j, a score consisting of some contribution c_{ij} weighted by the current particle weight w_{ij} is calculated and added to h_i. At the end of the history, the history score is the total weighted score for each substep j in the history.

$$h_i = \sum_j w_{\mathrm{ij}} c_{\mathrm{ij}} \tag{8.2.4}$$

Note that the values for the contribution c_{ij} and when it is added to the accumulator are determined by the tally type. At the end of the each history, the history score is added to two accumulators (power sums) - the first accumulator is for finding the tally average, S_1, and the second accumulator is for finding the uncertainty in the tally average, S_2.

$$S_1 = \sum_i h_i \tag{8.2.5}$$

$$S_2 = \sum_i h_i^2 \tag{8.2.6}$$

At the end of all N histories, the second sample central moment is found from the power sums

$$m_2 = \frac{S_2}{N} - \frac{S_1^2}{N^2} \tag{8.2.7}$$

and then the tally average is computed as $\overline{x} = \frac{S_1}{N}$ and the uncertainty in the tally average is $u = \sqrt{\frac{m_2}{N}}$.

The extended tally uses four accumulators — the first and second are the same as the simple tally — with the third and fourth accumulators used for finding the variance of the variance (VOV). These extra accumulators, S_3 and S_4, are calculated as

$$S_3 = \sum_i h_i^3 \tag{8.2.8}$$

$$S_4 = \sum_i h_i^4 \tag{8.2.9}$$

At the end of all N histories, the tally average $\overline{x}$ and uncertainty in the tally average u are found in the same way as a simple tally. For the VOV calculation, the third and fourth sample central moments are found as

At the end of all N histories, the tally average $\overline{x}$ and uncertainty in the tally average u are found in the same way as a simple tally. For the VOV calculation, the third and fourth sample central moments are found as

$$m_3 = \frac{S_3}{N} - \frac{3S_1S_2}{N^2} + \frac{2S_1^3}{N^3} \tag{8.2.10}$$

$$m_4 = \frac{S_4}{N} - \frac{4S_1S_3}{N^2} + \frac{6S_1^2S_2}{N^3} - \frac{3S_1^4}{N^4} \tag{8.2.11}$$

and then the VOV [MONACO-PFB97] and figure-of-merit (FOM) are found using

$$\text{VOV} = \frac{m_4 - m_2^2}{Nm_2^2} \tag{8.2.12}$$

$$\text{FOM} = \frac{1}{\left(\frac{u}{\overline{x}}\right)^2 T} \tag{8.2.13}$$

where T is the calculation time (in minutes).

Extended tallies are used for the total neutron flux, total photon flux and any responses for the Monaco tallies. Simple tallies are used for each group's flux and each group's contribution to a response.

Detailed, group-wise results for each tally are saved to separate files at the end of each batch of particles. Users can view these files (in the SCALE temporary directory) as the Monaco simulation progresses. Summaries of the extended tallies appear in the final Monaco output file.

Statistical tests

Statistical tests are performed on the extended tallies at the end of each batch. Results for each batch are stored in files and the results for the final batch are shown in the main output tally summary. The six tests are:

Table 8.2.2: Statistical tests used by tallies

	Quantity	**Test**	**Goal**	**Within**
1.	mean	relative slope of linear fit	= 0.00	±0.10
2.	standard deviation	exponent of power fit	= -0.50	$R^2 > 0.99$
3.	relative uncertainty	final value	< 0.05	
4.	relative VOV	exponent of power fit	= -1.00	$R^2 > 0.95$
5.	relative VOV	final value	< 0.10	
6.	figure-of-merit erit	relative slope of linear fit	= 0.00	±0.10

For the tests that are fit to a function with respect to batch (1, 2, 4, and 6), only the last half of the simulation is used. The basis for these tests is that in a well-behaved Monte Carlo, the mean should not increase or decrease as a function of the number of histories (N), the standard deviation should decrease with $\frac{1}{\sqrt{N}}$, the variance of the variance should decrease with $\frac{1}{N}$ and the figure-of-merit should neither

increase or decrease as a function of the number of histories (proportional to time). For tests 2 and 4, the coefficient of determination, R^2, from a forced fit to a function with the right exponent is used as the tally test.

Point detector tallies

Point detectors are a form of variance reduction in computing the flux or response at a specific point. At the source emission site and at every interaction in the particle's history, an estimate is made of the probability of the particle striking the position of the point detector. For each point detector, Monaco tallies the uncollided and total flux for each energy group, the total for all neutron groups, and the total for all photon groups. Any number of optional dose-like responses can be calculated as well.

Multigroup

After a source particle of group g is started, the distance R between the source position and the detector position is calculated. Along the line connecting the source and detector positions, the sum of the distance sj through each region j multiplied by the total cross section Σ_j^g for that region is also calculated. The contribution cg to the uncollided flux estimator is then made to the tally for group g.

$$c_g = \frac{1}{4\pi R^2} \exp\left(- \sum_j s_j \Sigma_j^g \right) \tag{8.2.14}$$

Continuous Energy

After a source particle with energy E is started, the distance R between the source position and the detector position is calculated. For each bin g of the tally energy structure, a specific energy E_g is sampled uniformly within the bin. Along the line connecting the source and detector positions, the sum of the distance sj through each region j multiplied by the total cross section $\Sigma_j\left(E_g\right)$ for that region. The contribution cg to the uncollided flux estimator is then made to the tally for group g. total cross section $\Sigma_j(E)$:

$$c_g = \frac{1}{4\pi R^2} \exp\left(- \sum_j s_j \Sigma_j(E) \right) \tag{8.2.15}$$

Only source particles contribute to the uncollided flux tally. At each interaction point during the life of the particle, similar contributions are made to each of the tallies. For each group g' that the particle could scatter into and reach the detector location, a contribution is made that also includes the probability to scatter from the current direction towards the detector and having the energy change from group g to group g'.

This type of tally is costly, since ray-tracing through the geometry from the current particle position to the detector location is required many times over the particle history. Point detectors should be located in regions made of void material, so that contributions from interactions arbitrarily close to the point detector cannot overwhelm the total estimated flux (as $\frac{1}{4\pi R^2 \to \infty}$).

Care must be taken in using point detectors in deep penetration problems to ensure that the entire phase space that could contribute has been well sampled-so that the point detector is not underestimating the flux by leaving out areas far from the source but close to the point detector position. One way to check this is by examining how the tally average and uncertainty change with each batch of particles used in the simulation. Large fluctuations in either quantity could indicate that the phase space is not being sampled well.

Region tallies

Region tallies are used for calculating the flux and/or responses over one of the regions listed in the SGGP geometry. Both the track-length estimate of the flux and the collision density estimate of the flux are calculated-and for each, the region tally contains simple tallies for finding flux in each group, the total neutron flux, and the total photon flux. For each of the optional response functions, the region tally also contains simple tallies for each group and the total response.

For the track-length estimate of flux, each time a particle of energy E moves through the region of interest, a contribution of l (the length of the step in the region) is made to the history score for the simple tally for flux for tally group g. The same contribution is made for the history score for the simple tally for total particle flux, neutron or photon, depending on the particle type.

If any optional response functions were requested with the tally, then the contribution of $\mathrm{lf}(E)$is made for the response group, where $f(E)$ is the response function value for energy E. The history score for the total response function is also incremented using $\mathrm{lf}(E)$.

At the end of all of the histories, the averages and uncertainties of all of the simple tallies for fluxes are found for every group and each total. These results then represent the average track-length over the region. To determine flux, these results are divided by the volume of the region. If the volume V of the region was not given in the geometry input nor calculated by Monaco, then the tally results will be just the average track lengths and their uncertainties. A reminder message is written to the tally detail file if the volume of the region was not set.

For the collision density estimate of the flux, each time a particle of energy E has a collision in the region of interest, a contribution of $\frac{1}{\Sigma}$ (the reciprocal of the total macroscopic cross section) is made to the history scores for the simple tally for flux for tally energy group g and for the total particle flux. At the end of the simulation, the averages and uncertainties of all of the simple tallies for every group flux and total flux are found and then divided by the region volume, if available.

Similar to the point detector tallies, region tallies produce a file listing the tally average and uncertainty at the end of each batch of source particles (a *.chart file). This file can be plotted using the simple 2-D plotter (ChartPlot) to observe the tally convergence behavior.

Mesh tallies

For a D Cartesian mesh or a cylindrical mesh (independent of the SGGP geometry), Monaco can calculate the track-length estimate of the flux. Since the number of cells (voxels) in a mesh can become quite large, the mesh tallies are not updated at the end of each history but are instead updated at the end of each batch of particles. This prevents the mesh tally accumulation from taking too much time but means that the estimate of the statistical uncertainty is slightly low.

Like the other tallies, mesh tallies can calculate optional response functions.

Since a mesh tally consists of many actual tallies, the statistical tests are a bit more complex than for the region and point detector tallies. Several statistical quantities and tests are used in Monaco similar to those in several recent studies [MONACO-KI11, MONACO-KS11] which look at a distribution of relative variances over the mesh tally. In Monaco, the basis of the statistical tests center on the distribution of relative uncertainties and its mean, $\bar{r}$, of the voxels (V) with score.

$$\bar{r} = \frac{1}{V} \sum R_i \tag{8.2.16}$$

where R_i is the relative uncertainty of the flux or dose in voxel i. If every voxel has been sampled well and its relative uncertainty $R_i \propto \frac{1}{\sqrt{N}}$, then the mean relative uncertainty of the voxels should also behave as $\frac{1}{\sqrt{N}}$. The variance of the mean relative uncertainty can be calculated and a figure of merit (FOM) for the mesh tally can be constructed using

$$FOM = \frac{1}{\bar{r}^2 T} \tag{8.2.17}$$

with the time T in minutes. The four tests measure over the simulation: 1) if ζ, the fraction of voxels with non-zero score, is constant; 2) if the mean relative uncertainty is decreasing as $\frac{1}{\sqrt{N}}$ (as measured by the coefficient of determination, R^2, of a fit to a curve with power of -0.5); 3) if the variance of the mean relative uncertainty is decreasing with $\frac{1}{N}$; and 4) if the FOM is constant.

Table 8.2.3: Mesh tally statistical tests

	Quantity	Test	Goal	Within
1.	ζ, fraction with score	relative slope of linear fit	= 0.00	±0.10
2.	$\bar{r}$, mean relative uncertainty	exponent of power fit	= -0.50	$R^2 > 0.99$
3.	variance of $\bar{r}$	exponent of power fit	= -1.00	$R^2 > 0.95$
4.	figure-of-merit	exponent of power fit	= 0.00	±0.10

For non-uniform meshes (especially cylindrical), these tests may not be the best measure of performance since different size voxels will have a wider variety of relative uncertainties. The user is also cautioned that if there are individual voxels within the mesh tally that have relative uncertainties that are not decreasing as $\frac{1}{\sqrt{N}}$, then the mesh tally statistical tests will not be meaningful. It is ultimately up to the user to decide if the mesh tally is performing well (is the goal of the mesh tally just to calculate dose, not flux?; are all spatial areas of the mesh tally equally important?; are all magnitudes of the flux or response values equally important?; etc.)

Mesh tallies can be viewed with the Mesh File Viewer, a Java utility that can be run from GeeWiz (on PC systems) or can be run separately (on any system). The Mesh File Viewer will show the flux for each group, the total flux for each type of particle and the optional responses. Uncertainties and relative uncertainties can also be shown for mesh tallies using the Mesh File Viewer. For more information on the Mesh File Viewer,

see its on-line documentation.

8.2.2.3 Continuous Energy Transport

Using multigroup data in Monte Carlo transport calculations is generally sufficient for most problems (both shielding and criticality). Many of the reaction cross sections vary slowly with energy, so energy "groups" can be made with one set of properties for the group. Multigroup treatments can further simplify radiation transport by combining the different types of reactions that can occur into a simple scattering matrix — particles then have certain probabilities to scatter from their current energy group to another energy group. If the user is not interested in knowing which specific type of interaction happened at each collision, this simplification can increase calculation efficiency.

One major drawback of the multigroup approach is in representing discrete gammas, such as the decay radiation from common isotopic sources. Consider a simple shielding simulation using cobalt-60. This isotope gives off two high-energy gamma rays when it decays (1173230 eV with intensity 99.85% and 1332490 eV with intensity 99.9826%). In the SCALE multigroup calculations, a cobalt-60 source spectrum is represented by a broad pdf, controlled by the group structure. This is shown in Fig. 8.2.1. for the fine 47-group structure and the broad 19-group structure.

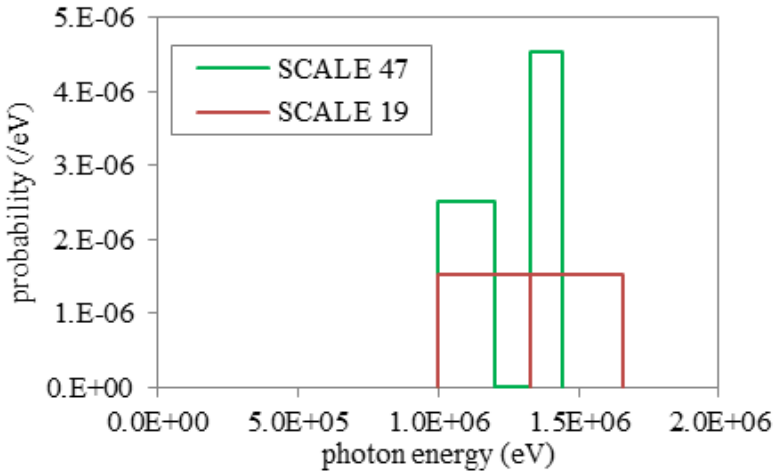

Fig. 8.2.1: The multigroup representation of a cobalt-60 source.

Note that in both group structures, 1.33 MeV is a group boundary, so the 1332490 eV line is represented by group that covers higher energies. The cross section for that group is lower than the cross section for the specific line, so multigroup transport calculations will tend to overestimate the number of photons penetrating a shield, which will overestimate dose rates.

Using CE and the two multigroup libraries, the total cross sections for the cobalt lines are listed in Table 8.2.4. Fig. 8.2.2. shows the total cross section of photons in tungsten, in both CE and the two SCALE multigroup structures. On the whole, the multigroup data represents the CE data well. Fig. 8.2.3. shows the same cross section information near the two cobalt lines, which shows how the multigroup cross sections average over quite large energy ranges.

Table 8.2.4: Total macroscopic cross section in tungsten (/cm).

	1173230 eV	1332490 eV
SCALE CE	1.03353	0.94864
SCALE 47	1.09066	0.92743
SCALE 19	1.05167	0.89289

The small differences in cross section can make large differences in the transport. Consider just 5 cm of tungsten. Using the cross sections in Table 8.2.4, the attenuation ($e^{-\mu x}$) of either line can vary by 30%.

In addition to source representation problems, multigroup transport is not adequate for applications where line spectra are measured. Because of the group structure, tally results will be averaged out within a group. With the fixed boundaries, specific lines in the tallies will not be able to be seen. For examples, in the 19-group library, there is no group around the 511 keV annihilation gammas — they are averaged in with other photons from 400 to 600 keV. No multigroup structure could contain thin groups around every line of interest.

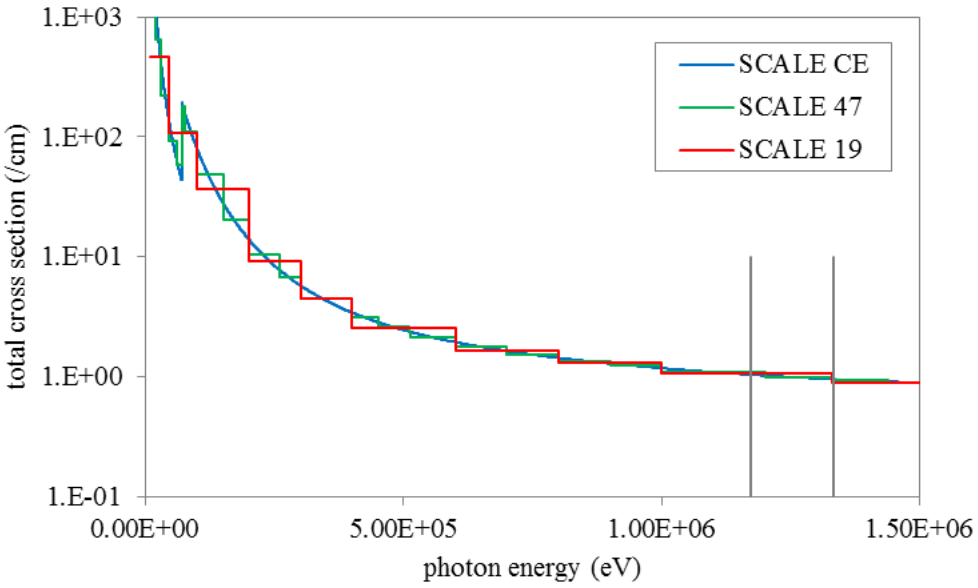

Fig. 8.2.2: Photon total cross section in tungsten. The energies of the cobalt-60 are displayed as lines at 1173230 and 1332490 eV.

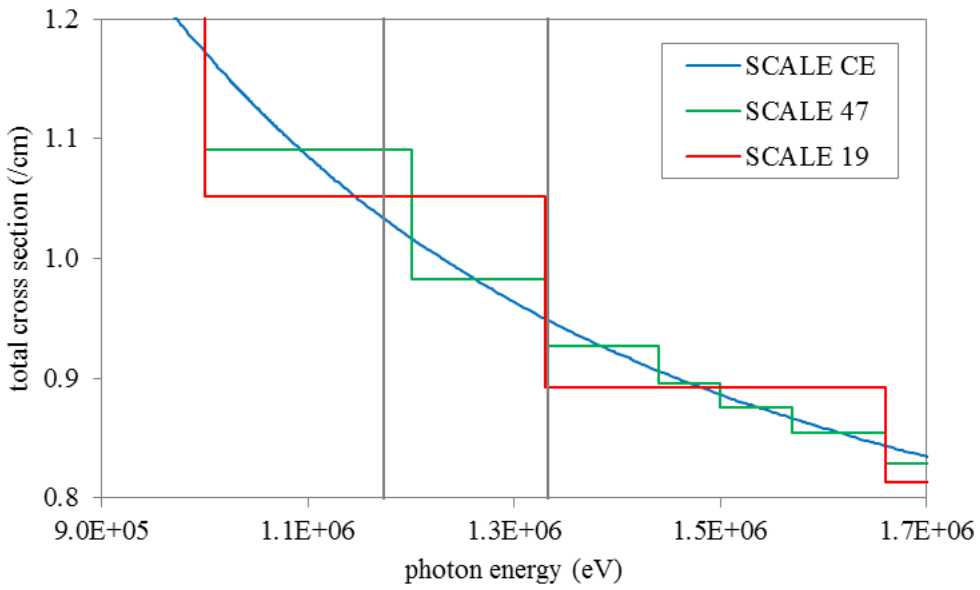

Fig. 8.2.3: Photon total cross section in tungsten, near the cobalt lines. The energies of the cobalt-60 are displayed as lines at 1173230 and 1332490 eV.

A sample problem involving a cobalt source and a slab of tungsten will compare the use of continuous-energy transport to multigroup transport, to demonstrate the large difference in results for single-line sources. For distributions, differences between multigroup and continuous-energy may not be very significant.

8.2.3 MONACO INPUT FILES

The input file for Monaco consists of two lines of text ("=monaco" command line and one for the problem title) and then several blocks, with each block starting with "read xxxx" and ending with "end xxxx". There are three blocks that are required and seven blocks that are optional. The cross section and geometry blocks must be listed first and in the specified order. Other blocks may be listed in any order.

Blocks (must be in this order):

- Cross Sections – (required) lists the cross-section file and the mixing table information
- Geometry – (required) SCALE general geometry description
- Array – optional addition to the above geometry description
- Volume – optional calculation or listing of region volumes
- Plot – create 2D slices of the SGGP geometry

Other Blocks (any order, following the blocks listed above):

- Definitions – defines locations, response functions, grid geometries, cylindrical mesh geometries, energy bin boundaries, time bin boundaries and various distributions used by other blocks
- Source – (required) description of multiple sources; with the spatial, energy, and directional distributions and particle type for each
- Tallies – description of what to calculate: point detector tallies, region tallies, or mesh tallies
- Parameters – how to perform the simulation (random number seed, how many histories, etc.)

- Biasing – data for reducing the variance of the simulation

The physical model blocks (Geometry, Array, Volume and Plot) follow the standard SCALE format. See the other SCALE references as noted in the following sections for details.

For the other six blocks, scalar variables are set by "keyword=value", fixed length arrays are set with "keyword $value_1$ ... $value_N$", variable length arrays are set with "keyword $value_1$ ... $value_N$ end", and some text and filenames are read in as quoted strings. Single keywords to set options are also used in some instances. The indention, comment lines, and upper/lower case shown in this document are not required-they are used in the examples only for clarity. Except for strings in quotes (like filenames), SCALE is not case sensitive.

After all of the blocks are listed, a single line with "end data" should be listed. A final "end" should also be listed, to signify the end of all Monaco input. See Example 8.2.1 for an overview of the Monaco input file structure.

8.2.3.1 Cross sections block

Monaco does its own mixing, so it needs a mixing table. For each element of each mixture, an identifier and a number density must be supplied. These can be found in the output of whatever sequence was used to make the cross-section file, such as CSAS-MG. Two coupled neutron/photon multigroup libraries were created specifically for shielding problems from ENDF/B-VII.0 data-the v7-200n47g fine-group and the v7-27n19g coarse-group libraries. CE libraries made from ENDF/BVII.0 are also available in SCALE.

Example 8.2.1: Overall input format for Monaco

```
=monaco                         %   name of sequence
Some title for this prob        %   title
read crossSections              %   List of isotopes/mixtures
   ...                          %       [required block]
end crossSections               %
read geometry                   %   SCALE SGGP geometry
   ...                          %       [required block]
end geometry                    %
read array                      %   SCALE SGGP arrays
   ...                          %       [optional block]
end array                       %
read volume                     %   SCALE SGGP volume calc
   ...                          %       [optional block]
end volume                      %
read plot                       %   SGGP Plots
   ...                          %       [optional block]
end plot                        %
read definitions                %   Definitions
   ...                          %       [possibly required]
end definitions                 %
read sources                    %   Sources definition
   ...                          %       [required block]
end sources                     %
read tallies                    %   Tally specifications
   ...                          %       [optional block]
end tallies                     %
read parameters                 %   Monte Carlo parameters
   ...                          %       [optional block]
end parameters                  %
read biasing                    %   Biasing information
   ...                          %       [optional block]
end biasing                     %
end data                        %   end of all blocks
end                             %   end of Monaco input
```

For example, if CSAS-MG was used to produce an AMPX file using the following input,

```
=csas-mg
Demonstration problem, three mixtures
v7-200n47g
read composition
    uo2   1 0.2 293.0 92234 0.0055 92235 3.5 92238 96.4945 end
    ss304 2 1.0 293.0 end
    h2o   4 1.0 293.0 end
end composition
end
```

in addition to creating an AMPX file, the output would include a tables similar to

```
m i x i n g   t a b l e    (THREAD = 00 )
entry   mixture   isotope   number density   new identifier   explicit temperature
    1       1       92234     2.73451E-07             92234             293.0
    2       1       92235     1.73272E-04             92235             293.0
    3       1       92238     4.71674E-03             92238             293.0
    4       1        8016     9.78057E-03              8016             293.0

```

For a CE calculation, instead of the keyword "ampxFileUnit=" (which refers to a given AMPX library), the keyword "ceLibrary=" should be used with a CE library name, enclosed in quotes. Also for CE, a default temperature can be set before any mixtures are defined using the "ceTempDefault=" temperature (in Kelvins). With each mixture, a specific temperature can be set using "temperature."

Other keywords that can be used in the cross-section block for multigroup problems include flags to turn on printing of different aspects of the cross-section mixing process ("printTotals", "printScatters", "printAngleProb", "printFissionChi", "printExtra", and "printLegendre"). The keyword "fullyCoupled" can be used to specify all groups to be treated as primary groups. These keywords do not work in CE problems since the point wise data contain an enormous number of points.

Users are encouraged to use Monaco by running the MAVRIC sequence, which creates the cross-section mixing table automatically, for both multigroup and CE calculations.

8.2.3.2 Geometry block

The geometry input uses the standard SGGP, similar to KENO-VI. Input instructions can be found in *Geometry Data* in the KENO-VI chapter of the SCALE manual.

Shielding calculations (Monaco, MAVRIC, SAS4) differ from their criticality cousins (KENO V.a, KENO-VI) in a very special way-sources and detectors can be located outside of the materials where the transport takes place. To accommodate this fact in Monaco and MAVRIC, make sure that a void region (a media record using mixture 0) surrounds the source area and any point detectors, if they are not located in a region of the actual geometry.

For example, if the objective is to calculate the effectiveness of a simple slab shield, the model geometry would consist of just one slab of material. The source would be on one side of the slab, and a detector would be on the other side of the slab. In Monaco (and the MAVRIC sequence), the input should list at least two regions: (1) the slab itself and (2) a void region outside of the slab containing both the source and detector positions.

Monaco tracks particles through the SGGP geometry as well as other geometries used for mesh tallies or mesh importance maps. Because Monaco must track through all of these geometries at the same time, users should not use the reflective boundary capability in the SGGP geometry.

The graphical user interfaces GeeWiz and Keno3D can be used on Windows platforms to develop and view the geometry.

8.2.3.3 Array, volume, and plot blocks

Geometry array input uses the standard SGGP, similar to KENO-VI. Input instructions can be found in KENO-VI chapter on *Array Data* of the SCALE manual.

Volumes of various geometry regions are used to calculate fluxes for those regions. Volumes can be input as part of the geometry input block above, or calculated by the SGGP using one of two different methods. See KENO-VI chapter on *Volume Data* for instructions.

The "read plot" block allows users to create a 2-D character or color plots of slices through a specified portion of the 3-D geometrical representation of the problem. These images can be saved as *.png files. For more information, see the KENO-VI chapter on *Plot Data*.

8.2.3.4 Definitions block

The definitions block defines different types of data (locations, detector response functions, grid geometries, cylindrical geometries, distributions, energy bin boundaries and time bin boundaries) that are used by some of the other blocks in Monaco. Individual data can be listed in any order. Identification numbers must be positive integers and unique within that type of data. Each type of data begins with a keyword and ends with an "end" and that same keyword. All of the different data types can have an optional title using the keyword "title=".

```
read definitions
    location 43
        ...
    end location
    response 45
        ...
    end response
    distribution 1
        ...
    end distribution
    response 12
        ...
    end response
end definitions
```

Locations

Locations ("location") require an identification number and the physical position in global coordinates using the "position" keyword (a fixed length array). A position is specified by listing its x, y, and z coordinates.

```
location  1
   title="Radial detector - close to surface"
    position 162.0 0.0 0.0
end location
location  2  position 0.0 0.0 295.6   end location
location  3
    title="Corner detector"
    position 162.0 0.0 295.6
end location
location 105 position   0.0 0.0 385.6   end location
location 106 position 252.0 0.0 385.6   end location
```

Response functions

Response functions ("response") require an identification number and information on how to build an energy dependent response function. There are three basic types of responses: 1) the general user-defined response, 2) a response based on cross-section data, and 3) a response based on a specific flux-to-dose conversion factor. For multigroup calculations, a fourth type of a response simply listing multigroup values is also available. Responses must be defined as either a neutron response or a photon response.

Type 1. A general user-defined response function can be either a binned histogram function (n+1 energies and n values) or a set of value/function pairs that will be linearly interpolated (n+1 energies and n+1 values). The energies (in eV) are set using the "bounds ... end" keyword. The response values are entered with the "values ... end" keyword. The energies can be entered from low energy to high energy order or the traditional high energy to low energy order but must be monotonic. The values array of the response is interpreted to correspond to the order of the bounds array. These two examples

```
response 11
    title="user-defined response, histogram"
    neutron
    bounds 1e7   8e6   6e6   4e6   2e6   1e5 end
    values    1.0   0.8   0.6   0.4   0.2    end
end response
response 12
    title="user-defined response, value/function pairs"
    photon
    bounds  1e5 2e6 4e6 6e6 8e6 1e7 end
    values 0.01 0.2 0.4 0.6 0.8 1.0 end
end response
```

are shown in Fig. 8.2.4 and Fig. 8.2.5.

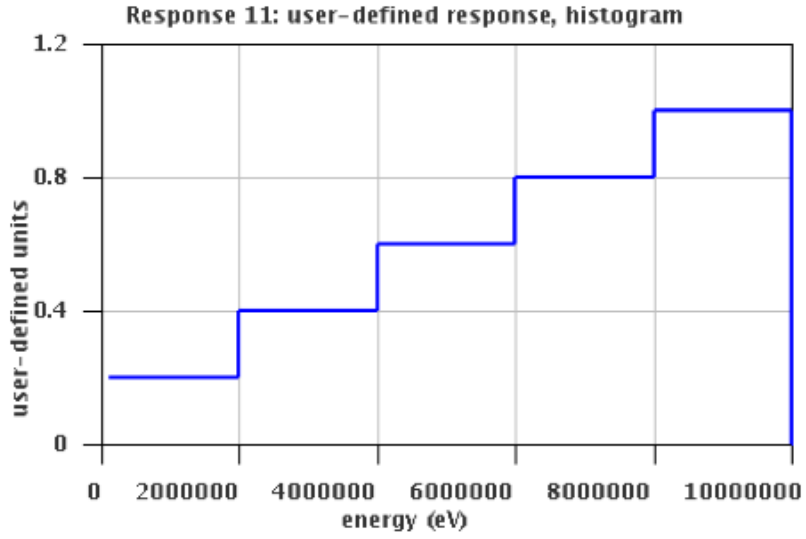

Fig. 8.2.4: Histogram-type response.

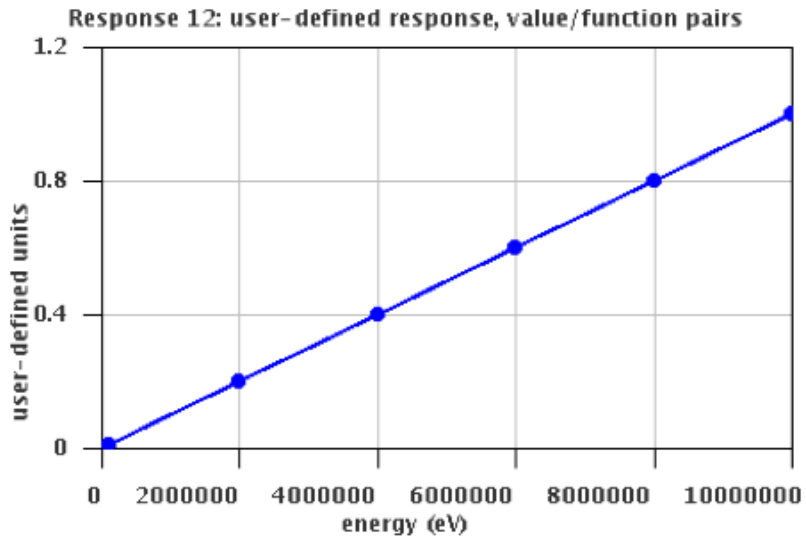

Fig. 8.2.5: Value/function pair response.

Type 2. Data from the cross-section library can also be used to define a response, for example in finding reaction rates. For the cross section (with units of barns) for a single isotope, the user specifies a material/ZAID/MT combination. The keyword "macro" can be used to multiply the cross section by the atom density of the ZAID in the material (which converts the units of the response from barns to /cm). Users can also specify just the material and MT numbers, to produce the macroscopic cross section of reaction MT for the entire material (with units of /cm). A partial list of common MT numbers is shown in Table F23.3.2 (the full list is in XSECLIB M04, Appendix B). To match some other sequences in SCALE, users can also use text strings to specify the ZAID and MT by using keywords "nuclide=" (for example, nuclide=U-235) and "reaction=" (for example reaction=fission). If the user requested a microscopic cross section response for a reaction in a CE problem, the response will be generated for the nuclide from the AMPX CE libraries even if the nuclide itself is not included in any of the material definitions in the problem. Available reaction lists depend on the nuclide and the list will be printed as a warning message in the output if a non-existing reaction is requested.

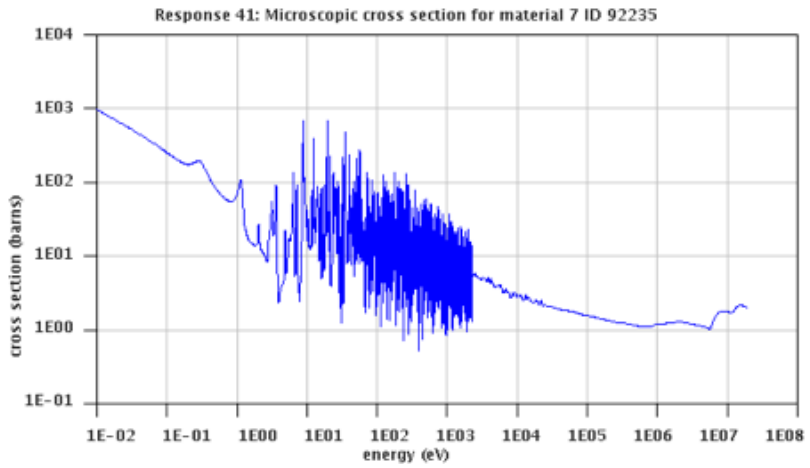

Fig. 8.2.8: CE ^{235}U total fission cross section.

Type 3. Flux-to-dose conversion factors are a little different in multigroup and continuous-energy implementations. The AMPX multigroup shielding libraries contain neutron and photon dose responses from several sources. These have been processed by the AMPX system (the jergens module). To form the multigroup values for the libraries, the original data was extrapolated to cover the entire energy range of the shielding libraries and was then collapsed into the group structures using a weighting spectrum. These dose responses can be accessed through Monaco/MAVRIC by defining a response object that uses the keyword "specialDose=" and then providing the MT number of the particular response. The dose responses available in the shielding libraries in are shown in Fig. 8.2.9. Note that the coupled responses in SCALE 6.1 are no longer used by Monaco, since responses are now defined to be either a neutron response or a photon response. When using the "specialDose=" keyword, the "neutron" or "photon" designation is ignored, since the particle type is inherent with the MT number.

```

Fig. 8.2.9: Flux-to-Dose conversion factor MT numbers

The standard flux-to-dose conversion factors have not been made part of the continuous-energy libraries. Routines have been added to the Monaco code base to generate data points to allow users to define responses based on the original references. Note that the responses in these references were defined over different energy ranges, as shown in Fig. 8.2.10.

Response	Neutron Energy Range (MeV)		Photon Energy Range (MeV)	
Henderson conversion factors	0.01	18	0.01	10
Claiborne-Trubey conversion factors			0.02	16
ANSI standard (1977) flux-to-dose-rate factors	2.5E-08	20	0.01	15
ANSI standard (1991) flux-to-dose-rate factors	2.5E-08	14	0.01	12
ICRU-44 Table B.3 (air) Kerma	2.5E-08	29		
ICRU-57 Table A.21 (air) Kerma			0.01	10
Ambient dose equivalent (ICRU-57)	1.0E-09	20.1	0.01	10
Effective dose (ICRU-57)	1.0E-09	18	0.01	10
Dosimetry for Criticality Accidents (ANSI/HPS N13.3-2013)	1.0E-09	20	0.01	10

Fig. 8.2.10: Energy ranges of the original Flux-to-Dose responses

The keyword "doseData=" can be used to create a response using the original, point-wise data (except for Claiborne-Trubey where the original data is a histogram). Data points are also extrapolated to cover the energy range of 10^{-5} to 2×10^7 eV for neutrons and up to 20 MeV for photons. (The optional keyword "noExtrapolation" can be used to get just the original data without the extrapolations.) The final response is formed by interpolating (lin-lin) between these points. For multigroup problems, these keywords will collapse the original data (with or without extrapolation) into a multigroup structure but without the weighting function

used to create the dose factors in the multigroup libraries. This will not match the multigroup responses in the those libraries.

```
read definitions
    response 1
        doseData=9031
    end response
    response 1
        doseData=9031  noExtrapolation
    end response
end definitions
```

As an example of the various forms of a flux-to-dose conversion factor, the ANSI 1991 values (MT=9031 and 9505) are shown in Fig. 8.2.11 through Fig. 8.2.14.

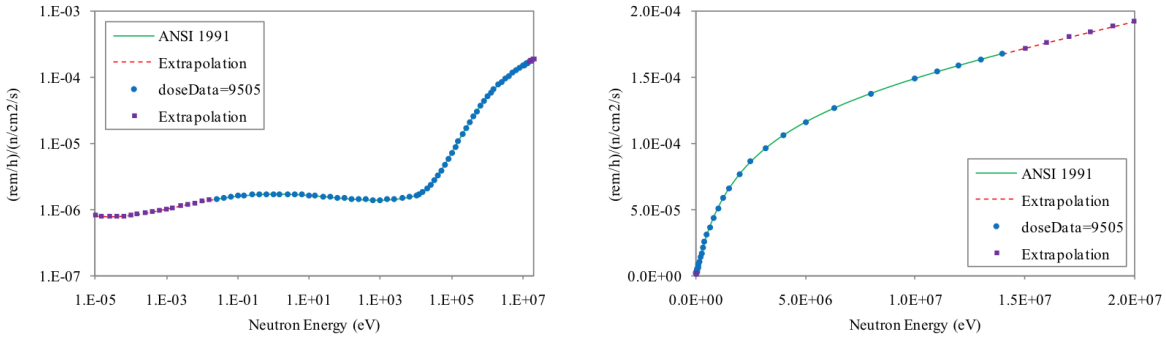

Fig. 8.2.11: ANSI 1991 neutron CE (left is log-log, right is linear-linear)

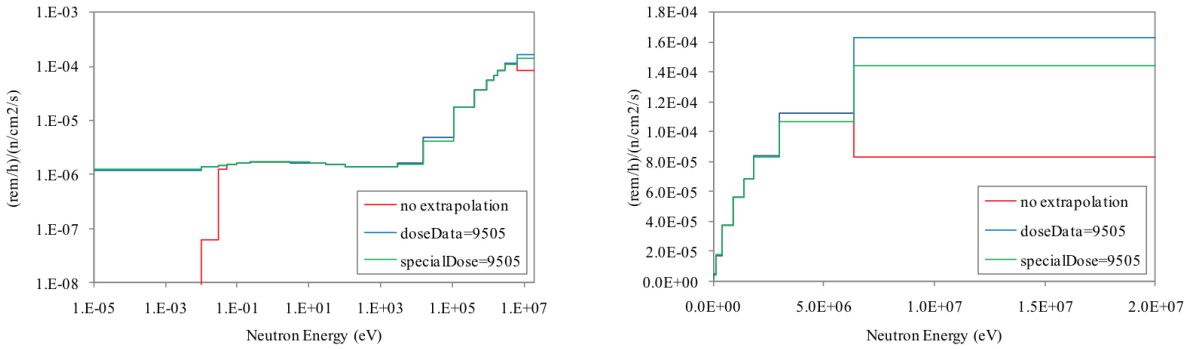

Fig. 8.2.12: ANSI 1991 neutron MULTIGROUP (left is log-log, right is linear-linear)

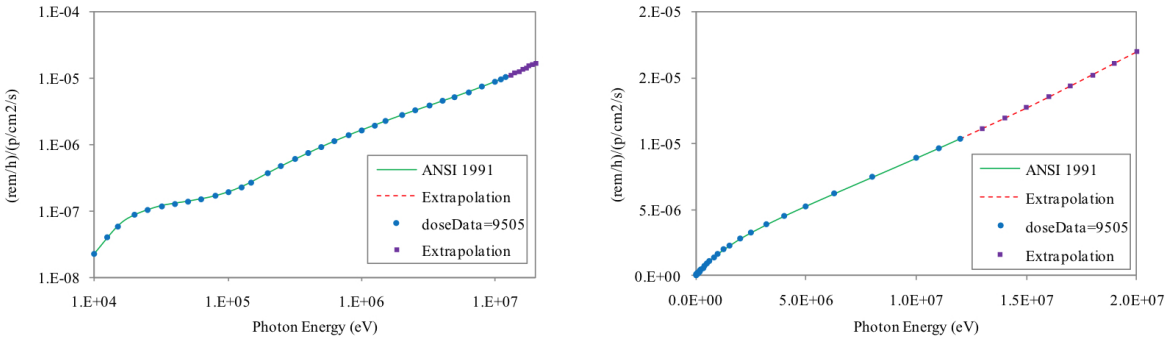

Fig. 8.2.13: ANSI 1991 photon CE (left is log-log, right is linear-linear)

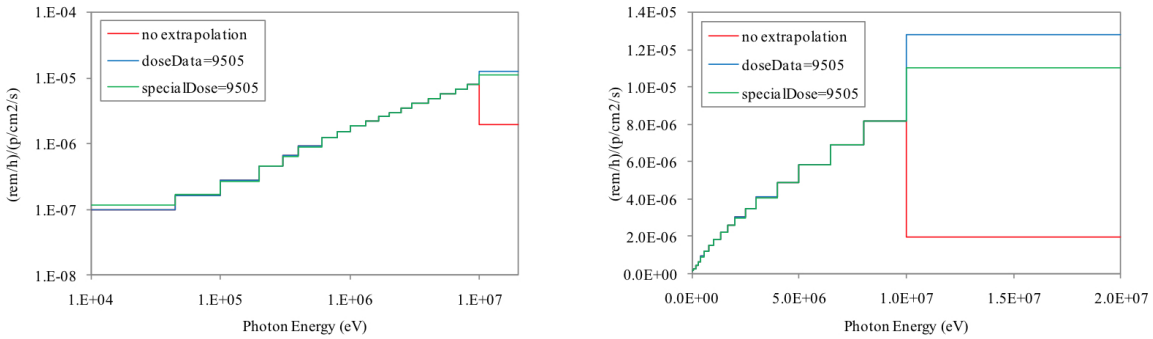

Fig. 8.2.14: ANSI 1991 photon MULTIGROUP (left is log-log, right is linear-linear)

The use of the `specialDose=` and `doseData=` keywords is summarized in Fig. 8.2.15. Users should understand that the only way to get the 'true' response described in the original references is to use the `doseData=` and `noExtrapolation` keywords. The traditional approach in SCALE has been to extrapolate the original data over the entire energy range of the problem, yielding higher dose rates than the 'true' response would.

keyword(s)	Multi-Group (MG)	Continuous Energy (CE)
specialDose=*MT*	uses pre-computed responses contained in the MG library: data points from reference, extrapolated to energy range of the library and collapsed to the library group structure using a weighting spectrum	this keyword is not allowed since there are no pre-computed dose responses contained within the CE libraries
doseData=*MT*	data points from reference, extrapolated over the range of 1.0d-11 to 20.0 MeV and collapsed to the library group structure without a weighting spectrum	data points from reference, extrapolated over the range of 1.0d-11 to 20.0 MeV
doseData=*MT* noExtrapolation	data points from reference and collapsed to the library group structure without a weighting spectrum	data points from reference using only the original energy range

Fig. 8.2.15: Use of the "specialDose=" and "doseData=" keywords.

Type 4. For multigroup calculations, since the energy structure is already known, a response can be defined by listing just the values for each group using the keyword "values ... end". The array length of this type of response should match the number of energy groups for that particle type in the cross-section library. Values should be entered in the standard multigroup order — from high energy to low energy. The shortcut keyword "unity" places a value of 1.0 as the response for each group.

```
response 19
    title="Total Photon Dose at Each Detector Point Location (ANSI 9504)"

end response
response 99
     title="put a 1 in every group"
     neutron
     unity
end response
```

The different response types all share some optional keywords. The keyword "makeChart" can be used to produce a *.chart file (called `\ *outputName*.resp\ *id*.chart`) so that the response can be plotted with the ChartPlot 2D plotter. To create files for every response, use the keyword `makeCharts` inside the definitions block but outside any particular response definition. The keyword `multiplier=` can be used with any type of response, which is useful for things such as units conversions. Multiple uses of the `multiplier=` keyword within one response definition will apply the product of all

multipliers to that response. Using the keyword `multiplier=` in the definitions block but outside any particular response will apply that multiplier to all responses. Keywords `eHigh=` and `eLow=` can be used to only keep the response values in a range between eHigh and eLow (both in eV). The keyword "lessOutput" can be used to suppress response data echoing in the output file and minimize output file size particularly for CE responses that can have fine point-wise data. It will cause to print only the first five and the last five points of the data if the number of bins is greater than twenty for binned histogram and value/function pairs type of responses.

The original flux-to-dose conversion factor references that were incorporated into Monaco are:

Grid geometries

Grid geometries ("gridGeometry") require an identification number and then a description of a 3D rectangular mesh by specifying the bounding planes of the cells in each of the x, y, and z dimensions. The keyword "xplanes ... end" can be used to list plane values (in any order). The keyword `xLinear n a b` can be used to specify n cells between a and b. The keywords "xplanes" and "xLinear" can be used together and multiple times — they will simply add planes to any already defined for that dimension. Any duplicate planes will be removed. Similar keywords are used for the y- and z-dimensions.

```
gridGeometry 3
    title="Boring uniform grid"
    xLinear 10 -100 100
    yLinear 10 -100 100
    zLinear 10 -100 100
end gridGeometry
gridGeometry 2
```

(continues on next page)

(continued from previous page)

```
    xplanes -100.0 -90.0 -99.0 -95.0 end
    xLinear  9 -90.0  0.0
    xLinear 18   0.0 90.0
    xplanes 95.0 100.0 99.0  end
    yLinear 20  100.0 -100.0
    zLinear 40  100.0 -100.0
end gridGeometry
```

When using multiple instances of the keyword *Linear and *planes for a given dimension, duplicates should be removed from the final list. In some cases, double precision math will leave two planes that are nearly identical but not removed (for example: 6.0 and 5.9999999). To prevent this, a default tolerance is set to remove planes that are within 10^{-6} cm of each other. The user is free to change this by using the keyword "tolerance=" and specifying something else. Note that the tolerance can be reset to a different value in between each use of *Linear or *planes.

The keyword "make3dmap" for a particular grid geometry definition will create a file called `outputName*.grid\ *id*.3dmap` which can be visualized using the Java Mesh File Viewer. Using the keyword `make3dmaps` in the definitions block but outside any particular gridGeometry definition will create a geometry file for each gridGeometry defined.

Cylindrical mesh geometries

Cylindrical geometries ("cylGeometry") require an identification number and then a description of a 3D cylindrical mesh by specifying the bounding planes of the cells in each of the r, θ, and z dimensions. The keywords `radii ... end`, `thetas ... end`, and `zplanes ... end` can be used to list the plane values in any order. The keywords `radiusLinear n a b`, `thetaLinear n a b`, and `zLinear n a b` can be used to specify n cells between a and b. Note that the keywords "thetas" and "thetaLinear" expect values between 0 and 2π. For entering values between 0 and 360°, use the keywords `degrees` and `degreeLinear` instead. The keywords for each dimension can be used together and multiple times — they will simply add planes to any already defined for that dimension. Any duplicate planes will be removed.

Cylindrical meshes are oriented along the positive z-axis by default. To change this, the user can specify the axis of the cylinder using the keyword `zaxis u v w` and specify the perpendicular direction where *theta* = 0 using `xaxis u v w`. To change the base position of the cylinder, use the keyword `position x y z`. Some examples of cylindrical mesh geometries include:

```
cylGeometry 12
    radiusLinear 20 100.0 168.0

```

Similar to the grid geometries, the user can use the keyword `tolerance=` to specify how close duplicate planes can be when being considered for removal. The keyword `makeCylMap` for a particular cylindrical geometry definition will create a file called `outputName*.cyl\ *id*.3dmap` which can be visualized using the Java Mesh File Viewer. Using the keyword "makeCylMaps" in the definitions block but outside any particular gridGeometry definition will create a geometry file for each gridGeometry defined. The Mesh File Viewer is written for rectilinear geometries and will not display circles. The only view that works in the Mesh File Viewer for cylindrical meshes is the *x*-*z* view, which will correctly show an *r*-*z* slice. The slider (marked "*y*") will control which *theta* value to display (from 0 to 2π).

Cylindrical meshes can only be used for tallies. They cannot be used for making mesh sources or for any importance calculations in MAVRIC.

Distributions

Distributions (`distribution`) require an identification number and several other keywords depending on the type of distribution. For a binned histogram distribution over n intervals, the keyword "abscissa ... end" is used to list the $n + 1$ bin boundaries and the keyword "truePDF ... end" is used to list the n values of the pdf integrated over those bins. For a pdf defined using a series of evaluated points over n intervals, use the keywords "abscissa ... end" and "truePDF ... end" listing the $n + 1$ values for each. The "truePDF" values should be the value of the pdf evaluated at the corresponding point in the abscissa array. The abscissa array should either be in increasing order or decreasing order — monotonic either way — with the truePDF array ordered accordingly.

For either the binned histogram or the value/function point pairs distributions, biasing can also be specified for a given distribution using the "biasedPDF ... end" keyword, the "weight ... end" keyword, or the "importance ... end" keyword, with a length that matches the truePDF array. Weights specify the suggested sampling weights for particles and importances specify the suggested importance. For biasing, the user only needs to specify just one of "biasedPDF", "weight" or "importance". The other arrays will be computed by Monaco.

For discrete distributions (such as gamma line sources), use the keyword "discrete ... end" to list the discrete abscissa values and use the keyword "truePDF ... end" to list the probabilities. The "biasedPDF ... end", "trueCDF ... end", and "biasedCDF ... end" keywords can also be used. Each array should have the same length–the number of discrete lines.

To visualize a distribution, add the keyword "runSampleTest" and a *.chart file will be produced showing the true pdf, the pdf used for sampling (the biased pdf) and the results of a sampling test using 10^6 samples. The file will be named using the output name of the SCALE job and the distribution identification number '*outputName*.dist*id*.chart' and can be viewed with the ChartPlot 2D Interactive Plotter. To perform a sampling test and create a *.chart file for all of the distributions in the definitions block, use the keyword "runSampleTests" inside the definitions block but outside any particular distribution.

Some example distribution inputs are listed below and shown in Fig. 8.2.16.

```
distribution 11
   title="a binned histogram"
   abscissa -5 -4 -3 -2 -1 0 1 2 3 4 5 end
   truePDF   1  2  3  4  5 4 3 2 2 2   end
end distribution
distribution 12
   title="value/function pairs"
   abscissa   -5 -4 -3 -2 -1 0 1 2 3 4 5  end
   truePDF     0  1  2  3  4 5 4 3 2 2 2  end
```

(continues on next page)

(continued from previous page)

```
end distribution
distribution 21
   title="a binned histogram with biasing"
   abscissa -5 -4 -3 -2 -1 0 1 2 3 4 5 end
   truePDF   1  2  3  4  5 4 3 2 2 2   end

end distribution
distribution 31
   title="a binned histogram using CDF's"
   abscissa -5 -4 -3 -2 -1  0  1  2  3  4 5 end
   trueCDF   1  3  6 10 15 19 22 24 26 28   end
end distribution
distribution 32
   title="a binned histogram with biasing using CDF's"
   abscissa -5 -4 -3 -2 -1  0  1  2  3  4 5 end
   trueCDF   1  3  6 10 15 19 22 24 26 28   end
   biasedPDF 3  5  6  7  8  9 10 12 14 16   end
end distribution
```

Other notes on distributions:

1) Binned histogram distributions can also be specified using cdf's (keywords "trueCDF" and "biased-CDF").

2) For distributions that will be used for source energy sampling, use abscissa values of eV.

3) For multigroup calculations using histograms, the keywords "neutronGroups" or "photonGroups" can be used instead of specifying the abscissa values. In this case, be sure to list the binned pdf values in order from the highest energy group to the lowest energy group.

4) For CE calculations, instead of specifying abscissa values, the bin boundaries of an energyBounds object (see next section) can be specified using "energyBoundsID=".

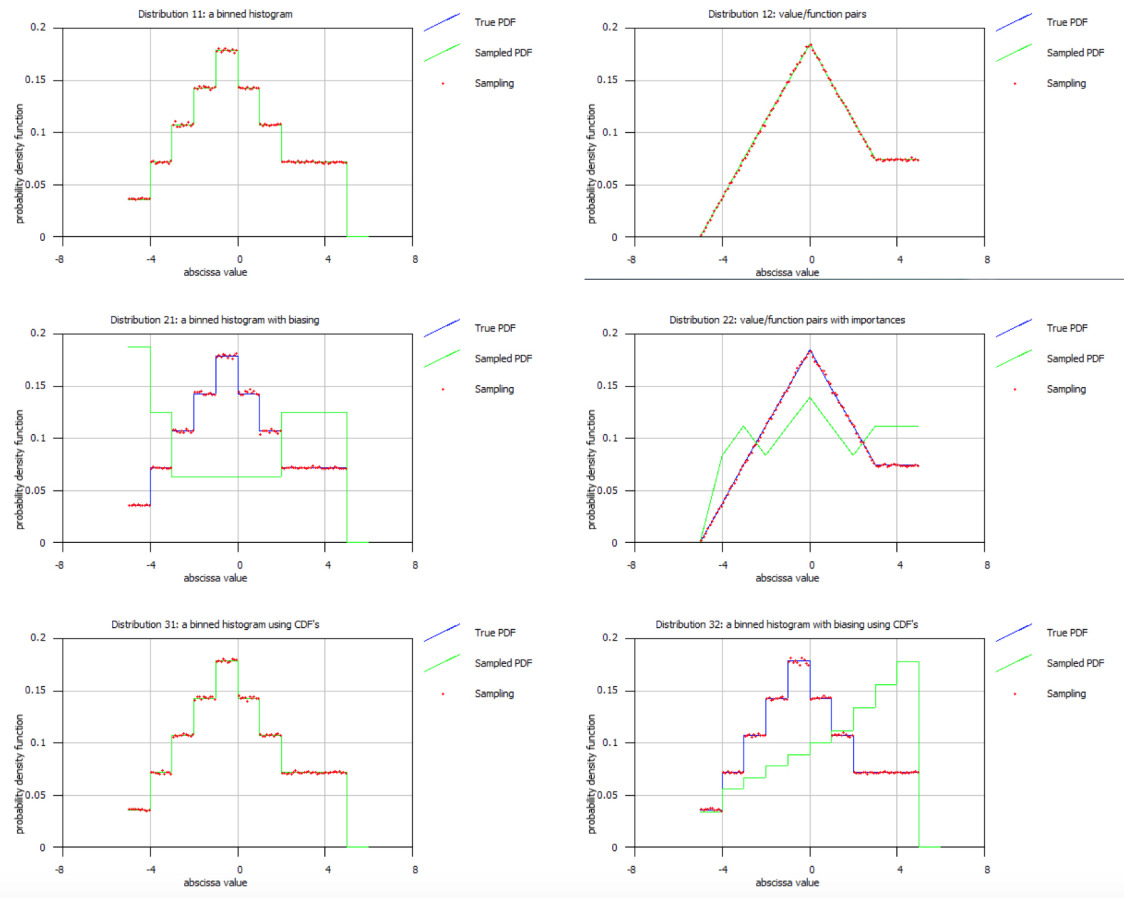

Fig. 8.2.16: Sampling tests for the distribution examples.

Several special (built-in) distributions are available in Monaco. To use one of these, specify the keyword "special=" with a distribution name in quotes and the keyword "parameters ... end" (if required) for that type of distribution. These special distributions are summarized in Table 8.2.8.

The Watt spectrum has the form

$$p(E) = ce^{-E/a}\sinh(\sqrt{bE}) \tag{8.2.18}$$

with the parameters a and b (with c as a normalization constant). For spontaneous fission of ^{252}Cf, values typically used are a=1.025 MeV and b=2.926/MeV. For thermal fission of ^{235}U, the parameters are a=1.028 MeV and b=2.249/MeV. For induced fission, the parameters a and b are, in general, functions of incident neutron energy. See Table 8.2.5 for an example. The Watt spectrum distribution will be displayed in the *.chart plot as a histogram distribution using the cross-section energy structure neutron groups but when sampled in Monaco, the continuous Froehner and Spencer[1] method is used to select an energy of source particles using a Watt spectrum distribution.

with the parameters a and b (with c as a normalization constant). For spontaneous fission of ^{252}Cf, values typically used are a=1.025 MeV and b=2.926/MeV. For thermal fission of ^{235}U, the parameters are a=1.028 MeV and b=2.249/MeV. For induced fission, the parameters a and b are, in general, functions of incident neutron energy. See Fig. 8.2.17 for an example. The Watt spectrum distribution will be displayed in the *.chart plot as a histogram distribution using the cross-section energy structure neutron groups but when

sampled in Monaco, the continuous Froehner and Spencer[1] method is used to select an energy of source particles using a Watt spectrum distribution.

Table 8.2.5: Special (built-in) distributions

Distribution	Parameters	Description
"wattSpectrum"	*a b n*	Watt spectrum distribution. Units are: *a* in MeV, *b* in /MeV. Optional parameter *n* specifies how many subintervals in each neutron group to use in integrating the pdf (default 100) for the histogram representation in the sampling test and mesh source representation.
"fissionNeutrons"	*m ZAID*	Spectrum of fission neutrons from the MULTIGROUP cross-section library for material *m* and nuclide *ZAID*.
"fissionPhotons"	*ZAID*	Spectrum of fission photons from nuclide *ZAID*.
"origensBinaryConcentrationFile"	*c s*	Spectrum from an ORIGEN-S binary concentration file case number *c*, spectra type *s*. For the spectra type *s*, values are: 1 - total neutron, 2 - spontaneous fission, 3 - (α,n), and 4 - delayed neutrons, 5 - photons. The ORIGEN-S filename should be supplied with the keyword filename= "..." and the path/filename in quotes.
"cosine"	*n*	Cosine function from -π/2 to π/2. Optional parameter *n* (default 100) is the number of value/function pairs to show in the sampling test.
"pwrNeutronAxialProfile"	none	Typical neutron PWR axial profile.
"pwrGammaAxialProfile"	none	Typical gamma PWR axial profile.
"pwrNeutronAxialProfileReverse"	none	Typical neutron PWR axial profile, reversed top to bottom.
"pwrGammaAxialProfile Reverse"	none	Typical gamma PWR axial profile, reversed top to bottom.
"exponential"	*a n*	Exponential function *eax* from -1 to 1. Optional parameter *n* (default 100) is the number of value/function pairs to show in the sampling test.
"origensDiscreteGammas"	*z a m*	Discrete gammas from the ORIGEN mpdkxgam database for isotope of atomic number *z*, mass *a* and metastable state *m*. (default is m=0)

For the ORIGEN-S binary concentration sources, the ORIGEN input file should be specified using the filename="..." with the path/filename in quotes. Note that the ORIGEN calculation has to be set to save the neutron or photon data will be used as a Monaco distribution. This can be done by specifying the number of photon or neutron groups on the 3$ (library integer constants) array and specifying the energy bin boundaries on the 83* and 84* (group structure) arrays. In Monaco, to show all of the cases in the binary concentration file, ask for case 0. To show what data is available for a particular case, ask for that case number and spectra type 0.

Other notes on special distributions: 1) Fission neutron distributions use MT=1018 for the specified ZAID of the specified isotope from the cross-section library. 2) Fission photon distributions are not read from the cross-section file but are instead read from a separate file containing only ENDF/B-VII.0 fission photon data. 3) The neutron and photon axial profile distributions come from the SCALE 5.1 SAS4 manual, Table S4.4.5. 4) Fission neutron distributions are not allowed in the CE problems, users are advised to use "wattSpectum" in order to get a similar distribution.

Energy (MeV)	a (MeV)	b (/MeV)
1.E-11	0.977	2.546
1.5	0.977	2.546
2	0.980	2.532
5	1.010	2.412
7	0.970	2.571
10	0.980	2.474
12.2	1.010	2.612
15	1.000	2.652
18	1.040	2.689
20	1.060	2.620
30	1.060	2.620

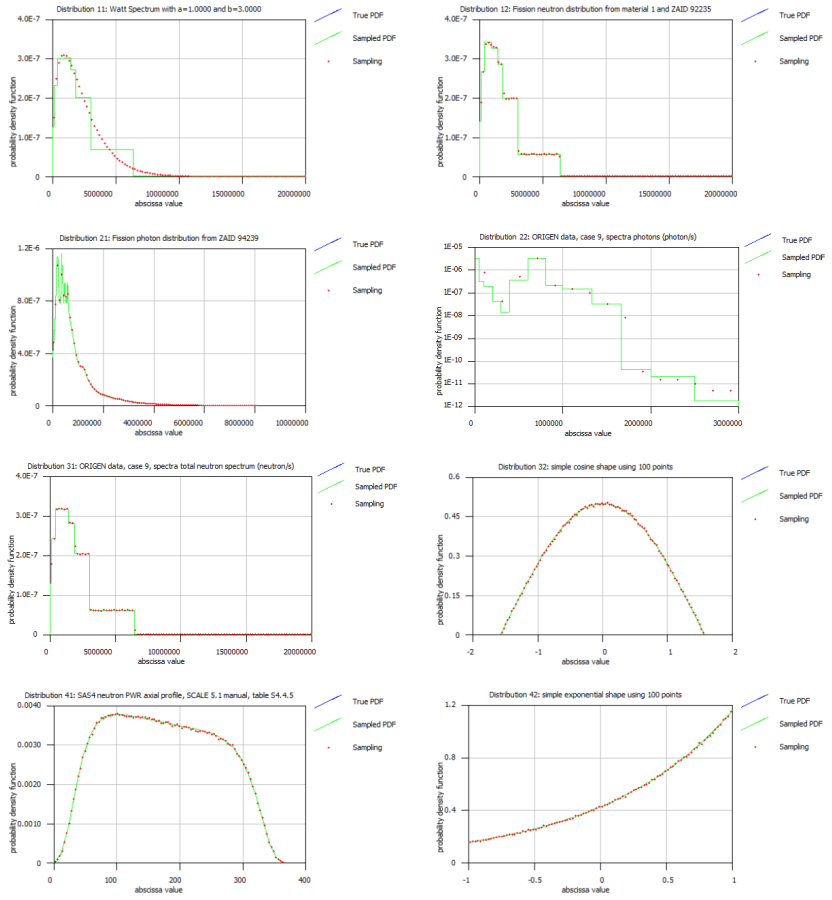

Fig. 8.2.18: Sampling tests for the special (built-in) distribution examples.

Energy boundaries

Energy boundaries ("energyBounds") require an identification number and a specification of a set of bin boundaries in energy (eV). Energy bounds objects are typically used in CE calculations for specifying and energy grid for tallies. The keyword "bounds ... end" can be used to list energy values (in eV, in any order). The keyword "linear *n a b*" can be used to specify *n* bins between *a* and *b*. Likewise, the keyword "logarithmic *n a b*" can be used for *n* bins logarithmically spaced between *a* and *b*. The keywords "bounds", "linear" and "logarithmic" can be used together and multiple times — they will simply add energy boundaries to any already defined. Any duplicate planes will be removed using the absolute tolerance, specified with the keyword "tolerance=". To specify one of the more common SCALE energy structures (handy for doing tallies one a standard structure in CE calculations), one of the following shortcut keywords can be used: "252n", "238n", "200n", "56n", "47p", "44n", "27n", or "19p".

These keywords will cause to load the energy structures from the MG cross-section libraries aliased in the "FileNameAliases.txt" with names of "xn252", "xn238", "xn200", "xn56", "xg47", "xn44", "xn27", and "xg19" relatively. If required energy structure is for neutrons and there is no alias for MG cross-section library or the library is missing, MG JEFF reaction data library will be searched as "n{NG}.reaction.data" to load the energy structure. These can be used in combination with the other keywords to use existing structures supplemented with extra boundaries.

```
energyBounds 1
    title="bounds command, check for duplicates"
    bounds 1 4 2 3 5 end
    bounds 7 6 10 5 9 8 7 end
end energyBounds
energyBounds 3
    title="logarithmic command"
    logarithmic  21  1.0 10000000.0
end energyBounds
energyBounds 11
    title="SCALE 19 group photon structure with extras"
    19p
    linear 10 6.0e6 7.0e6
end energyBounds
```

An energyBounds object can also be used to set the energy bin boundaries for a response (type1) instead of using the "bounds ... end" keyword. This is done by using with the keyword "energyBoundsID=" and referencing a defined energyBounds object. Likewise for distributions, instead of specifying the "abscissa ... end" keyword and listing abscissa values, an energyBounds object can be used. This allows the user to define a set of energy bin boundaries once and re-use them across multiple responses and definitions. When using the "energyBoundsID=" keyword, the data values should be entered in the standard multigroup order — from high energy to low energy. For a stand-alone multigroup Monaco calculation, do not use ID numbers of 1 or 2 for energyBounds objects — these ID numbers are reserved.

Time boundaries

Time boundaries ("timeBounds") are similar to energy bin boundaries but take values in seconds. These objects are only used in tallies in CE calculations.

```
timeBounds 2
    title="linear command"
    linear 10 0.0 10.0e-3
end timeBounds
timeBounds 7
    title="logarithmic command"
    logarithmic  6  1.0e-6 1.0
end timeBounds
```

8.2.3.5 Sources block

The sources block specifies what sources to use. Multiple sources are allowed and each is sampled according to its strength, relative to the total strength of all sources. Each source description must be contained with a "src *id*" and an "end src" (where the *id* is the source identification number). The sources block must contain at least one source.

For each user-defined source, the user can specify the spatial distribution, the energy distribution and the directional distribution separately. Many options for each distribution are available and defaults are used for most if the user does not specify anything. The source strength is set using the keyword "strength=" and the type of source is set using the keyword "neutron" or "photon". The "strength=" keyword is required for each source.

When using more than one source, the user can set the true strength of each using the keyword "strength=" and can also specify how often to sample each source using the keyword "biasedStrength=". The true strengths of the sources will be combined to form the true source distribution PDF. The biased strengths of sources will be combined to form a PDF from which to sample. The weights of the source particles will be properly weighted to account for the biased sampling strengths. For example, consider two sources of strengths 10^9 and 9×10^9 /sec that should be sampled in a ratio of 4:1. The biased sampling strengths are then set to 4 and 1. Monaco will sample the first source 80% of the time and the particles will be born with a weight of 0.125. The second source will be sampled 20% of the time and its particles will be born with weights of 4.5.

Spatial distribution

Keyword	Parameters	Possible degenerate cases
cuboid	x_{max} x_{min} y_{max} y_{min} z_{max} z_{min}	rectangular plane, line, point
xCylinder	*r* x_{max} x_{min}	circular plane, line, point
yCylinder	*r* y_{max} y_{min}	circular plane, line, point
zCylinder	*r* z_{max} z_{min}	circular plane, line, point
xShellCylinder	*r1 r2* x_{max} x_{min}	cyl., planar annulus, cyl. surface, line, ring, point
yShellCylinder	*r1 r2* y_{max} y_{min}	cyl., planar annulus, cyl. surface, line, ring, point
zShellCylinder	*r1 r2* z_{max} z_{min}	cyl., planar annulus, cyl. surface, line, ring, point
sphere	*r*	point
shellSphere	*r1 r2*	sphere, spherical surface, point

Note that other than the shell-type solids, the parameters are the same as the SGGP geometry specification of those solids. The SGGP keyword "origin" (followed by at least one of "x=", "y=", and/or"z=") is available for all of the different source solid bodies. For the cylinder based solid bodies, the direction of the axis of the cylinder can be set by using the keyword "cylinderAxis *u v w*", where *u*, *v*, and *w* are the direction cosines with respect to the global *x*-, *y*-, and *z*-directions.

The source can be limited to only be from the parts of the solid body that are inside a specific unit ("unit="), inside a specific region ("region=") within the specified unit, or made of a certain material ("mixture="). A mixture and a unit/region cannot both be specified since that would either be redundant or mutually exclusive.

If no source spatial information is provided by the user, the default is a point source located at the origin (in global coordinates). Like SGGP input, the geometry keywords used for the bounding shape are fixed lengths arrays and do not have an "end" terminator. They must be followed by the correct number of parameters.

The spatial distribution in each dimension of the cuboid shape is specified by using the keywords "xDistributionID=", "yDistributionID=", or "zDistributionID=" and pointing to a distribution defined in the definitions block. For the cylindrical shapes, "rDistributionID=" and "zDistributionID=" can be used. For spherical shapes, only the "rDistributionID=" can be specified. Distributions defined using abscissa values that are different than the length of the simple geometry bounding shape can still be used if the keyword "xScaleDist" (or "y", "z", or "r") is used. This linearly scales the distribution abscissa values to the length of the simple geometry bounding shape. Note that for cylindrical sources, since the axis can point in any direction, the z distribution is interpreted as the length along the axis, with the base position as z=0.

Energy distribution

"eDistributionID=" and pointing to one of the distributions defined in the definitions block. Energies will be sampled from the distribution in a continuous manner. For MULTIGROUP calculations, that energy will then be mapped onto the group structure of the cross-section library being used by Monaco. Each source should have an energy distribution that has abscissa values in units of eV. If no energy distribution is given, 1 MeV (translated to the current group structure if a multigroup problem) will be used.

To use the total of an energy distribution as the source strength, use the keyword "useNormConst" without either "strength=" or "fissions=". This will set the strength to be equal to the normalization constant of the distribution — the total of the distribution before it was normalized into a pdf. An optional "multiplier=" keyword can be used to increase or decrease that strength. For example, consider a case using the neutron spectrum information from a case of an ORIGEN-S binary concentration file that used a basis of an entire core. If the Monaco source was just one of the 200 assemblies, then the "multiplier=" keyword can be set to 0.005 so that the source strength is scaled appropriately.

Directional distribution

The directional distribution of the source is specified by using the keyword "dDistributionID=" and pointing to one of the distributions defined in the definitions block. The distribution will be used to sample the cosine of the polar angle, μ, from the reference direction. The reference direction, where $\mu = 1$, is set with the keyword "direction *u v w*", where *u*, *v*, and *w* are the direction cosines with respect to the global *x*-, *y*-, and *z*-directions. The default value for the reference direction is the positive *z*-axis (<0,0,1>). The keyword "dScaleDist" can be used to linearly scale the distribution abscissa values to the range of $\mu \in [-1, 1]$. If no directional distribution is specified with the keyword "dDistributionID=", then an isotropic directional distribution will be used.

Using a Monaco mesh source map file

The user can alternatively specify an existing Monaco mesh source map file-a binary file created by a previous MAVRIC or Monaco calculation. The mesh source map must be a binary file using the Monaco mesh source map format (a *.msm file). This option is specified with the "meshSourceFile=" keyword and the file name (and full path if necessary) in quotes.

```
read sources
    src 1
        meshSourceFile="c:\mydocu~1\previouslyMadeSource.msm"
    end src
end sources
```

If the "meshSourceFile=" keyword is used, all energy distribution keywords and most spatial distribution keywords will be ignored. Source keywords that can be used with a mesh source include "strength=" to override the source strength in the mesh source; "biasedStrength=" to set the sampling strength; "origin", "x=", "y=", and "z=" to place the origin of the mesh source file at a particular place in the current global

coordinate system; and the keywords for describing the directional distribution — "dDistributionID=", "direction *u v w*" and "dScaleDist".

Mesh sources are sampled using the following algorithm: First, a direction is sampled. Second, a voxel is sampled and a position is picked uniformly within the voxel. If that position does not match the optional limiters (unit, region, material specified in the mesh source), a new position is chosen within the voxel until a match is made. If a position cannot be found within the voxel after 10000 tries, Monaco will stop. (This can occur if the mesh voxel contained just a sliver of source volume when generated. For this case, the keyword "allowResampling" can be used to select a new voxel instead of stopping. In general, this keyword should not be used.)

Creating a mesh source

To create a mesh source out of the source definition, use the "meshSourceSaver" subblock inside the sources block. It is quite handy to visualize the sources and ensure they are what were intended. You must specify which one of the defined grid geometries to use (keyword "gridGeometryID=") and a filename for the resulting mesh source file (keyword "filename=" with the filename in quotes "*path\name*.msm"). For more than one source, each will be stored separately and the filename will include the source id number.

```
read sources
    src 1
        ...
        ...
    end src
    src 5
        ...
        ...
    end src
    meshSourceSaver
        gridGeometryID=7
        filename="meshSource.msm"
        subcells=3
    end meshSourceSaver
end sources
```

To create the mesh source, Monaco determines if the defined source exists within each cell. This is done by dividing each mesh cell into n × n × n subcells (from the keyword subCells=*n* with a default of *n*=2) and testing each subcell center. For every subcell center that is a valid source position (within the spatial solid and meets the optional unit, region, or mixture requirements), an amount of source proportional to the subcell volume is assigned to the mesh cell. The keyword subCells= can be used to better refine how much source is computed for the mesh cells at the boundary of a curved source region. Of course, more subcell testing takes more time. If a given source is degenerate in any dimension (point, line, or plane), that information will be stored in the resulting mesh source so that particles will not be sampled over the entire corresponding voxel but will have closer to the original spatial distribution. Likewise, if the original source had restrictions based on unit, region or mixture, those restrictions will be stored as part of the resulting mesh source.

The above process may miss small sources or degenerate sources (surfaces, lines, points) that do not lay on the tested subcell centers. If none of the mesh cells contain any source after the subcell method, then random sampling of the source is used. A number of source positions are sampled from the source (set by the "sourceTrials=" keyword, default of 1000000) and then placed into the proper mesh cell. If this method is used, the resulting mesh source file should be visualized to ensure that the statistical nature of the source trials method does not unduly influence the overall mesh source. To skip the subcell method and go directly to the source trials method, use "subCells=0".

The keyword "makeTotal" will make a single mesh source file which is the composite of all of the individual sources. Geometric degeneracies or restrictions to only sample particles from a specified unit, region or

material will only be kept if they are the same for all of the sources. For this reason, users may not wish to use a mesh source using the "makeTotal" keyword for transport but rather use it to verify that all of the sources have been input properly.

The keyword "reduce" can be used to only save the smallest rectangular portion of the mesh surrounding the voxels with non-zero source amounts. This can result in much smaller file sizes for sources that are small compared to the extents of the grid geometry.

Monaco mesh source files (*.msm) can be viewed with the Mesh File Viewer. Plots can be made showing the source values for each group (or total). The viewer can also show the geometry regions or material mixtures as well. Using the viewer is an easy way to confirm that the source definition was entered correctly. Note that the *.msm files actually only store the biased sampling distribution and the initial weights (to speed up the sampling process). So, in the viewer the "true" source is computed as the product of the sampled distribution and the weights. If groups with real source are set to zero importance, the viewer cannot recreate the original true source. The true source shown by the viewer is the amount of true source only in groups that have non-zero importance.

Mesh source advanced features

Two advanced features exist in the meshSourceSaver subblock — mainly used by the MAVRIC sequence when the importance map calculations use a different cross-section library than the final Monaco calculation.

The keyword "sampleFromMesh" can be used to tell Monaco to sample from the created mesh file(s) instead of the standard source definition. This can be useful in determining if the mesh source is fine enough to accurately represent the original source definition. If the "makeTotal" keyword was used, then Monaco will sample from the total mesh source file.

The keyword "meshBiasFile=" can be optionally be used when "sampleFromMesh" is on. This tells Monaco to sample from the mesh source file(s) version of the source definition that has been modified using just the importance information from the named mesh source file. For example, using a 27-group biased mesh source for a Watt spectrum source may not represent the high energy tail very well. In this case, it would be better to do a 200-group Monaco calculation but still use the importance information from 27-group mesh source file using "sampleFromMesh" and "meshBiasFile=".

8.2.3.6 Tallies block

The tallies block tells Monaco what to compute: fluxes at certain points in space (point detectors), fluxes in certain geometry regions, or fluxes in each voxel of a mesh grid. The computed fluxes can also be integrated with response functions to compute dose, reaction rate or some other dose-like quantity. Any number of optional response functions can be evaluated with each tally.

Each tally type begins with a keyword ("pointDetector", "regionTally", or "meshTally") and ends with an "end" and that same keyword. Individual tallies can be listed in any order. Identification numbers for each tally are required and must be positive integers and unique among the tally type. All three of the tally types can have an optional title using the keyword "title=" followed by the title enclosed in double quotes. Tallies should be defined as either a neutron tally or a photon tally.

```
read tallies
    pointDetector 1
        ...

```

Each tally computes the fluxes in each tally bin and the total flux. For multigroup calculations, the multigroup cross section group structure is used for all tallies. For CE calculations, each tally can use a different "energyBoundsID=", which points to one of the energy bounds defined in the definitions block. CE calculations can also use the keyword "timeBoundsID=" to specify a set of time bin boundaries. For one response function to integrate the fluxes with, the keyword "responseID=" can be used, where the value corresponds to the identification number of one of the response functions defined in the definitions block. For multiple response functions, the keyword array "responseIDs ... end" can be used.

Each tally type can be multiplied by using the "multiplier=" keyword. This is useful for units conversions or other types of scaling. Multiple uses of the multiplier keyword within one tally definition will apply the product of all multipliers to that tally. Using the keyword "multiplier=" inside the tallies block but outside any particular tally will apply that multiplier to all tallies.

Point detector tallies

A point detector tally computes the uncollided and total flux at a given location in space. This tally requires exactly one location and can use any number of optional response functions. The "locationID=" keyword is used to specify one of the locations listed in the definitions block. Point detectors should only use locations that are in void regions of the geometry.

Because point detectors estimate the flux at the location using a ray-trace from every collision site during the life of the particle, they can be quite expensive. For particles very far away from the detector location, the contributions to the tally can be quite small. Point detectors can be made to use the importance of the current particle location/energy to decide whether or not to make a contribution to the tally using the keyword "minSampProb=" and a value such as 0.1 or 0.01. This keyword specifies the minimum sampling probability for a given point detector. As the particle is transported, the probability p of making a contribution to the point detector tally is set by using the current weight of the particle, w, to be

$$p = \left(\frac{w_{\min}}{w}\right)^a \tag{8.2.19}$$

where the power a for each point detector was determined at the start of the simulation using the minimum sampling probability $p_{\min}$ to be

$$a = \frac{\ln\left(p_{\min}\right)}{\ln\left(\frac{w_{\min}}{w_{\max}}\right)} \tag{8.2.20}$$

where the minimum and maximum target weights, $w_{\min}$ and $w_{\min}$, were determined from either the region-based weight targets or the mesh-based importance map weight targets. So, when the current particle weight approaches the minimum target weight of the problem (in very important areas), the point detector contribution is made nearly 100% of the time. When the particle weight approaches the maximum target weight (in very unimportant areas), the contribution to the point detector tally is made with probability $p_{\min}$, saving quite a bit of computer time.

This option should only be used if the point detector location is in the area of high importance. For point detectors in areas of low importance, using this option may severely undersample the point detector where contributions would actually be the most significant, causing an underestimation of the flux. The default value for the minimum sampling probability is $p_{\min} = 1$, giving a default value of $a = 0$ so that the point detector contribution is made at every collision, independent of the current particle weight.

The keyword "minSampProb" used in the tallies block but outside any particular point detector tally specification will be applied to all point detectors.

Each point detector is summarized in the main output file. The uncollided and total flux for each particle type is listed as well as the values for the optional integrated response functions. Along with each of these quantities is a list of the standard deviation of the quantity, the relative uncertainty, the figure-of-merit and a summary of list of the statistical checks (passed or not). Group-by-group values of the fluxes and responses are listed in a separate file named "*outputName*.pd*id*.txt" where *outputName* is the name the user chose for his output file and "*id*" is the identification number corresponding to the point detector tally specification. This file also contains more information about the six statistical checks for flux and each response — their pass/fail values with each batch of simulated particles and their final numerical values at the end of the simulation. A second file called "*outputName*.pd*id*.chart" is also created which can be displayed using the ChartPlot 2D Interactive Plotter, to visually check the convergence behavior of the tally. The total neutron flux, the total photon flux, and the total response function value for each response as a function of batch can be viewed.

Region tallies

A region tally computes both the track-length estimate and the collision density estimate of the flux over a given geometry region (an SGGP "media"). This tally uses the keywords "unit=", "region=", and "mixture=" to limit the tally to one or more of those aspects. For example, "unit=2" and "region=3" are used to specify a region tally for the 3rd media listed for unit 2 of the SGGP geometry input. A mixture and a unit/region cannot both be specified since that would either be redundant or mutually exclusive. If the volume of the region is not given (or calculated) in the SGGP input, then instead of flux, the tally will compute average track length and average collision density.

Each region tally is summarized in the main output file. The total flux for each particle type is listed as well as the values for the optional integrated response functions. Along with each of these quantities is a list of the standard deviation of the quantity, the relative uncertainty, the figure-of-merit and a summary of list of the statistical checks (passed or not). Group-by-group values of the fluxes and responses are listed in a separate file named "*outputName*.rt*id*.txt" where *outputName* is the name the user chose for his output file and "*id*" is the identification number corresponding to the region tally specification. This file also contains more information about the six statistical checks for flux and each response — their pass/fail values with each batch of simulated particles and their final numerical values at the end of the simulation. A second file called "*outputName*.rt*id*.chart" is also created which can be displayed using the ChartPlot 2D Interactive Plotter, to visually check the convergence behavior of the tally. The total neutron flux, the total photon flux, and the total response function value for each response as a function of batch can be viewed.

Mesh tallies

A mesh tally computes the track-length estimate of the flux for every cell in a grid (mesh) geometry. This tally requires exactly one grid geometry or cylindrical geometry and can use any number of optional response functions. The "gridGeometryID=" or "cylGeometryID=" keyword is used to specify one of the mesh geometries listed in the definitions block. The group-by-group flux values, the total flux values and the total for each response are kept in memory during the simulation. Group-by-group contributions to the responses are not tallied during the simulation.

Mesh tallies can be limited to only save contributions to the voxel flux from track lengths through a certain unit, region or material using the keywords "unit=", "region=", and "mixture=". For example, to compute a mesh tally of a reaction rate of a specific isotope, the response function should only be multiplied by the amount of flux in the voxel that resulted in contributions from the material that contained that isotope. In this case, the keyword "mixture=" should be used so that the fluxes in each voxel represent only the flux from that material that holds the desired isotope.

A mesh tally saves the flux for each group, as well as the integrated response functions for each listed response for every cell of the grid geometry to a file called "*outputName*.mt*id*.3dmap" where *outputName* is the name the user chose for his output file and "*id*" is the identification number corresponding to the mesh tally specification. This file contains the group flux values and their absolute uncertainties. If any response functions were specified, then the responses and their uncertainties will be computed and stored in the same file. Monaco mesh tally files can be viewed with the Mesh File Viewer.

With each mesh tally, files are also created with the statistical test information - "*outputName*.mt*id*.flux" and "*outputName*.mt*id*.resp*xx*.txt" where *xx* is the responseID. The statistical tests can be turned off with the keyword "noStatChecks".

The Mesh File Viewer can be used to show the value, uncertainty, or relative uncertainty of any of the group fluxes, total fluxes, or responses tallied. For characterizing the mesh tally, the viewer can be used to display histograms of the relative errors-showing what fraction of the mesh cells had less than some amount of relative uncertainty. Images from the Mesh File Viewer can be saved as *.jpg, *.bmp, *.gif or *.png files or exported to other applications, such as MS Word.

Mesh tally files can become quite large-if the group-by-group fluxes are not important for a given problem, the keyword "noGroupFluxes" can be added to the mesh tally input. Instead of the group fluxes, only the total neutron and total photon fluxes will be written to the mesh tally file. If the group-by-group values for the response functions are required, the keyword "saveRespDetails" can be used to create separate mesh tally files of each response called "*outputName*.mt*id*.resp*id*.3dmap" where the second "*id*" is the response identification number. Note that for CE calculations, these group-by-group results are formed using the response function mapped onto the energy grid of the tally, since separate tallies of response by group are not made during the simulation.

The mesh tally keyword "weightless" will instruct Monaco to not include the particle weight in the contribution to the mesh tally for track lengths that cross the voxels of the mesh. Instead of a flux tally, this will compute the Monte Carlo particle density — a measure of the number of particles simulated by Monaco in each mesh cell and in each energy group.

Mesh tallies can use a cylindrical mesh instead of a rectilinear mesh. Use the keyword "cylGeometryID=" instead of "gridGeometryID=" and reference one of the defined cylindrical meshes defined in the definitions block. Both cannot be specified at the same time. The Java Mesh File Viewer can only show the *r*-*z* view of a cylindrical mesh tally.

8.2.3.7 Parameter Block

The parameter block sets the Monte Carlo parameters used by Monaco. Items can be listed in any order. The initial random number ("randomSeed=") is given as a 16-digit hexadecimal number. The number of histories per batch ("perBatch=") and the number of batches ("batches=") can be specified. After every batch of source particles, the tally files are saved to disk. To prevent long run times, a maximum run time in minutes ("maxMinutes=") can also be specified. Defaults are 10 batches of 1000 histories each, with no time limit. The value of batches is used to allocate arrays for the tally statistical tests — so do not make this overly large, even when using maxMinutes to control termination.

For MULTIGROUP, the particles contained in the library will be transported, unless turned off using the keywords "noNeutron" or "noPhoton." In CE, to prevent loading large amounts of unneeded cross-section information into memory, the user should specify which particles to transport, using the keywords "neutron" and/or "photon." Monaco also supports Doppler pre-broadening of the CE neutron cross sections. This is controlled by the "dopplerBroaden=" parameter. Integer options are 0 (disabled, default), 1 (broaden 1D cross sections only), 2 (broaden 1D and 2D cross sections), and 3 (broaden 2D cross sections normally and broaden 1D cross sections using a less robust, but faster, interpolation method).

The default behavior for Monaco is to create neutrons from fission events and create secondary gammas from neutron collisions. To turn off the creation of fission neutrons in all multiplying media (for example, when the source already includes them), use the keyword "fissionMult=0". For problems where the library has photon data but none of the tallies require photons, use the keyword "secondaryMult=0" to stop the creation of secondary photons from neutrons. In CE problems, the number of fission neutrons and secondary gammas can be simulated as one particle of each type having a high weight ("fissionMult=1", "secondaryMult=1") or as many particles as the physical yield for the reaction would dictate ("secondaryMult=2"), each with a weight corresponding to their probability of emission. If the user requests option 2 and the particle bank becomes too large, Monaco will drop the settings back to option 1. In MULTIGROUP, values of 1 and 2 are both treated as 1.

```
read parameters
   randomSeed=003ecd7b4e3e8b
   perBatch=100000  batches=100  maxMinutes=1440.0
   fissionMult=0
end parameters
```

In complex geometries, particles can sometimes "get lost" due to round-off errors in the ray-tracing. This would normally result in the code stopping, since lost particles usually indicate an undefined or doubly defined region of space. In order to tolerate a few lost particles without stopping the code, use the keyword "maximumLost=". Care should be taken not to increase this just to get around poorly defined geometry. To aid in geometry testing, the keyword "voidAllRegions" can be used. This keyword sets every region material to void so that tracks can stream through without interacting (faster). A large source and this keyword can be used to test a geometry input for gaps and overlaps. When the "voidAllRegions" keyword is used, mesh tally files will not contain material information, only the unit and region information.

Note that for both CE and MULTIGROUP, using fissionMult=0 only turns off the creation of neutrons from fission. The fission photons are controlled by the secondaryMult setting because some of the ENDF data evaluations do not separate fission gammas from other neutron collision gammas.When using a mesh-based importance map, if a particle is outside the importance map, the code will stop with the message "Could not find particle importance. The particle is outside of the importance map." If the importance map does not cover the entire problem, then the tallies may be missing part of their final values. If the user intends to use an importance map that does not cover the entire geometry and wants particles outside the importance map to have zero importance (they will then be killed), then the keyword "allowShortImpMap" can be used to

allow the use of a "short" importance map. Users must be sure that areas outside the importance map are unimportant to the problem.

8.2.3.8 Biasing Block

The optional biasing block lists the parameters for the standard Monaco variance reduction tools: forced collisions, region-based weight windows, and path-length stretching. This block also allows for the use of a previously made Monaco mesh importance map, such as those produced by the MAVRIC sequence.

Forced collisions

Forced collisions are one of the simplest variance reduction techniques. This makes a particle have a collision along its current flight direction before leaving the geometry. The collision is forced and the particle weight is reduced by the true probability of having a collision within the geometry. This is helpful in small or low-density geometries where many particles leave without interacting but can add computation time to ordinary problems. To use forced collisions, specify the "forcedCollisions" keyword. This requires the use of Russian roulette ("targetWeights" and "lowerWeights", see below).

Weight windows

Monaco can use Russian roulette for preventing low particle weights from being followed and splitting to prevent the production of very high weight particles. Either of these requires the target weight values ("targetWeights ... end") for each energy group and for each region to be listed. For CE calculations, the energy bin boundaries are specified with the keywords "nEnergyBoundsID=" and "pEnergyBoundsID=". For Russian roulette, the lower weight bounds must be specified ("lowerWeights ... end") and for splitting the upper weight bounds are listed ("upperWeights ... end"). The different weight arrays can have a length matching (1) the product of the number of energy groups and the number of regions, (2) the number of regions, or (3) the number of energy groups. In case 2, the values are repeated for each energy group. In case 3, the values are repeated for each region. For example, to specify only Russian roulette in a coupled neutron-photon problem with target and lower weights the same in each region the following is used. An example using the 27/19 multigroup library would be

```
read biasing
    targetWeights 27r1.0 19r0.1  end
    lowerWeights  27r0.1 19r0.01 end
end biasing
```

and for a CE calculation

```
read definitions
    energyBounds 1 27n end energyBounds
    energyBounds 2 19p end energyBounds
end definitions

read biasing
    nEnergyBoundsID=1  pEnergyBoundsID=2
    targetWeights 27r1.0 19r0.1  end
    lowerWeights  27r0.1 19r0.01 end
end biasing
```

Alternatively, to use Russian roulette and splitting, the target weights and a window ratio ("windowRatio=") can be specified. The window ratio is simply the ratio of the weight window upper bound to the weight window lower bound, with the target weight being the average of the upper and lower. If target weights $\overline{w}$ and a window ratio r are supplied, then the lower and upper weight bounds are found by using

$$w_{\min} = \frac{2}{r+1}\overline{w} \tag{8.2.21}$$

$$w_{\max} = \frac{2r}{r+1}\overline{w} \tag{8.2.22}$$

If only the window ratio is supplied, both Russian roulette and splitting will be turned on with the target weights for every energy group and every region set to 1.

A target weight of 0 will prevent particles of that energy group in that region from being transported. For example, to perform a neutron-only calculation using a coupled neutron-photon library, simply set the target weight values for all of the photon groups in every region to 0. The user should be careful not to "turn off" energy groups or regions that may impact (bias incorrectly) the final tally results.

Monaco always uses the implicit capture technique-at collision sites absorption is not simulated but instead the particle weight is reduced by the ratio of the scatter probability to the total interaction probability. Particles only stop if they escape the defined geometry. This generally produces tally results with lower uncertainties in less time, but for highly scattering or very large geometries, particles with very low weights will be tracked until their weight reaches the lower limit of real numbers in double precision. This is not typically what the user wants. So, for problems that are not using any weight windows or importance map, Russian roulette and splitting are automatically turned on using the a target weight of 1 for every energy group and every region and a window ratio of 5.

Path-length stretching

Path-length stretching allows particles going a certain direction to travel farther (with reduced weight) before interacting. Seventeen different directions are available, as listed in the Table 8.2.6. One of the directions is specified by using the "direction=" keyword and one of the direction strings listed in Table 8.2.10, in quotes. The amount of stretching is specified using the "pathStretch ... end" array, with values between 0 (no stretching) and 1 (lots of stretching), for each energy group and region. Items can be listed in any order. Similar to the weight window arrays, the "pathStretch" array can have a length matching (1) the product of the number of energy groups and the number of regions, (2) the number of regions, or (3) the number of energy groups. Values are repeated to fill in all of the regions and groups.

```
read biasing
    pathStretch  46r0.5 46r0.6 46r0.75 end
    direction="localZp"
end biasing
```

When stretching toward a given location (direction="location"), then the location ID number must be specified using the "locationID=" keyword. For CE calculations, energy boundary objects need to be defined using the keywords "nEnergyBoundsID=" and "pEnergyBoundsID=".

Table 8.2.6: Directions available for path-length stretching

Direction	Comment
`localXp`	+x direction in local coordinates
`localYp`	+y direction in local coordinates
`localZp`	+z direction in local coordinates
`localXm`	-x direction in local coordinates
`localYm`	-y direction in local coordinates
`localZm`	-z direction in local coordinates
`localYZ`	cylindrically away from x-axis (local)
`localXZ`	cylindrically away from y-axis (local)
`localXY`	cylindrically away from z-axis (local)

Table 8.2.6 – continued from previous page

Direction	Comment
	`globalXp` | +x direction in global coordinates
`globalYp`	+y direction in
`globalZp`	+z direction in
`globalXm`	-x direction in g
`globalYm`	-y direction in g
`globalZm`	-z direction in g
`outward`	spherically outw
`location`	in the direction

Mesh-based importance map

The user can alternatively specify an existing Monaco mesh-based importance map-a binary file created by a previous MAVRIC calculation. The mesh importance map must be a binary file using the Monaco mesh importance map format (a *.mim file). This option is specified with the "meshImpMapFile=" keyword and the file name (and full path if necessary) in quotes.

```
read biasing
    meshImpMapFile="c:\mydocu~1\previouslyMadeImpMap.mim"
    windowRatio=10.0
end biasing
```

If the "meshImpMapFile=" keyword is used, most other biasing block keywords cannot be used. The keyword "windowRatio=" can be used and its default value is five.

If particles leave the importance map but are still in the defined geometry, the simulation will be stopped. If the user wants to allow importance maps that do not cover the entire problem, the keyword "allowShortImpMap" should be used in the parameters block. In that case, areas outside the mesh importance map will be treated as completely unimportant-particles will be killed outside the mesh.

Note that for the most effective use of an importance map, the source should be biased to match. This is what the MAVRIC sequence does — it produces a biased source such that sampled particles are born with a weight matching the target weight of the importance map.

Monaco input summary

Below are summaries of the Monaco blocks and their available keywords.

Table 8.2.7: Keywords for the cross section block

block	keyword	type	length	default	required	restrictions/comments
read crossSections						
	maxNumMixtures=	integer		100	no	only required if more than 100 mixtures
	maxNumElements=	integer		100	no	only required if more than 100 elements in any mixture
	For multi-group calculations					
	ampxFileUnit=	integer			a*	unit number of AMPX working library
	iceFileUnit=	integer			b*	unit number of ICE cross sections
						*required: either a) ampxFileUnit= or b) iceFileUnit=
	For continuous energy calculations					
	ceLibrary=	character			yes	required for CE, contained in double quotes
	ceTempDefault=	real		293	no	set default temperature for CE mixtures
	mixture *id*	integer			yes	non-negative integer
	element	integer and real			yes	integer=z*1000+a, real=atom density
	temperature=	real		293	no	temperature for this mixture (CE only)
	end mixture					
	For multi-group calculations					
	printTotals		not present		no	prints total cross sections for each mixture
	printScatters		not present		no	prints 2D cross sections for each mixture
	printAngleProb		not present		no	print angles and probabilities for each mixture
	printFissionChi		not present		no	print fission spectrum chi for each mixture
	printExtra		not present		no	print extra 1D cross sections for each mixture
	printLegendre		not present		no	print Legendre coefficients for each mixture
	fullyCoupled		not present		no	treat all particles as primary particles
end crossSections						

Table 8.2.8: Keywords for the definitions block

block	keyword	type	length	default	required	restrictions/comments
read definitions						
	location *id*	integer			yes	non-negative integer, unique among positions
	title=	character		none	no	contained in double quotes (title="yada yada yada")
	position	real	3		yes	global coordinates (x,y,z)
	end location					
	Type 1: generic user-defined response (n values is histogram, n+1 values is value/function pairs)					
	response id	integer			yes	non-negative integer, unique among responses
	neutron/photon				yes	indicate either neutron or photon for the response type
	bounds	real	n+1	none	yes*	energy bin boundaries (eV)
	energyBoundsID=	integer			yes*	use a defined energyBounds objects for bounds *either bounds or energyBoundsID is required
	values	real	n or n+1		yes	non-negative real numbers
	end response					
	Type 2: Using a cross-section from the library (usually with units of barns)					
	response id	integer			yes	non-negative integer, unique among responses
	neutron/photon				yes	indicate either neutron or photon for the response type
	material=	integer			yes	which material
	ZAID=	integer			no	which isotope (ZAID=Z*1000+A) (omit to use cross section of entire material)
	MT=	integer			yes	which MT reaction number
	macro			not present	no	convert units from barns to /cm using ZAID atom density
	end response					
	Type 3: Flux-to-Dose conversion factors					
	response id	integer			yes	non-negative integer, unique among responses
	specialDose=	integer			yes	special dose factor from a MG library
	end response					
	response id	integer			yes	non-negative integer, unique among responses
	doseData=	integer			yes	generate data points from original flux-to-dose reference
	noExtrapolation			not present	no	do not use SCALE energy extrapolation
	end response					
	Type 4: Standard multi-group response function (MG only)					
	response *id*	integer			yes	non-negative integer, unique among responses
	neutron/photon				yes	indicate either neutron or photon for the response type
	values	real	ng		yes	non-negative real numbers
	end response					
	Optional keywords for any type of response					
	response *id*	integer			yes	non-negative integer, unique among responses
	title=	character	256	none	no	contained in double quotes (title="yada yada yada")
	multiplier=	real		1.0	no	multiplier for units conversion, etc.
	makeChart			not present	no	makes a *.chart file showing the input values and the mutli-group representation (for MG)
	eHigh=	real			no	keep only responses values below eHigh (eV)
	eLow=	real			no	keep only responses values above eLow (eV)
	lessOutput			not present	no	only show first 5 and last 5 points of response
	end response					
	makeCharts			not present	no	makes a *.chart file for each response
	multiplier=	real		1.0	no	multiplier applied to all defined responses
	lessOutput			not present	no	only show first 5 and last 5 points of response
end definitions						

ng is the number of groups in the multi-group cross section library for that type of particle

Table 8.2.9: More keywords for the definitions block

	gridGeometry *id*				yes	non-negative integer, unique among grid geometries
	title=	character	256	none	no	contained in double quotes (title="yada yada yada")
	xplanes	real	any		no	a list of real numbers (order not important) in *x* dimension
	xLinear n min max	int real real			no	adds *n*+1 planes evenly from min to max in *x* dimension
	yplanes	real	any		no	a list of real numbers (order not important) in *y* dimension
	yLinear n min max	int real real			no	adds *n*+1 planes evenly from min to max in *y* dimension
	zplanes	real	any		no	a list of real numbers (order not important) in *z* dimension
	zLinear n min max	int real real			no	adds *n*+1 planes evenly from min to max in *z* dimension
	tolerance=	real		1.E-06	no	for removing duplicate planes from *planes or *Linear
	make3dmap			not present	no	makes a *.3dmap file showing the grid geometry
	xdivide=	integer		1	no	Once all xplanes are entered, further divide them by this
	ydivide=	integer		1	no	Once all yplanes are entered, further divide them by this
	zdivide=	integer		1	no	Once all zplanes are entered, further divide them by this
	end gridGeometry					
	make3dmaps			not present	no	makes a *.3dmap file for each of the grid geometries
	cylGeometry *id*	integer			yes	non-negative integer, unique among cylindrical geometries
	title=	character	256	none	no	contained in double quotes (title="yada yada yada")
	radii	real	any		no	list of radii
	thetas	real	any		no	list of angles (0 to 2_{π})
	degrees	real	any		no	list of angles (0 to 360°)
	zPlanes	real	any		no	list of zplanes (relative to position where z=0)
	radiusLinear *n min max*	int real real			no	adds *n*+1 radii evenly from min to max
	thetaLinear *n min max*	int real real			no	adds *n*+1 theta planes evenly from min to max (0 to 2π)
	degreeLinear *n min max*	int real real			no	adds *n*+1 theta planes evenly from min to max (0 to 360°)
	zLinear *n min max*	int real real			no	adds *n*+1 *z* -planes evenly from min to max
	position	real	3	(0, 0, 0)	no	position from which to start radii and zplanes
	zaxis *u v w*	real	3	<0, 0, 1>	no	set the axis of the cylindrical mesh
	xaxis *u v w*	real	3	<1, 0, 0>	no	set the reference position of the cylindrical mesh
	tolerance=	real		1.E-06	no	for removing duplicate planes from *planes or *Linear
	makeCylMap			not present	no	makes a *.3dmap file showing the cylindrical mesh
	end cylGeometry					
	makeCylMaps			not present	no	makes a *.3dmap file for each of the cylindrical geometries
end definitions

	upperWeights	real	a*	none	no	non-negative real numbers
	windowRatio=	real		none	no	real number greater than one
	pathStretch	real	a*	none	no	valid range of values: [0.0,1.0)
	direction=	string		none	no	one of 17 strings, in quotes
	locationID=	integer		none		required for direction="location"
						*a is one of {ng*nr, nr, ng}
	mapMultiplier=	real		1.0	no	multiply *Weights by this factor
	For continuous energy					
	nEnergyBoundsID=	integer		not present	no	neutron energy bins for CE-Monaco calculations
	pEnergyBoundsID=	integer		not present	no	photon energy bins for CE-Monaco calculations
	Using a Monaco mesh importance map file					
	meshImpMapFile=	string		not present	no	legal file name for current system, in quotes
	mapMultiplier=	real		1.0	no	multiply targetWeights in imp. Map
end biasing						

ng is the number of groups in the MG cross section library or in the energyBounds specified for CE
nr is the number of regions in the geometry

8.2.4 MONACO OUTPUT

8.2.4.1 Main text output file

The Monaco output file first reviews the input Monaco received. First is a review of the geometry-showing which materials are used in each region and the volume of that region, if input or calculated. Then there is a detailed list of other Monaco input: cross-section parameters, data definitions, the sources, the tallies, the Monte Carlo parameters, and the biasing parameters. For calculations using an importance map, its summary is also given. The "Mesh Importance Map Characterization" shows where the importance map may be changing too fast and may require more refinement.

For each batch of source particles simulated, the output file lists the batch time and the starting random number for the next batch, which may be useful in rerunning just a portion of a problem. Once all of the batches are completed, a list of the various tally files that have been created is given. Finally, the tallies are summarized in a section titled "Final Tally Results Summary". For each point detector, the total neutron and photon fluxes (uncollided and total) are given as well as the final response values for each response function. For each region tally, the total neutron and photon fluxes (both track-length and collision density estimates) are listed, followed by the final response values for each response function. Along with each of the final quantities are the standard deviation of the quantity, the relative uncertainty, the figure-of-merit and a summary of list of the statistical checks (passed or not).

8.2.4.2 Tally files

In addition to the summary of tallies contained in the Monaco text output file, many other files are created containing the group-by-group details of the final tally data. Each mesh tally produces a file "*outputName*.mt*id*.3dmap" where *outputName* is the name the user chose for his output file and "*id*" is the identification number corresponding to the tally specification. This file can be viewed using the Mesh File Viewer capability of Fulcrum. Point detector tallies and region tallies each create files "*outputName*.pd*id*.txt" or "*outputName*.rt*id*.txt" to list the group-by-group results. They also produce chart files, "*outputName*.pd*id*.chart" or "*outputName*.rt*id*.chart", which contain the total neutron flux, the total photon flux, and the total response function value calculated at the end of each batch. This data can be used to look at tally convergence and can be viewed with the Interactive Plotter capabilities of Fulcrum. Table 8.2.18 lists the output files, based on the name of the main output file (here called *outputName)*, that are available to the user. These files will be copied back to the directory where SCALE was executed.

8.2.4.3 Diagnostic files

Three of the data types defined in the definitions block can create files or add output to the main text output file to allow the user to ensure items were interpreted by Monaco as they were intended. Responses that included the "makeChart" keyword will each produce a file "*outputName*.resp*id*.chart", where "*id*" is the response identification number, which can be displayed using the Interactive Plotter. Grid geometries that include the keyword "make3dmap" will each produce a file called "*outputName*.grid*id*.3dmap", where "*id*" is the grid geometry identification number, which can be visualized using the Mesh File Viewer. Likewise, cylindrical geometries with the keyword "makeCylMap" will create a file called "*outputName*.cyl*id*.3dmap". Distributions using the "runSampleTest" keyword will produce a file "*outputName*.dist*id*.chart", where "*id*" is the response identification number. The "runSampleTest" results will also be displayed in the main text output with each distribution listed in the Monaco input review.

Table 8.2.18: Output files created by Monaco

File Type	Filename	Viewer	Description
Output Summary			
	outputName.out		main text output file, contains results summary
Diagnostic Files			
	outputName.resp*id*.chart	P	response input and MULTIGROUP representation for response *id*
	outputName.grid*id*.3dmap	V	mesh version of geometry using grid geometry *id*
	outputName.cyl*id*.3dmap	V	mesh version of geometry using cylindrical geometry *id*
	outputName.dist*id*.chart	P	distribution input and sampling test for distribution *id*
Mesh Source Saver			
	filename.msm	V	mesh representation of a single source or total source
	filename.id.msm	V	mesh representation of multiple sources
	filename.sampling.msm	V	biased representation of a single source or total source
	*filename.*sampling.*id*.msm	V	biased representation of multiple sources
Tally Files			
	outputName.pd*id*.txt		detailed results for point detector tally *id*
	outputName.pd*id*.chart	P	batch convergence data for point detector tally *id*
	outputName.rt*id*.txt		detailed results for region tally *id*
	outputName.rt*id*.chart	P	batch convergence data for region tally *id*
	outputName.mt*id*.3dmap	V	mesh tally for meshTally *id*
	outputName.mt*id*.resp*xx*.3dmap	V	mesh tally of response by group for meshTally *id*, response *xx*
	outputName.mt*id*.flux.txt		detailed results for the group-wise flux of meshTally *id*
	outputName.mt*id*.tfluxtxt		detailed results for total flux of meshTally *id*
	outputName.mt*id*.resp*xx*.txt		detailed results for response *xx* of meshTally *id*

continues on next page

Table 8.2.18 – continued from previous page

File Type	Filename	Viewer	Description
V - can be displayed with the Mesh File Viewer capabilities Fulcrum. P - can be displayed with the 2D plotting capabilities of Fulcrum.			

8.2.4.4 Mesh source saver files

If the Mesh Source Saver was used, one mesh source file will be created for each defined source. For a single source, the filename will be whatever was listed with the "filename=" keyword or "source.msm" if nothing was given. For multiple sources, the filenames will include the source identification number, such as "source.*id*.msm". If there were multiple sources and the "makeTotal" keyword was used, the total will be stored in "source.msm". Note that if these files are desired, they must be manually copied back from the SCALE temporary area.

If the keyword "meshBiasFile=" was used, then for every mesh source generated above there will also be a biased mesh source that is used in sampling. These files have the names in the form of "source.sampling.*id*.msm".

8.2.4.5 Statistical checks on point detector and region tallies

With each region tally and point detector tally, detailed statistical information is provided in separate files, "*outputName*.rt*id*.txt" or "*outputName*.pd*id*.txt", just after the group-by-group values for the fluxes and responses. For the total fluxes and any responses of each tally, two tables are given.

First, the values of the tally and several statistical quantities are listed as a function of batch number. With each batch, the statistical tests are listed by number with one of the following: "X" for passing, "-" for failing or a blank if the test could not be performed yet. The second table lists the details of the final statistical checks for the last batch completed. This table lists the value for each of the six tests as well as what the goal is for that test.

As an example, consider a 1 Ci point source of Watt spectrum neutrons inside an r=20 cm sphere of polyethylene. Two tallies are used to find the neutron dose rate (rem/hr) 35 cm from the center of the sphere — a region tally (region between two concentric spheres with radii of 34 and 36 cm) and a point detector 35 cm away from the center of the sphere. Twenty batches of 1000 particles each were used in this example.

The first depiction of the region tally dose rate response is shown in Example 8.2.2. Since four of the tests involve curve fits to the table values over the last half of the simulation, the table is split showing each half of the simulation separately. The second depiction of the region tally, showing all of the details for the last batch, is shown in Example 8.2.3. These two tables show that this tally passed all the statistical tests for the entire second half of the simulation. This information, combined with the fact that this is a simple tally for a well-posed problem, indicates that this tally is well converged.

Example 8.2.2: Tally values for a well-converged tally.

Example 8.2.3: Final check for a well-converged tally.

```
  Final Statistical Check (fits are over the last half of the simulation)

quantity               check                      goal    actual  pass
---------------------- -------------------------  -------  --------  ----
1 mean                 rel slope of linear fit  =  0.00   -0.0118  yes
2 standard deviation   exponent of power fit    = -0.50   -0.5092  yes
3 relative uncertainty final value              <  0.05    0.0289  yes
4 relative VOV         exponent of power fit    = -1.00   -0.9833  yes
5 relative VOV         final value              <  0.10    0.0009  yes
6 figure-of-merit (FOM) rel slope of linear fit  =  0.00    0.0075  yes
---------------------- -------------------------  -------  --------  ----
```

Since the point detector is close compared to the size of the sphere, it should converge slower than the region tally. Contributions coming from different parts of the sphere have large differences in attenuation which will cause large fluctuations in the weights arriving at the point detector. The two statistical tables are shown in Example 8.2.4 and Example 8.2.5. This tally is not yet converged enough to pass most of the statistical tests. With thirty times the simulation time, this point detector tally will pass all six tests.

Fig. 8.2.19 shows the behavior of both the region tally (well-converged) and the point detector tally (not-yet-converged) for this example problem as a function of the simulation run time (shown as the twenty batches of particles). The batch values are shown as blue points and the fits for the last half of the simulation are shown as solid black lines. The average value for a tally should be constant, so test 1 looks at the slope of a linear fit over the tally average over the last half of the simulation. The uncertainty of the tally should decrease with the square root of the total number of particles ($\frac{1}{\sqrt{N}}$), so test 3 computes the slope of an exponential fit which should be close to -0.5 (green dotted line). The variance-of-the-variance (VOV) should decrease with $\frac{1}{N}$, so test 4 computes the slope of an exponential fit which should be close to -1.0. The tally figure-of-merit (FOM) should be constant. Test 6 computes the slope of the FOM values which should be zero.

Example 8.2.4: Tally values for a not-yet-converged tally.

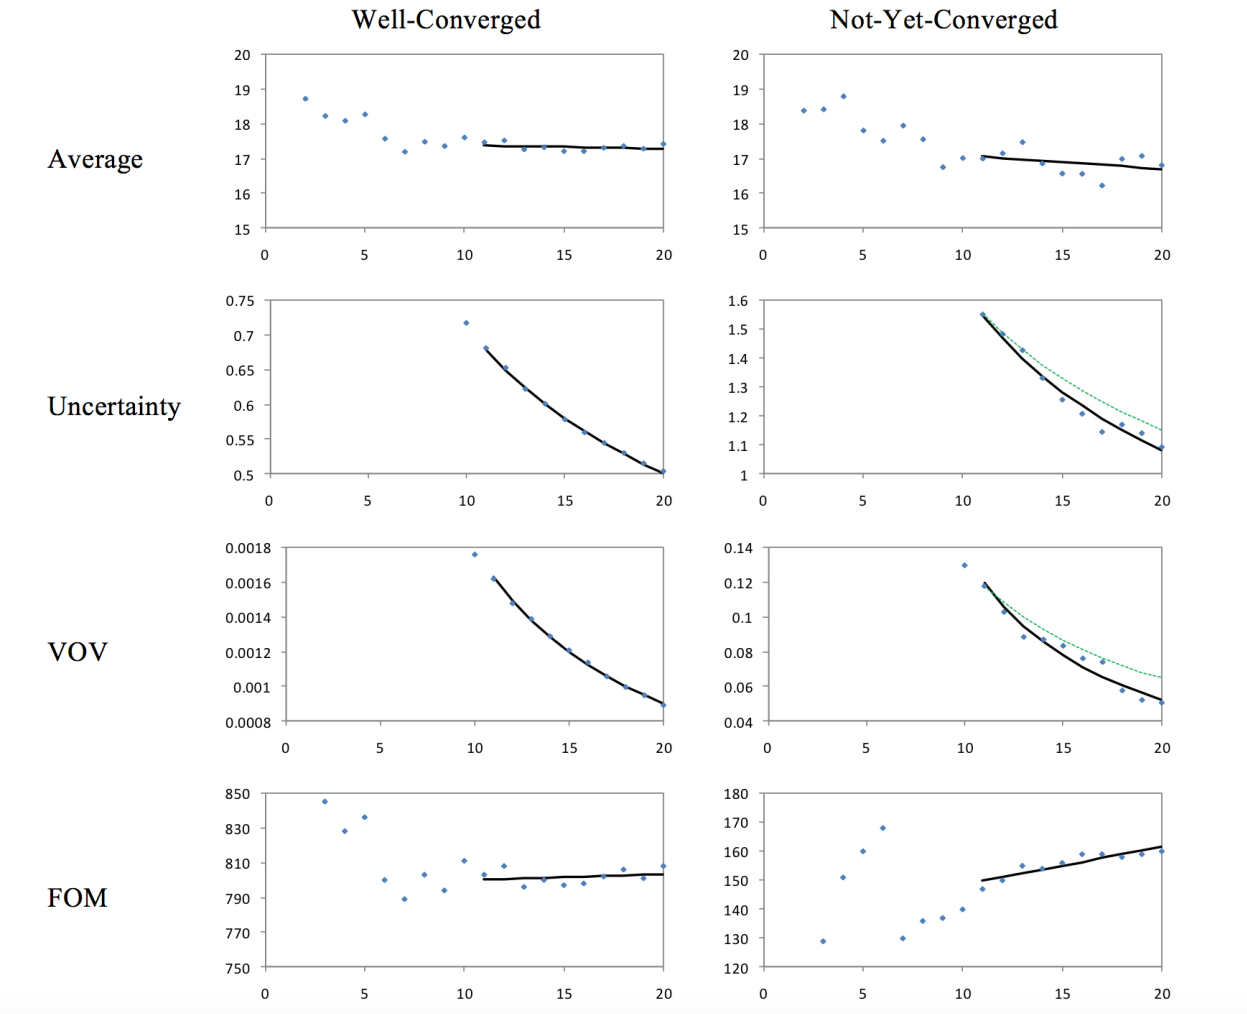

Fig. 8.2.19: Behavior of two tallies as a function of number of particle batches.

Note that the slope of the VOV is found by fitting an exponential curve through the calculated VOV values and is very sensitive to outliers. Users need to apply their own judgment to whether or not the VOV test implemented in Monaco is too strict (failing when the tally seems converged).

Mesh tallies produce similar tables - detailed statistical information is provided in separate files, "*outputName*.mt*id*.flux.txt" and "*outputName*.mt*id*.resp*xx*.txt", for the total flux and responses. First, the statistical values related to the mean relative variance are listed as a function of batch number. With each batch, the statistical tests are listed by number with one of the following: "X" for passing, "-" for failing or a blank if the test could not be performed yet. The second table lists the details of the final statistical checks for the last batch completed. This table lists the value for each of the four tests as well as what the goal is for that test.

8.2.5 EXAMPLE PROBLEMS

8.2.5.1 Neutron transmission through an iron sphere

In the early 1990s, several experiments were performed in order to benchmark ENDF/B-VI cross-section data for iron [MONACO-SWA93] This example problem will use Monaco to simulate one of these experiments: transmission of ^{252}Cf neutrons through a sphere of iron. The Monaco calculations will be compared to two sets of measurements, one by the Czechoslovakian National Research Institute (NRI) and the other by the Skoda Company.

The Monaco model for this sample problem (samplesinputmonaco.ironSphere.inp) will be quite simple-just a point source and a spherical shell of iron. Three different tallies are used which should all give the same result: a region tally (for a thin spherical shell at radius=100cm); a point detector tally at (x,y,z)=(100,0,0); and a coarse mesh tally, with one cell enclosing the point (x,y,z)=(100,0,0).

Input

First, the cross sections need to be computed. Here, csas-mg is used and the "activities" material is included to make sure the flux-to-dose conversion factors are added to the working library.

```
=csas-mg
Materials for Leakage spectrum of Cf-252 through an iron sphere
v7-27n19g
read composition
    wtptSphere 3 8.0 7   26054 5.767   26056 91.618  26057 2.187
                         26058 0.298    6000 0.07     15000 0.03
                         16000 0.03
        1.0 293.0 end
    activities 99 1.0 293.0 end
end composition
end
```

The Monaco input file starts with module name ("monaco") and a title.

```
=monaco
Leakage spectrum of Cf-252 through an iron sphere
```

The mixing table information can be found in the output of the above csas-mg run.

```
read crossSections
    ampxFileUnit=4
    mixture 3
        element     26054 5.150920E-03
        element     26056 7.891181E-02
        element     26057 1.850588E-03
        element     26058 2.478141E-04
        element      6000 2.807736E-04
        element     15031 4.666202E-05
        element     16032 4.283109E-05
        element     16033 3.380690E-07
        element     16034 1.897694E-06
        element     16036 9.015172E-09
    end mixture
end crossSections
```

The SGGP geometry consists of several nested spheres. The regions (in order) are a void for the ^{252}Cf source, the iron shield, a void out to the detector, a thin shell about 100 cm, and then a void to the problem boundary. The only volume that needs to be supplied is the fourth region, since that is where the flux tally will be.

```
read geometry
    global unit 1
        sphere   10   1.25
        sphere   11  25.0
        sphere   12  99.5
        sphere   13  100.5
        sphere   99  200.0
        media  0 1   10       vol=8.181230869
        media  3 1   11 -10   vol=65441.66572
        media  0 1   12 -11   vol=4060822.14
        media  0 1   13 -12   vol=125664.7533
        media  0 1   99 -13   vol=29258384.9
    boundary 99
end geometry
```

For the different tallies, responses, locations, and grid geometry objects need to be defined. For the source, one distribution needs to be defined.

```
read definitions
    response 1
        title="ANSI standard (1977) neutron flux-to-dose-rate factors  (rem/h)/(neutrons/cm2/s)"
        specialDose=9029
    end response
    location 1
        title="true detector location"
        position 100.0 0.0 0.0
    end location
    gridGeometry 1
        title="simple grid"
        xplanes -25 -15 -5 5 15 25 35 55 75 95 105 end
        yLinear 5 -25 25
        zLinear 5 -25 25
    end gridGeometry
    distribution 1
        title="Cf-252 neutrons, Watt spectrum a=1.025 MeV and  b=2.926/MeV"
        special="wattSpectrum"
        parameters 1.025 2.926 end
    end distribution
end definitions
```

The ^{252}Cf source can be modeled using the Watt spectrum with a=1.025 MeV and b=2.926/MeV, which was used for distribution 1. The strength is set so that the total flux at the detector (at r=100 cm) without the shield would be 1 n/cm^2/s. So, strength = 4π = 125664 n/s.

```
read sources
    src 1
        title="Cf-252 neutrons, Watt Spectra using a=1.025 MeV and b=2.926/MeV"
        neutron  strength=125663.70614
        sphere 0.1
        eDistributionID=1
    end src
end sources
```

Three tallies will be defined: a region tally over the fourth region of unit 1 (since this is a symmetric problem); a mesh tally using a coarse mesh over the entire problem; and a point detector tally at the true detector location.

```
read tallies
    regionTally 4
        title="example region tally"
        neutron
        unit=1 region=4
```

(continues on next page)

(continued from previous page)

```
        responseID=1
    end regionTally

    meshTally 1
        title="example mesh tally"
        neutron
        gridGeometryID=1
        responseID=1
    end meshTally
    pointDetector 2
        title="example point detector"
        neutron
        locationID=1
        responseID=1
    end pointDetector
end tallies
```

Monte Carlo parameters include the starting random number seed, the number of particles per batch, and the number of batches to simulate. Since we are only interested in simulating neutrons, use the keywords "neutrons" and "noPhotons" to transport neutrons and not photons. To prevent the production of fission neutrons and secondary gamma rays from neutron interactions, the keywords "fissionMult=0" and "secondaryMult=0" are used. In order to prevent a long run time, a maximum allowable run time using the "maxMinutes=" keyword could also be used.

```
read parameters
    randomSeed=8655745262010033
    perBatch=262000  batches=10
    neutrons  noPhotons
    fissionMult=0  secondaryMult=0
end parameters
```

Without any biasing parameters, Monaco will set the target weights of every energy group in every region to 1 and the values for weight lower bounds (Russian roulette) will be 1/3. Since "noPhotons" was listed in the parameters block, photons should not be generated. So, no biasing block is required.

If desired, a biasing block could be added to change the size of the weight windows (default is 5, giving lower weights of 1/3 and upper weights of 5/3). By using the default target weights of 1.0 and defining the windowRatio as 199, the lower weights are all set to 0.01 and the upper weights for splitting are 1.99.

```
read biasing
    windowRatio=199.0
end biasing
```

or the target weights and lower weights could be listed for every group, every region or for every group/region. For all regions having the same targets and lower bounds, the following could be used:

```
read biasing
    targetWeights  27r1.00 19r0.0 end
    lowerWeights   27r0.01 19r0.0 end
end biasing
```

If this last case were used, the "noPhotons" keyword would not be required since the target weights for all photon groups were explicitly set to 0.

Finally, the Monaco input file is ended with

```
end data
end
```

The complete input file `monaco.ironSphere.inp` is located in the SCALE `samples\input` directory.

Output

When Monaco finishes, there are several output files produced. First, the main output file lists summaries for each of the region tallies and point detector tallies. With each mesh tally, a *.3dmap file is produced which can be viewed with the Mesh File Viewer capabilities of Fulcrum. Region tallies and point detectors produce text files listing group-by-group results for fluxes and any optional responses. Both of these tallies also produce *.chart files which contain information about how the simulation progresses with each batch. These can be viewed with the Interactive Plotter capabilities of Fulcrum.

From the main output file, the final tally results summary is shown below:

```
Final Tally Results Summary
 ============================

Neutron Point Detector 2.  example point detector

    ------------------  -----------  -----------  -------  --------  -----------
```

The fluxes reported are the total fluxes. Note the close agreement between the point detector flux and the region tally track-length estimate. The region tally did not produce a collision-density estimate of flux since the region was a void. Also notice that the neutron dose (response 1) from both tallies match well. The tally details that are saved in the *.pd*.txt or *.rt*.txt files are shown in Table 8.2.19. Group values for the mesh tally were obtained through the Mesh File Viewer.

For the mesh tally, the total neutron flux and neutron dose can be visualized using the Mesh File Viewer, as shown in Fig. 8.2.20 and Fig. 8.2.21. Using the mouse in the viewer, the flux and the dose rate for the cell that contains the detector location (100,0,0) are found to be 1.004 ± 2.3% n/cm^2/s and 7.82 × 10^{-5} ± 2.4% rem/hr, respectively, matching the other tallies well, given the higher uncertainties for the mesh tally.

A comparison of the results of all three Monaco tallies to the two experimental measurements is shown in Fig. 8.2.22 through Fig. 8.2.26 for different cross section libraries. Note that the point detector results and the region tally results are the same for most of the energy range shown. The line representing the mesh tally result becomes broken in some plots because no neutrons of certain energy groups crossed this particular mesh cell. These four plots are each for 10 minutes of computation using a 2 GHz Linux processor.

Using the library with finer groups, the Monaco results show more of the structure seen in the experiments over the energy range from 0.01 MeV to 1.0 MeV, as shown in Fig. 8.2.23 and Fig. 8.2.24.

8.2.5.2 Neutrons through a heavy water sphere

Similar to the first example problem, ^{252}Cf neutrons were measured outside of a sphere filled with heavy water [MONACO-JTN+97] Two measurements were made: one without the iron/polyethylene shield and one with the shield. These two measurements were subtracted to account for scatter from the floor (which is about a 5% effect for energies above 10 keV). A great amount of detail is given for the materials and geometry of the source holder, insertion tube, and detectors in Ref. 6. For this sample problem, just the basics will be modeled in two inputs: `monaco.d2oSphereA.inp` and `monaco.d2oSphereB.inp`, both located in the SCALE `samples\input` directory.

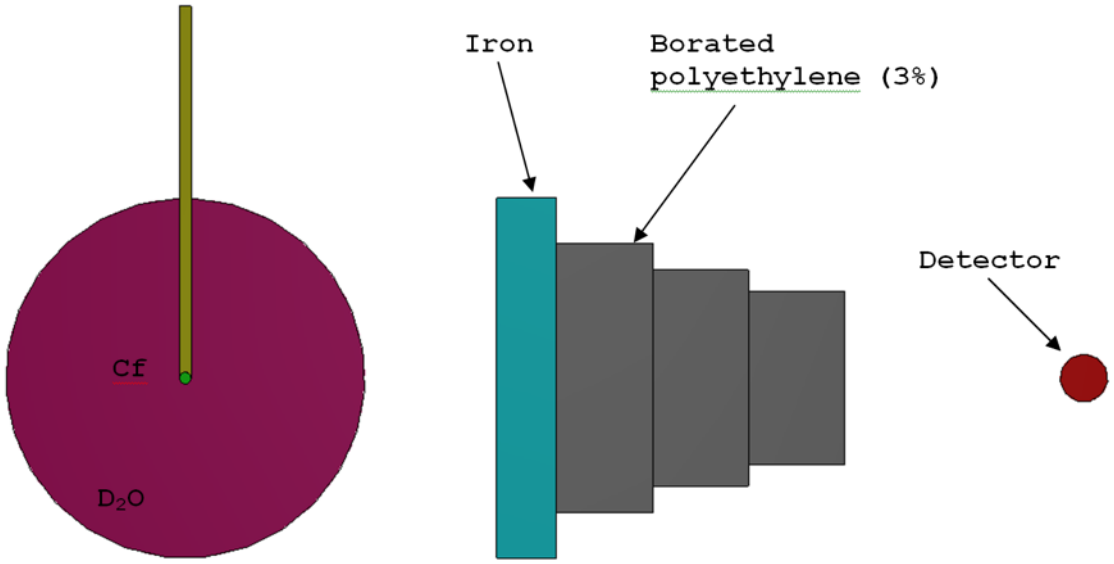

Fig. 8.2.27: Experimental setup.

Input

First, the cross sections for four materials need to be computed. Here, csas-mg is used:

```
=csas-mg
Leakage spectrum of Cf-252 through a heavy water sphere
v7-27n19g
read composition
    d2o          1 0.99286 293.0 end
    h2o          1 0.00714 293.0 end
    polyethylene 2 0.882   293.0 end
    boron        2 0.118   293.0 end
    iron         3 1.0     293.0 end
    orconcrete   4 1.0     293.0 end
end composition
end
```

The Monaco input file starts with module name (“monaco”) and a title.

```
=monaco
Leakage spectrum of Cf-252 through a heavy water sphere, shield in place
```

The mixing table information can be found in the output of the above csas-mg run. The newer ENDF/B-VII libraries contain isotopic data for iron, instead of just the elemental data in the older ENDF/B-V libraries.

```

The SGGP geometry consists of two nested spheres for the source and heavy water sphere. Four cylindrical shields made of either borated polyethylene or iron are placed between the sphere and the detector position (75,0,0). The experiment sat 2 m above the floor of an experimental hall that measured $10 \times 13 \times 25$ m. Here, the origin corresponds to the source at the center of the heavy water sphere.

```

(continued from previous page)

```
        media  4 1   42 -41
    boundary 42
end geometry
```

A second input file (`samples\input\monaco.d2oSphereA.inp`) was created for the geometry without the four xcylinder shields in place.

For this example, a point detector will be used to calculate the flux at the detector location and the source will require a Watt distribution.

```
read definitions
    location 1
        title="true detector location"
        position 75.0 0.0 0.0
    end location
    distribution 1
        title="Cf-252 neutrons, Watt spectrum a=1.025 MeV and  b=2.926/MeV"
        special="wattSpectrum"
        parameters 1.025 2.926 end
    end distribution
end definitions
```

The strength is set so that the total flux at the detector (at r=75 cm) without any shield would be 1 n/cm^2/s. So, strength = 4π $(75)^2$ = 70686 n/s.

```
read sources
    src 1
        title="Cf-252 neutrons, Watt fission spectrum, using a=1.025 and b=2.926"
        neutrons  strength=70685.834704
        sphere 0.1
        eDistributionID=1
    end src
end sources
```

Two tallies will be defined: a region tally over the third region of unit 1 and a point detector tally at the true detector location.

```
read tallies
    regionTally 3
        title="example region tally"
        neutron
        unit=1 region=3
    end regionTally

    pointDetector 2
        title="example point detector"
        neutron
        locationID=1
    end pointDetector
end tallies
```

Monte Carlo parameters include the starting random number seed, the number of particles per batch, and the number of batches to simulate. Since there are no photon tallies, the keyword “secondaryMult=0” is used so that photons are not produced nor transported.

```
read parameters
    randomSeed=8655745262010035
```

(continues on next page)

(continued from previous page)

```
    perBatch=18700  batches=90
    neutrons  noPhotons
    fissionMult=0  secondaryMult=0
end parameters
```

Finally, the Monaco input file is ended with

```
end data
end
```

Output

For the case without the xcylinder shields, the tally summaries from the main output file are reported as:

```
Neutron Point Detector 2.  example point detector
                         average      standard     relat      FOM    stat checks
    tally/quantity         value      deviation    uncert   (/min)   1 2 3 4 5 6
    -------------------  -----------  -----------  -------  --------  -----------
    uncollided flux     4.20334E-02  6.81217E-05  0.00162
    total flux          1.13349E+00  3.28455E-03  0.00290  1.18E+04  X X X X X X
    -------------------  -----------  -----------  -------  --------  -----------

 Neutron Region Tally 3.  example region tally
                         average      standard     relat      FOM    stat checks
    tally/quantity         value      deviation    uncert   (/min)   1 2 3 4 5 6
    -------------------  -----------  -----------  -------  --------  -----------
    total flux (tl)     1.00584E+00  1.47136E-01  0.14628  4.64E+00  - - - X X -
    total flux (cd)     0.00000E+00
    -------------------  -----------  -----------  -------  --------  -----------
```

Note that in this sample calculation (10 minutes), the region tally did not pass all of the statistical checks and the relative uncertainty for the region tally is very large due to the region's small size. This shows how useful a point detector tally can be in estimating fluxes for har-to-reach locations.

For the case with the xcylinder shields in place (450 minutes), the final results were:

```
Neutron Point Detector 2
                        average      standard     relat      FOM    stat checks
    tally/quantity         value      deviation    uncert   (/min)   1 2 3 4 5 6
    -------------------  -----------  -----------  -------  --------  -----------
    uncollided flux     8.37999E-05  1.44384E-07  0.00172
    total flux          1.26869E-01  1.10733E-04  0.00087  4.80E+03  X X X X X X
    -------------------  -----------  -----------  -------  --------  -----------

 Neutron Region Tally 3.  example region tally
                         average      standard     relat      FOM    stat checks
    tally/quantity         value      deviation    uncert   (/min)   1 2 3 4 5 6
    -------------------  -----------  -----------  -------  --------  -----------
    total flux (tl)     1.40236E-01  1.22375E-02  0.08726  4.80E-01  - - - X X -
    total flux (cd)     0.00000E+00
    -------------------  -----------  -----------  -------  --------  -----------
```

Here again, the region tally performed very poorly, showing that very few neutrons actually crossed the tally region. The four shields make this problem very slow to converge because rare particles can arrive at the detector after paths that see different amounts of shield.

The group-wise results list in the point detector detail files from each case can be subtracted and compared to the measurements and calculations listed in [MONACO-JTN+97]. The computed and measured neutron spectra seen by the detector are shown in Fig. 8.2.28 through Fig. 8.2.32 using different cross-section libraries. For each figure, the computational times for case "A", without the shields and case "B", with the shields,

were 10 minutes and 90 minutes, each on a 2 GHz Linux processor. For the CE case, 100 and 900 minutes were used to reduce the statistical uncertainties. Except for the 27/19 multigroup case shown above, none of the "B" cases passed all of the statistical tests.

8.2.5.3 Activation rate from a neutron howitzer

A *neutron howitzer* is a common laboratory-sized neutron source. A few curies of an alpha emitter is mixed with an isotope that has a large (α,n) cross section. This source is then stored in a large tank of moderating material (water, paraffin, etc.) with an access port. Materials can be placed into the access port for irradiation. Activation studies are a typical use of a neutron howitzer. Note that the large moderator tank also provides shielding for the users. Typical source strengths are such that users would probably not wish to spend large amounts of time in front of an open access port.

A typical size and shape for a neutron howitzer is an upright cylinder, outer radius of 30 cm by 70 cm in height. The outer wall, top, and bottom are made of 2 cm thick Plexiglas. The access port is a cylinder of radius 2 cm extending 5 cm away from the tank center through the side wall. A Plexiglas rod can be removed/inserted into the port for sample loading. The tank is filled with ordinary water. Fig. 8.2.33 shows a cutaway view of a very simplified model of the tank with the Plexiglas rod inserted into the access port, to prevent neutrons from streaming into the room. The source is located in the center of the tank and is small enough to be considered a point source. A small foil ($1 \times 1 \times 0.001$ cm) gold foil ^{197}Au is included as an activation sample.

The goal is to use Monaco to calculate the activation rate density, R, in units of /cm ^{3}/s, of the gold foil

$$R = \int \Sigma(E)\,\phi(E)\,dE \tag{8.2.23}$$

so that the activity, A, can be calculated as a function of time in the howitzer, T, and time outside the howitzer, t. Note that the half-life of ^{198}Au of 2.7 days (decay constant is λ=2.97 $\times$ 10^{-6} /s).

$$A = RV\left(1 - e^{-\lambda T}\right)e^{-\lambda t} \tag{8.2.24}$$

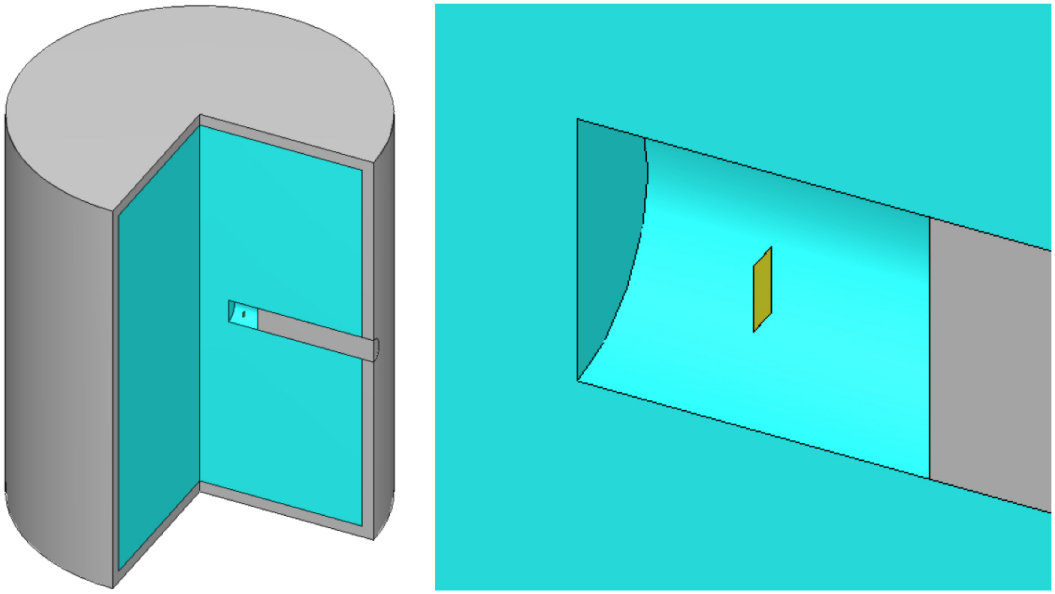

Fig. 8.2.33: Idealized geometry for a neutron howitzer.

Input file

The following input file represents the simple model of a neutron howitzer used for a gold foil activation experiment. The file `monaco.howitzer.inp` is located in the SCALE `samples\input` directory. CSAS-MG is used to generate the cross sections.

```

In addition to the main output file, the diagnostics from the definitions block are shown in Fig. 8.2.34 and Fig. 8.2.35 The final value for the activation rate density R is 2.65×10^5 /cm^3/sec. Note how the track length tally performs better than the collision density estimate for this thin foil region. But also note that after ten minutes, not all of the statistical checks are converged. Running this problem for longer times (even up to 10 hours) does not make all of the tests pass. Due to the very thin width of the of the tally region, most track-lengths across are very small but occasionally a very long track-length is recorded. This rare but high-value score tends to upset the convergence metrics. A tally region over a larger, more cuboid-like volume would make for a better behaved tally.

8.2.5.4 Graphite shielding measurements

K. Ueki of the Nuclear Technology Division, Ship Research Division in Japan performed many simple studies on a variety of shielding materials layered in different combinations. He and his colleagues used both neutron (^{252}Cf) and photon (^{60}Co) sources to investigate the shielding effectiveness of steel, graphite, and many hydrogen-containing materials as single shields or in combinations.

One such series of measurements was for pure graphite [MONACO-UOA92] A ^{252}Cf neutron source was placed in the center of a 50 cm cube of paraffin which had a 45° cone cut-out. A neutron meter was placed 110 cm from the source. Sheets of material, in 5 × 80 ×.

Table 8.2.20: Ueki's experimental results

Thickness (cm)	Dose equivalent attenuation
2	0.828810
5	0.721721
10	0.526054
15	0.364949
20	0.253182
25	0.170514
30	0.112591
35	0.074181

Input file

The following is a listing of the file monaco.graphite.inp located in the SCALE samplesinput directory. This represents a simple model of Ueki's experiment for the 20 cm graphite slab.

    ------------------  ----------  ----------  -------  --------  ----------
```

The plots generated by the "read plots" block are shown in Fig. 8.2.36

To compute the attenuation that Ueki measured, this dose rate can be divided by the dose rate from another Monaco calculation using a slab thickness of 0 cm-the unattenuated case. Combining the results of nine Monaco runs (eight different thicknesses and the unattenuated case), which were allowed to run long enough to achieve 1% uncertainty, gives the results shown in Table 8.2.21. Note how the runtime of the Monaco calculation increases with increasing shield thickness.

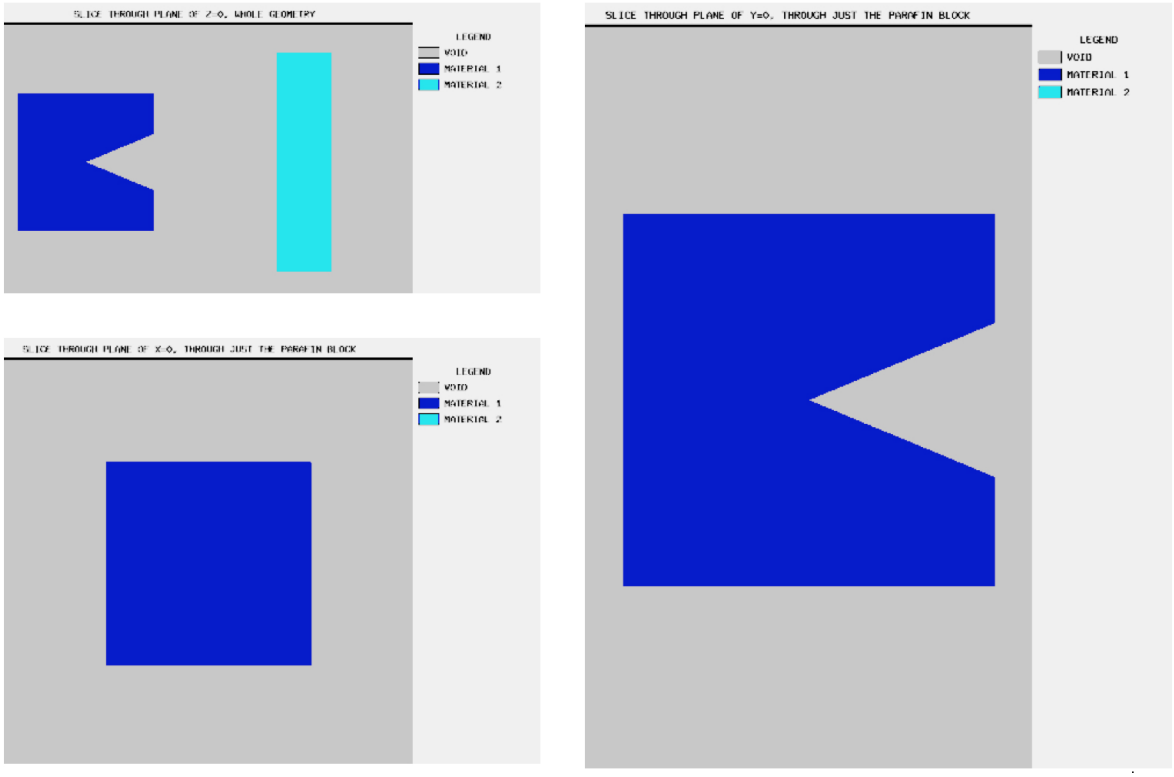

Fig. 8.2.36: Images (*.png files) generated with the “read plot” block.

and viewing the resulting *.3dmap file with the Mesh File Viewer can produce the image shown in Fig. 8.2.37.

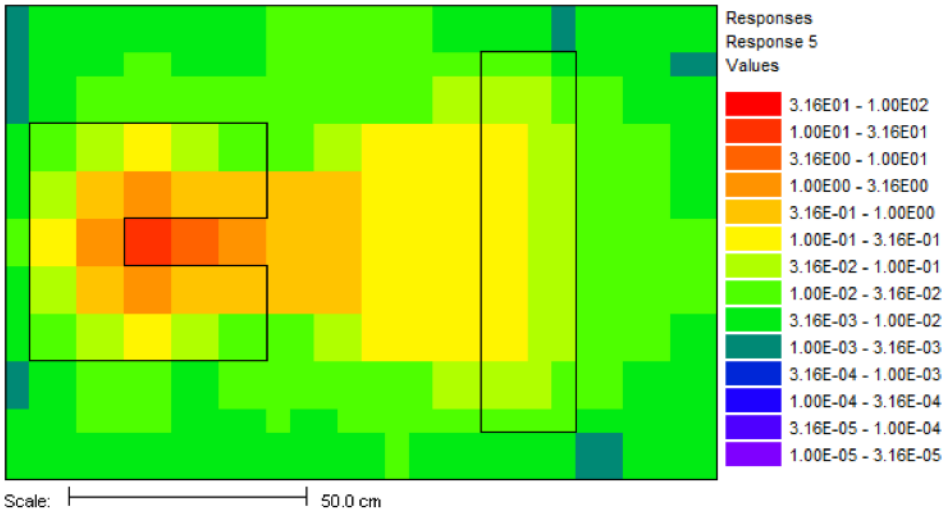

Fig. 8.2.37: Mesh tally showing neutron dose rate (rem/hr)

8.2.5.5 Simple shielding demonstration with line spectra

Sources containing line data are difficult to represent in multigroup. Comparing real measurements of line data to multigroup calculations is also difficult. This sample problem is not the simulation of a real measurement but is just a simple demonstration of the differences between continuous-energy simulation and the multigroup approach.

Consider an isotropic cobalt-60 source on one side of a slab of tungsten (5 cm thick) and the goal is to compute the photon flux and dose on the other side of the slab. Since the continuous-energy library does not have a built-in structure that could be used by tallies, the user needs to supply one (otherwise tally information is recorded in one bin covering the entire range of energy). The user can construct an energy boundaries object in the definitions block that is uniformly spaced, logarithmically spaced, based on one of the multigroup libraries or any combination of the above.

Input file

The sample problem `monaco.wSlab.inp`, is located in the `samples\input` directory. The materials input consist just of tungsten, in its natural isotopic abundances.

```
read crossSections
    ceLibrary="ce_v7.1_endf.xml"
    mixture 1
        element  74182 1.531781E-02
        element  74183 8.202875E-03
        element  74184 1.806470E-02
        element  74186 1.671717E-02
    end mixture
end crossSections
```

The geometry is a simple slab of tungsten, with a small air region on one side for a region tally.

```
read geometry
    global unit 1
        cuboid 10   2.5  -2.5  25.0 -25.0
                             25.0 -25.0
        cuboid 20   6.0   4.0   1.0  -1.0
                              1.0  -1.0
        cuboid 30  10.0 -10.0  25.0 -25.0
                             25.0 -25.0

    end energyBounds
end definitions
```

The source is a simple point source 5 cm to the left of the slab. Because the distribution of cobalt gamma rays was entered as gammas per decay, the keyword *useNormConst' will set the source strength to be the total of the energy distribution - about 2 photons/decay. The `multiplier' keyword is used to multiply that strength by 37 :math:*times` 10^9 decays/sec to get 1 Ci.

```
read sources
    src 1
        title="one Ci of cobalt-60"
        useNormConst
        multiplier=37e9
        sphere 0.0   origin x=-5.0 y=0.0 z=0.0
        photons
        eDistributionID=1
    end src
end sources
```

Both a region tally and a point detector tally are defined. Parameters are set for a 10 minute calculation.

```
read tallies

    noNeutrons  photons
    fissionMult=0  secondaryMult=0
end parameters
```

Output

Results for the dose rate from this continuous-energy calculation are shown in Fig. 8.2.39, along with results from two multigroup calculations and an MCNP calculation. To simulate the same type of physics used in the continuous-energy SCALE, the MCNP calculation used a photon cutoff energy of 0.01 MeV, EMCPF=100 MeV (detailed physics), IDES=1 (no electrons/no bremsstrahlung), NOCOH=0 (coherent scattering occurs), ISPN=0 (no photonuclear collisions), and NODOP=1 (no Doppler energy broadening).

The results from the SCALE multigroup calculations differ by 20%, due to how the source and the dose response function are represented. The 19-group structure represents the 1.33 MeV line with the 1.33-1.66 MeV, so it is expected that the computed dose will be high. With the 47-group structure, the 1.17 MeV line is represented by the 1-1.2 MeV group (too low — lower dose will result) and the 1.33 MeV line is represented by the 1.33-1.44 MeV group (too high — higher dose will result). The multigroup results are well-converged — just not as accurate as desired. The continuous-energy results should be more accurate.

9. DETERMINISTIC TRANSPORT

Introduction by S. M. Bowman

SCALE deterministic transport capabilities enable criticality safety, depletion, sensitivity, and uncertainty analysis, as well as hybrid approaches to Monte Carlo analysis. SCALE provides a one-dimensional (1D) transport solver for eigenvalue neutronics and fixed source neutron-gamma analysis with XSDRN, two-dimensional (2D) eigenvalue neutronics with NEWT, and a three-dimensional (3D) transport solver for hybrid acceleration of Monte Carlo fixed source and eigenvalue calculations with Denovo. Generally, the use of these transport solvers in SCALE is best accessed through the capability specific sequences: CSAS for criticality safety, TRITON for 1D and 2D depletion, TSUNAMI-1D for sensitivity and uncertainty analysis, and MAVRIC for 3D fixed source hybrid Monte Carlo analysis.

XSDRN

XSDRN is a multigroup discrete-ordinates code that solves the 1D Boltzmann equation in slab, cylindrical, or spherical coordinates. Alternatively, the user can select P1 diffusion theory, infinite medium theory, or Bn theory. A variety of calculational types is available, including fixed source, eigenvalue, or search calculations. In SCALE, XSDRN is used for several purposes: eigenvalue (k_{eff}) determination; cross section collapsing; and computation of fundamental-mode or generalized adjoint functions for sensitivity analysis.

NEWT

NEWT (New ESC-based Weighting Transport code) is a multigroup discrete-ordinates radiation transport computer code with flexible meshing capabilities that allow 2D neutron transport calculations using complex geometric models. The differencing scheme employed by NEWT-the Extended Step Characteristic approach-allows a computational mesh based on arbitrary polygons. Such a mesh can be used to closely approximate curved or irregular surfaces to provide the capability to model problems that were formerly difficult or impractical to model directly with discrete-ordinates methods. Automated grid generation capabilities provide a simplified user input specification in which elementary bodies can be defined and placed within a problem domain. NEWT can be used for eigenvalue, critical-buckling correction, and source calculations, and it can be used to prepare collapsed weighted cross sections in AMPX working library format.

Like other SCALE modules, NEWT can be run as a standalone module or as part of a SCALE sequence. NEWT has been incorporated into SCALE TRITON control module sequences. TRITON can be used simply to prepare cross sections for a NEWT transport calculation and then automatically execute NEWT. TRITON also provides the capability to perform 2D depletion calculations in which the transport capabilities of NEWT are combined with multiple ORIGEN depletion calculations to perform 2D depletion of complex geometries. In the TRITON depletion sequence, NEWT can also be used to generate lattice-physics parameters and cross sections for use in subsequent nodal core simulator calculations.

DENOVO

Denovo [DTESSC10], is a parallel 3D discrete-ordinates code available in SCALE as part of two control module sequences for different applications, as described below. Because Denovo can only be run in SCALE via the Monaco with Automated Variance Reduction using Importance Calculations (MAVRIC) or Denovo Eigenvalue Calculation (DEVC), it is not documented separately in the section entitled "Deterministic Transport" in this manual.

The MAVRIC hybrid Monte Carlo radiation shielding sequence employs the Consistent Adjoint Driven Importance Sampling (CADIS) and Forward-Weighted CADIS (FW-CADIS) methodologies. Denovo is used

to generate adjoint (and, for FW-CADIS, forward) scalar fluxes for the CADIS methods in MAVRIC. This adjoint flux information is then used by MAVRIC to construct a space- and energy-dependent importance map (i.e., weight windows) to be used for biasing during Monte Carlo particle transport and as a mesh-based biased source distribution. For use in MAVRIC/CADIS, it is highly desirable that the S_N code be fast, positive, and robust. The phase-space shape of the forward and adjoint fluxes, as opposed to a highly accurate solution, is the most important quality for Monte Carlo weight-window generation. Accordingly, Denovo provides a step-characteristics spatial differencing option that produces positive scalar fluxes as long as the source (volume plus in-scatter) is positive. Denovo uses an orthogonal, nonuniform mesh that is ideal for CADIS applications because of the speed and robustness of calculations on this mesh type. Denovo can be run stand-alone in MAVRIC to perform fixed source calculations using the *PARM=forward* (for forward Denovo) or *PARM=adjoint* (for adjoint Denovo). See the MAVRIC chapter for details.

The other sequence that uses Denovo is the DEVC sequence. DEVC generates a reasonably accurate starting source through a Denovo eigenvalue calculation. Denovo can be run stand-alone in DEVC for calculating criticality eigenvalue problems. This sequence reads an input file very similar to a CSAS6 input file that contains an extra block of input for describing the Denovo mesh grid and calculational parameters.

9.1 XSDRNPM: A ONE-DIMENSIONAL DISCRETE-ORDINATES CODE FOR TRANSPORT ANALYSIS

L. M. Petrie, N. M. Greene, M. L. Williams

ABSTRACT

XSDRNPM is a discrete-ordinates code that solves the one-dimensional Boltzmann equation in slab, cylindrical, or spherical coordinates. Alternatively, the user can select P_1 diffusion theory, infinite medium theory, or B_n theory. A variety of calculational types is available, including fixed source, eigenvalue, or "search" calculations. In SCALE, XSDRNPM is used for several purposes: eigenvalue (k-effective) determination, cross-section collapsing, shielding analysis, computation of fundamental-mode or generalized adjoint functions for sensitivity analysis, and for producing bias factors for use in Monte Carlo shielding calculations.

ACKNOWLEDGMENTS

W. W. Engle has been very generous with the use of his notes on S_n theory and on discussing details of various procedures in XSDRNPM which were lifted directly from his ANISN program.

The authors also wish to thank R. H. Odegaarden (the former technical monitor at the U.S. Nuclear Regulatory Commission) who supplied the necessary incentives for completing this report.

9.1.1 INTRODUCTION

XSDRNPM is a one-dimensional (1-D) discrete-ordinates transport code and is the latest in a series of codes in the XSDRN [XSDGCJ69] family. As such, it contains several unique characteristics, as will be detailed in this report, though a large portion of the theoretical bases and intended uses of the program are the same for all versions.

9.1.1.1 Functions performed

The function of XSDRNPM is twofold: (1) perform a 1-D discrete-ordinates calculation in slab, cylindrical, or spherical geometry (optionally, a 1-D diffusion theory or infinite medium |Bn| calculation can be made), and (2) use the fluxes determined from its spectral calculation to collapse input cross sections and write these into one of several formats.

A great deal of flexibility is allowed in describing a problem for XSDRNPM. The number of spatial intervals, the number of energy groups, the number of nuclides, the quadrature order, the order of fits to the angular variation in basic cross sections are all arbitrary and are limited only by computer and monetary resources.

The flux calculation can be performed according to several options, including fixed source calculations, k-calculations, and dimension search calculations.

A variety of weighting options are allowed, including zone, cell, or a special "vein" weighting option which is described herein.

Background on XSDRNPM

Development of the XSDRN1 program started in the mid-1960s. The goal was to develop a program that would combine features from the GAM-II, [XSDJD63] ANISN, [XSDEJ67] and THERMOS [XSDHon61] programs in a more unified and general way than would be possible if one simply elected to use these codes individually.

The salient features to be retained from the programs were as follows:

GAM-II
: The Nordheim Integral Treatment was desired for resonance self-shielding; the generality of including cross sections for an arbitrary number of processes, along with the provisions for truncating zero or impossible transfers in the scattering matrices, was also a requirement.

ANISN
: One-dimensional discrete-ordinates or diffusion theory or infinite-medium theory was to be available to generate a spectrum for cross-section collapsing.

THERMOS
: The ability to perform detailed 1-D spectral calculations, including upscatter effects, was required for the thermal region.

The whole code was required to be dynamically dimensioned to allow calculations for arbitrary group structures, spatial structures, angular quadratures, etc.

The XSDRN program that embodied these features was released in 1969.

In the early 1970s, the Defense Nuclear Agency (DNA) initiated support for the AMPX system, which was to be a total cross-section generation system capable of performing all tasks necessary to take basic neutron and gamma-ray cross-section data and process these data into the proper form needed for weapons effects calculations. Since XSDRN already encompassed many of the features needed, it was selected as a basis for modules in the new system. In this case, experience gained in the original construction of XSDRN served to suggest that a more modular approach would have been better with independent tasks being done in separate, smaller, easier-to-manage programs. Therefore, the code was split into NITAWL-II (for resonance self-shielding and some basic cross-section data manipulation) and XSDRNPM (for spectral calculations and cross-section collapsing). In retrospect, if the AMPX development were initiated today, XSDRN would have been split even further, into perhaps as many as six or seven programs.

The XSDRNPM module differs from XSDRN in several respects:

- It will perform coupled neutron-gamma calculations.
- It allows any mixture to be represented to an arbitrary order of anisotropic representation, whereas XSDRN only allowed through order 3.

- It will perform an adjoint calculation, whereas the option was never provided in XSDRN. In 2010, a generalized adjoint solution was also added.
- It is considerably more efficient in the manner in which data storage is used and, hence, will run much larger problems in less core storage.
- It employs improved thermal flux scaling techniques for better problem convergence.
- Input specifications have been reordered, and more defaults have been provided to make the use of this module easier.
- It will calculate S_n constants for any order for any of the three 1-D geometries available.
- Mixture-dependent fission spectra are calculated and used in XSDRNPM, which takes into account all fissionable nuclides in a problem.

AMPX was released in 1976, about the same time as the U.S. Nuclear Regulatory Commission (NRC) support for the SCALE system was initiated. Although separate versions of XSDRNPM were initially maintained for AMPX and SCALE, in recent years the same version is used for the two systems.

9.1.1.2 Applications in SCALE

XSDRNPM is used in several places in SCALE. In SAS1, XSDOSE uses fluxes from a 1-D shielding calculation to determine a dose rate. Within the CSAS5 and CSAS6 control modules, XSDRNPM is used in the sequences to perform eigenvalue calculations and cell weighting of cross sections. TSUNAMI-1D uses XSDRN to compute forward and adjoint fluxes (fundamental-mode and generalized adjoint) for sensitivity and uncertainty analysis.

Notes on the use of various spectral calculational options

As noted earlier, four options are available in XSDRNPM for calculating fluxes, k-effectives, etc.:

1. S_n theory,
2. diffusion theory,
3. infinite medium theory, and
4. B_n theory.

However, XSDRNPM is primarily an S_n code. The latter three options are provided for reasons of completeness and are not nearly as optimized as they would be in other codes for which these are the primary spectral calculation options.

Without a very detailed calculational study, it is perhaps impossible to be able to quantify the degree of adequacy or inadequacy of any of these methods for performing a particular problem. However, some general comments can be made which may provide some guidance with their selection.

First, S_n theory is the most correct of the options and will solve a larger class of problems. It is the most complicated and time-consuming of the four, but it still runs very fast for most cases. There are problems for which it (or some alternative method based on a solution of the Boltzmann equation) is the only one of the four methods which is adequate. Many shielding applications fall in this class. In deep-penetration problems, anisotropic effects can dominate, thus requiring an accurate treatment of the anisotropy of both flux and cross section. It is well known that diffusion theory is not very accurate when used to calculate systems involving regions of very dissimilar cross-section values, such as is the case when control rods are interspersed in a reactor core. Because of the anisotropy involved in gamma-ray problems, S_n theory should be used.

Diffusion theory, on the other hand, is certainly the most successful of the four methods in terms of the amount of use it has for designing reactors, etc. In cases involving reasonably large, homogeneous regions, it is generally adequate, such as is the case for a large class of "reactor" applications. For most problems, the diffusion theory option should run appreciably faster than S_n theory, since it has essentially one equation to solve, versus number-of-angles equations for S_n theory. This equation also can be explicitly solved using a matrix inversion procedure, whereas the S_n theory requires a more time-consuming iterative procedure. However, in many cases with large numbers of groups (200 to 300), the greater fraction of the calculational time can be spent calculating the scattering source terms, which tends to lessen the impact of time spent on a more correct theory. (This same observation can also be made of the infinite medium and B_n method.)

The infinite medium option is the fastest of the four methods and can be used safely to perform calculations for large homogeneous regions, wherein the spectrum may be needed to collapse cross sections. This option only determines the first moment of the flux, and is, therefore, quite suspect for many applications, such as calculating diffusion coefficients.

The B_n option shares many of the same restrictions as the infinite-medium method; however, this treatment does (as its name implies) use a buckling approximation to account for leakage from the large homogeneous region, thereby giving higher order flux moments that can be used, for example, to determine diffusion coefficients.

9.1.1.3 Selection of output cross-section library formats

XSDRNPM will, on option, collapse cross sections and write the collapsed sets into four different formats:

1. ANISN3 BCD Library,
2. ANISN3 Binary Library,
3. CCCC [XSDCar74] ISOTXS Library, or
4. AMPX [XSDWWCD15] Working Library.

The choice of the output cross-section format is determined by the computer code that will use the data. XSDRNPM always produces an AMPX working library when cross sections are collapsed, and all other formats are produced by reformatting data from this library. Therefore, for archival purposes, if a collapsed library is to be saved, the working format is the best choice, because it is the most general of those provided. AMPX working libraries are used by all multi-group transport codes currently in SCALE, including DENOVO (3D orthogonal mesh discrete ordinates code), NEWT (2D arbitrary mesh discrete ordinates code), and KENO and MONOCO (multigroup Monte Carlo codes. Stand-alone modules exist for converting AMPX working libraries to the other formats.

ANISN formats are used by older ORNL transport codes such as ANISN (a 1-D discrete-ordinates code), by DORT/TORT [XSDRSCEJ79] [two-dimensional (2-D) and three dimensional (3D) discrete-ordinates codes], and by MORSE [XSDEme75] (a multigroup Monte Carlo code). The formats are quite comprehensive and can handle coupled neutron-gamma calculations, arbitrary orders of anisotropy, upscattering, etc. The major shortcoming of the format is its lack of internal documentation as to its structure (e.g., no provisions exist for specifying where a particular kind of cross section is located in the library or even if it is included). ANISN libraries can be produced in a free-form card-image BCD format or in a binary form.

The CCCC (Committee on Computer Code Coordination) ISOTXS file is a format for neutron cross sections that is one of several "standard interfaces" developed to facilitate the exchange of data between different computer codes. It is a self-defined format, which has provisions for identifying cross sections in the library. Scattering matrices can be supplied for elastic, inelastic, and (n,2n) scattering.

9.1.2 THEORY AND PROCEDURES

This section describes the models and procedures which are employed in XSDRNPM.

9.1.2.1 One-dimensional discrete-ordinates theory

The time-independent Boltzmann transport equation can be written:

$$\vec{\Omega} \bullet \nabla\psi(\vec{r}, E, \vec{\Omega}) + \sum_i (\vec{r}, E)\psi(E, \vec{r}, \vec{\Omega}) = S(\vec{r}, E, \vec{\Omega}) \tag{9.1.1}$$

This expression is a balance condition that states simply that losses due to leakage (first term) and collisions (second term) must equal the source of neutrons, at some point in space r energy E, and in direction Ω per unit volume and energy and solid angle. Other terms in the expression are $\sum_t(r, E)$ the total macroscopic cross section of the medium, which is typically assumed isotropic, and the flux, $\psi(r, E, \Omega)$.

The source term $S(r, E, \Omega)$ has three components:

1. a scattering source, $S(r, E, \Omega)$,
2. a fission source, $F(r, E, \Omega)$, and
3. a fixed source, $Q(r, E, \Omega)$.

The scattering source is given by:

$$S(r, E, \Omega) = \int_0^{4\pi} d\Omega' \int_0^{\infty} dE' \sum_s (r, E' \rightarrow E, \Omega' \rightarrow \Omega)\, \psi(r, E', \Omega') \Bigg). \tag{9.1.2}$$

The fission source term, typically, is written

$$F(r, E, \Omega) = \frac{1}{4\pi k}\chi(r, E) \int_0^{4\pi} d\Omega' \int_0^{\infty} dE' \nu(r, E')\, \Sigma_f(r, E')\, \psi(r, E', \Omega'), \tag{9.1.3}$$

where $\sum_s (r, E' \rightarrow E, \Omega' \rightarrow \Omega)$ is the macroscopic scattering cross section per unit energy for scattering from energy E' to E, $\chi(r, E)$ is the fraction of the fission neutrons per unit energy produced at r and E, $\upsilon(r, E)$ is the average number of neutrons produced per fission, $\sum_f(r, E)$ is the macroscopic fission cross section and k is the "effective multiplication constant." Note that, as in the case of the total cross-section value, χ,Σf, and υ are assumed to be isotropic. XSDRN computes a weighted-averaged fission spectrum based on the fissionable materials at r.

Three common coordinate systems are shown in Fig. 9.1.1. XSDRNPM is a 1-D code, which means that in the case of the slab, it is calculating at points along one axis where the system is assumed to extend to infinity along the other two axes. If we assume a calculation along the x-axis, this says that there is no leakage in the y or z directions, and our directions by angles referenced to the x-axis. In the case of the cylinder, the length (z-axis) is infinite and the calculation is for points (shells) located at distance r from the central axis. For the sphere, the calculation is of shells located at radius, r, from the center of the spherical system.

Fig. 9.1.2 illustrates the 1-D coordinate systems for slabs, cylinders, and spheres. Note that the directions are cones in the case of the slab and sphere, whereas in the case of the cylinder, the same simple symmetries do not hold (a cone around the radius does not strike the next cylindrical shell at the same distance from a point on a radius) and the directions must be specifically described. Symmetries in the 1-D cylinder, however, allow one to only describe directions for one quadrant of the direction sphere about a point as will be noted in Sect. 9.1.2.2.

The 1-D geometries allow considerable simplification to be made to Eq. Eq. (9.1.1), especially in the leakage term $\bar{\Omega} \bullet \nabla\psi$. It is traditional to calculate the angular flux as a function of angles expressed in direction-cosine units; i.e., $\mu = \cos\phi$ and $\eta = \cos\xi$. This requires $\psi(x, E, \mu)$ for slabs, $\psi(x, E, \mu, \eta)$ for cylinders and $\psi(r, E, \mu)$ for spheres. Table 9.1.1 gives leakage terms expressed in conservation form for the three geometries.

Table 9.1.1: One-dimensional leakage terms.

Geometry	$\vec{\Omega} \bullet \nabla\psi$
Slab	$\mu\frac{\partial\psi}{\partial x}$
Cylinder	$\frac{\mu}{r}\frac{\partial(r\psi)}{\partial r} - \frac{1}{r}\frac{\partial(\eta\psi)}{\partial\phi}$
Sphere	$\frac{\mu}{r^2}\frac{\partial(r^2\psi)}{\partial r} + \frac{1}{r}\frac{\partial[(1-\mu^2)\psi]}{\partial\mu}$

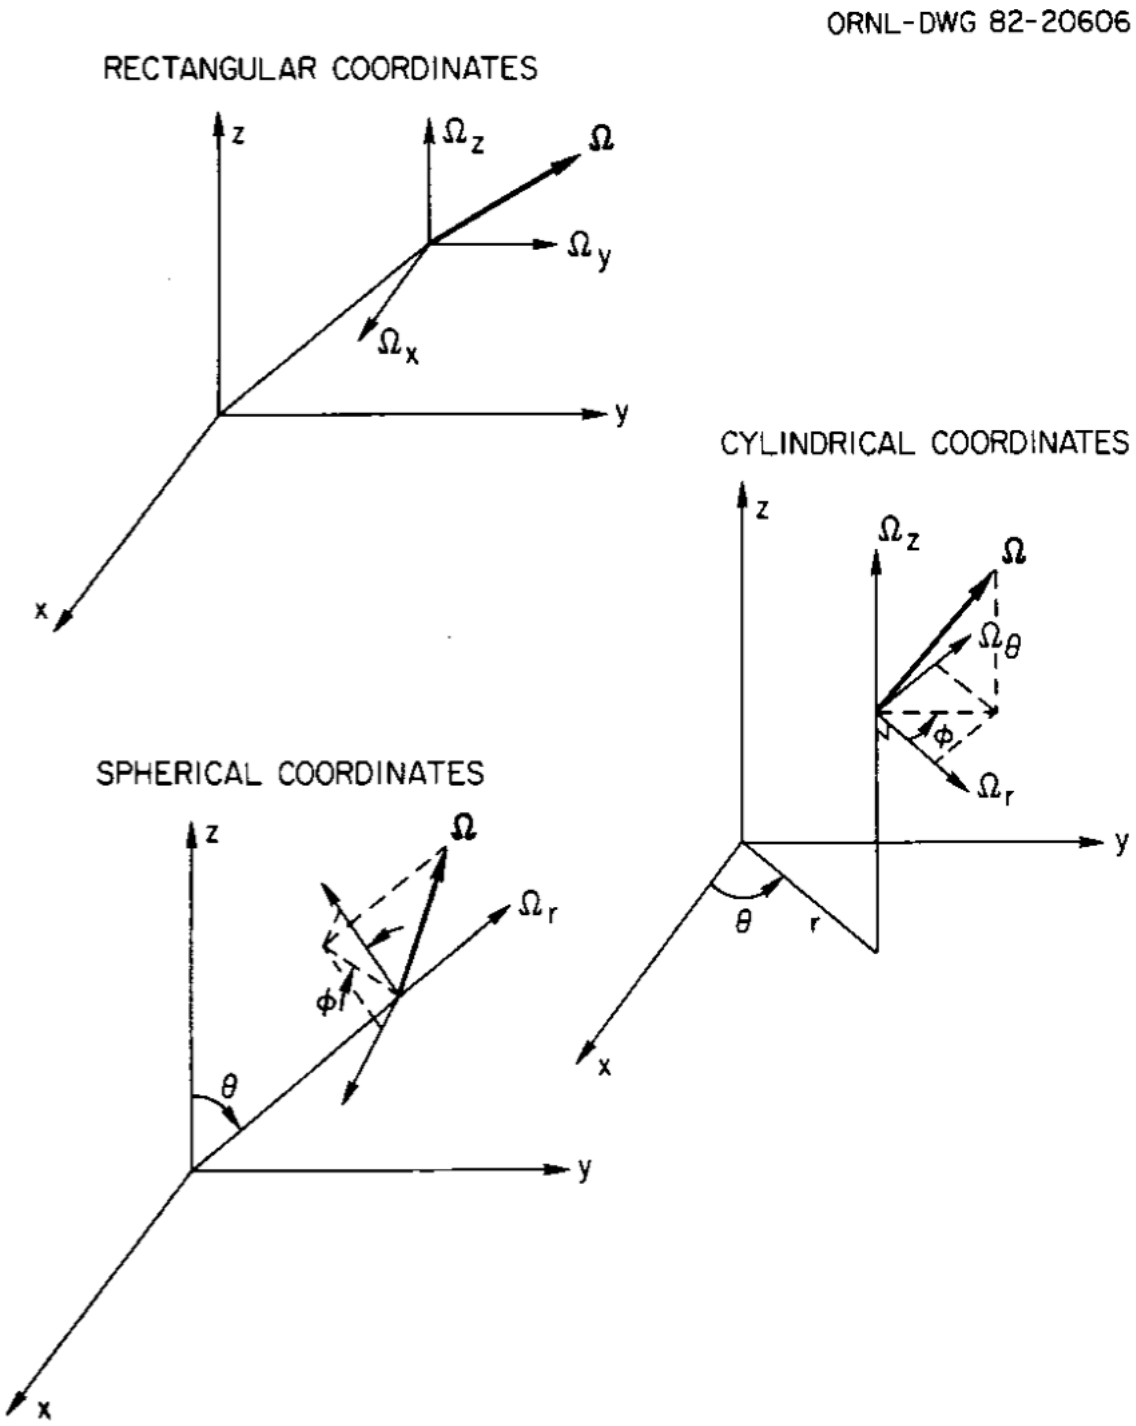

Fig. 9.1.1: Three common coordinate systems.

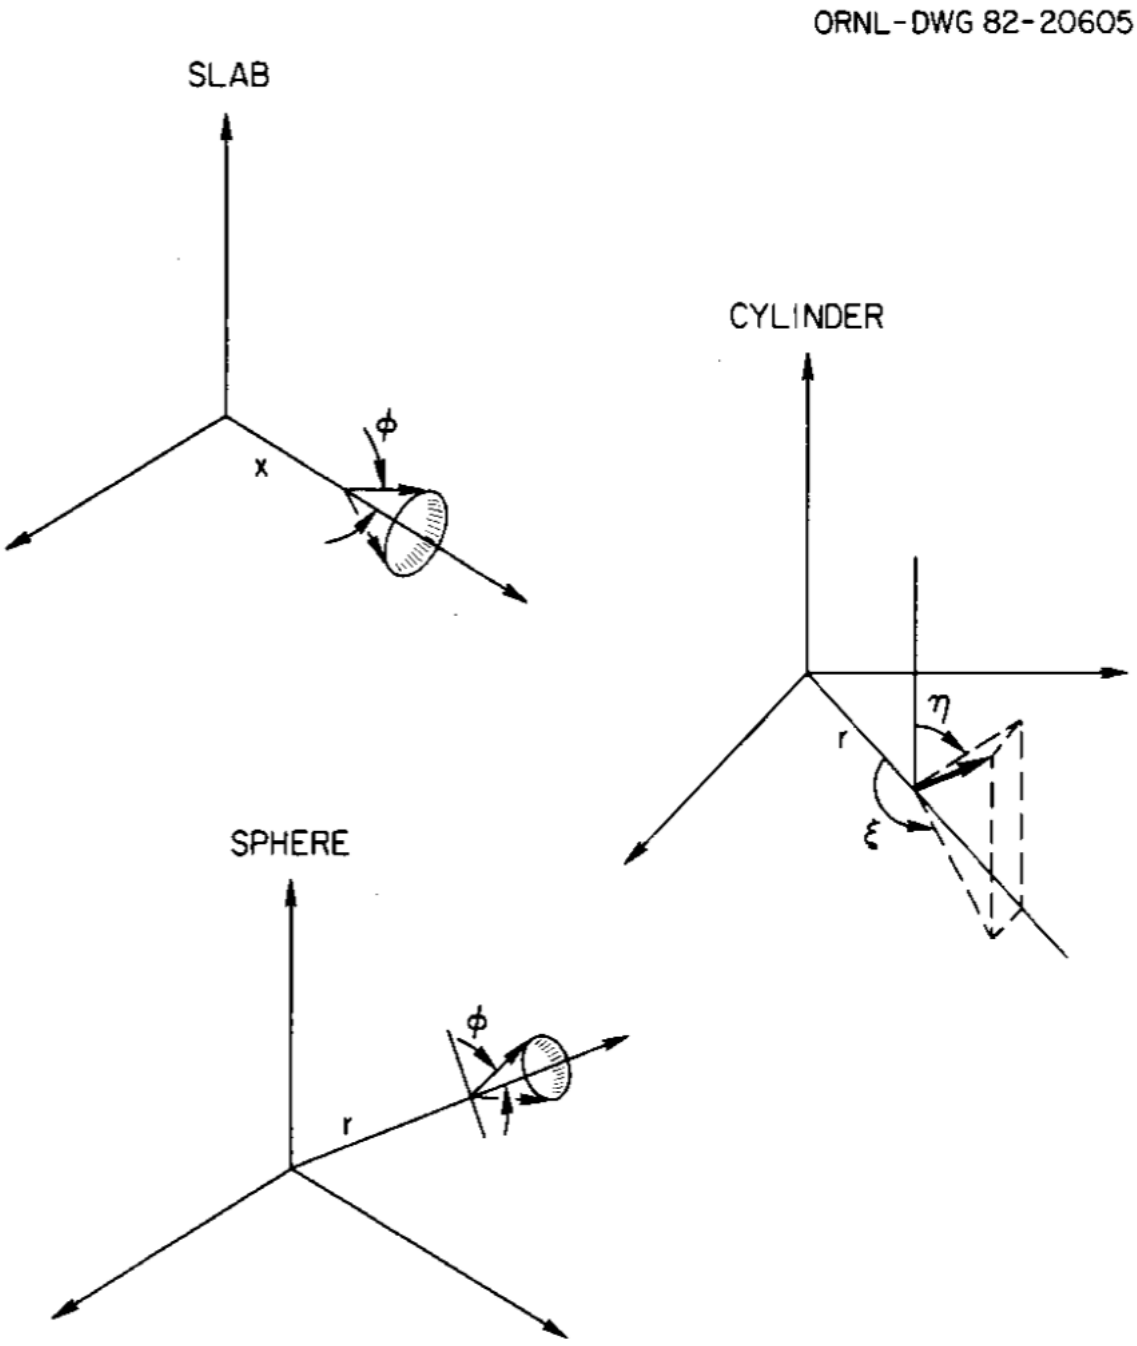

Fig. 9.1.2: Three 1-D coordinate systems.

9.1.2.2 Multigroup one-dimensional Boltzmann equation

In multigroup schemes, the continuous-energy (CE) balance equations are converted to multigroup form by first selecting an energy structure and then writing a multigroup equivalent of the point equation which requires multigroup constants that tend to preserve the reaction rates that would arise from integrating the CE equations by group. First we define the following multigroup values for g,

$$\psi_g(x,\mu) = \int_g dE\psi(x,E,\mu) \tag{9.1.4}$$

and

$$\psi_g(x) = \int_{-1}^{1} d\mu\psi_g(x,\mu) \tag{9.1.5}$$

and

$$\Sigma_{tg}(x) = \frac{\int_g dE\Sigma_{tg}(x,E)W(x,E)}{\int_g dEW(x,E)}, \tag{9.1.6}$$

where *W(x.E)* is the weighting function used to compute the multigroup cross sections at a particular location. To rigorously conserve reaction rates, the weight function should be angle-dependent, but this causes the multigroup cross section to vary with direction; therefore the usual approach is to represent the weight function by an approximation to the scalar flux spectrum. In energy ranges where the CE cross sections have fine-structure due to resonances, the multigroup data must be self-shielded prior to the multigroup transport calculations.

The following multi-group form of 1-D equation can be derived for the slab case:

$$\mu\frac{\partial\psi_g(x,\mu)}{\partial x} + \sum_{tg}(x)\psi_g(x,\mu) = S_g(x,\mu) + F_g(x,\mu) + Q_g(x,\mu). \tag{9.1.7}$$

The equations for the cylinder and sphere are essentially the same, in this notation, except for the differences in the leakage terms from Table 9.1.1.

In Eq. Eq. (9.1.7) , S_g, F_g, and Q_g are the scattering, fission, and fixed sources, respectively. The scattering term is discussed in Sect. 9.1.2.3. The multigroup form of the fission source is

$$F_g(x,\mu) = \frac{\chi_g}{2\pi k}\sum_{g'}\overline{\nu\sum_{fg'}}(x)\psi_{g'}(x), \tag{9.1.8}$$

where χ_g is the fraction of the fission neutrons that are produced in group g, and $\overline{\nu\Sigma_{fg'}}$ is the average of the product of ν, the average number of neutrons produced per fission and Σ_f, the fission cross section.

9.1.2.3 Scattering source term

In discrete-ordinates theory, one typically calculates the Legendre moments of the flux, $\psi_{g,l}$, defined for slab and spherical geometries by

$$\psi_{g,l} = \frac{1}{2}\int_{-1}^{1} d\mu\psi_g(\mu)P_1(\mu). \tag{9.1.9}$$

Cylindrical geometry has a similar expression containing spherical harmonic functions rather than Legendre polynomials, shown in the next section.

The group-to-group scattering coefficients are, themselves, fit with Legendre polynomials, such that

$$\sigma\left(g' \rightarrow g, \mu\right) = \sum_{l=0}^{ISCT} \frac{2l+1}{2} \sigma_l\left(g' \rightarrow g\right) P_l(\mu). \tag{9.1.10}$$

In this example, we have a fit of order ISCT.

Note: AMPX cross-section libraries contain the $2l + 1$ factor in the $\sigma_t\left(g' \rightarrow g\right)$ matrix.

Slab and Spherical Geometries

Because of the symmetries in 1-D slabs and spheres, only one angle is needed to describe a "direction." In the case of the slab, the angle is taken with reference to the x-axis, while for the sphere; it is with reference to a radius vector between the point and the center of the sphere. This means that the flux can be expanded in ordinary Legendre polynomials, such that

$$\begin{array}{l} \psi(r, E, \mu) = \sum_{l=0}^{\infty} \psi_l(r, E) P_l(\mu) \\ \psi_l(r, E) = \int_{-1}^{1} \frac{d\mu}{2} P_l(\mu) \psi(r, E, \mu) \end{array} . \tag{9.1.11}$$

When Eq. Eq. (9.1.11) and Eq. Eq. (9.1.10) are introduced into Eq. Eq. (9.1.2), the following expression is derived for the scattering source:

$$S\left(r, E, \mu\right) = 2\pi P_l(\mu) \int_0^{\infty} dE' \int_{-1}^{1} d\mu' \sum_{l=0}^{ISCT} \frac{2l+1}{2} \sum_{s_l} \left(r, E' \rightarrow E\right) P_l\left(\mu'\right) \psi_l\left(r, E'\right) \tag{9.1.12}$$

where *ISCT* is the order of fit to the fluxes and cross sections.

Cylindrical Geometry

The situation is more complicated in the case of the 1-D cylinder where the flux (and cross section) must be given as a function of two angles. Consider Fig. 9.1.3.

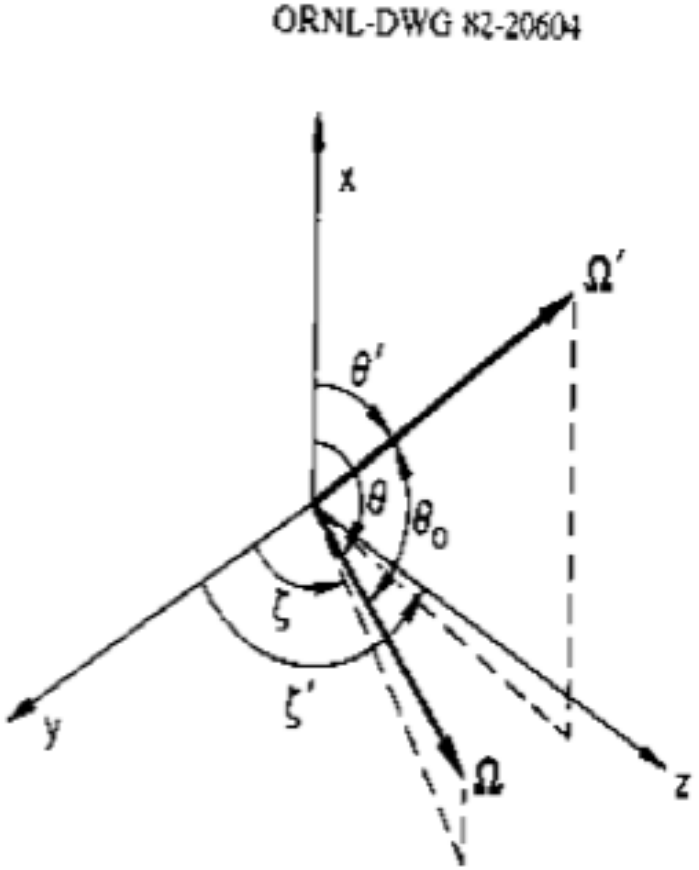

Fig. 9.1.3: One-dimensional cylindrical scattering coordinates.

The addition theorem for associated Legendre polynomials can be used to transform from scattering angle coordinates to the real coordinates required in the cylindrical case:

$$P_l(\mu_0) = \sum_{n=-1}^{1} \frac{(l-n)!}{(l+n)!} P_l^n(\mu) P_l^n(\mu') e^{in(\zeta-\zeta')}, \tag{9.1.13}$$

where $\mu_0 = \cos\theta_0$; $\mu = \cos\theta$ and $\mu' = \cos\theta'$.

If we note that

$$\begin{aligned} \sigma_s(r, E' \to E, \Omega' \to \Omega) &= \sigma_s(r, E' \to E), P_l(\Omega' \bullet \Omega) \\ &= \sigma_s(r, E' \to E), P_l(\mu_0) \end{aligned} \tag{9.1.14}$$

Eq. Eq. (9.1.13) can be introduced into Eq. Eq. (9.1.2) to yield

$$S(r,E,\mu) = \int_0^\infty dE' \int_{-1}^{1} d\mu' \int_0^{2x} d\zeta \psi(r,E',\mu',\zeta') \sum_{l=0}^{ISCT} \frac{2l+1}{2} \sigma_{s_l}(r,E' \rightarrow E) \times \sum_{n=-1}^{l} \frac{(l-n)!}{(l+n)!} P_l^n(\mu) P_l^n(\mu') e^{in(\zeta-\zeta')} \quad . \tag{9.1.15}$$

Now it is convenient to recall that

$$\cos x = \frac{e^{+ix} + e^{-ix}}{2}, \tag{9.1.16}$$

which can be introduced into Eq. Eq. (9.1.15) and rearranged to give

$$\begin{aligned} S(r,E,\mu) = & \sum_{l=0}^{ISCT} \frac{2l+1}{2} \int_0^\infty dE' \sigma_{s_l}(r,E' \rightarrow E) \left[P_l(\mu) \int_{-1}^{1} d\mu' \int_0^{2\pi} d\zeta \psi(r,E',\mu',\zeta') P_l(\mu') \right] \\ & + \sum_{n=1}^{l} 2 \frac{(l-n)!}{(l+n)!} P_l^n(\mu) \left[\int_{-1}^{1} d\mu' \int_0^{2\pi} d\zeta \psi(r,E',\mu',\zeta') P_l^n(\mu') \cos\left[n(\zeta-\zeta')\right] \right] \end{aligned} \quad . \tag{9.1.17}$$

We now define moments of the flux, ψ_l by

$$\phi_l(r,E) = \int_{-1}^{1} d\mu' \int_0^{2\pi} d\zeta \psi(r,E,\mu',\zeta') P_1(\mu') \tag{9.1.18}$$

It is also convenient to make use of the trigonometric relationship

$$\cos\left[n(\zeta-\zeta')\right] = \cos n\zeta \cos n\zeta' + \sin n\zeta \sin n\zeta', \tag{9.1.19}$$

and

$$\psi_l^n(r,E) = \sqrt{2 \frac{(l-n)!}{(l+n)!} \int_{-1}^{1} d\mu'} \int_0^{2\pi} d\zeta \psi(r,E,\mu',\zeta') P_l^n(\mu') \sin n\zeta' \tag{9.1.20}$$

With a 1-D cylinder, the flux is symmetric in ζ; therefore, it is an even function, and the terms involving sin n ζ will vanish. This fact yields the following expression for Eq. Eq. (9.1.17) :

$$\begin{aligned} S(r,E,\mu) = & \sum_{l=0}^{ISCT} \frac{2l+1}{2} \int_0^\infty dE' \sigma_{s_l}(r,E' \rightarrow E) \\ & P_l(\mu) \psi_l(r,E') + \sum_{n=l}^{l} \sqrt{2 \frac{(l-n)!}{(l+n)!}} P_n^l(\mu) \cos n\zeta \psi_l^n(r,E) \Big] \end{aligned} \tag{9.1.21}$$

We observe further that for an even function in ζ, the odd l and odd (l-n) moments must all vanish, such that the following moments are nonzero for various orders of scattering:

ISCT	Nonzero flux moments
0	ψ_0
1	ψ_0, ψ_1^1
2	$\psi_0, \psi_1^1, \psi_2, \psi_2^2$
3	$\psi_0, \psi_1^1, \psi_2, \psi_2^2, \psi_3^1, \psi_3^3$
4	$\psi_0, \psi_1^1, \psi_2, \psi_2^2, \psi_3^1, \psi_3^3, \psi_4, \psi_4^2, \psi_4^4$

In general, [ISCT(ISCT + 4)/4] + 1 flux moments are required.

9.1.2.4 Discrete-ordinates difference equations

In formulating the S_n equations, several symbols are defined which relate to a flux in an energy group g, in a spatial interval i, and in an angle m.

Typically, the flux is quoted as an integral of the flux in an energy group g, whose upper and lower bounds are E_g^U and E_g^L respectively.

$$\psi_g = \int_{E_g^L}^{E_g^U} dE\psi(E). \tag{9.1.22}$$

A mechanical quadrature is taken in space, typically IM intervals with IM + 1 boundaries. Likewise, an angular quadrature is picked compatible with the particular 1-D geometry, typically MM angles with associated directional coordinates and integration weights.

The different equations are formulated in a manner which involves calculating so-called angular fluxes, $\psi_{g,i,m}$ at each of the spatial interval boundaries, and also cell-centered fluxes, $\psi_{g,i+1/2,m}$ at the centers of the spatial intervals. The centered fluxes are related to the angular boundary fluxes by "weighted diamond difference" assumptions as will be described below.

Units on angular fluxes are per unit solid angle w_m and per unit area. Units on the centered fluxes are track length per unit volume of the interval. In both cases the fluxes are integrated in energy over the group g.

The areas and volumes for the three geometries are listed in Table 9.1.2

Table 9.1.2: One-dimensional areas and volumes.

Geometry	Area	Volume
Slab	1.0	$x_{i+1} - x_i$
Cylinder	$2\pi r_i$	$\pi\left(r_{i+1}^2 - r_i^2\right)$
Sphere	$4\pi r^2$	$4/3\pi\left(r_{i+1}^3 - r_i^3\right)$

Discrete-ordinates equation for a slab

Consider a spatial cell bounded by (x_i, x_{i+1}) and write the loss term for flow through the cell in direction μ_m. The net flow in the x-direction out the right side is the product of the angular flux times the area times the solid angle times the cosine of the angle:

$$w_m\mu_m A_{i+1}\psi_{g,i+1,m}. \tag{9.1.23}$$

The net loss from the cell is the difference between the flow over both boundaries:

$$w_m\mu_m\left(A_{i+1}\psi_{g,i+1,m} - A_i\psi_{g,i,m}\right). \tag{9.1.24}$$

The loss in the spatial cell due to collisions is given by the product of the centered angular flux (in per unit volume units) times the total macroscopic cross section times the solid angle times the volume:

$$w_m\sigma_{g,i+1/2}V_i\psi_{g,i+1/2}, m. \tag{9.1.25}$$

The sources in direction μ_m are given by the product of the solid angle times the interval volume times the volume-averaged source (sum of fixed, fission, and scattering) in the direction m:

$$w_m V_i S_{g,i+1/2}, m. \tag{9.1.26}$$

The slab equation is obtained by using Eqs. Eq. (9.1.24), Eq. (9.1.25), and Eq. (9.1.26) and substituting proper values for area and volume:

$$w_m\mu_m\left(\psi_{g,i+l,m}-\psi_{g,i,m}\right)+w_m\sigma_{g,i+1/2}\psi_{g,i+1/2,m}\left(x_{i+l}-x_i\right)=w_mS_{g,i+1/2'm}\left(x_{i+l}-x_i\right). \tag{9.1.27}$$

In an MM angle quadrature set, there are MM of these equations and they are coupled through the assumption on how the cell-centered flux relates to the boundary angular fluxes, the sources, and the boundary conditions, as will be discussed later.

Discrete-ordinates equations for sphere and cylinder

The development of the equations for these geometries is analogous to that for the slab except that the leakage terms are more complicated. Consider Fig. 9.1.4.

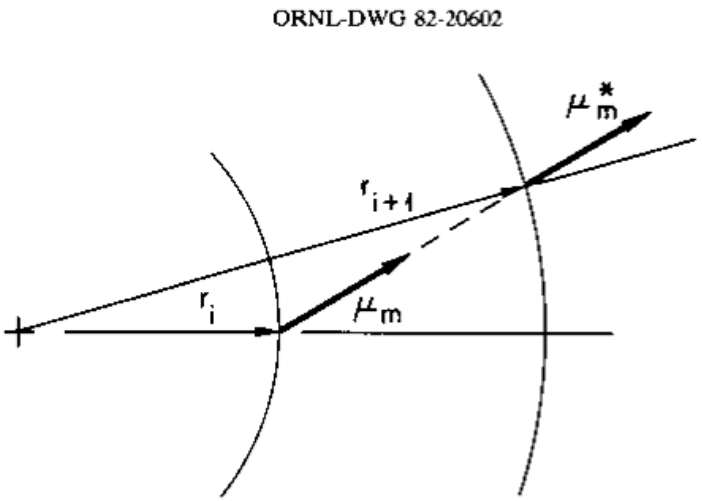

Fig. 9.1.4: Angular redistribution in spherical geometry.

Recall that the directions are taken with reference to the radius vector for a sphere. A particle traveling in direction μ_m at r_i will intersect the radius vector to the next point r_{i+1} at a different angle μ_m^*. The same effect also exists for the cylinder, though in this case the direction coordinates are more complicated. Because of the effect, a loss term is included for the "angular redistribution." It is defined in a manner analogous to Eq. Eq. (9.1.24) as

$$\alpha_{i+1/2},m+1/2\quad\psi_{g,i+1/2,m+1/2}-\alpha_{i+1/2,m-1/2}\psi_{g,i+1/2,m-1/2} \tag{9.1.28}$$

where the α coefficients are to be defined in such a manner as to preserve particle balance. In this case one speaks of $m+1$ and $m-1/2$ as the corresponding angles to μ_m on the I + lth and ith boundaries, respectively. (See Fig. 9.1.5) Here we are interested in an angle μ_m at the center of interval i which redistributes to $\mu_{m-\frac{1}{2}}$ at boundary i and to $\mu_{m+\frac{1}{2}}$ at boundary I + 1.

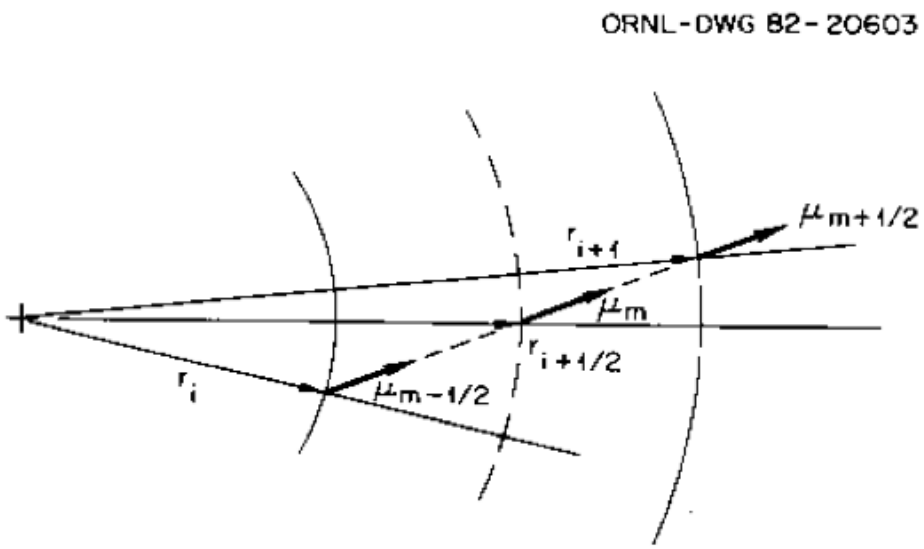

Fig. 9.1.5: Angular redistribution.

Obviously, it is necessary that the net effect of all redistributing be zero, in order to maintain particle balance. This condition is met if

$$\sum_{m=1}^{MM} \alpha_{m-1/2}\psi_{m-1/2} + \alpha_{m+1/2}\psi_{m+1/2} = \alpha_{1/2}\psi_{1/2} + \alpha_{MM+1/2}\psi_{MM+1/2} = 0, \tag{9.1.29}$$

where we have dropped the group and interval indexes.

In order to develop an expression for determining the α's consider an infinite medium with a constant isotropic flux. In this case, there is no leakage and the transport equation reduces to

$$\sum_t \phi = S. \tag{9.1.30}$$

This condition requires that

$$\mu_m w_m \left(A_{i+1}\psi_{g,i+1,m} - A_i\psi_{g,i,m}\right) + \alpha_{i+1/2}, m + 1/2 \quad \psi_{g,i+1/2}, m + 1/2 - \alpha_{i+1/2,m-1/2}\psi_{g,i+1/2,m-1/2} = 0, \tag{9.1.31}$$

which when we note that all the ψ terms in the infinite medium case are equal becomes

$$\mu_m w_m \left(A_{i+1} - A_i\right) = -\alpha_{m+1/2} + \alpha_{m-1/2}, \tag{9.1.32}$$

which is a recursion relationship for α.

From Eq. Eq. (9.1.29) we see that the conservation requirement can be met if

$$\alpha_{1/2} = \alpha_{MM+1/2} = 0 \tag{9.1.33}$$

for any values of flux, and is, therefore, used to evaluate the α's along with Eq. eq:*eq9-1-27* or eq:*eq9-1-28*. (Note that had we included the redistribution term in the slab equation, Eq. eq:*eq9-1-28* would have given zeroes for the terms, which is as one would expect for this geometry.)

The final discrete-ordinates expression for spheres and cylinders is then derived by summing expressions Eqs. eq:*eq9-1-20*, eq:*eq9-1-24*, eq:*eq9-1-21* and setting it equal to expression Eq. eq:*eq9-1-22*.

S_n quadratures for slabs

XSDRNPM will automatically calculate quadrature sets for each of the 1-D geometries, or a user can, if he wants, input a quadrature.

In the case of the 1-D slab, the quadrature is a double Gauss-Legendre set based on recommendations from [XSDCL65].

The ordering of the directions for a slab is shown in Fig. 9.1.6.

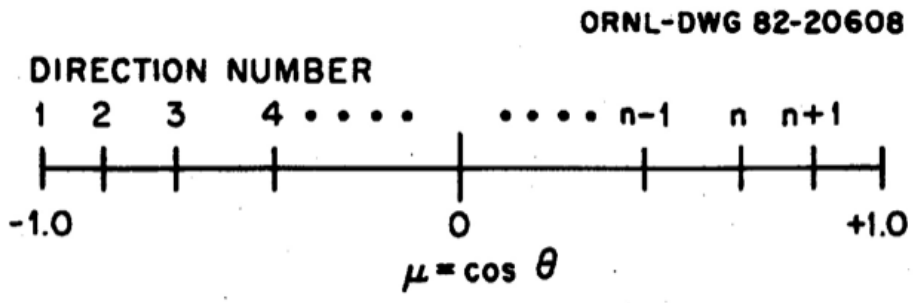

Fig. 9.1.6: Ordering of S_n directions for slabs and spheres.

Note that in referring to the quadratures for any of the geometries, we do not attempt to define an explicit area on a unit sphere, but rather speak of characteristic directions with associated weights. In the case of the slab, it is convenient to think of "directions" which are shaped like cones, because of the azimuthal symmetry around the x-axis.

In an nth order quadrature, there are n +1 angles with the first angle being taken at $\mu = -1.0$. This first angle is not required for the slab, but is needed for the curvilinear geometries because of the angular redistribution terms, as will be noted later. It is included in the slab case for reasons of uniformity of programming, etc.

Several requirements are made regarding the angles and weights in the quadrature set.

The arguments relating to angular redistribution can be expected to show that

$$\sum_{m=1}^{MM} \mu_m w_m = 0.0. \tag{9.1.34}$$

This situation is ensured if the weight of the $\mu = -1.0$ direction is zero and the other directions and weights are symmetric about $\mu = 0$. (The $\mu = 0$ direction is never included in the quadrature set because of its singularity.)

Further, it is required that

$$\sum_{m=1}^{MM} w_m = 1.0. \tag{9.1.35}$$

Due to the above normalization of the quadrature weights, the discrete ordinates angular flux is not "per steradian" but rather "per direction-weight". The calculated angular flux can be converted to steradians by dividing by 4π.

S_n *quadratures for spheres*

The quadratures generated for spheres are Gauss-Legendre coefficients as recommended by [XSDEme75].

The ordering and symmetry requirements for spheres are the same as for slabs.

In the case of the sphere, the initial ($\mu = -1.0$) direction is required, because the difference equations involve three unknown values for each direction, $\mu_m : \psi_m$ and the fluxes at the two "redistributed" angles $\psi_{m-\frac{1}{2}}$ and $\psi_{m+\frac{1}{2}}$. It is obvious that an angle along the radius will not involve the redistribution; hence, the expression for this direction involves only ψ ($\mu = -1.0$) as unknowns. Angle 2 proceeds by assuming $\psi_{2-\frac{1}{2}}$ is given by ψ_1 and also uses a weighted diamond difference model to relate ψ_m, $\psi_{m-\frac{1}{2}}$, $\psi_{m+\frac{1}{2}}$, as will be described below. Subsequent angles will then have values for $\psi_{m-\frac{1}{2}}$ calculated by the previous angle equations.

S_n *quadratures for cylinders*

The quadrature sets for cylinders are more complicated (see Fig. 9.1.2) because the directions must be specified with two angles, ξ and η where $\alpha = \sin\ \eta\ \cos\ \xi$ and $\beta = \cos\eta$.

In this case, practice is to use n/2 levels of directions for an n*th* order set. The levels correspond to fixed values of *eta*. The number of angles by level starts with three in level 1, five in level 2, seven in level 3, etc. (Note that since cylindrical geometry is curvilinear, each level will start with a $\eta = \pi$ direction that has zero weight for reasons analogous to those given for the spherical case. Fig. 9.1.7 shows the ordering of the directions for an S_6 quadrature set. Angles 1, 4, and 9 are the starting directions (zero weight) for the levels.

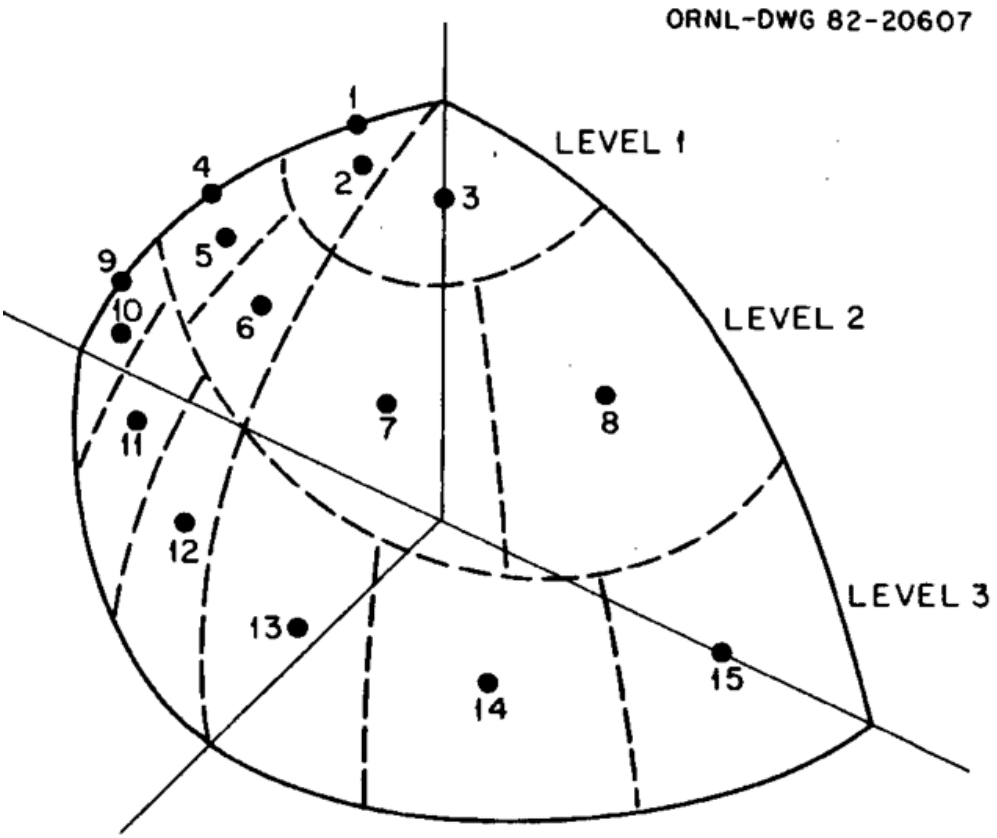

Fig. 9.1.7: Ordering of the directions for an S_6 cylindrical set.

In general, an n*th* order quadrature will contain n(n + 4)/4 angles. The cosines, μ, and the weights are stored in two arrays internally in the code; and, since the weights for the 1*st*, 4*th*, and 9*th* angles are zero, the cosines for the corresponding levels are placed in these locations in the arrays.

The cylindrical sets are based on Gauss-Tschebyscheff schemes as recommended by [XSDEme75] with Gaussian quadratures in β and Tschebyscheff quadratures in α.

9.1.2.5 Weighted-difference formulation for discrete-ordinates equations

In order to solve the discrete-ordinates equations, an assumption is required concerning the relationship of the various flux terms: $\psi_{i,m}, \psi_{i+1,m}, \psi_{i+1/2,m}, \psi_{i,m-1/2}, \psi_{i+1,m-1/2}$.

The solution of the equations involves three major loops: an outer loop over energy groups, a loop over angles, and a loop over the spatial mesh. The spatial loop is made either from the origin to the outside boundary or from the outside to the origin, depending on whether the angle is directed outward or inward, respectively.

Two models are widely used for expressing flux relationships: (1) the step model and (2) the diamond-difference linear model.

The "step model" is a histogram model whereby one sets the centered flux value to the appropriate boundary value, depending on which way the mesh sweep is going. If, for example, the sweep is to the right in space, then

$$\psi_{i+1/2,m} = \psi_{i,m} \tag{9.1.36}$$

or if to the left,

$$\psi_{i+1/2}, m = \psi_{i+1,m}. \tag{9.1.37}$$

Likewise, in angle:

$$\psi_{\mathrm{i}+1/2}, m = \psi_{i+1,m-1/2}. \tag{9.1.38}$$

The step model involves a very crude approximation, but has the marked advantage of helping to ensure positivity of flux values as long as scattering sources are positive.

In the "diamond-difference" model, the centered fluxes are assumed linear with the edge values:

$$\begin{aligned} \psi_{i+1/2} &= 0.5\,(\psi_i + \psi_{i+1}) \\ \psi_m &= 0.5\,(\psi_{m-1/2} + \psi_{m+1/2}) \end{aligned} \tag{9.1.39}$$

Unfortunately, though the linear model is clearly a better model than the step model, care must be taken by selecting a fine spatial mesh, or the linear extrapolation can lead to negative flux values. In some cases, the situation is so severe that it is impractical to take enough mesh points to eliminate the problems. Because of these difficulties XSDRNPM uses a different approach, as described below.

The weighted diamond difference model [XSDREJ77] was developed in an attempt to take advantage of the "correctness" of the linear model, while retaining the positive flux advantages of the step model.

A solution in some S_n codes is to use the linear model in all cases where positive fluxes are obtained and to revert to step model otherwise. Unfortunately, this method leads to artificial distortions in the fluxes.

Note that if one writes

$$\psi_{i+1/2} = a\psi_i + (1 - a)\psi_{i+1} \tag{9.1.40}$$

$$\psi_m = b\psi_{m-1/2} + (1-b)\psi_{m+1/2} \tag{9.1.41}$$

that the same expression can be used to express linear or step model (e.g., $a = b = \frac{1}{2}$ is equivalent to linear, while $a = b = 1.0$ can be used for the step model).

In the weighted model, the intention is to use the linear model when fluxes are positive but to select values for a and b in the range

$$1/2 \le a \text{ or } b \le 1.0 \tag{9.1.42}$$

that ensure positivity, if the source is positive.

At this point, it is convenient to rewrite the discrete-ordinates expression in a simplified notation, without the obvious subscripts on energy group, angle, etc.

$$w\mu\left(A_{i+1}\psi_{i+1} - A_i\psi_i\right) + \alpha_{m+1/2}\psi_{m+1/2} - \alpha_{m-1/2}\psi_{m-1/2} + w\sigma V\psi = wVS. \tag{9.1.43}$$

Combining Eqs. Eq. (9.1.43) and Eq. (9.1.40) or Eq. (9.1.41) yields the following expressions for ψ_{1+1} and $\psi_{m+1/2}$:

$$\psi_{i+1} = \frac{SV + C_2\psi_{m-1/2} + \left[\mu A_i - (1-a)D_1\right]\psi_i}{aD} \tag{9.1.44}$$

$$\psi_{m+1/2} = \frac{SV + C_1\psi_i + \left[\frac{\alpha_{m-1/2}}{w} - (1-b)D_2\right]\psi_{m-1/2}}{bD}, \tag{9.1.45}$$

where

$$C_1 = \mu\left[A_i + A_{i+1}\left(\frac{1}{\alpha} - 1\right)\right] \tag{9.1.46}$$

$$C_2 = \frac{\alpha_{m-1/2}}{w} + \frac{\alpha_{m+1/2}}{w}\left(\frac{1}{b} - 1\right) \tag{9.1.47}$$

$$D = \Sigma V_i + \frac{\mu A_{i+1}}{a} + \frac{\alpha_{m+1/2}}{wb} \tag{9.1.48}$$

$$D_1 = D - \frac{\mu A_{i+1}}{a} \tag{9.1.49}$$

$$D_2 = D - \frac{\alpha_{m+1/2}}{wb}. \tag{9.1.50}$$

In determining a and b, the "theta-weighted" model uses arbitrary multipliers θ_s on SV and θ_n on the C_2 $\psi_{m-\frac{1}{2}}$ or C_1 ψ_i terms in Eqs. Eq. (9.1.44) and Eq. (9.1.45). (In [XSDTREJ80], a thorough discussion is given on the history of using different choices of θ_s and θ_n and the advantages and disadvantages of each method.) In XSDRNPM, a value of 0.9 is used for θ_s and θ_n following the practice in the DOT-IV code.7

For ψ_{i+1} in Eq. Eq. (9.1.44) to be positive, the numerator should be positive, thereby requiring

$$\left[\mu A_i - (1-a)D_1\right]\psi_i < SV + C_2\psi_{m-1/2}, \tag{9.1.51}$$

which in the θ-weighted case becomes

$$\left[\mu A_i - (1-a)D_1\right]\psi_i < SV\theta_s + C_2\psi_{m-1/2}\theta_n. \tag{9.1.52}$$

A similar expression can be written for b using Eq. Eq. (9.1.45).

For reasons of accuracy, it is desirable to use $a = b = \frac{1}{2}$. Therefore, when a or b is determined to be less than $xfrac12$ it is automatically set to $xfrac12$.

9.1.2.6 Boundary conditions

XSDRNPM allows a boundary condition to be specified for each of the two "outside" boundaries of its 1-D geometries. The options are the following:

1. Vacuum boundary – all angular fluxes that are directed inward at the boundary are set to zero (e.g., at the left-hand boundary of slab, $\psi(\mu > 0) = 0$, etc.).

2. Reflected boundary – the incoming angular flux at a boundary is set equal to the outgoing angular flux in the reflected direction (e.g., at the left-hand boundary of a slab),

$$\psi_{in}(\mu) = \psi_{\text{out}}(-\mu) \tag{9.1.53}$$

3. Periodic boundary – the incoming angular flux at a boundary is set equal to the outgoing angular flux in the same angle at the opposite boundary.

4. White boundary – the angular fluxes of all incoming angles on a boundary are set equal to a constant value such that the net flow across the boundary is zero, that is,

$$\psi_{in} = \frac{\sum_m^{out} w_m \mu_m \psi_m}{\sum_m^{in} w_m |\mu_m|} \tag{9.1.54}$$

This boundary condition is generally used as an outer-boundary condition for cell calculation of cylinders and spheres that occur in lattice geometries.

5. Albedo boundary – this option is for the white boundary condition except that a user-supplied group-dependent albedo multiplies the incoming angular fluxes. This option is rarely used, as it is difficult to relate to most practical situations.

9.1.2.7 Fixed sources

Two types of inhomogeneous or fixed sources can be specified in XSDRNPM.

In the first case, an isotropic group-dependent volumetric source can be specified for any or all spatial intervals in a system.

In the second case, an angle- and group-dependent boundary source can be specified for any or all boundaries between spatial intervals in a system, excepting the left-most boundary. In this case, one specifies not a source but a flux condition on the boundary. If one uses the "track length" definition for flux, it is easy to show that the flux condition is related to a source condition by

$$\psi_m^s = \frac{S_m}{\mu_m}. \tag{9.1.55}$$

(This equation says that an isotropic source on a boundary would be input as a constant divided by the cosine of the direction.)

In conventional fixed-source calculations, the total fixed source in the system can be normalized to an input parameter, XNF. In the volumetric source case, the source values will be normalized such that

$$XNF = \sum_{g=1}^{IGM} \sum_{i=1}^{IM} Q_{g,i} V_i, \tag{9.1.56}$$

and in the boundary source case,

$$XNF = \sum_{g=1}^{IGM} \sum_{i=1}^{IM} A_{i+1} \sum_{m=1}^{MM} \mu_m \psi_m^s(g,i) w_m. \tag{9.1.57}$$

In the case where both volumetric and boundary sources are specified, the two sums are normalized to XNF.

The fixed source for a generalized adjoint calculation corresponds to a particular response ratio of interest. The generalized adjoint equation only has a solution for responses that are ratios of linear functionals of the flux, and in this case the source will contain both positive and negative components. These types of sources are described in more detail in ref:*9-1-2-15-1* and in the SAMS chapter, in *Generalized Perturbation Theory*.

9.1.2.8 Dimension search calculations

XSDRNPM has three options for searching for dimensions such that the system will produce a specified effective multiplication factor, k_{eff}. The options are selected by a parameter IEVT in the 1$ array and are as follows:

1. zone width search (IEVT = 4),
2. outer radius search (IEVT = 5),
3. buckling search (IEVT = 6).

By default, the search is made to produce a k_{eff} value of unity. For k_{eff}'s other than unity, IPVT (3$ array) is set to unity and the desired k_{eff} is input as PV (5* array).

Other input parameters which apply specifically to all search calculations are in the 5* array and are EV, the starting eigenvalue guess, EVM, the eigenvalue modifier, EQL, the eigenvalue convergence, and XNPM, the new parameter modifier. These parameters are discussed in more detail below.

Zone-width search (IEVT = 4)

With this option, one can vary the width of any or all zones in a case. Note that it is also possible to change zone widths at different rates.

This option requires the inputting of a zone width modifier array (41*) which is used to specify the relative movements of the zones according to the following expression:

$$\Delta Z_j^f = \Delta Z_j^i \left(1 + EV^* ZM_j\right) \tag{9.1.58}$$

where $\Delta Z_j^i, \Delta Z_j^f$ are the initial and final widths of zone j, respectively, ZM_{j} is the zone width modifier for the zone (as input in the 41* array), and EV is the final "eigenvalue" for the problem. Note that a zero value for ZM will specify a fixed zone width. Negative values for ZM are allowed.

Outer radius search (IEVT = 5)

With this option, all zones are scaled uniformly in order to make the system attain the specified k_{eff}. The final zone widths are found by multiplying the initial values by the final "eigenvalue:"

$$Z_j^f = EV\left(Z_j^i / Z_p^i\right). \tag{9.1.59}$$

Buckling search (IEVT = 6)

This option is used to search for "transverse" dimensions that will yield a specified k_{eff} for a system. This means that the search is for the height for a 1-D cylinder or the y- and/or z-dimensions in a 1-D slab.

For this option, the final dimensions are given by

DY = $DY_0 \times$ EV,

and

DZ = $DZ_0 \times$ EV,

where DY_0 , DZ_0 are the initial dimensions input in the 5* array.

Search calculation strategy

All the "dimension searches" use the same simple strategy. The calculations start by using the input eigenvalue (EV from the 5* array) to determine initial dimensions for the system. These dimensions allow the code to calculate a k_{eff} . The eigenvalue modifier (EVM in the 5* array) is then used to change the dimensions as follows:

IOPT = 4 (Zone width search)

$$\Delta Z_j^f = \Delta Z_j^i \left[1 + (EVM + EV)^* ZM_j\right] \tag{9.1.60}$$

IOPT = 5 (Outer radius search)

$$\Delta Z_j^f = (EVM + EV)\left(\Delta Z_j^i\right) \tag{9.1.61}$$

IOPT = 6 (Buckling search)

DY = DY_0 (EV + EVM)

DZ = DZ_0 (EV + EVM).

The new dimensions are then used in a new calculation which determines a second k_{eff} value.

XSDRNPM searches for a unity value of k_{eff} by default; however, when IPVT = 1 (3$ array), a nonunity value can be specified in PV (5* array) and the search will be made on this value.

Once the two k_{eff}'s are known, which are based on eigenvalues of EV and EV + EVM, respectively, a linear fit is used to project to the next value for EV. This yields an expression of the form

$$EV_{\text{next}} = EVM\frac{(PV - k_1)}{(k_2 - k_1)} + EV, \tag{9.1.62}$$

where k_1 and k_2 are the first and second value of *keff*, respectively. After this iteration, the procedure is to fit a quadratic to the three most recent k_{eff} values in order to obtain an estimate for the next EV.

The procedure continues until a relative convergence of EQL (5* array) or better is obtained on EV.

To prevent oscillations in the search, extrapolations are limited by XNPM, the new parameter modifier from the 5* array.

9.1.2.9 Alpa Search

It is possible to make some of the searches described in Sect. 9.1.2.8 in a more "direct" fashion than the strategy described in Sect. 9.1.2.8.4. XSDRNPM has two such options: (1) the alpha search and (2) a direct buckling search. These are described below.

Alpha search

The time-dependent form of the Boltzmann equation is identical with Eq. Eq. (9.1.1), except for the inclusion of a time-gradient term on the left-hand side:

$$\frac{1}{\mathrm{v}}\frac{\partial\psi(r,E,\Omega,t)}{\partial t}. \tag{9.1.63}$$

All other flux terms in the expression also would include the time (t) argument.

In some analyses it is reasonable to assume that the time variation of the flux is exponential, that is,

$$\psi(r,E,\Omega,t)=\psi(r,E,\Omega)e^{at}. \tag{9.1.64}$$

When this variation is introduced into the expanded form of Eq. Eq. (9.1.1), the exponential terms all cancel leaving a leading term:

$$\frac{\alpha}{\mathrm{v}}\psi(r,E,\Omega) \tag{9.1.65}$$

which is in the same form as the $\Sigma_t\psi$ term.

If one considers integrating over energy, angle, and space, the following expression can be derived:

$$P-A-L-\alpha V=0 \tag{9.1.66}$$

where

where

P ≡ production in the system,

A ≡ absorptions in the system,

L ≡ leakage from the system,

V ≡ $\int_0^\infty dE\int_0^{4\pi}d\vec{\Omega}\int_{system}d\vec{r}\,\frac{\psi(\vec{r},E,\vec{\Omega})}{\mathrm{v}}$

Since all terms other than α can be determined from a calculation, it is possible to determine α directly, thereby avoiding a scheme like that used for dimension searches. In the balance expression, the fission component of the production term is adjusted for the case of a non-unity k_{eff} value (IPVT = 1 in the 3$ array).

An α-search has several practical applications. If, for example, a subcritical assembly is pulsed by a source, the time-dependence of the flux is expected to die off exponentially. Another way to interpret the α-search is as that amount of 1/v absorber which could be added or taken away from a system in order to achieve criticality. This number could be of interest when certain control materials are used, such as $^{10}B_5$, which is a "1/v" material.

Direct-buckling search

A "direct"-buckling search can be made using a procedure analogous to that described in Sect. 9.1.2.9.1. Recall that the buckling is introduced in order to represent a transverse leakage through the use of a $DB^2\,\psi$ term. This suggests that the foregoing balance expression be written:

$$P - A - L - \alpha DB^2 X = 0, \tag{9.1.67}$$

where

$$X \equiv \int_0^{\infty} dE \int_0^{4\pi} d\Omega \int_{\text{system}} dr\psi(r, E, \Omega). \tag{9.1.68}$$

In this case, the diffusion coefficients, D_{g}, are determined from

$$D_g = \frac{1}{3\Sigma_{tr_g}}, \tag{9.1.69}$$

where

$$\Sigma_{tr_g} = \Sigma_{t_g} - \Sigma_{1_g}, \tag{9.1.70}$$

and Σ_1 is the within-group term from the P_1 scattering matrixes:

$$\Sigma_{1_{\text{g}}} = \sum_t (\,\text{g} \rightarrow \text{g}')\,. \tag{9.1.71}$$

The original B^2 value is determined as specified in Sect. 9.1.2.12, and the α is the square of the search parameter, that one multiplies by the original B^2 value in order to determine the final buckling and, hence, the dimensions of the system.

9.1.2.10 Iteration and convergence tests

Two parameters are used to specify the required levels of convergence on an XSDRNPM calculation. These are EPS and PTC, both given in the 5* array. The flux calculations proceed through a series of iterations until either convergence is achieved or the specified iteration limit is exceeded.

The basic iteration strategy in XSDRNPM is now described. The discrete-ordinates difference equation is solved for the first angle and the first energy group. This sweep generally is made from the last interval boundary to the center of the system, and it uses the flux guess supplied as part of the input along with the boundary conditions. The second angle is then calculated, etc., until all angles in the quadrature are treated. At the end of this sweep, new scalar fluxes for the midpoints of all intervals have been determined. The angular sweep continues until either the point scalar fluxes are converged to within PTC or until the code makes IIM inner iterations. An exception to this "inner iteration" pattern occurs on the first outer (defined below) iteration whenever a fission density guess is used, instead of the flux guess. In this case, the program uses 1-D diffusion theory to determine a scalar flux value for all intervals and the angular sweeps are not made until the second outer iteration. After the first group is completed, the calculation goes to the second group and repeats the above procedure. This continues until all groups have been treated.

The pass through all groups, angles, and intervals is called an outer iteration. Most of the convergence checks on the outer iteration have to do with reaction rates involving all energy groups and are made against the EPS parameter mentioned above. For a coupled neutron-gamma problem, outer iterations are only performed for

the neutron groups until convergence is achieved, then the final converged pass is made over all groups. In discussing these checks, it is convenient to define several terms:

Q ≡ total fixed source in the system

F ≡ total fission source in the system

D ≡ total outscatter rate in the system

$D \equiv \sum_{i}^{intervals} \sum_{g}^{groups} \sum_{g' \neq g}^{groups} \psi_{i,g} \sigma_{g \to g'} V_i$

$\psi_{i,g}$ ≡ scalar flux in intervals i and group g

$\sigma_{g \to g'}$ ≡ macroscopic scattering cross section from group g to group

V_i ≡ volume of interval i

k ≡ outer iteration number

IGM ≡ total number of energy groups

$\lambda_k \equiv \frac{Q+F_k}{Q+F_{k-1}}$

$G_k \equiv \frac{D_k}{Q+F_k}$

$\lambda'_k \equiv \frac{G_{k-1}}{G_k}$

$U_k \equiv$ total upscatter rate $= \sum_i \sum_g \sum_{g'<g} \psi_{i,g} \sigma_{g \to g'} V_i$

$\lambda''_k \equiv U_K / U_{k-1}, U_{k-1} \neq 0_j = 1, U_{k-1} = 0$

An inner iteration in XSDRNPM consists of sweeping one time through the entire spatial mesh for all the S_n angles for one energy group. When the fluxes for a particular group are being calculated, inner iterations (j) will continue until (a) the number of inner iterations for this outer iteration exceeds IIM (the inner iteration maximum) or (b) until

(1)

$$\max_i \left| \frac{\psi_{i,g}^{j} - \psi_{i,g}^{j-1}}{\psi_{i,g}^{j}} \right| \leq PTC \tag{9.1.72}$$

At the end of an outer iteration, the following checks are made:

(2)

$$|1.0 - \lambda_k| \leq EPS \tag{9.1.73}$$

(3)

$$R \left|1.0 - \lambda'_k\right| \leq EPS \tag{9.1.74}$$

(4)

$$R \left|1.0 - \lambda''_k\right| \leq EPS \tag{9.1.75}$$

R is a convergence relaxation factor and is set internally to 0.5 in XSDRNPM. If all convergence criteria are met, if ICM (the outer iteration maximum) is reached, or if ITMX (the maximum execution time) is exceeded, the problem will be terminated with full output; otherwise, another outer iteration will be started.

9.1.2.11 Group banding (scaling rebalance)

As described above, the normal mode of operation in XSDRNPM is to do inner iterations on a group until it converges, then go to the next group. For groups where there is no upscatter, the scattering source to a group depends only on higher energy groups for which the fluxes have already been calculated. A fixed source problem with no fission and no upscattering can, therefore, be converged in one outer iteration. Since fission sources and upscattering sources are calculated with fluxes from the previous outer iteration, multiple outer iterations must be done to converge problems involving these kinds of sources. For problems involving many fine thermal groups (groups with both upscatter and downscatter), a special convergence problem arises. Because the groups are fine, within-group scattering is small and the flux calculation is dominated by scattering sources from other groups. This situation leads to a very slow reduction in scattering source errors from one outer iteration to the next. XSDRNPM has a special "group banding" option for treating this problem. It involves collecting several groups together into a band and doing one inner for each group in the band while collecting particle balance information. This balance information is then used to solve for one set of flux rebalance factors to apply to each group in the band. Because the band is much wider than an individual group, the scattering that remains within the band is a much larger fraction of the total scattering source for the band. This condition leads to considerably faster convergence from one outer iteration to the next. The group banding option in XSDRNPM is triggered by the seventh entry in the 2$ array. The absolute value of this entry indicates the number of bands to be used. If the number is negative, these bands are only for the thermal groups. Normally there is no need to band together groups other than the thermal groups. An entry of -1 indicates that all the thermal groups will be treated as one band. This mode is one that is used successfully for many problems, but occasionally will cause a problem to not converge. For these problems using two or three bands for the thermal groups has been successful.

The code generates a default banding structure, but this structure can be overridden by inputting a 52$ array.

9.1.2.12 Buckling correction

XSDRNPM allows "buckling" corrections to be made for the transverse (non-calculated) dimensions in its 1-D slab and cylindrical geometries. Three input parameters-DY, DZ, and BF (5* array)-may be involved.

In the case of the 1-D slab, the height DY and the width DZ can be input. The buckling correction uses an expression based on asymptotic diffusion theory to account for leakage in the transverse direction and is treated analogous to an absorption cross section, that is,

Transverse Leakage = $DB^2\psi$

where B is the geometric buckling and is given by

$$B^2 = \left(\frac{\pi}{Y}\right)^2 + \left(\frac{\pi}{Z}\right)^2 \tag{9.1.76}$$

and Y and Z are the height and width of the slab, respectively, and include extrapolation distances.

Recall that the "extrapolation distance" is defined as the linear extrapolation distance such that if one extrapolated to a zero flux value at this distance from the boundary, the interior flux shape in the body would be correctly represented. The distance can be shown to occur at $0.71\lambda_{tr}$, where λ_{tr} is the transport mean free path given by $1/\Sigma_{tr}$. Note that for a slab, there are two extrapolation distances to include (one on either side) for the height and width, such that

$$Y = DY + 1.42\lambda_{tr}, \tag{9.1.77}$$

and

$$\mathrm{Z} = \mathrm{DZ} + 1.42\lambda_{tr}. \tag{9.1.78}$$

The 1.42 factor (= 2 *X* 0.71) is input in the BF parameter of the 5* array.

In calculating λ_{tr}, a transport cross section, Σ_{tr}, is determined from

$$\Sigma_{tr} = \Sigma_t - \Sigma_{s1} \tag{9.1.79}$$

which varies as a function of energy group and zone. The Σ_{s1} term is the within-group term from the P_1 scattering matrix.

In the case of the 1-D cylinder, the procedure is the same as for the slab except that the buckling is determined from

$$B^2 = \left(\frac{\pi}{Y}\right)^2, \tag{9.1.80}$$

since only one transverse dimension is needed.

The diffusion coefficient in the leakage term is determined from

$$D = \frac{1}{3\Sigma_{tr}} \tag{9.1.81}$$

Note that when comparing with codes or treatments using a fixed value of buckling for every group, a user can force this situation in XSDRNPM by inputting a zero value for BF and DZ and setting DY to determine the required buckling value.

9.1.2.13 Void streaming correction

In real slab and cylindrical geometries, void regions offer streaming paths that are nonexistent in the 1-D cases with quadratures that do not include a vertical angle. A correction for this effect has been suggested by Olsen [XSDOls65], who uses an adjustment to the absorption cross section to account for the transverse leakage.

If one considers a slab of height H, the void streaming correction is introduced through an adjustment to the total cross section and is given by

$$\frac{\sqrt{1-\mu_m^2}}{H/2}, \tag{9.1.82}$$

where μ_m is the cosine of the direction.

In the case of a cylinder of height H, the adjustment is

$$\frac{\mu_m}{H/2}. \tag{9.1.83}$$

These streaming corrections are very approximate and do not properly account for the fact that the streaming is enhanced near the ends of a void channel; however, they are probably better than the alternative, which is to make no correction at all.

9.1.2.14 Cross-section weighting

XSDRNPM weights cross sections according to the following four options:

1. "Cell" weighting,
2. "Zone" weighting,

3. "Region" or "vein" weighting, and
4. "Inner cell" weighting.

In all cases the "averaged" cross sections are defined in a manner that conserves reaction rates, that is,

$$\bar{\sigma}_G \int_{\text{space}} dr N_D(r) \int_G dE\psi(E,r) = \int_{\text{space}} dr N(r) \int_G dE\sigma(E,r)\psi(E,r), \tag{9.1.84}$$

where

$\bar{\sigma}_G \equiv$ average cross section in group G,

$N_D(r) \equiv$ number density used in the definition for the weighting option selected,

$\psi(E,r) \equiv$ weighting spectrum,

$N(r) \equiv$ real number density as a function of spatial position,

$\sigma(E,r) \equiv$ cross section in unreduced form.

If we convert to multigroup notation and use W for the weighting spectrum (instead of ψ), Eq. Eq. (9.1.84) becomes

$$\bar{\sigma}_G \sum_{\substack{\text{applicable}\\ \text{spatial}\\ \text{regions}\\ j}} N_D^j \sum_{g\varepsilon G} W_g^j = \sum_{\substack{\text{applicable}\\ \text{spatial}\\ \text{regions}\\ j}} N^j \sum_{g\varepsilon G} \sigma_g^j W_g^j , \tag{9.1.85}$$

$$W_g^j \equiv \int_j dr \int_g dE\psi(E,r) \tag{9.1.86}$$

"Cell Weighting"

Cell weighting is consistent with homogenizing the cross sections in a heterogeneous cell. This is the recommended option to prepare cross sections for a real reactor calculation that will be made with a 2- or 3-D model of the reactor. Most of these codes have no provisions for explicitly representing individual fuel pins which are interspersed in a moderator region.

Cell-weighted cross sections are defined in a manner that attempts to preserve the reaction rates which occur in a representative cell from the reactor. In Eq. Eq. (9.1.85) the weighting involves the following substitution:

$$N_D^j \equiv \bar{N} = \frac{\sum_j^{cell} V^j N^j}{\sum_j^{cell} V^j} \tag{9.1.87}$$

where

$V_{\text{ j}} \equiv$ volume of zone j.

"Zone" weighting

Zone weighting is the simplest of the three XSDRNPM weighting options. Each zone produces a unique set of cross sections which preserves reaction rates for the zone. In Eq. Eq. (9.1.85), the spatial sum is over the zone considered, and $N_{\text{ j}}\, N_D^j$ and are unity.

Zone weighting is used very frequently, especially for problems whose collapsed cross sections are to be used in a problem whose geometrical and material layout is similar to that in the weighting problem.

"Region" weighting

"Region-" or "vein-" weighted cross sections are weighted "where-the-nuclide-is." In most problems, there are nuclides of secondary importance which do not need a separate "zone-weighted" set for every region in which the nuclide occurs. Examples are the components of stainless steel. Stainless steel is encountered in a variety of locations and flux environments, but generally one set of cross sections for iron, chromium, manganese, nickel, etc., will suffice for most reactor calculations.

In Eq. Eq. (9.1.85), the spatial sum is over all zones which contain the nuclide of interest with

$$N_D^j = N^j \tag{9.1.88}$$

"Inner-cell" weighting

For inner-cell weighting, cell weighting is performed over specified innermost regions in the problem. Nuclides outside these regions are not weighted.

This option is generally employed as follows: A "cell" is described in exactly the same manner as for cell weighting (Sect. 9.1.2.14.1) except that in this case it is surrounded by a homogeneous representation for the remainder of the core and by blankets, reflectors, etc. The flux calculation is made over this complete system, which should have a more realistic treatment of the leakage across the outer boundary of the interior cell. The cell weighting is subsequently made only over the interior cell.

Multigroup weighting equations

1. Cell weighting

$$\bar{\sigma}_G \equiv \frac{\sum_j^{IZM} N^j \sum_{g\varepsilon G} \sigma_g^j W_g^j}{\bar{N} \sum_j^{IZM} \sum_{g\varepsilon G} W_g^j} \tag{9.1.89}$$

where

$$\bar{N} \equiv \frac{\sum_j^{IZM} V^j N^j}{\sum_j^{IZM} V^j} \tag{9.1.90}$$

$$W_g^j \equiv \psi_g^j = \int_j \psi_g(r) dr. \tag{9.1.91}$$

2. Zone weighting

$$\overline{\sigma_G^j} \equiv \frac{\sum_{g\varepsilon G} \sigma_g^j W_g^j}{\sum_{g\varepsilon G} W_G^j}. \tag{9.1.92}$$

3. Region weighting

$$\bar{\sigma}_G \equiv \frac{\sum_j N^j \sum_{g\varepsilon G} \sigma_g^j W_g^j}{\sum_j N^j \sum_{g\varepsilon G} W_g^j}. \tag{9.1.93}$$

Transfer matrices

Collapsing transfer matrices is not quite so simple as collapsing cross sections with a single value per group. A group-to-group term in the broad group sense conserves the scattering rate from one group to the other, that is,

$$\bar{N}^* \bar{\sigma} (G \to G') \psi_G \equiv \int_{\text{space}} dr N(r) \int_g dE \psi(E, r) \int_{g'} dE' \sigma (E \to E') \tag{9.1.94}$$

where the asterisk (*) denotes that the number density on the left side of the equation is consistent with the weighting desired. Therefore, the multigroup forms of the weighting equations for components of the transfer matrices are as follows:

1. Cell weighting

$$\bar{\sigma}_{G \to G'} \equiv \frac{\sum_j^{IZM} N^j \sum_{g \varepsilon G} W_g^j \sum_{g' \varepsilon G'} \sigma^j (g \to g')}{\bar{N} \sum_j^{IZM} \sum_{g \varepsilon G} W_g^j} \tag{9.1.95}$$

2. Zone weighting

$$\bar{\sigma}_{G \to G'} \equiv \frac{\sum_{g \varepsilon G} W_g^j \sum_{g' \varepsilon G'} \sigma^j (g \to g')}{\sum_{g \varepsilon G} W_g^j}. \tag{9.1.96}$$

3. Region weighting

$$\bar{\sigma}_{G \to G'} \equiv \frac{\sum_j N^j \sum_{g \varepsilon G} W_g^j \sum_{g' \varepsilon G'} \sigma^j (g \to g')}{\sum_j N^j \sum_{g \varepsilon G} W_g^j}. \tag{9.1.97}$$

Theoretically, the higher-than-zero order $\sigma_l (g \to g')$ should be weighted over ψ_l. Since these functions are generally positive-negative, ψ_l weighting does not always work in practice, and XSDRNPM weights the $\sigma_l (g \to g') , \quad > 0$, by the scalar flux, which is positive. This procedure gives usable values for most cases.

Weighting of $\bar{\nu}$

In weighting parameters such as $\bar{\nu}$, the average number of neutrons produced per fission, one is interested in preserving the fission source; therefore, the weighting is over $\sigma_f \psi$ instead of just ψ. The weighting procedure in XSDRNPM is to calculate $\left(\overline{\nu\sigma_f}\right)_G$ and $(\sigma_f)G$ using the appropriate choice from Eqs. Eq. (9.1.95), Eq. (9.1.96), or Eq. (9.1.97). Then

$$\bar{\nu}_G = \frac{(\overline{\nu\sigma_F})_G}{\left(\sigma_f\right)_G}. \tag{9.1.98}$$

Transport cross sections

Transport cross sections are not as directly related to the physical properties of a material as much as other group-averaged values. Instead of a reaction rate, these numbers must attempt to preserve a "flux gradient," which not only depends on the cross sections of the material, but is also very strongly influenced by the geometry and the other nuclides in the vicinity of a material.

Two options are provided in XSDRNPM to generate transport cross sections-options based on the "consistent" and "inconsistent" methods for solving the *Pl* transport equations. These approximations are referred to as the "outscatter" and "inscatter" approximations because of the nature of the equations used.

Outscatter approximation (inconsistent method)

In the outscatter approximation, the assumption is made that

$$\sigma_{tr}^{g} = \sigma_{t}^{g} - \bar{\mu}^{g}\sigma_{s}^{g}. \tag{9.1.99}$$

When one notes that

$$\bar{\mu}^{g} \equiv \frac{\sigma_{1}^{g}}{3\sigma_{0}^{g}} \tag{9.1.100}$$

and that

$$\sigma_{1}^{g} = \sum_{g'} \sigma_{1}\left(g \rightarrow g'\right), \tag{9.1.101}$$

where the $\sigma_{l}\left(g \rightarrow g'\right)$ terms are the P_1 coefficients of the scattering matrix, the origin of the term "outscatter" to designate the approximation is evident.

Inscatter approximation (consistent method)

In the "consistent" solution of the P_1 point transport equations, it can be shown that

$$\sigma_{tr}(E) = \sigma_{t}(E) - \frac{1}{3J(E)} \int_{0}^{\infty} dE' \sigma_{1}\left(E' \rightarrow E\right) J\left(E'\right), \tag{9.1.102}$$

where $J\left(E'\right)$ is the current.

If one multiplies the equation by J(E), integrates over group g, and converts to group-averaged form by dividing by $\int_{g} J(E)dE$ the following expression is derived:

$$\sigma_{tr}^{g} = \sigma_{t}^{g} - \frac{1}{3J_{g}} \sum_{g'} \sigma_{1}\left(g' \rightarrow g\right) J_{g'}. \tag{9.1.103}$$

This is the "inscatter" approximation. It is consistent because the transport values are explicitly derived from the P_0 and P_1 equations. As a general rule, the transport values from this treatment are "better" than those from the "inconsistent" treatment. However, in some cases (notably hydrogen at lower energies), negative numbers may be calculated which are unusable and the more approximate approach must be used.

Weighting function for transport cross section

Unfortunately, the matter of choosing a current to use in the "transport" weighting is not simple. In real problems, currents are positive-negative as a function of energy and space. When cross sections are averaged over positive-negative functions, the "law-of-the-mean" no longer holds and the average value can be anything. This unbounded nature leads to real problems in diffusion calculations.

Approximations that inherently guarantee positive currents are generally used in other codes that circumvent the positive-negative problem. For example, in *Bn* theory the current is given by

$$j \sim B\psi \tag{9.1.104}$$

where B and ψ are both positive.

In XSDRNPM, more direct routes that ensure positivity are taken (e.g., one might set $\mathrm{W_g} \equiv \left|\mathrm{W_g}\right|$). This is crudely supported by the following argument:

Consider a 1-D cylindrical calculation. In two dimensions, the current is a vector combination, that is,

$$J = J_r + J_z. \tag{9.1.105}$$

In XSDRNPM, the z direction is treated by using a buckling approximation, that is,

$$J_z = B\psi. \tag{9.1.106}$$

In the weighting calculation, we want to weight over the magnitude of the current. In XSDRNPM, the z current is imaginary, since we are not calculating a z-direction:

$$J = J_r + iB\psi. \tag{9.1.107}$$

The magnitude of a complex quantity is

$$J = \frac{(J_r + iB\psi)(J_r - iB\psi)}{\sqrt{(\text{Value}_r)^2 + B^2\psi^2}}, \tag{9.1.108}$$

which is always positive.

In a discrete-ordinates calculation, the current is easily obtained since it is the first flux moment.

XSDRNPM has the following options for calculating the current:

1.
$$J_g = \sqrt{\left(\psi_1^g\right)^2 + \left(DB\psi_g\right)^2} \tag{9.1.109}$$

2.
$$J_g = \left|\psi_1^g\right| \tag{9.1.110}$$

3.
$$J_g = DB^2\psi_g + \int_0^1 d\mu\mu\psi\left(g, r_{\text{outside}}, \mu\right) \tag{9.1.111}$$

4.
$$J_g = \frac{\psi_0^g}{\Sigma_t^g} \tag{9.1.112}$$

5.
$$J_g = DB\psi_g \tag{9.1.113}$$

The first option is the recommended option; option 2 treats only the current in the primary direction; option 3 will always be positive and is a weighting over the total leakage from the system. Option 4 is sometimes referred to as a "bootstrap" approximation; option 5 is equivalent to that used in codes that employ B_n theory.

Once the currents are determined, the transport values are determined as set forth in the equations discussed above. For example, consider cell weighting and the "inscatter" approximation,

$$\sigma_{tr}^G = \frac{\sum_j N^j \sum_{g\varepsilon G}\left\{J_g\sigma_t^g - \frac{1}{3}\sum_{g'}\sigma_1\left(g' \to g\right)J_g'\right\}}{\bar{N}\sum_j^{IZM}\sum_{g\varepsilon G} J_g} \tag{9.1.114}$$

For cell weighting and the "outscatter" approximation,

$$\sigma_{tr}^G = \frac{\sum_j N^j \sum_{g\varepsilon G} J_g\left\{\sigma_t^g - \frac{1}{3}\sum_{g'}\sigma_1\left(g' \to g\right)\right\}}{\bar{N}\sum_j^{IZM}\sum_{g\varepsilon G} J_g} \tag{9.1.115}$$

9.1.2.15 Adjoint calculations

XSDRNPM will, upon option, solve the adjoint forms of the 1-D transport equation.

Several special procedures apply for the adjoint calculation:

1. The iteration pattern discussed in Sect. 9.1.2.10 is reversed in energy. The scheme starts with the last (lowest energy) group and proceeds to the first group.
2. The angular quadrature is treated as if it has the reverse directions associated with the angle (e.g., many quadratures start with $\mu_1 = -1.0$). In the adjoint case, this direction is for $\mu_1 = +1.0$.
3. All edits of input fluxes and collapsed cross sections are given in their normal ordering, as opposed to many codes which require their reversal.

Adjoint calculations have many uses and advantages. As opposed to the forward calculation which yields particle density values, the adjoint fluxes are more abstract and can be thought of as particle importance.

Consider, for example, the problem of determining the response of a detector to particles as a function of their energy and direction. Assume the detector is a cylindrical fission chamber that utilizes a foil of ^{235}U. The most obvious way to attack this problem is to mock up the detector and make a series of runs that contain sources of identical strength in different angles and energy groups. If an S_8 (24 angles) quadrature were used with 50 energy groups, the 12×50 or 600 independent calculations could be used to completely determine the responses. (Here we have taken note that half of the angles will point away from a detector and, hence, produce no response.) The adjoint calculation produces all 600 responses in one run that is no more difficult and time consuming than the typical forward case. In the adjoint case, the detector response (i.e., the fission cross section of ^{235}U would be specified as a source in the foil region and the adjoint fluxes given as a function of energy and angle would be interpreted as the source of neutrons necessary to produce a response of the magnitude to which one required the response to be normalized.

A second important use of adjoint calculations is to establish good biasing factors for Monte Carlo codes. Two recent reports [XSDHof82, XSDHT82] discuss the time and accuracy advantages of this approach for shielding and criticality applications and give some real examples as to how to make the calculations.

Perturbation theory uses adjoint and forward fluxes in combination in a manner that determines changes in responses that would arise from changing parameters used in a calculation. One [XSDWRHB79] interesting application is to determine the sensitivity of a calculation to changes in one or more cross-section value changes.

Generalized adjoint calculations

Generalized adjoint solutions are needed for generalized perturbation theory (GPT) applications such as sensitivity and uncertainty analysis. The generalized adjoint solution differs from both a conventional external source case and a fundamental mode eigenvalue calculation: It has the transport operator for an adjoint eigenvalue equation, but contains a fixed source term as well. The eigenvalue transport operator is singular, which forces certain restrictions on the allowable sources. The generalized adjoint source term is associated with a particular response ratio of interest in a critical system, such as

$$R = \frac{\sum_{g=1}^{IGM} \sum_{i=1}^{IM} H_N(g,i)\psi_{i,g}V_i}{\sum_{g=1}^{IGM} \sum_{i=1}^{IM} H_D(g,i)\psi_{i,g}V_i} \tag{9.1.116}$$

where H_N and H_D are response functions defining the response of interest and $\psi_{i,g}$ is the scalar flux from a prior forward eigenvalue solution of the same problem. The generalized adjoint source for this response is

defined as

$$Q^*(g,i) \equiv \frac{1}{R}\frac{\partial R}{\partial \psi_{i,g}} = \frac{H_N(g,i)}{\sum_{g=1}^{IGM}\sum_{i=1}^{IM} H_N(g,i)\psi_{i,g}V_i} - \frac{H_D(g,i)}{\sum_{g=1}^{IGM}\sum_{i=1}^{IM} H_D(g,i)\psi_{i,g}V_i} \tag{9.1.117}$$

The above source expression is computed automatically whenever XSDRN is executed in the TSUNAMI-1D sequence, but must it be computed and input by the user if XSDRN is run standalone for a generalized adjoint case.

In order to obtain a unique solution and avoid numerical problems, the generalized adjoint solution is "normalized" to contain no fundamental harmonic of the adjoint eigenvalue calculation. This is done by sweeping out the adjoint fundamental mode "contamination" from the fission source after each outer iteration, as described in the SAMS chapter, in *Generalized Perturbation Theory*. This operation requires both forward and adjoint eigenvalue solutions from prior XSDRN calculations. External files containing the fundamental mode forward and adjoint fluxes are input to the generalized adjoint calculation.

Unlike conventional fixed source and eigenvalue calculations, the generalized adjoint flux has both negative and positive components. This causes some XSDRN acceleration features such as space-dependent rebalance and group-banding to not function properly; and thus these are turned off internally. Typically the outer iterations for generalized adjoint solution converge much slower than an eigenvalue calculation. More background on GPT and generalized adjoint properties can be found in [XSDWil86].

9.1.2.16 Coupled neutron-photon calculations

In XSDRNPM, it is possible to do a neutron or a photon calculation, depending only on whether the input libraries are for neutrons or gamma rays. It is also possible to do a "coupled neutron-photon" calculation which automatically determines the gamma-ray sources arising from neutron induced interactions in its photon calculation. This calculation, of course, requires an input cross-section library containing three classes of data:

1. neutron cross sections, including neutron-to-neutron transfer matrices,
2. photon production cross sections (i.e., neutron-to-gamma transfer matrices), and
3. gamma-ray cross sections, including gamma-ray-to-gamma-ray transfer matrices.

At present there are no provisions for treating neutrons produced from gamma interactions other than having the user introduce these sources by hand in a sort of iterative procedure, though this reaction is certainly not unknown (cf., deuterium, beryllium-9, and carbon-13). There are several cases where the (γ, n) interaction can be important. If, for example, one looks at neutrons in a water-moderated pool reactor or in a water spent fuel storage tank at large distances from the fuel, the dominant source is from the neutrons produced by the deuterium in the water.

Normally the neutron-photon calculation requires no more input than a single particle run, except in the case where extraneous neutron and/or gamma-ray sources need to be specified. Most output edits will be split into a neutron and a gamma-ray part and will be labeled as such

9.1.2.17 Diffusion theory option

XSDRNPM can make a 1-D diffusion theory calculation in user-specified energy groups (enter 1's for the appropriate groups of the 46$ array). In this case, the P_1 diffusion equations [XSDAld63] are solved:

$$A_{I+1}\psi_{1,I+1} - A_I\psi_{1,I} + \sigma_0\left(\psi_{0,I} + \psi_{0,I}\right) = S_0^* \tag{9.1.118}$$

$$\bar{A}_I\left(\psi_{0,I+1} - \psi_{0,I}\right) + \sigma_1\left(\psi_{1,I+1} + \psi_{1,I}\right) = S_1^*, \tag{9.1.119}$$

where

$$\psi_1 \equiv P_1 \text{ current} \tag{9.1.120}$$

$$\sigma_0 = \left[\Sigma_t - \Sigma_0(g \to g)\right]\frac{V_I}{2.0} \tag{9.1.121}$$

$$\sigma_1 = \left[3.0\Sigma_t - \Sigma_1(g \to g)\right]\frac{V_I}{2.0} \tag{9.1.122}$$

$$S_0^* = P_0 \text{ sources less the within-group term} \tag{9.1.123}$$

$$S_1^* = P_1 \text{ sources less the within-group term} \tag{9.1.124}$$

$$\bar{A}_I = \frac{A_I + A_{I+1}}{2} \tag{9.1.125}$$

$$V_I = \text{ volume of Ith interval.} \tag{9.1.126}$$

Solving Eq. Eq. (9.1.118) for $\psi_{0,I+1}$ and substituting into Eq. Eq. (9.1.119), one can write

$$\psi_{1,I+1} = \frac{\bar{A}_I S_0^* - 2\sigma_0\bar{A}_I\psi_{0,I} - \sigma_0 S_1^* + \psi_{1,I}\left(\sigma_0\sigma_1 + \bar{A}_I A_I\right)}{\bar{A}_I A_{I+1} - \sigma_0\sigma_1}. \tag{9.1.127}$$

Solving Eq. Eq. (9.1.119) for $\psi_{1,I}$ and substituting into Eq. Eq. (9.1.118) , one can write

$$\psi_{0,I+1} = \frac{A_{I+1}S_1^* - 2\sigma_1\bar{A}_I\psi_{1,I} - \sigma_1 S_0^* + \psi_{0,I}\left(\sigma_0\sigma_1 + \bar{A}_I A_{I+1}\right)}{\bar{A}_I A_{I+1} - \sigma_0\sigma_1}. \tag{9.1.128}$$

If one assumes

$$\psi_{1,I+1} = P_{I+1}\psi_{0,I+1} - q_{I+1} \tag{9.1.129}$$

$$\psi_{1,I} = P_I\psi_{0,I} - q_I \tag{9.1.130}$$

and plugs Eqs. Eq. (9.1.127) and Eq. (9.1.128) into , solving for $\psi_{1,I}$ yields:

$$\begin{array}{l}\psi_{1,I} = \frac{P_{I+1}\left(\sigma_0\sigma_1 + \bar{A}_I A_{I+1}\right) + 2\sigma_0\bar{A}_I}{\sigma_0\sigma_1 + \bar{A}_I A_I + P_{I+1}2\sigma_1\bar{A}_I}\psi_{0,I} \\ -\frac{S_0^*\left(\bar{A}_I + \sigma_1 P_{I+1}\right) - S_1^*(\sigma_0 + A_{I+1}P_{I+1}) + q_{I+1}\left(\bar{A}_I A_{I+1} - \sigma_0\sigma_1\right)}{\sigma_0\sigma_1 + \bar{A}_I A_I + P_{I+1}2\sigma_1\bar{A}_I}\end{array} \tag{9.1.131}$$

which by inspection and comparison with Eq. Eq. (9.1.130) gives expressions for P_{I} and q_{I}.

Equations Eq. (9.1.129) and Eq. (9.1.130) can be substituted into Eq. Eq. (9.1.118) and solved for $\psi_{0,I+1}$:

$$\psi_{0,I+1} = \frac{\psi_{0,I}\left(A_I P_I - \sigma_0\right) + A_{I+1}q_{I+1} - A_I q_I + S_0^*}{A_{I+1}P_{I+1} + \sigma_0}, \tag{9.1.132}$$

which is the expression used in XSDRNPM. The procedure solves for arrays of P_{I} and q_{I} which are plugged back into the above expression to yield the fluxes.

9.1.2.18 Infinite-medium theory option

It is possible to force the flux calculation in XSDRNPM to use an infinite medium option for any or all energy groups by entering 2's in the appropriate positions in the 46$ array. When a multiregion calculation is requested, the program will first determine spatially averaged cross sections to use in the infinite-medium expression and then place the infinite-medium flux in all spatial regions for use in any subsequent calculations, such as cross-section weighting. All higher flux moments are set to zero.

The balance expression is

$$\left[\Sigma_t^g - \Sigma(g \to g)\right]\psi_g = \frac{1}{k}F_g + S_g, \tag{9.1.133}$$

where F_g is the fission source in group g, S_g is the sum of any fixed source and inscattering source, and $\sum_t^g$ and $\Sigma(g \to g)$ are homogenized total and group-to-group scattering cross sections.

9.1.2.19 B_N theory option

XSDRNPM can make a B_n calculation in user-specified energy groups (enter 3's for the appropriate groups of the 46$ array). As in the infinite-medium option discussed in Sect. 9.1.2.18, cross sections in a multiregion system are not homogenized.

The B_n equations [XSDHTS76] can be written

$$\begin{aligned}\frac{l+1}{2l+1}iB\psi_{l+1} + \frac{l}{2l+1}iB\psi_{l-1} + \Sigma_t\psi_l = S(u)\delta_l^0 \\ + \int du'\Sigma_s^l(u' \to u)\,\psi_l(u') \quad l = 0, 1, \quad , N-1\end{aligned} \tag{9.1.134}$$

$$\frac{N}{2N+1}iB\psi_{N-1} + \gamma\Sigma_t\psi_N = \int du'\Sigma_g^N(u' \to u)\,\psi_N(u') \tag{9.1.135}$$

$$\psi_{-1} = 0 \tag{9.1.136}$$

$$\gamma = 1 + \frac{N+1}{2N+1}\frac{iB}{\Sigma_T}\frac{Q_{N+1}(-\Sigma_t/iB)}{Q_N(-\Sigma_t/iB)} \tag{9.1.137}$$

where δ_l^0 is the Kronecker delta function and Q_N is a Legendre polynomial of the second kind. In mutigroup form, the above expressions become:

$$\begin{aligned}\frac{l+1}{2l+1}iB\psi_{l+1}^g + \frac{l}{2l+1}iB\psi_{l-1}^g + \Sigma_t^g\psi_l^g = S_g\delta_l^0 \\ + \sum_{g'}\Sigma_l(g' \to g)\,\psi_l^g \quad l = 0, 1, \quad N-1\end{aligned} \tag{9.1.138}$$

$$\frac{N}{2N+1}iB\psi_{N-1}^g + \gamma\Sigma_t^g\psi_N^g = \sum_{g'}\Sigma_N(g' \to g)\,\psi_N^g \tag{9.1.139}$$

$$\psi_{-1}^g = 0. \tag{9.1.140}$$

In Eqs. Eq. (9.1.134) and Eq. (9.1.138), the S term includes fission, fixed, and scattering source components.

9.1.3 XSDRNPM INPUT DATA

The input data to XSDRNPM consist of a title card and up to five data blocks, depending on the particular problem. All data in these blocks are entered using the FIDO formats discussed in the chapter on FIDO.

In the description that follows, the quantity in square brackets is the number of items in an array. The quantity in braces is the condition which requires the array to be input. If no condition is specified, an array must be input. Default parameters that are used if an array is not input are shown in parentheses if nonzero.

****

Title Card - Format (20A4)

This is the title card for the problem. It will be used to label the problem output.

Data Block 1

This block contains information to set up various array dimensions and most calculational and editing options. Various convergence criteria and special constants can be input.

0$$ Logical Assignments [17]

1. LPUN – Logical number for punched card output (7).
2. LRSF – Random-access scratch for fluxes (10).
3. LAWL – Input AMPX working library (4).
4. LANC – ANISN binary or CCCC ISOTXS library (20).
5. LOWL – Output weighted library (3).
6. LANG – Angular flux scratch file (16).
7. LSFF – Scalar flux output file (17).
8. LSF2 – Sequential scratch space (18).
9. LSF3 – Sequential scratch space (19).
10. LRSM – Random-access scratch for macroscopic cross sections (8).
11. LRSX – Random-access scratch for macroscopic cross sections (9).
12. LACF – Activities output file (75).
13. LBTF – Balance table output file (76).
14. LIDF – Input dump file (73).
15. LSEN – Sensitivity output file (6).
16. LEXT – Not used (0).
17. LISF – Scalar flux input guess file (0).

1$ General Problem Description [15]

1. IGE - problem geometry (1)

0 - homogeneous (This causes a BN calculation to be made for all zones – Sect. 9.1.2.19)

1 - slab

2 - cylinder

3 - sphere

2. IZM – number of separate material regions or zones. (1)
3. IM – number of spatial intervals in the problem. (1)
4. IBL – the boundary condition at the left-hand boundary of the system. (1)

   0 - vacuum boundary

   1 - reflected boundary

   2 - periodic boundary

   3 - white/albedo boundary

Boundary conditions are discussed in Sect. 9.1.2.6.

5. IBR - the boundary condition at the right-hand boundary of the system. (1)

   0 - vacuum boundary

   1 - reflected boundary

   2 - periodic boundary

   3 - white/albedo boundary

6. MXX – the number of compositions used in the problem mock-up.
7. MS – the number of entries in the mixing table which specifies the makeup of the MXX compositions.
8. ISN – the order of angular quadrature to be used. If ISN > 0, XSDRNPM will calculate an angular quadrature for the appropriate geometry. If ISN < 0, the calculation is bypassed, and the user must supply a set in the 42# and 43# arrays.
9. ISCT – the order of scattering. Flux moments will be calculated through this order.
10. IEVT – the type of calculation. (1)

    0 - fixed source

    1 - k calculation

    2 - α calculation (flux is assumed to have an $e^{-\alpha t}$ time variation)

    3 - inoperable in present version

    4 - zone width search

    5 - outer radius search

    6 - buckling search

    7 - direct buckling search

11. IIM – the inner iteration maximum used in an Sn calculation. (10)
12. ICM – the outer iteration maximum. (10)

    After ICM outer iterations, the problem will be forced into the termination phase and the program will continue as if full convergence was attained. A message to this effect is printed.
13. ICLC – theory option. (0)

    0 - use S_n theory always

    N - use alternative theory (diffusion, infinite medium, or Bn) for N outer iterations, after which revert back to Sn theory.

    -N - always use alternative theory
14. ITH – forward/adjoint selector. (0)

    0 - solve the forward Boltzmann equation.

    1 - solve the adjoint Boltzmann equation.
15. IFLU – Generalized adjoint calculation flag. (0)

    0 - standard calculation

    1 - Generalized adjoint calculation. Requires input forward and adjoint fundamental mode fluxes on units 31 and 32, respectively

2$ Editing and Special Options [10]

1. IPRT – fine-group mixture cross-section edits. (-1)

   -2 - no edits

   -1 - edit 1-D cross sections

   0-N - edit through PN cross sections. 1-D edits are made, also.
2. ID1 – flux editing options. (0)

ID1	Print Angular fluxes	Print Scalar fluxes	Punch*a* Scalar fluxes
-1	No	No	No
0	No	Yes	No
1	Yes	Yes	No
2	No	Yes	Yes
3	Yes	Yes	Yes
a The fluxes will be punched in a format suitable for restarting an XSDRNPM calculation.			

3. IPBT – balance table edits. (0)

   -1 - none

   0 - make fine-group balance tables

   1 - make fine- and broad-group balance tables

4. ISX – broad-group flux edit as a function of interval. (0) (0/1 = no/yes)
5. ISEN – outer iteration acceleration. Input a zero. (0)
6. IBLN – control number of outer iteration groups. (0)
7. NBANDS – number of flux rebalance bands. (0) < 0, then this is the number of bands in the thermal range.
8. IFSN – If > 0 means no fission source if IEVT=0. (0)
9. ISQ3 – sequence number of file opened on unit LOWL. (1)
10. IDM4 – not used. (0)

The structure of the "activity" and the "balance table" files are described in Appendix A.

3$ Various Options [12]

1. IFG – cross-section weighting. (0)

   0 - none required

   1 - collapse cross sections
2. IQM – volumetric sources. (0)

   0 - none

   N - N volumetric source spectra will be input in the 31* array
3. IPM – boundary sources. (0)

   0 - none

   N - N boundary source spectra will be input in the 32* array
4. IFN – starting guess. (0)

   0 - flux guess (33# array)

   1 - fission density guess (34# array)
5. ITMX – maximum time allowed for the flux calculation in minutes. A value of zero specifies that the calculation should not be terminated because of time; otherwise the problem will be forced into the termination phase when ITMX is exceeded. (0) Bear in mind that this is an internal timing check and has no connection with operator or system terminations due to excessive times.
6. IDAT1 – external data storage. (0)

   0 - keep all arrays in core if possible

   1 - store mixture cross sections externally on a direct access device

   2 - store cross sections and fixed sources externally on direct access devices
7. IPN – diffusion coefficient option for transverse leakage corrections. (3)

0 - determine a transport cross section for each zone using P0 and P1 cross sections and, hence, a diffusion coefficient from 1/3 Σ_{tr}.

1 - spatially average the diffusion coefficients determined as for the above option and use it for all zones.

2 - spatially average the transport cross sections for all zones and determine a diffusion coefficient to be used in all zones by taking one over three times this value.

3 - flux weight the transport cross sections for all zones and determine a diffusion coefficient to be used in all zones by taking one over three times this value.

Normally, the first option (IPN = 0) is adequate; however, in cases involving regions of low concentration (near void) and, hence, very low transport cross sections, the very large diffusion coefficients lead to nonphysical behavior. In this case, the IPN = 3 option has been demonstrated to operate the best.

8. IDFM – density factors. (0)

   0 - none

   1 - read in density factors in the 38* array

9. IAZ – activity calculation trigger. (0)

   0 - none

   N - calculate the reaction rates by material zone for N different processes specified in the 49$ and 50$ arrays

10. IAI – spatially dependent activity rates. (0)

    0 - none

    1 - calculate reaction rates in each interval for IAZ processes

11. IFCT – thermal upscatter scaling. (0)

    0 - none

    1 - use upscatter scaling for accelerated problem convergence

12. IPVT – parametric eigenvalue search. (0)

    0 - none

    1 - a search calculation will be made for an eigenvalue equal to PV

    2 - an α loss term with α = PV will be added to the transport equation.

The term α will depend on the IEVT option selected

4$ Cross-Section Weighting Options [XSDEme75] {IFG = 1}

Note: Currently XSDRNPM does not support outputting weighted cross section libraries in a format other than AMPX. The following items are still allowed to be entered into XSDRNPM input files for legacy inputs, but anything not relating to AMPX library format will have no effect.

---

1. ICON – type of weighting. (See Sect. 9.1.2.14)

-N - inner cell (with N zones in the cell). Cell weighting is performed

over the N innermost regions in the problem. Nuclides outside these regions are not weighted.

-1 - cell

0 - zone

1 - region or vein

3. ITP – collapsed output format desired.

   0-19 – cross sections are written only in the AMPX weighted library formats on logical 3. A weighted library is always written when IFG= 1. 20-29 – (deprecated feature). 30-39 – (deprecated feature). 40-49 – (deprecated feature).

   The various values of ITP (modulo 10) are used to select the different transport cross-section weighting options mentioned earlier. The options are:

   ITP = 0 => $\sqrt{\left(\psi_1^g + \left(DG\psi_g\right)\right)^2}$

   ITP = 1 => absolute value of current

   ITP = 2 => $DB^2\psi_g$+ outside leakage

   ITP = 3 => $\psi / \sum_t^g$

   ITP = 4 => $DB\psi_g$

   ITP = other values are reserved for future development and should not be used.

4. IPP – weighted cross-section edit option -1.

   -2 – none

   -1 – edit 1-D data

   0-N – edit through *PN* cross-section arrays. 1-D edits are given.

5. IHTF – (deprecated feature)
6. NDSF – (deprecated feature)
7. NUSF – (deprecated feature)
8. IAP – (deprecated feature)
9. (deprecated feature)

5* Convergence Criteria and Assorted Constants [12]

1. EPS – overall problem convergence. (10:sup:-*4*)
2. PTC – scalar flux convergence. (10:sup:-*5*)
3. XNF – normalization factor. (1.0)

   When IEVT = 0, the fixed sources are normalized to XNF.

   For IEVT > 0, the fission source is normalized to XNF.

   When XNF = 0.0, no normalization is made.

   XNF should only be specified as 0 for a fixed source problem (IEVT = 0).

4. EV – starting eigenvalue guess for search calculations.

5. EVM – eigenvalue modifier used in a search calculation. The following is a tabulation of recommended values for EV and EVM.

IEVT	Calculation type	EV	EVM
0	Fixed source	0	0
1	k-calculation	0	0
2	Direct α-search	0	0
3	–	–	–
4	Zone width search	0	-0.1
5	Outer radius search	Starting outer radius	-0.1*EV
6	Buckling search	1.0	-0.1
7	Direct buckling search	0.0	0.0

6. BF – buckling factor (1.420892). This parameter is two times the multiplier on the "extrapolation" distance used to determine where a linearly extrapolated line from the asymptotic flux shape would go to zero (e.g., for slabs, the extrapolation distance is $0.71\lambda_{tr}$ and, hence, BF 1.42).

7. DY – first transverse dimension in centimeters used in a buckling correction to calculate leakage normal to the principal calculation direction (i.e., the height of a slab or a cylinder).

8. DZ – second transverse dimension in centimeters used for a buckling correction (i.e., the width of a slab).

9. VSC – void streaming correction. This is the height of a void streaming path in a cylinder or slab in centimeters. See Sect. 9.1.2.13.

10. PV – parametric eigenvalue or value for α used when IPVT > 0. When IPVT = 1 and IEVT > 1, this is the value of k-effective on which the search calculation is to be made (0.0)

11. EQL – eigenvalue convergence for a search. (10^{-3})

12. XNPM – new parameter modifier used in search calculations. (0.75)

T Terminate data block.

Data Block 2

This block contains information on the composition of the materials used in the calculation. Also included is an array to select special cross sections for ANISN and an array to identify cross sections written on the CCCC ISOTXS library.

Note: Currently XSDRNPM does not support outputting weighted cross section libraries in any format other than AMPX. XSDRNPM will still read the deprecated arrays, but they will have no effect.

10$ (deprecated array)

12$ (deprecated array)

11$ Composition Numbers in Mixing Table [MS]

If the input multigroup library was previously self-shielded by running the XSProc module, the composition numbers are the mix numbers given in the READ COMP block of XSProc. If the input library has not been previously self-shielded, enter all zeros.

Note: this is a new array added in SCALE 6.2 which MUST be present when using a microscopic library produced by the XSProc module. It may be omitted if using a macroscopic library from XSProc

---

13$ Local Mixture Numbers in Mixing Table [MS]

The values range from 1 to MXX, and are used only in XSDRN for referencing mixtures in the mixing table.

14$ Isotope Identifiers in Mixing Table [MS]

A set of data with this identification must be on unit LAWL, the XSDRNPM working library, though the code will not make checks to ensure this is the case.

15* Isotope Concentrations in Mixing Table [MS]

16$ (deprecated array)

18U (deprecated array)

T Terminate Data Block

Data Block 3 {IEVT = 0}

This block is used to specify fixed sources. ..

30$ Source Spectrum Number by Interval [IM]

31* Volumetric Source Spectra [IQM*IGM]

32* Surface Source Spectra [IPM*IGM*MM]

Each of the IQM or IPM spectra is specified in the 31* or 32* array and are stacked one after the other in that array. If both volumetric and surface sources are used in the same problem, the surface source number is multiplied by (IQM + 1) when entered in the 30$ array.

A volumetric spectrum will consist of IGM (number of energy groups) entries which are the relative integrated values of the source in each group.

A surface source is always assumed to be on the right-hand side of a spatial interval. It is input as was the volumetric source, except that each group contains entries for the MM angles in the S_n quadrature chosen for the problem. Note that a surface source is an **integrated** value and is actually a flux condition in the Sn|equations.

In the 30$ array, a zero entry specifies that no source is in an interval.

Data Block 4

This data block contains starting guesses for fluxes and fission densities. If fluxes are read from an external device (LISF>0), this data block is omitted. Both arrays in this block are double-precision arrays, which will require the use of the "#" array designator; otherwise the number of entries read into the arrays will be incorrect or may contain nonsensical values for the starting guess.

33# Flux Guess [IM*IGM] {IFN=0}

A guess for the scalar flux is specified in the order: ((FLUX(I,J),I=1,IM),J=1,IGM), where IM is the number of spatial intervals and IGM is the total number of energy groups. For fixed-source problems, without better information, use zeroes. For eigenvalue problems, a nonzero flux guess must be used. The fluxes punched by using the ID1 parameter in the 2$ array can be used here in restart calculations.

34# Fission Density Guess [IM] {IFN=1}

This is a guess at the number of fission neutrons produced in an interval. When IFN = 1, XSDRNPM uses diffusion theory for the first outer iteration, after which it reverts to the normal mode.

T Terminate this data block.

Data Block 5

This block contains the remaining data needed for an XSDRNPM calculation.

35* Interval Boundaries [IM+1] (cm)

This array describes the spatial quadrature into which the problem model is divided. The boundaries are nonnegative for curvilinear geometries and in increasing order. Usually they will start with a zero value, though this is not necessary. The origin for slab geometry may be negative.

36$ Zone Number for Each Spatial Interval [IM]

Spatial zones should be contiguous.

38* Density Factors by Interval [IM] {IDFM>0} (1.0)

These factors are used to effect a density variation in a mixture as a function of spatial interval. Zero for a density factor affords a convenient way for modeling a void region.

39$ Mixture Numbers by Zone [IZM]

The mixture that is in a zone is specified here.

40$ Order of Scattering by Zone [IZM] (ISCT)

This is the order, *l*, of the *Sn Pl *calculation which is desired in a zone. This number should be no larger than ISCT.

41* Radius Modifiers by Zone [IZM] {IEVT=4}

These parameters specify the relative movement of the width of a zone in a zone width search. A zero indicates that a zone's width is fixed. (See Sect. 9.1.2.8)

42# Weights of the Angles in the Discrete-Ordinates Quadrature MM = ISN + 1 for slabs and spheres, ISN*(ISN + 4)/4 for a cylinder.

Input this set if you wish to override those provided by XSDRNPM. See Sect. 9.1.2.4.3, Sect. 9.1.2.4.4, or Sect. 9.1.2.4.5.

43# Cosines of the Angles in the Discrete-Ordinates Quadrature [MM]

Input this set if you wish to override those provided by XSDRNPM. See Sect. 9.1.2.4.3, Sect. 9.1.2.4.4, or Sect. 9.1.2.4.5.

46$ Calculational Option by Group [IGM] {ICLC>0}

0 - perform discrete-ordinates calculation for this group.

1 - perform a diffusion calculation for this group for ICLC outer iterations; use discrete-ordinates theory after this.

2 - perform a homogeneous calculation for this group for ICLC outer iterations; then revert back to discrete-ordinates theory.

3 - perform a homogeneous calculation using *Bn* theory for this group.

47* Right-Boundary Albedos by Group [IGM] {IBR=3} (1.0)

A right-boundary albedo is specified for each fine group. The return current is distributed isotropically in angle.

48* Left-Boundary Albedos by Group [IGM] {IBL=3} (1.0)

As for the 47* array but for the left boundary. Note that if IBR or IBL is 3 and the corresponding 47* or 48* array is omitted, XSDRNPM fills the array with 1.0's effecting a boundary with zero net current and with isotropic neutron return.

49$ Material Number for Activities [IAZ] {IAZ>0}

50$ Process Number for Activities [IAZ] {IAZ>0}

The 49$ and 50$ arrays provide a means of obtaining the activity (reaction rate) for any process for which cross sections are available in the XSDRNPM calculation. A representative activity table entry is shown below:

ACTIVITY TABLE ENTRY	
49$	50$
M	N

This entry specifies that the activity N for material M be calculated for all parts of the system which contain that material.

If N is < 0, a density of 1.0 is used to calculate activities instead of densities in the mixing table. Allowable process identifiers are given in Appendix M4.B.

If M is < 0, the activities by interval will be multiplied by a 1-D area as follows:

1.0 for a slab (IGE=1)

$2 \times r$ for a cylinder (IGE=2)

$4 \times r^2$ for a sphere (IGE=3)

51$ Broad-Group Numbers [IGM] {IFG>0}

This array contains the broad-group numbers into which the fine groups are collapsed in a flux-weighting calculation. For example, if the first five fine groups are to be collapsed to the first broad group, the first five entries in the 51$ array are 1, etc. A zero value can be used to ignore (or truncate) a group.

52$ Lower Band Group Numbers [NBANDS]

Group numbers giving the last group in a flux rebalance band. Overrides the default set supplied by XSDRNPM.

9.1.3.1 Abbreviated XSDRNPM input description

9.1.4 XSDRNPM INPUT/OUTPUT ASSIGNMENTS

The following logical units can be required in an XSDRNPM calculation.

Default Logical Unit	Purpose
3	Weighted Library (Produced by XSDRNPM)
4	Working Library (Input)
5	Card Input
6	Standard Output
7	Punch Fluxes or ANISN Libraries
8	Scratch Direct-Access Device for External Cross-Section Storage
9	Scratch Direct-Access Device for Mixing and Weighting Operations
10	Scratch Direct-Access Device for External Flux Moment Storage
16	Angular Fluxes
17	Scalar Fluxes
18	Scratch Device
19	Scratch Device
20	ANISN Binary Libraries or CCCC ISOTXS Interface
31	Fundamental mode forward angular flux input unit for generalized adjoint calculation (iflu>0)
32	Fundamental mode adjoint angular flux input unit for generalized adjoint calculation (iflu>0)
73	Dump of Input and Derived Data
75	Activities
76	Balance Tables

9.1.5 XSDRN SAMPLE PROBLEM

In this section, the input and output for a sample case involving a bare, homogeneous 16-cm sphere of a 93% enriched *UO2-F2* solution is presented. The input AMPX working format cross-section library will be read from logical unit 4.

The input working library is a temporary 238-group library created by CSAS-mg containing the following nuclides:

Nuclide	Identifier[a]
$^{235}U_{92}$	92235
$^{238}U_{92}$	92238
^{1}H	1001[b]
$^{16}O_{8}$	8016
$^{19}F_{9}$	9019
a These are the identifiers of the sets of data on the library created for the problem. *b* Water-bound kernel.	

An S_{16} quadrature is selected with 32 spatial intervals. Activities are requested for $^{235}U_{92}$ absorption and fission and $^{238}U_{92}$ absorption.

9.1.6 OUTPUT CROSS SECTIONS

One of the most common uses of XSDRNPM is to collapse cross sections and write them onto a file for input into another computer code. At present, two options are allowed:

1. Output library in AMPX Working Library format. This library is always written when cross sections are collapsed.
2. Output library in ANISN binary or BCD *format* [XSDJD63]. The binary library is written on logical 20 by default; the BCD library is produced on logical 7. The identifiers on this library range from 1 to the total number of blocks required to accommodate the data.

9.1.7 ERROR MESSAGES

During the course of a problem, XSDRNPM makes many checks to determine if input data are in the required form. If inconsistencies are spotted, a message is printed, and the problem may be terminated. Some of these messages are listed below along with a brief description of their possible cause.

DATA N N arrays have been input with incorrect length. See the messages produced as arrays are read to determine specific arrays.

SN-1 N The Nth entry in the S_n quadrature directions is zero. (43# array)

SN-2 0 The S_n weights do not sum to 1.0. (42# array)

SN-3 0 The sum of the products of S_n weights and directions is not 0.0, that is, the directions are not symmetric. (42# and 43# arrays)

FIXS 0 Fixed source calculation requested (IEVT=0) and total fixed sources are zero.

Q-HI N A volumetric source spectrum numbered N has been requested where N is greater than IQM.

B-HI N A boundary source spectrum numbered N has been requested where N is greater than IPM.

FISS 0 IEVT≥ 1 and the total fission source is zero.

8101 N The N^{th} radius is negative.

8102 N The N^{th} radius is less than the $(N-1)^{th}$ radius.

8103 N Zone N dimensions have become negative in a zone width search.

MIX N A request has been made to use the N^{th} component from the mixing table, but this nuclide has not been requested from a library.

Several messages may be encountered during an XSDRNPM run which indicate problems with either the code or the setup:

ROOT L The polynomials from which the default angles are derived are incorrect.

BAND N The number of bands specified is greater than the number of groups.

WAT1 N The number of sets of weighted cross sections is incorrect.

WAT2 N The number of sets of weighted cross sections is incorrect.

9.1.8 APPENDICES

9.1.8.1 Special XSDRNPM Files

Three special files that can be optionally produced by XSDRNPM are described in this appendix. (See Sect. 9.1.5 and the discussion of the logical units in the 0$ array.) The files will be created with file names of the form **ftNNfXXX.EXT** where **NN** is the 2 digit logical unit number (from the 0$$ array), **XXX** is a 3 digit number which is incremented by one starting with one to make the name unique, and **EXT** is an extension identifying which type of file it is (**acf** for activity file, **btf** for balance table file, and **idf** for input and derived data file).

Activity file

The data on the activity file depends on what input options are specified. The data is in ASCII sets, which consist of a label record followed by the record(s) of the activity. There will be at most **IAZ** sets ordered as the 49$ and 50$ arrays. The first sets of data will be the activities by interval (if the input parameter **IAI** was specified). A set will be formatted as below.

activity by interval for nuclide *nnnnnnnn* **reaction type** *rrrrrrrr*

Activity(first interval)

.

.

.

.

Activity(last interval)

The preceding set will be repeated **IAZ** times. Then sets giving the activities by zone will be given. They will be formatted as below.

activity by zone for nuclide *nnnnnnnn* **reaction** *rrrrrrrr*
Activity(first zone)

.

.

.

.

Activity(last zone)

Balance table file

The contents of the balance table are defined in Table 9.1.4 and Table 9.1.5. The structure of the "balance table file" written to **LBTF** is:

Record 1 **KEFF, SP**

KEFF - $k_{effective}$ for problem

SP - search parameter for case

Record 2 - Sets of ASCII data consisting of a label record followed by data records.

Record last

A set of data is as follows (igp is the total number of groups plus one):

fine(few) group summary for zone *zzzzz* **set type**

Set type data(group 1)

Set type data(group 2)

.

.

.

.

Set type data(group igp)

The data for a set type will be written for each zone of the problem, plus a system summary if there is more than one zone. After one set type is finished, the next set type will be written. The order of the set types is as follows:

fixed source

fission source

absorption rate

total leakage

fission rate

flux

<n,2n> rate

buckling loss

right current

left current

right leakage

left leakage

The fine group summary data will be written if **LBTF** is > 0. After the fine group data is finished, the few group summary data will follow if a weighting calculation is specified with a broad group collapse.

Input and derived data file

The contents of the input and derived data file (specified by **LIDF**) is as follows:

Record 1 – **title** (80 characters)

Record 2 – **1$ $ array** (label)

Record 3,4 – **data from 1$ array**

Record 5 – **2$ $ array** (label)

Record 6 – **data from 2$ array**

Record 7 – **3$ $ array** (label)

Record 8,9 – **data from 3$ array**

Record 10 – **4$ $ array** (label)

Record 11 – **data from 4$ array**

Record 12 – **5** array** (label)

Record 13,14 – **data from the 5* array**

Record 15 – **cross section parameters** (label)

Record 16 – **total groups, neutron groups, gamma groups, first thermal group**

Record 17 – **nuclides on library** (label)

Records 17a – **list of nuclides on the cross section library**

Record 18 – **mixture numbers** (label)

Records 18a – **data from the 13$ array**

Record 19 – **component numbers** (label)

Records 19a – **data from the 14$ array**

Record 20 – **densities** (label)

Records 20a – **data from the 15* array**

Record 21 – **cccc identifiers** (label)

Records 21a – **data from the 16$ array**

Record 22 – **neutron energy group boundaries** (label)

Records 22a — **list of the energy boundaries for the neutron groups**

Record 23 – **neutron lethargy group boundaries** (label)

Records 23a – **list of the lethargy boundaries for the neutron groups**

Record 24 – **neutron weighted velocities** (label)

Record 24a – **list of the neutron average velocities**

Record 25 – **gamma energy group boundaries** (label)

Record 25a – **list of the energy boundaries for the gamma groups**

Record 26 – **gamma lethargy group boundaries** (label)

Records 26a – **list of the lethargy boundaries for the gamma groups**

Record 27 – **gamma weighted velocities** (label)

Records 27a – **list of the gamma velocities**

Record 28 – **broad group numbers** (label)

Records 28a – **list of the broad group numbers by fine group - 51$ array**

Record 29 – **group band** (label)

Records 29a – **group band numbers by fine group**

Record 30 – **calculation type** (label)

Records 30a – **calculation type by fine group**

Record 31 – **right albedo** (label)

Records 31a – **list of the right boundary albedos by group - 47* array**

Record 32 – **left albedo** (label)

Records 32a – **list of the left boundary albedos by group - 48* array**

Record 34 – **mixture by zone** (label)

Records 34a – **data from the 39$ array**

Record 35 – **order of scattering by zone** (label)

Records 35a – **data from the 40$ array**

$\sum_{n,pn}$ = the cross section for producing p neutrons, p=2,3,. . . ,p an integer
D = the diffusion coefficient (used in providing a buckling correction for 2 and 3 dimensions)
B^2 = the buckling for the second and third dimensions (includes an extrapolation distance)
max(LL,0) means that a positive Left Leakage is a source into the zone
min(RL,0) means that a negative Right Leakage is a source into the zone. It is included with a minus sign to make it a pos
max(RL,0) means that a positive Right Leakage is a loss from the zone
min(LL,0) means that a negative Left Leakage is a loss from the zone. It is included with a minus sign to make it a positiv

9.1.8.2 XSDRNPM Mixed Cross Sections

When **IPRT** (2$$ array) is set > -1, XSDRNPM prints the mixed reaction rate cross sections that are used in its calculations. The order of the cross sections for each group is given below in Table 9.1.6. The diffusion coefficient is used in computing buckling corrections, and in some of the options for computing the current used in weighting the transport cross section. The upscatter cross section is used to checking upscatter convergence. The <n,2n> cross section is used in computing the balance for the balance tables. It is actually a weighted sum of all the multiple neutron exit reactions other than fission. These are all treated in XSDRNPM as scattering reactions. Chi is the fission spectrum, and is used to distribute the fission source in energy space. The fission cross section is used to compute the fission rate reported in the balance tables. The absorption cross section is used to compute the absorptions in the balance tables, and to compute the absorption term in the eigenvalue. Nu*fission cross section is used to generate the source term for all except a fixed source calculation. The total cross section is used to determine the neutron transport.

Table 9.1.6: Order of mixed reaction cross sections

9.2 NEWT: A NEW TRANSPORT ALGORITHM FOR TWO-DIMENSIONAL DISCRETE-ORDINATES ANALYSIS IN NON-ORTHOGONAL GEOMETRIES

M. A. Jessee, M. D. DeHart

ABSTRACT

NEWT (**N**ew **E**SC-based **W**eighting **T**ransport code) is a multigroup discrete-ordinates radiation transport computer code with flexible meshing capabilities that allow two-dimensional (2-D) neutron transport calculations using complex geometric models. The differencing scheme employed by NEWT, the Extended Step Characteristic approach, allows a computational mesh based on arbitrary polygons. Such a mesh can be used to closely approximate curved or irregular surfaces to provide the capability to model problems that were formerly difficult or impractical to model directly with discrete-ordinates methods. Automated grid generation capabilities provide a simplified user input specification in which elementary bodies can be defined and placed within a problem domain. NEWT can be used for eigenvalue, critical-buckling correction, and source calculations and it can be used to prepare collapsed weighted cross sections in AMPX working library format.

Like other SCALE modules, NEWT can be run as a standalone module or as part of a SCALE sequence. NEWT has been incorporated into the SCALE TRITON control module sequences. TRITON can be used simply to prepare cross sections for a NEWT transport calculation and then automatically execute NEWT. TRITON also provides the capability to perform 2-D depletion calculations, in which the transport capabilities of NEWT are combined with multiple ORIGEN depletion calculations to perform 2-D depletion of complex geometries. In the TRITON depletion sequence, NEWT can also be used to generate lattice-physics parameters and cross sections for use in subsequent nodal core simulator calculations.

ACKNOWLEDGMENTS

The author expresses gratitude to B. T. Rearden and S. M. Bowman for their supervision of the SCALE project and review of the manuscript. The author acknowledges R. Y. Lee of the U.S. Nuclear Regulatory Commission (NRC) and A. P. Ulses (formerly NRC) for their support of the development of NEWT. Appreciation is extended to G. Ilas, B. L. Broadhead, Deokjung Lee (formerly ORNL), and B. J. Ade for their review of this or previous versions of the manuscript. The efforts of Z. Zhong (Argonne National Laboratory), A. P. Ulses (formerly NRC), K. S. Kim, C. F. Weber, G. Ilas, and K. T. Clarno (Oak Ridge National Laboratory) in methods development and testing of the code have been invaluable in the continued evolution and improvement of the code.

9.2.1 INTRODUCTION

NEWT (**N**ew **E**SC-based **W**eighting **T**ransport code) is a two-dimensional (2-D) discrete-ordinates transport code developed based on the Extended Step Characteristic (ESC) approach [NEWTDeh92] for spatial discretization on an arbitrary mesh structure. This discretization scheme makes NEWT an extremely powerful and versatile tool for deterministic calculations in real-world non-orthogonal problem domains. The NEWT computer code evolved from the earlier proof-of-principle CENTAUR code [NEWTDeh92] and has been developed to run within SCALE. Thus, NEWT uses AMPX-formatted cross sections processed by other SCALE modules. If cross sections are properly prepared, NEWT can be run in stand-alone mode. NEWT can also be used within the TRITON control module for transport analysis, depletion analysis, and sensitivity and uncertainty analysis.

9.2.1.1 How to use this manual

This users' manual is intended to assist both the novice and the expert in the application of NEWT for transport analysis. As such, the document is divided into subsections, each with a specific purpose. Not all sections will be of value to all users. It is not intended that the user of this manual read through the manual from start to end. Rather, the manual is designed to serve as a reference, with each section meeting different needs. This introductory section has been written to provide a general overview of the background, nature, functionality, and applications of NEWT; it should prove of interest to users at all levels. Sect. 9.2.2 provides detail on the theory of NEWT in terms of derivations, equations, and relationships used in the NEWT solution. This information will be of interest to those with a background in transport methods desiring a comprehensive understanding of the NEWT solution scheme. However, this information may provide too much detail or simply not be relevant for the beginning user or someone desiring to improve or expand an existing model. These users will find Sect. 9.2.3 to be of more value, where input data requirements and formats are described in detail, along with examples of each data type. This information is supplemented by Sect. 9.2.4, in which complete sample inputs with descriptions of the features of each model are provided. Sect. 9.2.5 describes the components of an output listing obtained from a successful NEWT calculation.

9.2.1.2 Background

The radiation transport equation, a linearized derivative of the Boltzmann equation, provides an exact description of a neutral-particle radiation field in terms of the position, direction of travel, and energy of every particle in the field. Both stochastic (Monte Carlo simulation) and deterministic (direct numerical solution) forms of the transport equation have been developed and are used extensively in nuclear applications. Each approach has its strengths and weaknesses. Stochastic approaches are extremely effective for problems with complex geometries where the calculations of integral quantities, such as radiation dose and neutron multiplication factors, are desired. However, calculations to obtain accurate differential information, such as the neutron flux as a function of space and energy, can be difficult and inefficient at best and prone to inaccuracies (even if the integral quantity is correct). Deterministic techniques, such as integral transport, collision probability, diffusion theory, and discrete-ordinates methods, are better suited for problems where differential quantities, such as the neutron flux as a function of energy or space, are desired. However, integral transport, collision probability, and diffusion approximations are based on simplifying assumptions, which can limit their applicability. The discrete-ordinates approach is a more rigorous approximation to the transport equation but is typically very limited in its flexibility to describe complex geometric systems.

Discrete-ordinates approaches are derived from the integro-differential form of the Boltzmann transport equation, where space, time, and energy dependencies are normally treated by the use of a finite-difference grid, while angular behavior is treated by considering a number of discrete directions in space. The angular solution is coupled to a scalar spatial solution via some form of numerical integration. Because of the direct angular treatment of the discrete-ordinates approach, angularly dependent distribution functions can be computed; thus, this approach is the preferred method of solution in many specific applications where angular anisotropy is important. However, as indicated earlier, it is often limited in applicability because of the geometric constraints of the orthogonal grid system associated with the finite-difference numerical approximation.

9.2.1.3 Discrete-ordinates solution on an arbitrary grid

The ESC approach was developed to obtain a discrete-ordinates solution in complicated geometries to handle the needs of irregular configurations. Deterministic solutions to the transport equation generally calculate a solution in terms of the particle flux; the flux is the product of particle density and speed and is a useful quantity in the determination of reaction rates that characterize nuclear systems. General 2-D *xy* discrete-ordinates methods perform calculations that provide four side-averaged fluxes and a cell-averaged flux for each cell in a rectangular problem grid; iteration is performed to obtain a converged distribution. This approach is usually termed the diamond-difference approach. Using the ESC approach, a more flexible and completely arbitrary problem grid may be defined in terms of completely arbitrary polygons. Side-averaged fluxes for each polygon in the problem domain are computed and are used to calculate a cell-averaged flux. This process is repeated for each cell in the problem domain, and as with the traditional approach, iteration is performed for convergence. This geometric flexibility is a significant enhancement to existing technology, as it provides the capability to model problems that are currently difficult or impractical to model directly.

9.2.1.4 Functions performed

NEWT provides multiple capabilities that can potentially be used in a wide variety of application areas. These include 2-D eigenvalue calculations, forward and adjoint flux solutions, multigroup flux spectrum calculations, and cross section collapse calculations. NEWT provides significant functionality to support lattice-physics calculations, including assembly cross section homogenization and collapse, calculation of assembly discontinuity factors (for internal and reflected assemblies), diffusion coefficients, pin powers, and group form factors. Used as part of the TRITON depletion sequence, NEWT provides spatial fluxes, weighted multigroup cross sections, and power distributions used for multi-material depletion calculations and coupled depletion and branch calculations needed for lattice-physics analysis.

9.2.2 THEORY AND PROCEDURES

This section provides the theoretical basis for the ESC discretization technique, the NEWT solution algorithm, and cross section processing procedures used by NEWT. Although this information is not necessary to be able to use NEWT for transport calculations, it provides a deeper understanding of the basic operations performed within NEWT.

9.2.2.1 Boltzmann transport equation

The neutron transport equation may be presented in various forms, and simplifications are often applied to tailor the equation to the requirements of a specific application. In nuclear engineering applications, the transport equation is often written in terms of the angular neutron flux as the dependent variable. The angular neutron flux is defined as the product of the angular neutron density and the neutron velocity. The time-independent form of the linear transport equation is then expressed as [NEWTDH76]

$$\Omega \cdot \nabla\psi(\mathbf{r}, \Omega, E) + \sigma_t(\mathbf{r}, E)\psi(\mathbf{r}, \Omega, E) = Q(\mathbf{r}, \Omega, E), \tag{9.2.1}$$

where

$\psi(\mathbf{r}, \Omega, E) \equiv$ angular flux at position per unit volume, in direction Ω per unit solid angle and at energy E per unit energy;

$\sigma_t(\mathbf{r}, E) \equiv$ total macroscopic cross section at position $\mathbf{r}$ and energy E; and

Q ≡ source at position $\mathbf{r}$ per unit volume, in direction Ω per unit solid angle and at energy E per unit energy.

The source Q is generally composed of three terms:

1. a scattering source,

$$S(\mathbf{r}, \Omega, E) = \int_{4\pi} d\Omega' \int_0^\infty dE' \sigma_s(\mathbf{r}, \Omega' \rightarrow \Omega, E' \rightarrow E)\, \psi(\mathbf{r}, \Omega', E'), \tag{9.2.2}$$

where

$\sigma_s(\mathbf{r}, \Omega' \rightarrow \Omega, E' \rightarrow E) \equiv$ macroscopic scattering cross section at position $\mathbf{r}$ from initial energy E' and direction Ω' to final energy E and direction Ω,

2. a fission source,

$$F(\mathbf{r}, \Omega, E) = \chi(\mathbf{r}, E) \int_0^\infty dE' \nu(\mathbf{r}, E')\, \sigma_f(\mathbf{r}, E')\, \psi(\mathbf{r}, \Omega, E'), \tag{9.2.3}$$

where

$\sigma_f(\mathbf{r}, E')$ ≡ macroscopic fission cross section at position **r** and energy E' (assumed to be isotropic),

$\nu(\mathbf{r}, E')$ ≡ number of neutrons released per fission event at position **r** and energy E',

$\chi(\mathbf{r}, E)$ ≡ fraction of neutrons that are born at **r** and at energy E, and

3. an external or fixed source, S(**r** ,E).

In general, the transport equation can be difficult to apply and can be solved analytically only for highly idealized cases. Hence, simplifications and numerical approximations are often necessary to apply the equation in engineering applications. Traditional discrete-ordinates methods are based on a finite-difference approximation to solve the flux streaming (leakage) term. Such differencing schemes are intimately tied to the coordinate system in which the differencing equations are developed, and it becomes difficult to represent non-orthogonal volumes within that coordinate system. For example, it is not possible to exactly represent a cylinder in a 2-D Cartesian coordinate system; one must approximate the cylinder with a number of rectangular cells. A close approximation can require a large number of computational cells. However, the ESC approach for discretizing computational cells allows the use of non-orthogonal computational cells composed of arbitrary polygons. Using this method, practically any shape can be represented within a Cartesian grid to a very close approximation. The ESC approach is discussed in the following sections.

9.2.2.2 The step characteristic approximation

Efficient application of discrete-ordinates methods is difficult when dealing with complicated non-orthogonal geometries because of the nature of finite difference approximations for spatial derivatives. An alternative to the discrete representation of the spatial variable is achieved in the method of characteristics, in which the transport equation is solved analytically along characteristic directions within a computational cell. The angular flux is solved along the *s*-axis, where this axis is oriented along the characteristic direction Ω. Since only the angular flux in direction Ω is of concern, then the streaming term can be rewritten as

$$\Omega \cdot \nabla\psi(\mathbf{r}, \Omega, E) = \frac{d\psi(s, E)}{ds}. \tag{9.2.4}$$

Hence Eq. (9.2.1) can be written in the characteristic form (omitting E for clarity) as

$$\frac{d\psi(s)}{ds} + \sigma_t(s)\psi(\mathrm{s}) = Q(s), \tag{9.2.5}$$

which has a solution of the form [NEWTHil76]

$$\psi(s) = \psi_0 e^{-\sigma_t s} + e^{-\sigma_t s} \int_0^s Q e^{\sigma_t s'} ds', \tag{9.2.6}$$

where s is the distance along the characteristic direction Ω, and ψ_0 is the known angular flux at s=0. The value for ψ_0 is given from boundary conditions for known cell sides, and angular fluxes on unknown sides are computed using Eq. Eq. (9.2.6). Methods for the determination of an appropriate value for ψ_0 and for evaluation of the integral term vary in different solution techniques.[4-9] [NEWTAL81, NEWTALMJW79, NEWTHil76, NEWTLA81, NEWTLat68, NEWTLat69, NEWTLM84]. One of the simplest schemes employing the Method of Characteristics is the Step Characteristic (SC) method developed by Lathrop [NEWTAL81]. In this approach, the source Q and macroscopic total cross section σt are assumed to be constant within a computational cell and the angular flux is assumed constant on the cell boundaries of incoming direction. Integration of Eq. Eq. (9.2.6) can be performed to obtain

$$\psi(s) = \psi_0 e^{-\sigma_t s} + \frac{Q}{\sigma_t}\left(1 - e^{-\sigma_t s}\right). \tag{9.2.7}$$

Fig. 9.2.1 shows a sample computational cell in which the SC method can be applied. For a given characteristic direction Ω, the angular flux on any unknown side may be expressed in terms of a suitable average of fluxes from known sides, which contribute to the unknown side. For the characteristic direction Ω shown in Fig. 9.2.1, the unknown "top" flux ψ_T may be computed as a linearly weighted average of contributions from known sides ψ_B and ψ_L. The fluxes on each of the two known sides are taken to be constant along the length of each side, representing the average angular flux in direction Ω and must be specified from external boundary conditions or from a completed calculation in an adjacent cell.

The set of characteristic directions is chosen from a quadrature set, so that the resulting angular fluxes may be numerically integrated to obtain a scalar flux. Knowing the lengths of the sides of a rectangular cell (ΔDelta`y) and the direction cosines of Ω in the *x*-*y* plane (μ and η), a function for the length *s* can easily be determined. The solution for from Eq. Eq. (9.2.7) can then be integrated along the length of each unknown side to determine the average angular flux of the unknown side. Once the angular flux is known on all four sides, a neutron balance on the cell can be used to determine the cell's average angular flux.

Although the SC method described above is based on rectangular cells, the derivation of Eq. Eq. (9.2.7) makes no assumptions about the shape of the cell. It merely requires knowledge of the relationship between cell edges along the direction of the characteristic. Hence, the method is not restricted to any particular geometry. Because it is an extension of the SC approach into generalized cells, the method developed here for generalized geometries is referred to as the Extended Step Characteristic (ESC) method.

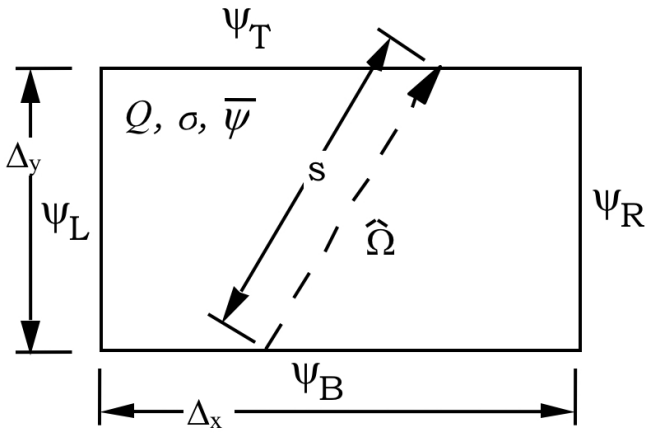

Fig. 9.2.1: Typical rectangular cell used in the step characteristic approach.

9.2.2.3 The Extended Step Characteristic approach

The theory of the ESC approach is developed and explained in detail in [NEWTDeh92]. However, the work has evolved significantly from that time, most notably in the elimination of a requirement for non-reentrant polygons (convex). The following subsections describe the primary equations applied in the ESC approach as currently applied in NEWT.

Cell properties and geometries

The two primary assumptions of the ESC method are that (1) within each computational cell all properties (i.e., σt and Q) are uniform and (2) cell boundaries are defined by straight lines. The restriction of a computational cell to boundaries consisting of a set of straight lines results in computational cells that are limited to polygons. However, as will be seen later, no restrictions are placed on the shape of the polygon or on the number of sides in the polygon. However, the size of the polygon will be limited. In practical applications, properties are unlikely to remain constant over significant volumes. Thus this approach, like many other differencing schemes, is a poor approximation when cell volumes become too large. Although σt is a material property and may remain spatially constant, the source term Q, which depends on the neutron flux, will vary with position. However, since the solution would become exact in an infinitesimally small cell, it is expected that the approximation will be reasonable for computational cells in which the change in the flux (and therefore the source) is small over the domain of the cell.

As a result of this geometric configuration, each side of a cell can have one of three possible attributes relative to particle flow in a given characteristic direction, as illustrated in Fig. 9.2.2: (1) flow can enter the cell when crossing a side (as shown by sides E and F in the figure); (2) flow can exit the cell when crossing a side (sides B and C); or (3) in a special case, flow may be parallel to the orientation of a given side (sides A and D). Expressed mathematically, these relationships become

$$\text{Category 1} : \Omega_k \cdot \hat{n}_i < 0 \tag{9.2.8}$$

$$\text{Category 2} : \Omega_k \cdot \hat{n}_i > 0 \tag{9.2.9}$$

$$\text{Category 1} : \Omega_k \cdot \hat{n}_i = 0 \tag{9.2.10}$$

where $\hat{n}_i$ is a unit vector in the cell-outward direction normal to side i, and Ω_k is the k^{th} discrete element of a set of characteristic directions. A category 1 side will be termed an "incoming" side with respect to the direction Ω_k, and a category 2 side will be referred to as an "outgoing" side. For simplicity, the definition of Eq. Eq. (9.2.10) will be included as a special case of Eq. Eq. (9.2.8) for an incoming side. Thus, Eq. Eq. (9.2.8) can be rewritten as

$$\text{Side } i \text{ is incoming with respect to } \Omega_k : \Omega_k \cdot \hat{n}_i \leq 0 \tag{9.2.11}$$

$$\text{Side } i \text{ is outgoing with respect to } \Omega_k : \Omega_k \cdot \hat{n}_i > 0 \tag{9.2.12}$$

To solve for fluxes (flow) on outgoing sides of a cell, one must know fluxes on all incoming sides. Each incoming side of each cell will be given from a boundary condition or will be the outgoing side of an adjacent cell.

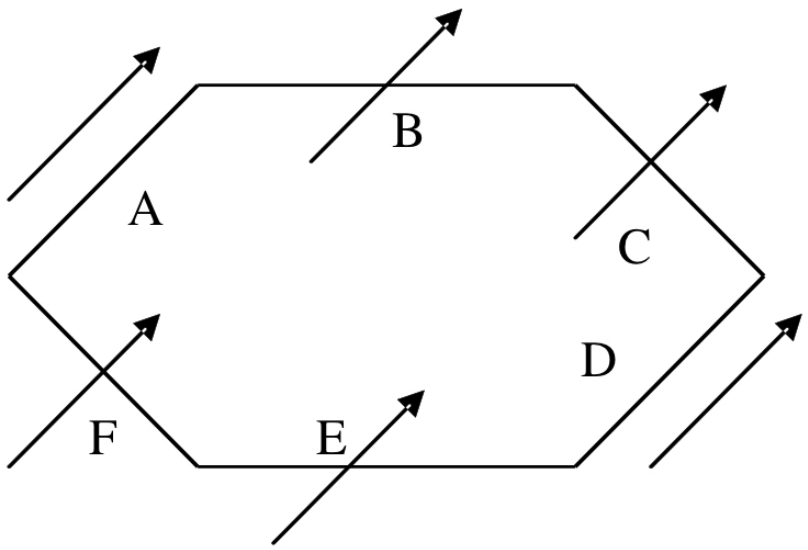

Fig. 9.2.2: Orientation of the sides of a cell with respect to a given direction vector.

Relationships between cells

In the ESC method, the shape of the computational cell and the form of the neutron balance differ from that used in traditional discrete-ordinates methods. Nevertheless, the relationships between cells are treated essentially as they would be in traditional approaches. The entire problem domain is mapped in terms of a set of finite cells. Each side of each cell is adjacent to either an external boundary condition or another cell. For each discrete direction, cells are swept in a predetermined order beginning at a known boundary (from a specified external boundary condition) moving in the given direction. The precise order of sweep is such that as the solution for one cell is obtained, the cell provides sufficient boundary conditions for the solution of an adjacent cell. Hence, cells sharing a given side share the value of the angular flux on that side. Knowledge of the flux on all incoming sides of a cell is sufficient to solve for all outgoing sides. Once the angular flux has been determined for all sides of the cell for the given direction, it is possible to use a neutron balance to compute the average value of the angular flux within the cell.

The sweeping of cells continues for a given direction until all cell fluxes have been calculated. The procedure is then repeated for the next direction until all directions have been computed. At this point, the cell average angular fluxes are known for each cell for each direction used. Numerical quadrature can then be used to determine the average scalar flux in each cell in the problem domain. The scalar fluxes are used to determine fission and scattering reaction rates in each cell and to update the value of the cell average source, Q. The process is repeated, and the iteration continues until all scalar fluxes converge to within a specified tolerance.

This approach can be performed assuming a single energy group or any number of discretized energy groups. The multigroup approach used in the ESC method is the standard approach used in most multigroup methods and is independent of the shape of each computational cell. Hence, the details of the multigroup formalism will be omitted from this discussion.

The set of characteristic directions

The characteristic solution to the transport equation gives only the angular flux in the direction of the characteristic direction vector Ω_k. To compute interaction rates within a cell, one must compute scalar fluxes. In computing the scalar flux from the set of angular fluxes, it is convenient to choose the set of characteristic directions from an appropriate quadrature set. Then the set of computed angular fluxes can be combined with appropriate directional weights and summed to obtain a scalar flux solution within a cell. Therefore, it is most appropriate to choose characteristic directions from an established set of base points and weights. Such quadrature sets that have been developed and used in numerous earlier discrete- ordinates approaches are used in NEWT. No restriction is placed on the nature or order of the quadrature set, as long as it is sufficient to adequately represent the scalar flux from computed angular fluxes.

Angular flux at a cell boundary

As in the development of the SC method, as well as most finite-difference methods, the ESC approach does not explicitly determine the flux distribution as a function of position along the sides of a computational cell. Instead, the angular flux on each cell side is represented in terms of the average angular flux along the length of the side. This is sufficient to determine the net leakage across each cell side, which is needed in order to maintain a cell balance. An average value of the flux for an incoming side must be specified from a boundary condition or from the prior solution of an adjacent cell. The average flux along a given outgoing side can be computed by integrating the flux along the side and dividing by the length of the side. However, the form of the distribution of the angular flux on the side must be known to perform this integration. This distribution can be determined from the properties of the cell and from the average flux on each of the known incoming sides.

Because the characteristic solution [Eq. Eq. (9.2.6)] allows calculation of the angular flux at any point s in a single cell given an initial condition, the exact value of the flux can be computed at any point on any outgoing side if the flux along each incoming side is known. As an initial condition, it is assumed that the angular flux in some characteristic direction is known at some starting point, $s = 0$ [i.e., $\psi(0) = \psi_0$], on an incoming side. To determine the flux at some point on an outgoing side, one need know only the distance s measured along a characteristic direction to the appropriate incoming side. This method can then be expanded to determine a functional form of the flux for every point on the outgoing side, which can be integrated to produce the average outgoing flux on the side.

To develop a mathematical relationship between two arbitrary sides of a cell, one should first consider two arbitrary coplanar line segments in space whose endpoints each lie on a pair of parallel lines laid in the direction Ω_k, as shown in Fig. 9.2.3. Points B_1 and B_2 can be considered to be the "projections" of A_1 and A_2, respectively, relative to Ω_k. Because s is the distance between a point on segment A and its projection on segment B, it can be seen that s varies linearly in moving from the "beginning" to the "end" of the pair of segments.

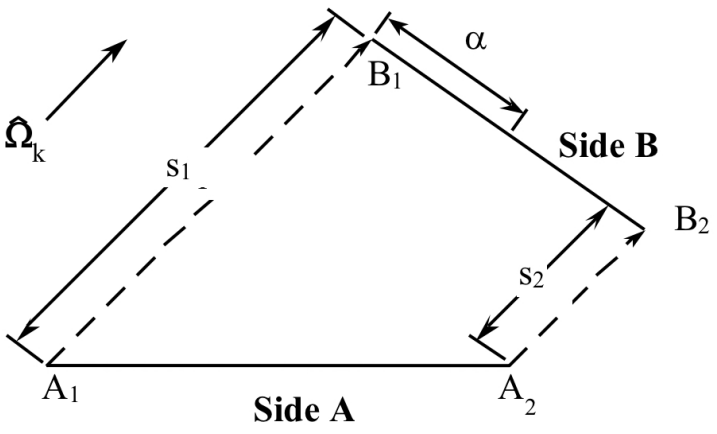

Fig. 9.2.3: Line endpoints for computation of average fluxes.

If α is the distance along segment B measured from endpoint B_1 and B has a total length L, then the distance s between A and B along direction Ω_k can be written as a linear function in terms of the position α:

$$s(\alpha) = s_1 + \left(\frac{s_2 - s_1}{L}\right)\alpha, \tag{9.2.13}$$

where s_1 and s_2 are related to the distances along the characteristic direction between A_1, B_1 and A_2, B_2, respectively. (It is important to note that the length s is the same as the distance between the endpoints only when the characteristic vector lies in the plane of the computational cell. This is not necessarily the case, depending on the choice of quadrature directions. This situation is discussed in more detail later.)

If $\psi(\alpha)$ is the angular flux on side B at a distance α from B_1, then $\bar{\psi}_B$, the average value of ψ on B, is given by

$$\bar{\psi}_B = \frac{\int_0^L \psi(s(\alpha))d\alpha}{\int_0^L d\alpha}. \tag{9.2.14}$$

Equation Eq. (9.2.6), the solution to the characteristic equation in the step approximation, can be rewritten in terms of the average known angular flux on side A

$$\psi_B(s) = (\bar{\psi}_A - Q/\sigma_t)\, e^{-\sigma_t s} + Q/\sigma_t. \tag{9.2.15}$$

Inserting Eqs. Eq. (9.2.13) and Eq. (9.2.15) into Eq. Eq. (9.2.14) and simplifying yields

$$\bar{\psi}_B = \frac{1}{L}\int_0^L \left[(\bar{\psi}_A - Q/\sigma_t)\exp\left(-\sigma_t\left(s_1 + \left(\frac{s_2 - s_1}{L}\right)\alpha\right)\right) + Q/\sigma_t\right] d\alpha. \tag{9.2.16}$$

For the special case in which A and B are parallel, $s_1 = s_2$ and the second term in the exponential drops out. Equation Eq. (9.2.16) can easily be integrated to obtain

$$\bar{\psi}_B = (\bar{\psi}_A - Q/\sigma_t)\, e^{-\sigma_t s_1} + Q/\sigma_t. \tag{9.2.17}$$

In the more general case, $s_1 \neq s_2$, the result is slightly more complicated:

$$\bar{\psi}_B = \frac{(\bar{\psi}_A - Q/\sigma_t)}{\sigma_t\,(s_2 - s_1)}\left[e^{-\sigma_t s_1} - e^{-\sigma_t s_2}\right] + Q/\sigma_t. \tag{9.2.18}$$

Equations Eq. (9.2.17) and Eq. (9.2.18) can also be written in a simplified form:

$$\bar{\psi}_B = \beta_{AB}\bar{\psi}_A + (1 - \beta_{AB})\, Q/\sigma_t \tag{9.2.19}$$

where

$$\beta_{AB} = \begin{cases} \frac{e^{-\sigma_t s_1} - e^{-\sigma_t s_2}}{\sigma_t (s_2 - s_1)} & s_1 \neq s_2 \\ e^{-\sigma_t s_1} & s_1 = s_2 \end{cases} \tag{9.2.20}$$

Thus far, this development has considered only the special case where contributions to side B are the result only of the cell internal source and a single incoming side (i.e., side A). For an arbitrarily shaped cell and discrete direction Ω_k, it is likely that the outgoing side would receive contributions from two or more incoming sides, as illustrated in Fig. 9.2.4, for a cell with three incoming sides (X, Y, and Z) contributing to the flux on a single outgoing side (B). In such a situation, the outgoing side can be subdivided into multiple components. Side B of Fig. 9.2.4 can be represented by three components, B_X, B_Y, and B_Z, representing contributions from line segments X, Y, and Z, respectively. The average angular flux $\bar{\psi}$ can be computed for each component of side B using Eq. Eq. (9.2.19); then $\bar{\psi}_B$, the average flux for the entire length of B, can be calculated by the length-weighted average of each component. In general, for a given side B composed of n components, the average flux of the side is given by

$$\bar{\psi}_B = \sum_{i=1}^{n} \frac{\bar{\psi}_i i}{L_B} \tag{9.2.21}$$

where

ℓ_i is the length of the projection of the ith side onto B, and

$\bar{\psi}_i$ is the average flux computed for segment B_i due to the flux on side i

Using Eqs. Eq. (9.2.19) and Eq. (9.2.21), one can compute the average flux on each of the outgoing sides for a given cell, once the angular flux on each incoming side is known. At this point, only distances s_1 and s_2 and the lengths ℓ_i and L need be determined to estimate fluxes in an iterative process. These can be computed from the geometry of the cell and the direction Ω_k.

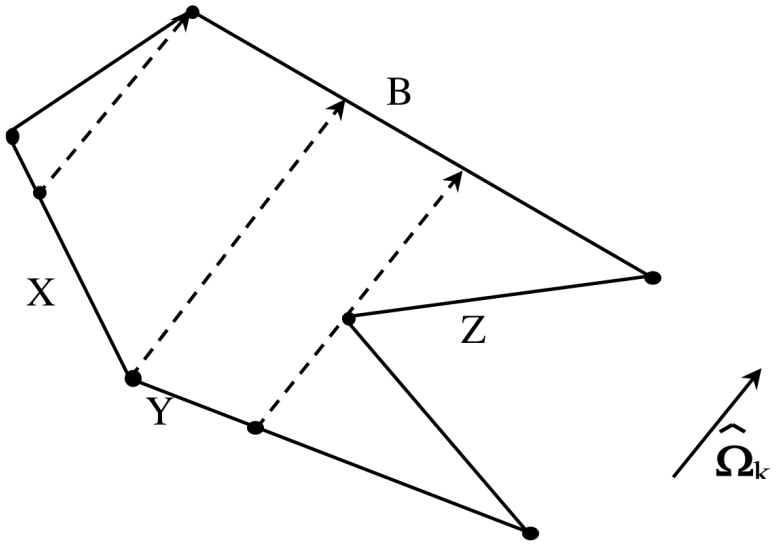

Fig. 9.2.4: Contributions of multiple incoming sides to an outgoing side.

Mapping a characteristic vector into the two-dimensional problem domain

Even in a 2-D x-y system in which the scalar flux is constant with respect to the z axis, the angular flux has components in the z direction. Thus, to obtain the scalar flux at a point on the x-y plane, one must integrate over the unit sphere in all 4π directions of Ω. Recall that the choices of characteristic directions for this model were selected to be the same as the set of directions composing a conventional quadrature set. Quadrature sets specified in the literature [NEWTCL65, NEWTCar70, NEWTLee62] and used in other discrete-ordinates codes [NEWTEJ67, NEWTLB73] are based on a unit sphere and are usually specified in terms of μ_k and η_k, the respective x and y components of Ω_k, where is one of a set of discrete directions composing the quadrature set. Because Ω_k is a unit vector, ξ_k, the z component of the direction, is implicit: $\xi_k = \sqrt{1-\mu_k^2-\eta_k^2}$. However, because of the 2D nature of the problem, the z component is never explicitly used. It is therefore sufficient to evaluate the angular flux at a finite number of points in 4π of Ω-space in terms of just the μ_k and η_k components of the discrete directions Ω_k. One must recognize, however, that the length of the path traveled by particles moving in a direction out of the x-y plane is always longer than the x-y projection of the path, by a factor of $\left(\mu^2+\eta^2\right)^{-1/2}$. Thus, for any path length s' measured in the x-y plane for a given direction Ω_k, the true path length traveled is s, where

$$s = \frac{s'}{\sqrt{\mu^2+\eta^2}}. \tag{9.2.22}$$

This is illustrated in Fig. 9.2.5.

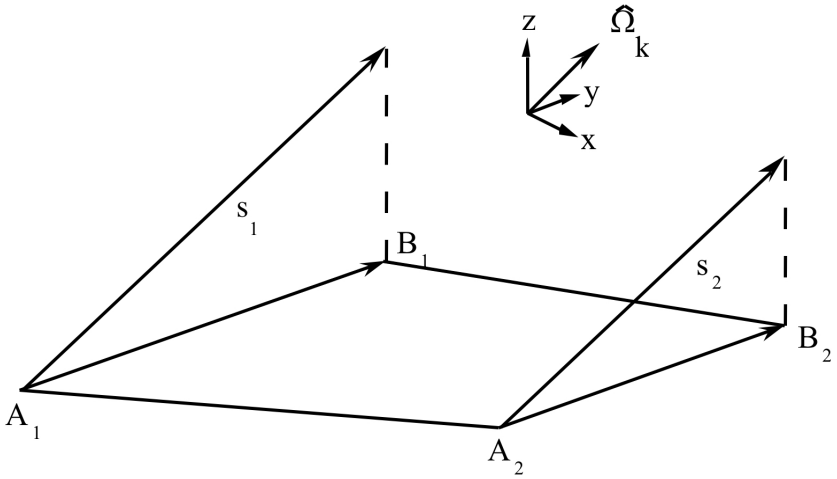

Fig. 9.2.5: Relationship between s_1 and s_2 and their projections in the x-y plane.

Neutron balance within a computational cell

Once angular fluxes have been computed for all sides of a cell, it is necessary to compute the cell-averaged angular flux. To enforce conservation, a balance condition is applied to the cell. This provides the equation necessary to determine the average flux in the cell. The neutron balance for an arbitrary cell in steady state may be expressed as

$$\begin{bmatrix} \text{net number of} \\ \text{neutrons moving in} \\ \text{direction } \hat{\Omega} \text{ escaping} \\ \text{from the cell} \end{bmatrix} + \begin{bmatrix} \text{number of neutrons} \\ \text{removed from the cell} \\ \text{or from direction } \hat{\Omega} \\ \text{by interactions} \end{bmatrix} = \begin{bmatrix} \text{number of} \\ \text{neutrons produced} \\ \text{in the cell moving} \\ \text{in direction } \hat{\Omega} \end{bmatrix} \tag{9.2.23}$$

or, expressed mathematically,

$$\oint_s n \cdot \hat{\Omega}_k \psi dS + \sigma_t \bar{\psi} V = QV, \tag{9.2.24}$$

where n is the outward normal direction at each side of the cell and V is the 2-D volume of the cell. Note that in this context, S represents the surface area or perimeter of the cell. Hence, for a cell with m sides, each of the sides having a constant angular flux $\bar{\psi}_i$ and an outward normal direction n_i,

$$\bar{\psi}_{cell} = \frac{Q}{\sigma_t} - \frac{1}{\sigma_t V} \sum_{i=1}^{m} \bar{\psi}_i \int_{S_i} \mathrm{n}_i \cdot \hat{\Omega}_k dS_i. \tag{9.2.25}$$

Because each cell is restricted to be a polygon, each side in the cell will be a straight line and $\mathrm{n}_i \cdot \hat{\Omega}_k$ will be constant along the length of the side. Equation Eq. (9.2.25) can then be simplified to obtain

$$\bar{\psi}_{cell} = \frac{Q}{\sigma_t} - \frac{1}{\sigma_t V} \sum_{i=1}^{m} \bar{\psi}_i \left(\mathrm{n}_i \cdot \hat{\Omega}_k \, \mathrm{L}_i \right), \tag{9.2.26}$$

where $\mathrm{L_i}$ is the length of the *i*th side and the term in parentheses represents a leakage coefficient for the side.

9.2.2.4 Coarse-mesh finite-difference acceleration

Beyond cell discretization and solution described above for the ESC approach, the NEWT iterative approach is similar to that used in other discrete-ordinates methods. Inner iterations are used to solve spatial fluxes in each energy group to generate updated source terms; outer iterations use these source terms to converge all energy groups. This source-iteration approach can be somewhat slow to converge, especially when significant scattering is present. Hence, it is desirable to apply some form of acceleration to the iterative solution used by NEWT. To this end, a coarse-mesh finite-difference acceleration (CMFD) approach has been added to NEWT. The CMFD formulation uses a simplified representation of a complex problem, in which selected rectangular regions are derived from the global NEWT Cartesian grid and homogenized. The CMFD formulation utilizes coupling correction factors for each homogenized cell to dynamically homogenize the constituent ESC-based polygonal cells during the iterative solution process such that the heterogeneous transport solution can be preserved. Dynamic-group collapse is also possible with a two-level CMFD formulation in which alternating multigroup and two-group calculations are performed. By extending the concept of the equivalence theory to energy and angle, it is possible to apply a consistent lower-order formulation in the form of a homogenized pin-cell, few-group, diffusion-like finite-difference scheme. This simplified lower-order formulation is much less expensive to solve, and its solution can be used to accelerate the original higher-order transport solution in NEWT, resulting in much faster convergence of the fission and scattering source distributions. This work is described in detail in [NEWTZDX+08] and in previous versions of the NEWT manual.

Although the original implementation of the CMFD acceleration method is extremely efficient and actively maintained, its use is limited to rectangular-domain configurations (e.g., square-pitched fuel lattices). An alternative CMFD acceleration method has been developed to support triangular- and hexagonal-domain configurations (e.g., triangular-pitched fuel lattices such as the VVER or prismatic graphite models). The new CMFD acceleration method does not require the coarse-mesh cells to be rectangles but rather arbitrary polygons. However in the current implementation, the "unstructured" coarse-mesh cells are still constructed from the global NEWT Cartesian grid. Therefore, for a hexagonal configuration, interior coarse-mesh cells will be rectangular shape whereas cells near the boundary will be triangular or trapezoidal shapes.

The new unstructured CMFD iterative solution scheme is essentially identical to the original solution scheme; the two methods differ only in how the lower-order system is solved. Additionally the two-group acceleration is not employed in the unstructured CMFD method. Input options for both CMFD methods are described in Sect. 9.2.3.2.

9.2.2.5 Assembly discontinuity factors

In nodal multi-assembly or core calculations, lattice transport solutions are used to generate few-group homogenized cross sections. These cross sections are in general obtained from single-assembly transport calculations with zero-current boundary conditions. Generation of few-group homogenized cross sections for nodal calculations typically includes the generation of discontinuity factors (i.e., additional parameters used to preserve both reaction rates and the interface currents in the homogenization process). The discontinuity of the flux at an assembly interface that can arise by the use of homogenized cross sections is illustrated in Fig. 9.2.6. The so-called "homogeneous" flux, computed in the nodal calculation, is discontinuous at the assembly interface, as opposed to the exact "heterogeneous" flux, computed in the transport calculation, which is continuous at the assembly interface. The interface condition employed in nodal calculations between two assemblies (nodes) i and i+1 is given as

$$\phi^{+}_{i,\,\text{homogeneous}} \cdot F^{+}_{i} = \phi^{-}_{i+1,\,\text{homogeneous}} \cdot F^{-}_{i+1}, \tag{9.2.27}$$

where F^{+}_{i} and F^{-}_{i+1} are assembly discontinuity factors (ADFs) on each side of the interface between assemblies i and i+1.

The ADF on the assembly interface is defined as the ratio of the heterogeneous flux $\phi_{\text{heterogeneous}}$ at that assembly interface to the homogeneous flux evaluated at the interface, denoted $\phi^{+}_{i,\,\text{homogeneous}}$ (or $\phi^{-}_{i+1,\,\text{homogeneous}}$):

$$F^{+}_{i} = \frac{\phi_{\text{heterogeneous}}}{\phi^{+}_{i,\,\text{homogeneous}}}, F^{-}_{i+1} = \frac{\phi_{\text{heterogeneous}}}{\phi^{-}_{i+1,\,\text{homogeneous}}}. \tag{9.2.28}$$

Fluxes, and therefore ADFs, vary with energy; therefore, few-group homogenized cross sections are always accompanied by corresponding few-group ADFs.

In a single-assembly calculation with zero-current boundary conditions, the heterogeneous flux at each boundary is easily calculated as the surface-averaged scalar flux on the boundary, whereas the homogenous flux at each boundary is simply the assembly-averaged flux. Hence, for each energy group, the ADF is calculated for each boundary as the ratio of the average flux on that boundary to the average flux across the assembly.

In other configurations, such as a multi-assembly calculation or an assembly located on the edge of a core next to the core baffle and reflector, the ADF calculation requires more effort. For reflector situations, NEWT applies a simple one-dimensional (1-D) multigroup diffusion approximation to determine the ADF at the assembly boundary. In this approximation, it is assumed that the reflector is infinite and that the scalar flux goes to zero at infinity. The reflector ADF can be determined analytically using this boundary condition along with the known surface-averaged current and scalar flux evaluated at the assembly/reflector interface.

The reflector ADFs computed by NEWT may potentially be different from the ADFs calculated using the diffusion approximations employed by the nodal code. Moreover, ADFs computed for multi-assembly or hexagonal-domain configurations will depend on the nodal method employed. For these reasons, NEWT supports the option to edit surface-averaged scalar flux and current values along user-defined line segments so that appropriate ADFs can be computed directly by the nodal code. The input options for the single-assembly ADF, reflector ADF, and arbitrary line-segment edit are discussed in Sect. 9.2.3.11.

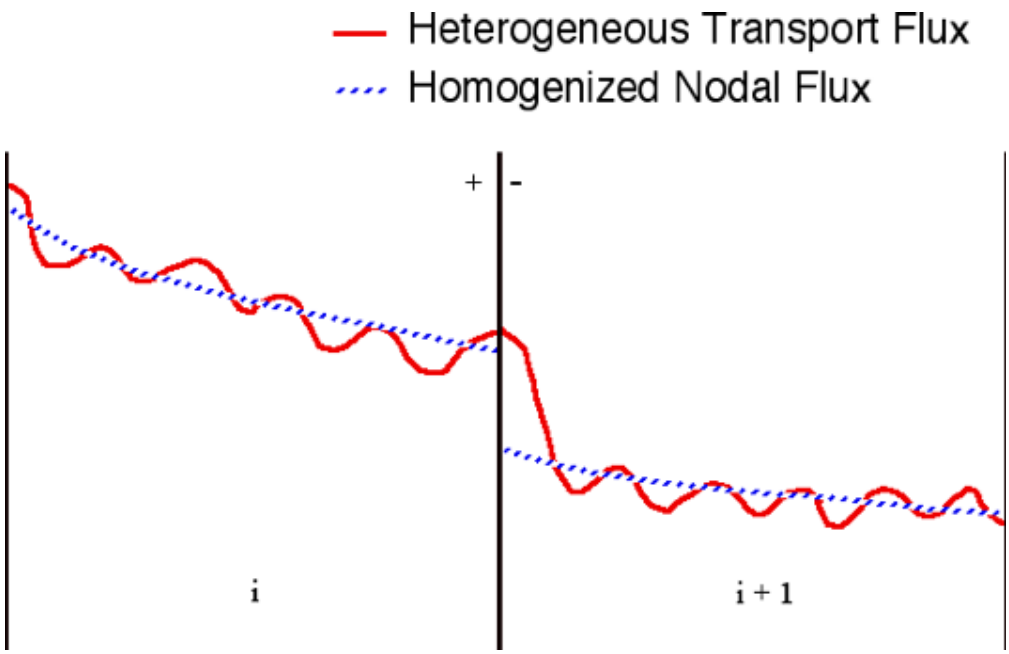

Fig. 9.2.6: Heterogeneous vs homogeneous fluxes in a multi-assembly solution.

9.2.3 INPUT FORMATS

NEWT input is free form and keyword based, similar in form to the input for many other modules in the SCALE code package. Input may start with a title card record, but this line may be omitted if desired; remaining data are supplied in data blocks. The order of the data blocks is arbitrary (with two exceptions), and many blocks are optional. Only one instance of a data block is allowed.

9.2.3.1 Overview of newt data blocks

The NEWT input deck data blocks are defined by keyword delimiters in the following form:

```
read keyword        [data]      end keyword
```

Read routines are terminated by the "end *keyword*" label, and any intervening carriage returns or line feeds are ignored. Thus, data can also be entered in this format:

```
read keyword
[data]
[data]
end keyword
```

Within each block, specific control or specification parameters are input. Each block contains a fixed set of input parameters (also defined by keyword).

As with other keyword-driven modules within SCALE, lines beginning with a single quote (') in the first column are treated as comments and ignored.

The keyword name and general contents of each data block are as follows:

Block type	Recognized keywords	Description
Problem control parameters Sect. 9.2.3.2	parameter, parameters, param, parm, para	General problem parameters-r
Material properties Sect. 9.2.3.3	material, materials, matl	Assigns characteristics (e.g., F
Broad group collapse Sect. 9.2.3.5	collapse, coll	Defines broad group energy ra
Simple-body geometry Sect. 9.2.3.6	geometry, geom	Defines basic grid structure ar
Boundary conditions Sect. 9.2.3.7	bounds, bnds	Defines boundary conditions t
Array specifications Sect. 9.2.3.9	array	Defines composition of all arr
Homogenization instructions Sect. 9.2.3.10	homog, hmog, homo	Defines mixtures to be flux we
Assembly discontinuity factors Sect. 9.2.3.11	adf	Assigns type and location of p
Flux plane Sect. 9.2.3.12	flux	Allows definition of an x- or y
Mixing table Sect. 9.2.3.13	mixtable, mixt	Mixing table specification (op
Source definition Sect. 9.2.3.4	src, source	Defines particle source strengt

Each of the following subsections describes the parameters associated with a specific data block, lists default values (if available), and describes meaning of the parameter and its effect on a NEWT calculation.

9.2.3.2 Parameter block

Parameter Block keyword = param, parm, para, parameter, or parameters

The Parameter block contains problem control parameters and must come immediately after the title card if one is used. Valid parameter specifications are described below. For each keyword, allowable values are listed in parentheses, and the default (if any) is listed in brackets. Input that can take an arbitrary integer value is indicated by an *IN*; similarly, any parameter that can take an arbitrary real/floating point value is indicated by *RN* as the allowable value. However, note that SCALE read routines do allow input of integers for real numbers, and vice versa; the number will be converted accordingly. The order of the parameters within the block is arbitrary, and may be skipped if a default value is desired for that parameter. Control parameters are set in the order in which they are input; this means that the same parameter may be listed multiple times, but only the final value is used.

Convergence and acceleration parameters

epseigen=(*RN*) - Convergence criterion for k_{eff}. [0.0001]

epsinner=(*RN*) - Spatial convergence criterion for inner iterations. [0.0001]

epsouter=(*RN*) - Spatial convergence criterion for outer iterations. [0.0001]

epsthrm=(*RN*) - Spatial convergence criterion for thermal-upscattering iterations, if enabled. [same value as **epsouter**]

epsilon=(*RN*) - Simultaneously sets all (spatial and eigenvalue) convergence criteria to the same value. [uses individual defaults]

converg=(*cell/mix*) - Sets the region within which convergence testing is applied. Use of *cell* will force converged scalar fluxes in every computation cell, while *mix* will relax convergence such that averaged scalar fluxes within a mixture are converged. The latter is useful for mixtures in which fluxes become very small-large reflectors or near a vacuum BC. [cell]

therm=(*yes/no*) - Enables/disables thermal-upscattering iterations. [yes]

inners=(*IN*) - Maximum number of inner iterations in an energy group. [5]

therms=(*IN*) - Maximum number of thermal-upscattering iterations, if enabled. [2]

outers=(*IN*) - Maximum number of outer iterations. NEWT will stop with an error code if more than *outers* outer iterations are required for convergence. [250]

inrcvrg=(*yes/no*) - If inrcvrg=yes, NEWT will continue outer iterations until all convergence criteria are met. If inrcvrg=no, NEWT will stop whenever outer iteration and k_{eff} convergence criterion are met, regardless of the convergence of inner or thermal-upscattering iterations. [no]

cmfd=(*no/rect/yes/part*) - CMFD acceleration option. If cmfd=no, CMFD acceleration is not employed. If cmfd=rect, the CMFD method is employed. The original NEWT CMFD method can be applied only to rectangular-domain configurations. If cmfd=yes, the unstructured CMFD method is employed. The new unstructured CMFD method can be applied to rectangular-, triangular-, and hexagonal- domain configurations. If cmfd=part, an alternative version of the unstructured CMFD method is employed and uses a "partial-current" acceleration scheme. Alternatively, users can use cmfd=0/1/2/3 for no, rect, yes, and part, respectively. [no]

cmfd2g=(*yes/no*) - Enables/disables the second-level two-group CMFD accelerator within the CMFD solver. This parameter has an effect only when cmfd=rect is set. [yes]

accel=(*yes/no*) - Enables/disables source (k_{eff}) acceleration. This parameter is automatically disabled if unstructured CMFD is employed (cmfd=yes or cmfd=part). [yes]

xcmfd=(*IN),* **ycmfd**=(*IN),* **xycmfd**=(*IN)* - These inputs specify the number of fine-mesh cells in the global NEWT grid per coarse-mesh cell. These options are used only when CMFD acceleration is enabled. The parameter *xcmfd* specifies the number fine-mesh cells per coarse-mesh cell in the x-direction. Likewise, *ycmfd* specifies the number of fine-mesh cells per coarse-mesh cell in the y-direction. The parameter *xycmfd* simultaneously sets *xcmfd* and *ycmfd* to the same value. In a special case for rectangular-domain configurations in which the entire domain is completely filled by a square-type array (see Sect. 9.2.3.9), *xycmfd=0* sets the coarse mesh based on the size of the array elements.

Important: User Guidance: Default convergence parameters are recommended for general analysis. Larger convergence criteria are useful for debugging if shorter run time is desired over solution accuracy. Smaller convergence criteria are recommended for generating reference solutions or benchmark calculations. CMFD acceleration should be applied whenever possible. The CMFD method with second-level 2-group acceleration should be applied for rectangular-domain configurations [e.g., light water reactor (LWR) assembly models (**cmfd=rect**), by default **cmfd2g=yes**]. The unstructured CMFD method should be applied for triangular- or hexagonal-domain configurations (**cmfd=yes**). If NEWT detects an unstable CMFD condition, a warning message is printed and NEWT continues with CMFD disabled. NEWT may also provide a terminating error message if improper selection of the coarse mesh is detected. Internal investigation has shown that the coarse mesh should be approximately the same size as the unit cell used in the model. For LWR assembly models, a fine mesh of 4 x 4 is recommended for the square-pitched unit cell, implying that **xycmfd** should be 4 only if the global unit has a mesh. If individual meshes are used in each unit definition, then the global unit coarse-mesh cells should be sized based on the unit cell size and, therefore, **xycmfd=1** should be used. The values of **xcmfd** and **ycmfd** do not have to be a common factor of the number of fine-mesh cells in a given direction (NEWT will make the last coarse-mesh cell smaller than the other coarse-mesh cells), but it is highly recommended.

Users can gauge solution convergence by the outer iteration edit as it is printed to the terminal window (echo=yes, see below). One can terminate a calculation prematurely (via the Control-C option on most platforms) if convergence or iteration parameters need to be modified.

In adjoint mode, CMFD acceleration is not currently supported and NEWT automatically disables its use if cmfd=yes, =rect, or =part. In adjoint mode with defined fixed source [i.e., generalized perturbation theory (GPT) analysis], it is observed that tighter convergence and iteration parameters are needed to properly remove fundamental mode contamination. (For more details, see SAMS chapter: Generalized Perturbation Theory.) To facilitate the CMFD options and larger convergence criteria for the forward calculations as well as smaller convergence criteria for GPT adjoint calculations, the following parameters are also available.

---

gptepsinner=(RN) - Spatial convergence criterion for inner iterations in GPT analysis. [0.0001] **gptepsouter**=(RN) - Spatial convergence criterion for outer iterations in GPT analysis. [0.001] **gptepsthrm**=(RN) - Spatial convergence criterion for thermal-upscattering iterations, if enabled, in GPT analysis. [same value as **gptepsouter**] **gptsepsilon**=(RN) - Simultaneously sets all spatial convergence criteria to the same value in GPT analysis. [uses individual defaults] **gpttherm**=(yes/no) - Enables/disables thermal-upscattering iterations in GPT analysis. [yes] **gptinners**=(IN) - Maximum number of inner iterations in an energy group in GPT analysis. [500] **gpttherms**=(IN) - Maximum number of thermal-upscattering iterations, if enabled, in GPT analysis. [10] **gptouters**=(IN) - Maximum number of outer iterations in GPT analysis. NEWT will stop with an error code if more than outers outer iterations are required for convergence. [2000]

Important: User Guidance: Default values for GPT convergence may change with future releases, as more experience is gained and user feedback is received. If the GPT calculation is not converging because of fundamental mode contamination, it is recommended that convergence criteria be decreased and/or inner and thermal-upscattering iteration limits be increased. If the solution convergence is slow, **gptinners** can potentially be decreased. Again, it is highly recommended that **echo=yes** be used to monitor speed of convergence.

Output editing

drawit=(*yes/no*) - Create a PostScript file showing the grid structure determined from input. Two files are created-the first showing the grid structure and the second showing the material placement. (Features and use of this simple graphics capability are described further in Sect. 9.2.5.12.1) [no]

echo=(*yes/no*) - During the iteration phase of execution, output is generated at the beginning of each outer iteration. This same information can be printed to SCALE message file (.msg) during iteration by setting echo=yes. [no]

prtbalnc=*(yes/no)* - Flag indicating whether or not balance tables for fine-group mixtures should be printed. [no]

prtbroad=(*yes/no/1d*) - Flag indicating whether or not broad group cross sections should be printed in problem output. The *1d* option indicates that 2-D scattering tables are not to be printed. This flag has no effect if collapse=no is specified. [no]

prthmmix=(*yes/no*) - Flag indicating whether or not homogenized mixture macroscopic cross sections should be printed in problem output. Homogenized cross sections are printed only if Homogenization Block is provided (Sect. 9.2.3.10). [yes]

prtflux=*(yes/no)* - Create a PostScript plot file showing flux distribution for each energy group in problem. If an energy collapse is performed, a second plot file is generated for the fluxes of the collapsed group structures. [no]

prtmxsec=(*yes/no/1d*) - Flag indicating whether or not mixture macroscopic cross sections should be printed in problem output. The *1d* option indicates that 2-D scattering tables are not to be printed. [no]

prtmxtab=(*yes/no*) - Flag indicating whether or not the input mixing table should be printed in problem output. [no]

prtxsec=(*yes/no/1d*) - Flag indicating whether or not input microscopic cross sections should be printed in problem output. The *1d* option indicates that 2-D scattering tables are not to be printed. [no]

timed=(yes/no) - Turns on printing of iteration timing and CPU use data. [no]

det=(*IN*) - Specifies the mixture used to represent a local power range monitor (LPRM) and/or Traversing In-core Probe (TIP) detector located within a fuel lattice. The mixture must also be included in a homogenization block in order to obtain detector cross sections. [has no default]

Important: With the exception of*__prthmmix__*, all output edit options are disabled unless requested by the user. The output edits are disabled by default to minimize the size of the output. The__drawit__option is recommended to generate PostScript plots of the model grid structure and material placement. As previously mentioned, the__echo__and__timed__options are recommended to monitor solution convergence. If the timed option is enabled, each line in the outer iteration edit will be longer than 80 characters. Therefore, it is recommended that Windows users should increase the Command Window size from 80 characters to 132* characters.

Angular quadrature

sn=(*2/4/6/8/10/12/14/16*) - Order of Sn level symmetric quadrature set. [6]

nazim=(*IN*) - Number of equally spaced azimuthal directions in a product quadrature set. Used in tandem with *npolar* keyword (both must be specified). Total number of angles in the product quadrature set is the product of *nazim* and *npolar*. [No default. If not specified, level symmetric quadrature default is used.]

npolar=(*IN*) - Number of polar angles in a product quadrature set (determined using a Gauss-Legendre polynomial). Used in tandem with *nazim* keyword (both must be specified). Total number of angles in the product quadrature set is the product of *nazim* and *npolar*. [No default. If not specified, level symmetric quadrature default is used.]

dgauss=(yes/no) - Enables/disables use of double Gauss-Legendre product quadrature set. If disabled, single Gauss-Legendre product quadrature sets are used. [no]

Important: If both level symmetric quadrature sets and product quadrature sets are requested, the level symmetric quadrature set is to be used. Level symmetric quadrature sets are recommended for general analysis. If reflective boundary conditions are desired for hexagonal-domain configurations, product quadrature sets must be used and nazim must be a multiple of 3. If reflective boundary conditions are desired for triangular-domain configurations, product quadrature sets must be used and*__nazim__*must be an odd number.*

Control options

adjoint=(*yes/no*) - This keyword specifies either a forward (adjoint=no) or adjoint (adjoint=yes) calculation. [no]

forward=(*yes/no*) - This keyword specifies either a forward (forward=yes) or adjoint (forward=no) calculation. If adjoint and forward are both specified, NEWT uses the last specification. [yes]

gpt=(*yes/no*) - This keyword specifies whether this is a GPT adjoint calculation. The *gpt* keyword is active only for adjoint calculations. [no]

Important: The TRITON control module automatically sets the values for forward, adjoint, and gpt keywords; therefore, they can typically be omitted from the Parameter Block. Default values are recommended unless running stand-alone NEWT adjoint calculations.

---

run=(*yes/no*) - A run=no calculation will perform all setup calculations normally performed before beginning iterations and then will stop. It is useful for debugging input and obtaining plots of the input geometry. Run=yes will perform a complete calculation. [yes]

premix=(*yes/no*) - This flag indicates whether the cross section library contains microscopic (premix=no) or macroscopic (premix=yes) cross sections. In essence, it creates a mixing table with a mixture fraction of 1.0 for each mixture on the library. Other mixing tables are ignored. The premixed cross section option is active only for stand-alone NEWT calculations. [no]

kguess=(*RN*) - Initial guess at eigenvalue for an eigenvalue calculation. This parameter may be entered but is not used if a source calculation is performed or a restart file is used to determine the initial guess. [1.0]

restart=(*yes/no*) - If restart=yes is specified, NEWT will open file *restart_newt* and read scalar fluxes and fission rates, enabling a restart from the point at which a previous calculation ended. The file *restart_newt* is always written by NEWT at the end of every successful calculation. The code assumes that all geometry is unchanged from the previous calculation but does allow restart with a different angular quadrature set and P_n scattering coefficients. A low-order solution can be used to accelerate a higher-order solution by restarting using the converged flux of the lower-order solution. [no]

savrest=(*yes/no*) - Determines whether or not a geometry restart file *worf* is written at the end of a calculation. If written, it will overwrite any existing geometry restart file. [yes]

Important: The default values of savrest and kguess are recommended. The TRITON control module automates generation and reuse of the geometry restart file, as well as the initial guess of the eigenvalue. Keywords run, premix, and restart can generally be omitted unless the following conditions are applicable:

- TRITON T-NEWT sequence calculation or stand-alone NEWT calculation with user-supplied restart file, restart=yes.
- Stand-alone NEWT calculation with user-supplied premixed cross section file, premix=yes.
- Interested only in performing setup calculations to debug input and generate geometry plots, run=no, and/or PARM=CHECK in the TRITON sequence input.

---

solntype=(keff/b1/src) - Specifies solution mode type: keff is eigenvalue, b1 is eigenvalue mode followed by a buckling correction, and src is fixed source (no eigenvalue calculation). Fixed source calculations require

additional data for the source specification (see Materials and Source data blocks in Sect. 9.2.3.3 and Sect. 9.2.3.4). [keff]

collapse=(*yes/no*) - If collapse=yes is specified, a flux-weighted collapse is performed by material number; cross sections for each nuclide in each material in the problem are collapsed to a specified (or default) group structure based on the average flux in that material. If collapse=yes, NEWT will look for the *collapse* parameter block; if not found, NEWT will generate cross sections based on the original group structure. If a Homogenization block is present, then collapse is always set to yes. [no]

saveangflx=(*yes/no*) - Option to save angular flux solution. Because the angular flux can require significant file storage. [no]

Important:

Keyword threads should be omitted in favor of the SCALE command line -I option. Keywords solntype, collapse, and saveangflx should be omitted unless the following conditions are applicable.

- For homogenized few-group cross section generation for nodal calculations, solntype **should be b1**. This option will perform a critical spectrum calculation, which will be folded into cross section homogenization calculation. The critical spectrum is also folded into the generation of ADFs and reaction rates for depletion calculations.
- Generation of a new collapsed cross section library, collapse=yes.

Geometry processing options

combine=(*yes/no*) - Automatic grid generation can result in very small grid cells in some locations. Setting parameter combine to *yes* performs automatic combination of smaller grid cells into adjacent neighbor of same material, if possible. Combine is automatically set to *no* if CMFD is enabled; this setting cannot be overridden. [no]

clearint=(*yes/no*) - Grid generation option that removes the global NEWT grid if a local unit grid is supplied. (For meshing options, see the *boundary* keyword in the Geometry block description in Sect. 9.2.3.6) By default, clearint is set to yes, which means the global grid is removed if local grids are provided. If CMFD acceleration is enabled, clearint is set to no, which means both the global grid and optional local grids are used. [yes]

grid_tol=(*RN*) - Tolerance used in determining if polygon vertices are numerically identical during NEWT grid generation. [0.000001]

cell_tol=(*RN*) - Tolerance used in determining if polygon vertices are numerically identical during NEWT cell generation. [0.000001]

line_tol=(*RN*) - Tolerance used in determining if polygon vertices are numerically identical during NEWT line generation. [1.0e-10]

Important: The default values for all geometry-processing keywords are recommended and can be omitted. For problems with very fine mesh, tighter grid and cell tolerances should be applied. For problems that terminate with a ray-tracing error (i.e., tracer error), tighter grid and cell tolerances should be applied.

Critical spectrum options

useb1=(*yes/no*) -Turns on/off the use of the B1 approximation to determine the critical spectrum. If useb1 is set to no, the P1 approximation is used. [yes]

b2=(*RN*) - Material buckling factor, in units of $1/cm^2$. [0.0]

height=(*RN*) - Height (transverse dimension) in centimeters. Used in a geometric buckling correction to calculate leakage normal to the plane of the input 2-D model. Keywords **dz=** and **deltaz=** are equivalent. When set to zero (default), no buckling correction is performed. [0.0]

bf=(*RN*) - Twice the extrapolation distance multiplier used to determine the geometric buckling correction. [1.420892]

Important: If critical spectrum corrections are to be applied, the default values listed above are recommended along with **solntype=b1**. In this option, NEWT will search for the material buckling value such that the homogenized infinite-medium system is critical. NEWT currently uses the B1 approximation as the default. If the P1 approximation is preferred, useb1should be set to no. The infinite-medium B1 (or P1) buckling search is performed in the energy group structure as the original model.

Alternatively, the user can supply the material buckling value using the b2 keyword, and specifying the B1 (default) or P1 approximation (**useb1=no**). In this case, **solntype** should be set to **keff**.

Alternatively, if the user knows the transverse dimension, a geometry buckling factor can be applied, derived from the user-defined **height** and extrapolation distance term **bf** as the following:

$B_g^2 = \left(\frac{\pi}{H+z/\sigma_{tr}}\right)^2$

In this formula, H is keyword height, z is keyword bf, and σ_{tr} is the collapsed, homogenized macroscopic transport cross section.

File unit options

Important: It is highly recommended that the file unit options below be omitted or that default values be used. Alternate file unit values are acceptable for stand-alone NEWT calculations, but changing their values may adversely impact other SCALE modules if NEWT is invoked through a SCALE sequence.

---

hmoglib=(*IN, 0<IN<100*) - This input value specifies the unit number to which a collapsed and homogenized cross section library is written if homogenization instructions are provided (ft*IN*f001). [13]

mixtab=(*IN, 0<IN<100*) - NEWT is able to use a mixing table prepared by SCALE (which may be generated using the T-XSEC sequence). The value of *IN* defines the filename that NEWT will try to locate to read mixing data (i.e., mixtab=92 will cause NEWT to seek the file named ft92f001). This is the default filename produced by the T-XSEC sequence. Alternatively, a mixing table may be specified in NEWT input in the *read mixtable* block; if such a mixing table is supplied, the value of *mixtab* is ignored. [92]

wtdlib=(*IN, 0<IN<100*) - This input value specifies the unit number to which a collapsed cross section library is written if *collapse=yes* is specified (ft*IN*f001). *IN* must be positive and less than 100. [30]

xnlib=(*IN, 0<IN<100*) - This number indicates the filename containing cross sections prepared in a problem-dependent AMPX working library format. The input xnlib=*IN* will cause NEWT to open file ft*IN*f001. This is the only method for providing cross sections as input for NEWT [NEWTHil76].

Examples of input for the parameter block are given below. Note that the two inputs are functionally identical. In the first example, parameters are specified, while in the second example, the input is structured differently and takes advantage of default values.

```
read parm
  solnmode=keff adjoint=no run=yes prtflux=no prtbroad=yes
  mixtab=92 xnlib=4 wtdlib=30 collapse=yes accel=yes sn=6
  outers=100 epsinner=1.0e-4 epsouter=1.0e-4 epseigen=1.0e-5
  kguess=1.34 restart=no prtxsec=yes prtmxsec=yes prtmxtab=yes
end parm

read parm collapse=yes outers=100 epseigen=1.0e-5 kguess=1.34
prtxsec=yes prtmxsec=yes prtbroad=yes end parm
```

9.2.3.3 Material Block

Material block keyword = matl, material, materials

The Material block is always required. Material data must be specified for each mixture used in the calculation. The general format of the Material block is as follows:

```
READ materials
      mix=M pn=N srcid=I com='embedded comment' end
END materials
```

where

M = mixture ID;

N = P_n order for scattering in mixture M (by default, N is 1);

I = Source ID number (the source description for each source ID number is given in the Source block).

Up to 80 characters of text may be entered after *com*=, delimited by single quotes (‘) or double quotes (‘’). A mixture specification is required for each mixture used in the NEWT calculation. The order of the keywords in each specification is unimportant, and only the mix= keyword is required; however, each mixture specification **must** be terminated by the **end** keyword.

A sample Material block is provided below for three different mixtures. Each mixture is specified in a different manner to illustrate different input formats. In this example, P3 scattering is applied in mixture 3, and water and P1 are applied in the other mixtures. The pn= keyword is omitted for mixture 1. The com= keyword is omitted for mixture 2.

```
READ materials
  mix=3  pn=3  com='water' end
  mix=1  com='3.0 enriched fuel' end
  mix=2  pn=1  end
END materials
```

Consider this same set of mixtures but with a fixed source identified by source ID 100 in mixture 1. This specification could be written as follows:

```
READ materials
  mix=3  pn=3  com='water' end
  com='3.0 enriched fuel' mix=1  pn=1 srcid=100 end
  pn=1  mix=2 end
END materials
```

9.2.3.4 Source block

Source block keyword=source, src

The Source block contains source strength specifications associated with a given source ID. The source is assigned to a mixture via the srcid= keyword in the Material block (Sect. 9.2.3.3). Data are input using a keyword-based format:

```
READ source
      id=I typ=T com='embedded comment' src=X end
END source
```

where

I = Source ID number,

T = Source type,

X = List of source strength values, according to type T.

Up to 80 characters of text may be entered after *com*=, delimited by single quotes (‘). The comment string is optional-the remaining parameters are required. Currently, only two source types are supported; the definition of X depends on the source type.

Source type 0 (*typ=0*): A single value of X is supplied-this source strength is placed in all energy groups.

Source type 1 (*typ=1*): *G* values of X are supplied, one value for each energy group. FIDO-type repeat command is supported.

An example of a source specification for two different sources is the following.

```
READ source
      id=1 typ=1 com='44-g fuel source' src=0.44 0.32 0.25 0.01 40r0.0 end
      id=5 typ=0 src=0.001 end
END source
```

The Material block is used to associate a given source definition with a given mixture. The same source may be placed in multiple mixtures. For generalized adjoint calculations-which require a fixed source derived for the generalized response of interest (see *Generalized Perturbation Theory* in the SAMS chapter)-the TRITON control sequence automatically prepares the NEWT Source block.

9.2.3.5 Collapse block

Collapse block keyword = coll, collapse

The Collapse block contains the broad (collapsed) group assignment for each energy group in the original input group structure. Broad group assignments must be contiguous. A FIDO-type repeat factor is allowed. For example, given that a calculation is performed using a 44-energy-group library, in which it is desired to collapse the first 9 groups into a single group, the second 17 groups into a second broad group, and the remaining 18 groups into a third group, either of the following could be used.

```
read collapse
1 1 1 1 1 1 1 1 1 2 2 2 2 2 2 2 2 2 2 2 2 2
2 2 2 2 3 3 3 3 3 3 3 3 3 3 3 3 3 3 3 3 3 3
end collapse

read coll 9r1 17r2 18r3 end coll
```

If a collapsing operation is requested, then upon the completion of the transport iteration, NEWT performs a collapsing operation on all cross sections for all mixtures in the problem. Cross sections are flux weighted using the average flux in the mixture in which each nuclide resides and saved in an AMPX working-format library at the unit specified by the *wtdlib*= parameter (default=30). Collapsed, or "broad group," cross sections may also be printed by setting the parameter *prtbroad=yes* (default=no). Note that the energy boundaries of the collapsed cross section are always a subset of the boundaries of the parent library. Cross sections may not be collapsed to arbitrary energy boundaries.

9.2.3.6 Geometry block

Geometry block keyword = geom, geometry

The Geometry block is always required. This data block contains geometric descriptions for all bodies included in the model. NEWT geometry input is performed based on the SCALE Generalized Geometry Package (SGGP) paradigm employed in the KENO-VI Monte Carlo code within SCALE. Those familiar with SGGP as applied in KENO-VI will find the new format very familiar; however, they will quickly realize that the NEWT geometry package contrasts most sharply with the 3-D implementation in KENO-VI because NEWT is a 2-D code. Hence, third dimension (z-axis) specifications are omitted, along with other inherently 3-D bodies supported by KENO-VI. Two other more subtle differences are seen: (1) users must specify the underlying grid structure associated with each *unit*, and (2) curved surfaces (e.g., cylinders) are approximated as N-sided polygons, with user control. Details on these differences are described in the following subsections and illustrated in examples.

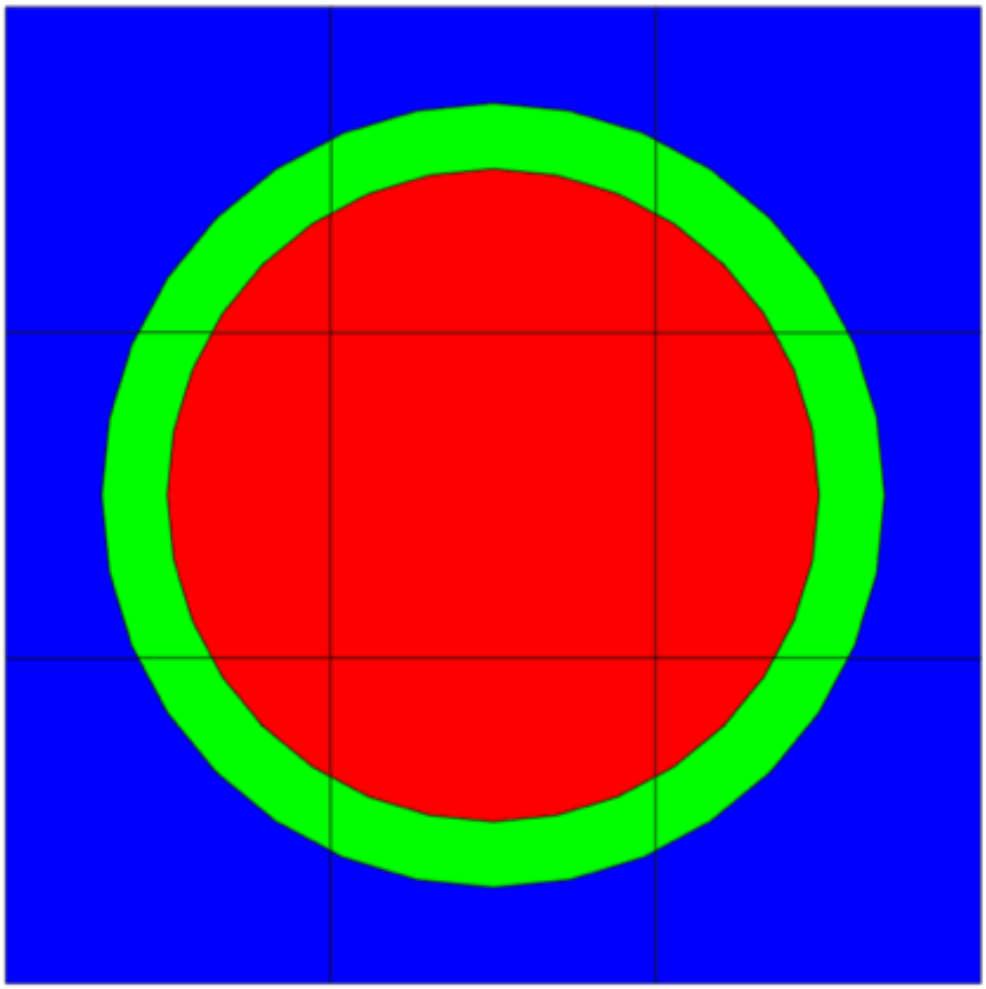
The SGGP approach for model development is combinatorial in nature. Hence, intersections are allowed, and the user is given enormous flexibility to specify, translate, rotate, and combine bodies to create complex configurations. However, the novice user must first focus on the basics of model development, as outlined in this subsection. Sample inputs are provided in Sect. 9.2.4 to demonstrate the development of more complicated models.

Geometric arrangements in NEWT are based on a fundamental building block called a unit. Different units can be arranged in an array. Fig. 9.2.7 illustrates a simple unit and an array of such units. Arrays of units can be contained inside larger units, and in principle, any level of nesting can be achieved. Within a unit, various shapes can be specified, each representing some geometrically distinct medium. In every geometry specification, a single global unit, which forms the outer boundary for the entire problem, must be specified.

Note that in the models pictured in Fig. 9.2.7, bodies are laid within a Cartesian grid. This is a hallmark of any NEWT model-the body specifications combined with an underlying grid structure are used to define a computational grid in which the NEWT ESC solution algorithm is applied. Fig. 9.2.8 illustrates the grid structure associated with the array example above. The model consists of a set of arbitrary polygons used to spatially discretize the bodies of interest. The underlying Cartesian mesh may be specified for any unit; a Cartesian mesh **must** be specified for the global unit. The mesh for the global unit is the primary mesh for the entire problem and is often referred to as the base grid, whereas the mesh for constituent units within the global unit constitutes localized refinement and may be referred to as the local, or unit, grid.

The NEWT geometry block consists of specifications for a set of basic building blocks known as units. A *unit* is defined as a collection of shapes, one of which must be defined as the unit boundary. A complete unit specification consists of a header and three distinct components:

1. **Bodies:** shapes, holes, or array placements that define the bodies within the unit;
2. **Media** specifications that define the material content (composition) of the various shapes; and
3. **Boundary** definition that defines the extent of the unit and its associated grid structure.



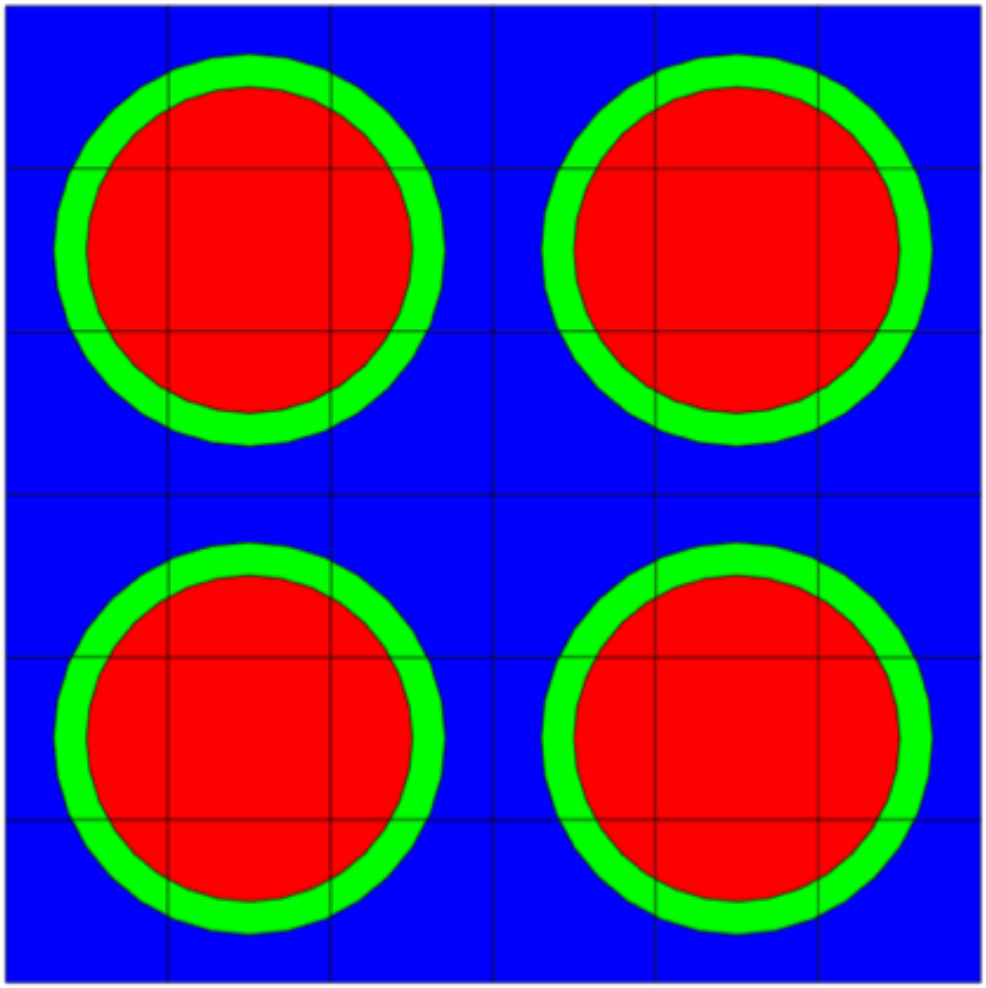


Fig. 9.2.7: A simple unit (top) and an array of units (bottom).

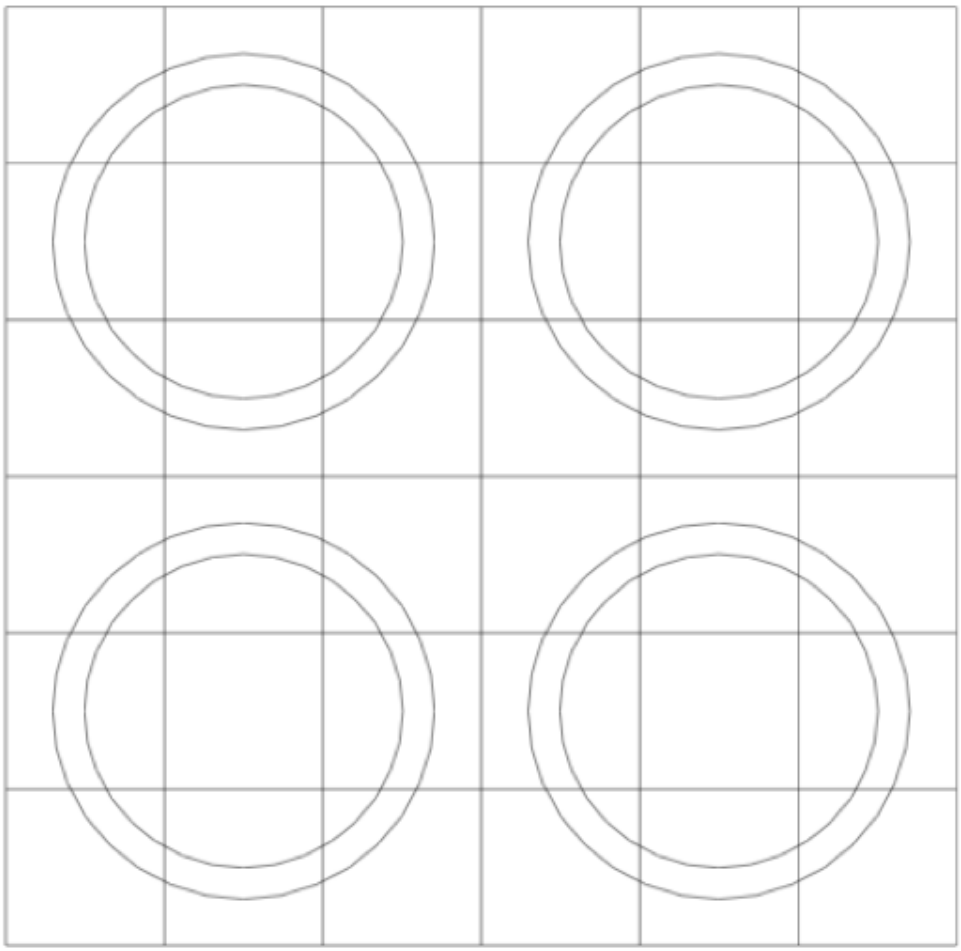

Fig. 9.2.8: Computational grid structure in a NEWT model.

Every unit begins with a header consisting of the keyword *unit* followed by a unique integer label (*unit_id)* that serves to identify the unit:

```
unit unit_id
```

The header is followed by a complete unit description consisting of the three components described above; each of these components of the unit specification is described in the following subsections. In every NEWT model, one unit must be defined as the *global unit*. This unit defines the global coordinate system for the entire problem, and all other units (if any) must fit within the global unit. Specification of the global unit is accomplished simply with the format:

```
global unit unit_id
```

The global unit may occur anywhere in the list of units. If only one unit is defined in an input, it must be identified as the global unit.

As indicated earlier, the geometry block consists of a list of one or more units. Each unit is terminated by the beginning of another unit or by the end of the geometry block. Conceptually, a geometry block will have the following structure:

```
read geom
global unit 1
(unit specifications)
unit 2
(unit specifications)
unit 3
(unit specifications)
...
unit 10
(unit specifications)
end geom
```

The unit numbers are arbitrary and can occur in any order, although they must be unique; they serve simply as labels.

The remainder of this section describes the various components of units.

Bodies

Every unit contains a set of body specifications in terms of (1) basic *shapes* that are placed directly within a unit; (2) one or more arrays, each of which is defined elsewhere and placed within a unit with an *array placement* operator; and (3) holes. Units **must** contain at least one *shape* specification, which is used to define the spatial boundaries of the unit. Additional shape specifications may be used as needed. Holes and/or array placements are optional; there is no theoretical limit on the number of each that may be used within a unit.

Shapes

Shapes are simple predefined bodies. NEWT currently supports six shapes:

1. cylinder,
2. cuboid,
3. hexprism,
4. rhexprism (rotated hexprism),
5. wedge, and
6. polygon.

The names of these shapes are generally associated with 3-D bodies but are used in NEWT to be consistent with KENO-VI nomenclature. In NEWT, a cylinder is equivalent to a circle, a cuboid is equivalent to a rectangle, a hexprism is equivalent to a hexagon, and a wedge is equivalent to a triangle.

Because the SGGP is combinatorial in nature, intersection and overlap of shapes is permitted. For this reason, no specific mixture is associated with each shape. Combinatorial logic allows a fraction of a shape to be filled with one mixture, while the remainder or another fraction thereof may be assigned a different mixture. This is discussed further in the section **Media Specifications** in the description of *media* assignment (Sect. 9.2.3.6.17).

Each shape is specified by name, an associated body identification (*body_id*) number, and dimensioning data. The *body_id* number is arbitrary but must be unique within each unit. Specific formats for each shape are provided below.

Cylinder

Cylinder

The cylinder specification has the following format:

```
cylinder  body_id  radius  [modifier_list]
```

where radius is the radius of the circle. The circle will be centered at (0,0). The modifier list is an optional set of operations that may be performed on each shape. One of the modifiers allowed is the *origin* modifier, which lets one translate the origin of a shape to a different location. Modifier commands are described later in this section.

Cuboid

The cuboid specification has the following format:

```
cuboid  body_id  xmax, xmin, ymax, ymin  [modifier_list]
```

where (x_{min}, y_{min}) and (x_{max}, y_{max}) represent the lower-left and upper-right vertices of a rectangle on a Cartesian coordinate system. Note that the cuboid is explicitly placed by its coordinates; no translation is required (or allowed).

Hexprism and rhexprism

Both hexprisms are specified in a manner identical to that of a cylinder:

```
hexprism body_id  radius  [modifier_list]
rhexprism  body_id  radius  [modifier_list]
```

where *radius* is the inner/minor radius of the hexagon. A standard hexagon (*hexprism)* is oriented with vertices at the top and bottom, as illustrated in Fig. 9.2.9. A rotated hexagon (*rhexprism*) is oriented with vertices on the left and right sides, as illustrated in Fig. 9.2.10. Both types of hexprisms, like cylinders, are by default placed with their origins at (0,0). However, like cylinders, they can also be translated in space via the *origin* translation command.

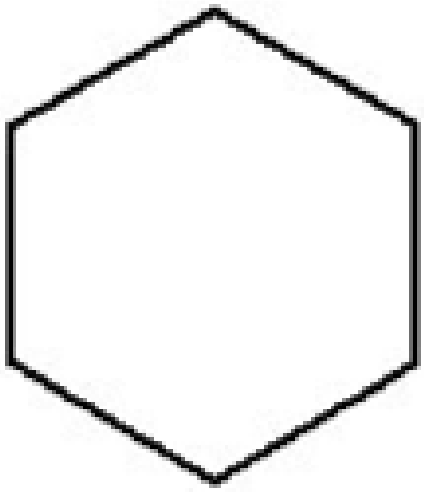

Fig. 9.2.9: Orientation of a standard hexprism.

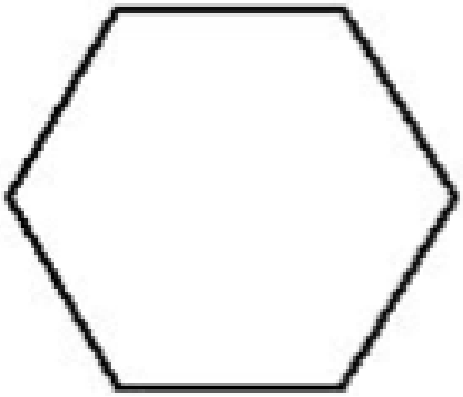

Fig. 9.2.10: Orientation of a rotated hexprism.

Wedge

A wedge, or triangle, specification has the following format:

```
wedge  body_id  xbase xpt ypt [modifier_list]
```

where the vertices of the shape are defined as (0,0), (x_{base},0), and (x_{pt},y_{pt}). Thus, one side always lies on the x-axis. The modifiers *origin* and *rotate* may be used to position and orient the triangle in the problem domain. Fig. 9.2.11 illustrates placement of a wedge using these parameters.

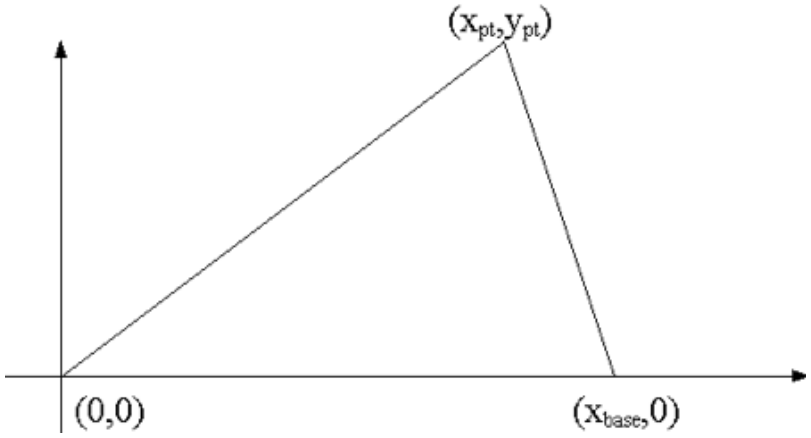

Fig. 9.2.11: Initial positioning of the wedge body.

Polygon

The polygon specification has the following format:

```
polygon  body_id  x0, y0, x1, y1, ..., xN, yN, x0, y0
```

where (x_i, y_i) are the polygon vertices (the first and last pair in this list refer to the same vertex). Note that the polygon is explicitly placed by its coordinates; no translation is required (or allowed).

Example of shape specifications

Use of shapes within a unit can be illustrated with a simple example. Consider a unit, arbitrarily labeled with *unit_id*=10, containing a cuboid and two cylinders. Each shape is given a unique (but arbitrary) *body_id*.

```
unit 10
cuboid   11   3.0   -5.0   1.0   -2.0
cylinder 12   0.8
cylinder 13   0.6
```

The cuboid is explicitly placed by its coordinates; the two cylinders will by default be placed at (0,0). Use of the *origin* command to relocate cylinders is introduced below. Fig. 9.2.12 illustrates the body placement that occurs for the given example.

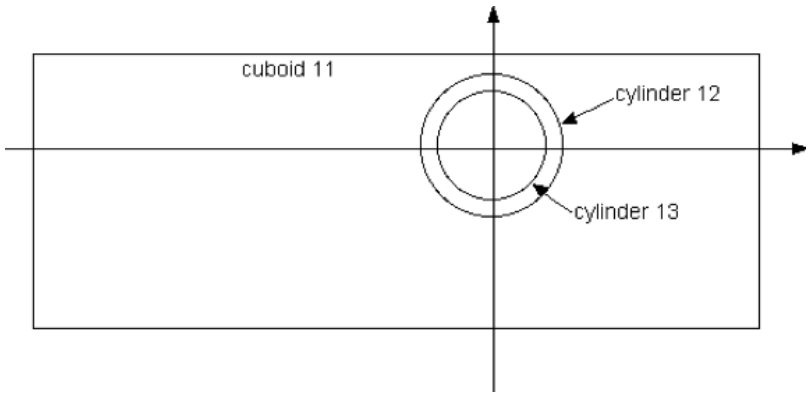

Fig. 9.2.12: Body placement for two cylinders and a cuboid.

Shape modifier commands

Modifier commands are provided as a means to perform specific functions relative to the input shape. The five available modifier commands and the shapes to which they may be applied are listed here:

origin - translation of center bodies (cylinders, hexprisms, rhexprisms);

rotate - rotation of bodies with respect to the transverse axis (all);

chord - removal of a portion of a body with x-plane and y-plane cuts (cylinders, hexprisms, rhexprisms);

com - addition of a comment to a specific shape (all);

sides - number of sides used to approximate a circle (cylinder, default is 12).

The format for each of these commands follows.

ORIGIN

The *origin* modifier is used to translate the origin of a cylinder or hexprism from the default origin of (0,0) to some other location. It has the format

```
origin x=xnew y=ynew
```

where (x_{new}, y_{new}) is the new center of the shape. The modifier *origin* may not be applied to cuboids, as the location of a cuboid is explicitly set by its shape specification. If not specified, each ordinate is set to zero, such that

```
origin x=5
```

is equivalent to

```
origin x=5 y=0 .
```

For example, consider a cuboid whose lower-left and upper-right corners are located at (0,0) and (1,1), respectively. If one places a cylinder with radius 0.3 in the center of this box [i.e., centered at (0.5, 0.5)], this would be specified as follows:

```
unit 1
cuboid 10 1.0 0.0 1.0 0.0
cylinder 20 0.3 origin x=0.5 y=0.5
```

This configuration is illustrated in Fig. 9.2.13.

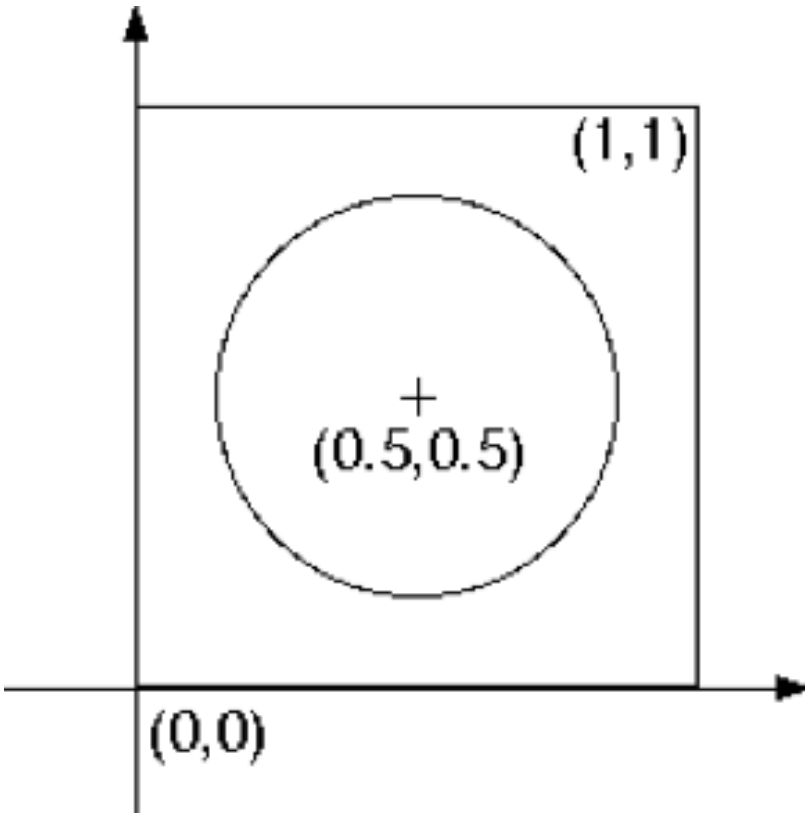

Fig. 9.2.13: Relocation (translation) of a cylinder using origin.

Rotate

The *rotate* body modifier is used to rotate a body around its geometric center. It can be applied to any body type, but rotation of a cylinder has no real meaning. The format of the *rotate* modifier is as follows:

```
rotate a1=A
```

where *A* is the angle of rotation, in degrees, in a counterclockwise direction. All bodies lie in the (x,y) plane, with rotation around the z-axis, but with respect to the centroid of the body. Rotation always occurs **before** translation (via *origin*), irrespective of the order of *rotate* and *origin* commands in the modifier list for a body. KENO-VI allows rotation about the x and y axes as well, through a2= and a3=; however, only rotation about the z axis is permitted in NEWT.

As an example, consider a 1 by 1 cm cuboid centered at (0,0), place a smaller 0.5 by 0.5 cm cuboid inside it, and rotate it 30 degrees clockwise.

```
unit 1
cuboid 10 0.5 -0.5  0.5 -0.5
cuboid 10 0.25 -0.25  0.25 -0.25 rotate a1=-30
```

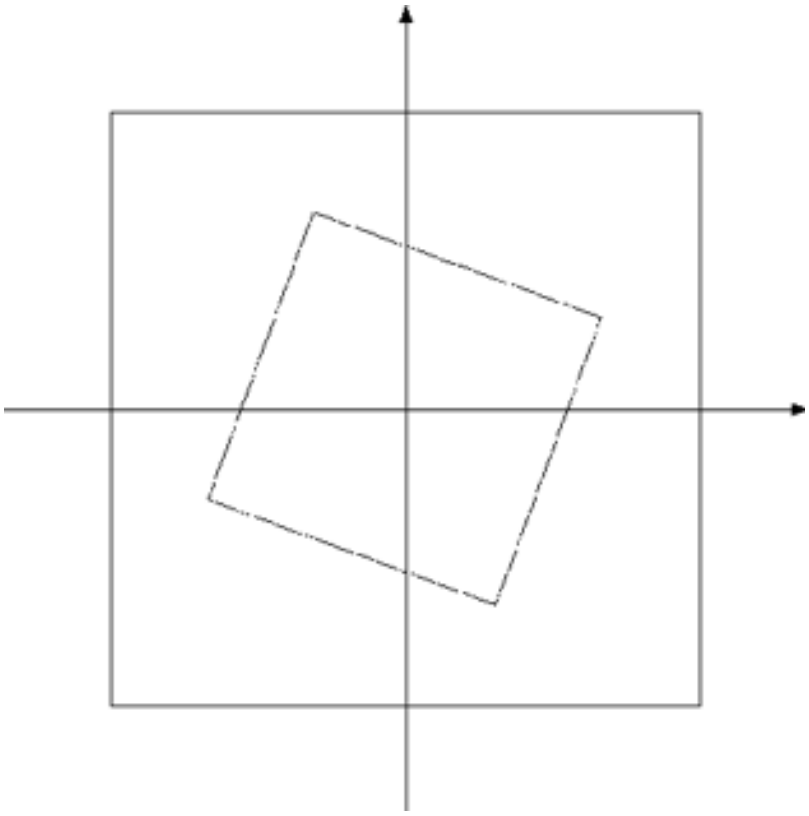

Fig. 9.2.14: Rotation of a cuboid.

Fig. 9.2.14 illustrates the configuration generated using this specification. Note that clockwise rotation was performed by specifying a negative angle. In this case, the centroid of the inner cuboid coincides with (0,0); however, the same geometric rotation would have occurred if the bodies had not been centered at (0,0).

Chord

The *chord* modifier is used to remove a portion of a body. It provides for horizontal and/or vertical cuts on a body, with the portion of the body on a specified side of that body discarded. Chords may be applied to cylinders or hexprisms but may not be applied to cuboids. (Such "cuts" may be explicitly defined in the body definition.) The format of the specification combines the selection of the plane (horizontal or vertical cut), location of the plane, and the portion of the body to be retained, all in one terse modifier.

The four possible chord specifications for a body are as follows:

```
chord +x=xplane
chord +y=yplane
chord -x=xplane
chord -y=yplane
```

where *xplane* and *yplane* are the ordinates on the x and y axes, respectively. The sign on x and y indicates the portion of the body to be retained after the cut. A plus (+) sign indicates that the portion of the body in the positive (increasing x or y) direction should be kept, and a minus (-) sign indicates that the portion of the body in the negative direction of the cut plane (decreasing x or y) direction is retained. Chords are applied **after** any translation (*origin*) or rotation (*rotate*) modifier operations. Multiple chords may be specified for a single body to obtain multiple cuts. The keyword *chord* **must** precede each specification.

The use of chords is best illustrated by example. Fig. 9.2.15 through Fig. 9.2.18 show unit body descriptions with various chord specifications.

```
unit 10
cuboid 1 0.5 -0.5 0.5 -0.5
cylinder 2 0.25 chord +x=0.0
```

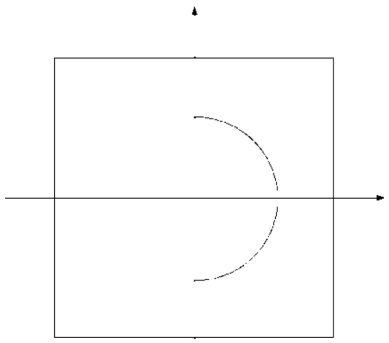

Fig. 9.2.15: Example of chord +x behavior.

```
unit 10
cuboid 1 0.5 -0.5 0.5 -0.5
cylinder 2 0.25 chord -y=0.0
```

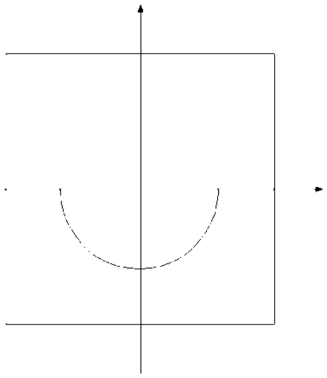

Fig. 9.2.16: Example of chord -y behavior.

```
unit 10
cuboid 1 0.5 -0.5 0.5 -0.5
cylinder 2 0.25
  origin x=0.5  y=-0.5
  chord -x=0.5 chord +y=-0.5
```

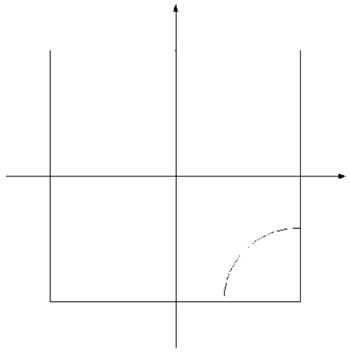

Fig. 9.2.17: Use of two chords to create a quarter-cylinder body.

```
unit 10
cuboid 1   0.5 -0.5 0.5 -0.5
cylinder 2 0.5
  chord -x=0.25 chord +x=-0.25
  chord -y=0.25 chord +y=-0.25
```

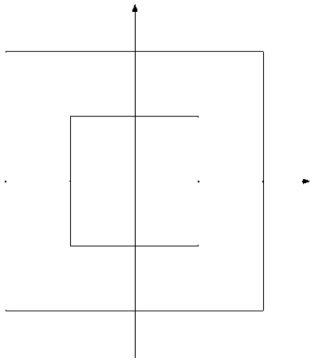

Fig. 9.2.18: Use of four chords on a cylinder to create a square body.

In Fig. 9.2.15, a chord is placed at x=0 and the positive portion relative to the chord (x >0) is retained because +x mode is specified. Since the cylinder is centered at (0, 0), this chord cuts the cylinder in half and retains the right half of the cylinder. The unit in Fig. 9.2.16 uses the same cylinder but with a chord cutting at the plane located at y=0. The bottom half (y < 0) is kept because -y is specified.

Fig. 9.2.17 is somewhat more complicated but represents perhaps the most common use of chords in lattice models. In this case, it is desired to create a one-quarter cylinder located in the bottom right quadrant of a cuboid. A 1 by 1 cm square cuboid is centered at (0, 0), and a cylinder is placed at (0.5, -0.5), which is the lower right-hand corner of the cuboid. Since we are interested only in the portion of the cylinder within the cuboid, we choose to keep the top (+x) and left (-y) portions of the cylinder. This requires two separate chord modifiers. (Each chord specifies only one cutting plane.) Additionally, because the cylinder was relocated to a new origin, the chords are specified such that the cuts go through the new origin.

Note that there is no requirement that a chord cut through the origin of a body. Fig. 9.2.18 illustrates the use of four chords to set four cutting planes. A 0.5 cm cylinder is specified centered within the unit cuboid. All four of the four permitted cutting planes are specified. We have effectively created a cuboid by retaining the portion of the cylinder above (+y) the xz plane located at y= -0.25, below (-y) the plane at y=+0.25, to the right (+x) of the yz plane at x= -0.25, and to the left (-x) of the plane located at x=+0.25. There is, of course, a much more direct means to create a cuboid-this example is provided only for illustrative purposes.

For guidance on how to cut a cylinder at an oblique angle, refer to Sect. 9.2.3.6.15.

Com

The *com* modifier is a means to label specific bodies. It is provided primarily for consistency with KENO-VI. At this time, NEWT simply reads and then ignores *com* data. It can, however, be used as a means to help annotate an input listing. The format for the *com* modifier is as follows:

```
com="comment string"
```

where *"comment string"* is any text description of up to 132 characters, delimited by single (‘) or double quotes (“). For example, the input description of Fig. 9.2.18 is shown here with comments added via *com* modifiers.

```
unit 10
cuboid 1   0.5 -0.5 0.5 -0.5 com="unit cuboid centered at (0,0)"
cylinder 2 0.5 com="cylinder with four chords"
  chord -x=0.25 chord +x=-0.25
  chord -y=0.25 chord +y=-0.25
```

Sides

The *sides* modifier applies only to cylinders and is unique to NEWT (i.e., it is not used in KENO-VI). Because NEWT’s solution grid is based on arbitrary polygons, all cells must be straight sided. Hence, the curved surfaces of a cylinder are approximated as an N-sided regular polygon. By default, N=12. The *sides* operator allows the user to override the default. The format is very simple:

```
sides=N
```

where N is the number of sides desired for the full cylinder. In general, a 12-sided polygon provides an adequate approximation of a cylinder. Use of additional sides will create a cylinder that has a smoother appearance and increase the computational effort required to solve the cells associated with the cylinder.

Fig. 9.2.19 shows a model built with three nested cylinders inside a unit cuboid. Cylinder 10 is the innermost cylinder, with no *sides* modifier; hence, it uses the default 12-sided approximation. The second cylinder is specified with sides=16; the refinement in this approximation is seen in the figure. Finally, cylinder 30 is specified with 40 sides-this is visually a very close approximation to a cylinder.

```
unit 10
cuboid 1   0.5 -0.5 0.5 -0.5
cylinder 10 0.2
cylinder 20 0.3 sides=16
cylinder 30 0.4 sides=40
```

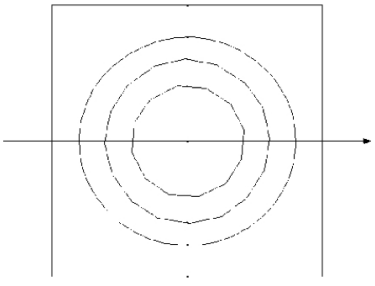

Fig. 9.2.19: Use of the sides modifier for cylinders.

Holes

The next level of complexity within a *unit* is provided through the use of a *hole* specification. The *hole* specification is simply a means by which one unit may be placed within another unit. In some instances, a well-defined set of structures, assembled as a *unit*, needs to be placed within a larger unit. NEWT provides two methods to do this-holes and arrays. Arrays are used to place a unit (or a number of similar units) in a regular repeating pattern within an enclosing unit. A *hole*, on the other hand, is a means to place a single unit. This is often used when units being placed do not have a regular repeating pattern.

The format for a *hole* specification within a unit is as follows:

```
hole unit_id [modifier_list]
```

where *unit_id* is the identification number for the unit that is being placed within the current unit. (A unit cannot be placed within itself.) Unlike the shapes described earlier, holes do not have a distinct identification number of their own-they are simply a mechanism to place a unit defined elsewhere.

By default, the *hole* operator places the origin of the new unit at the origin (0,0) of the current unit. The *origin* modifier may also be used with a *hole* specification to position the placed unit at a location other than (0,0) of the current unit. However, placement of the body is **always** relative to the origin of the original unit, which can be defined in a number of different ways.

Holes are also associated with a particular shape. Hole specifications must immediately follow the shape into which they are being placed. Holes redefine the boundaries of a shape by figuratively cutting holes in that shape into which units are placed. When mixtures are defined for a given shape (through media specifications, described below), the mixture is placed throughout the region, except in the space excluded by the hole placements.

The *rotate* modifier can also be applied to a hole, as can the *com* modifier. However, *chord* specifications cannot be used to remove a portion of a hole. To construct a cylinder that is cut at an oblique angle, users should construct a cylinder that is cut by a chord and then use the *hole* operator combined with the *origin* and *rotate* modifiers to place and rotate the unit to the desired position and orientation. This can be particularly useful in hexagonal or triangular geometries.

As an example, consider a unit, unit_id=1, consisting of two concentric cylinders, and a second unit, consisting of two concentric cuboids. Descriptions for these two units are given below. Note that these are incomplete unit specifications; other components of the unit specification have not yet been introduced. However, for the purposes of this example, incomplete unit specification will suffice.

```
unit 1
cylinder  12   0.8
cylinder  13   0.6

unit 2
cuboid 12 0.8 -0.8 0.8 -0.8
cuboid 13 0.6 -0.6 0.6 -0.6
```

Now suppose that we wished to place two of the unit 1 cells and one of the unit 2 cells inside unit 3, with unit 2 rotated by 45°. We can define a cuboid as unit 3 and place the units 1 and 2 inside the cuboid using *hole* specifications:

```
unit 3
cuboid 10 4.5 0.0 4.5 0.0
hole 1 origin x=1.3 y=1.3
hole 1 origin x=1.3 y=3.3
hole 2 origin x=3.1 y=2.3 rotate a1=45
```

In this example, a square cuboid is defined such that its lower-left corner is situated at (0,0). Three hole operations are used: the first to place unit 1 at (1.3, 1.3), the second to place another instance of unit 1 2 cm above the first, at (1.3, 3.3). Lastly, unit 2 is placed inside unit 3 at (3.1, 2.3) and then rotated 45°. Fig. 9.2.20 illustrates how such a unit would appear.

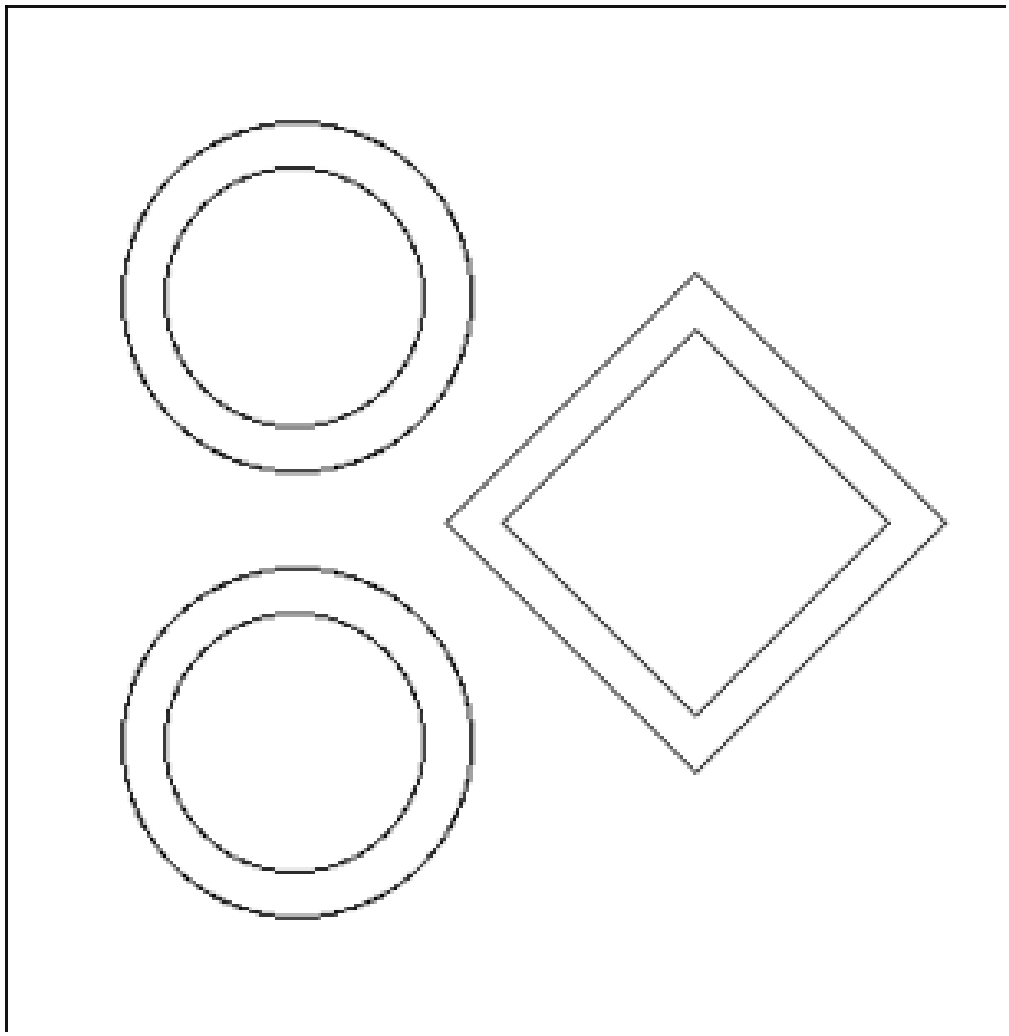

Fig. 9.2.20: Unit placement within a unit using holes.

Array placement

As indicated in the previous section, arrays are a method for arranging one or more units within another unit. Arrays specifications are typically used when units are placed in a repeating pattern. While the *hole* specification is used to place different units within a given unit, the array placement specification is used to place an *array* within a unit.

All arrays are specified (declaration of size, type, and fill) in the array data block, as described in Sect. 9.2.3.9. The array placement operator is used to locate an array within a unit. The format for the array placement operator is as follows:

```
array arrayid body_id place i j xij yij
```

where *arrayid* is the identification number assigned to the array in the array data block and *body_id* is the identification number of the *shape* into which the array is placed. The remainder of the array placement operator is used to fix the position of the array within the body, identified by *body_id*. A general discussion of this concept follows, after which the actual placement of the array is described.

Arrays are defined by two dimensioning parameters-the number of rows and the number of columns. Each element of an array is filled by a unit; each unit has its own local coordinate system. In other words, one unit may have the origin (0,0) in its local coordinate system defined as the lower-left corner while another unit may have its origin defined at its geometric center. The array itself has no coordinate system; it is simply a list of relative positions of units, defined by their row/column position. The *place* directive of the array placement operator is used to locate the array within the body into which it is being placed.

In the *place* directive, *i* represents the column (counting from left to right) and *j* represents the row (counting from bottom to top) of a specific element of the array. The coordinate system of that specific unit is used to set the position of the entire array. The coordinates *xij* and *yij* represent the location in the current unit where the array is to be placed. Placement occurs by situating the origin of the unit in column i, row j at coordinate (x:sub:*ij*,y_{ij}). Placement of arrays within a unit is best understood through examples. Consider three (partial) unit specifications, as defined and illustrated in Fig. 9.2.21.

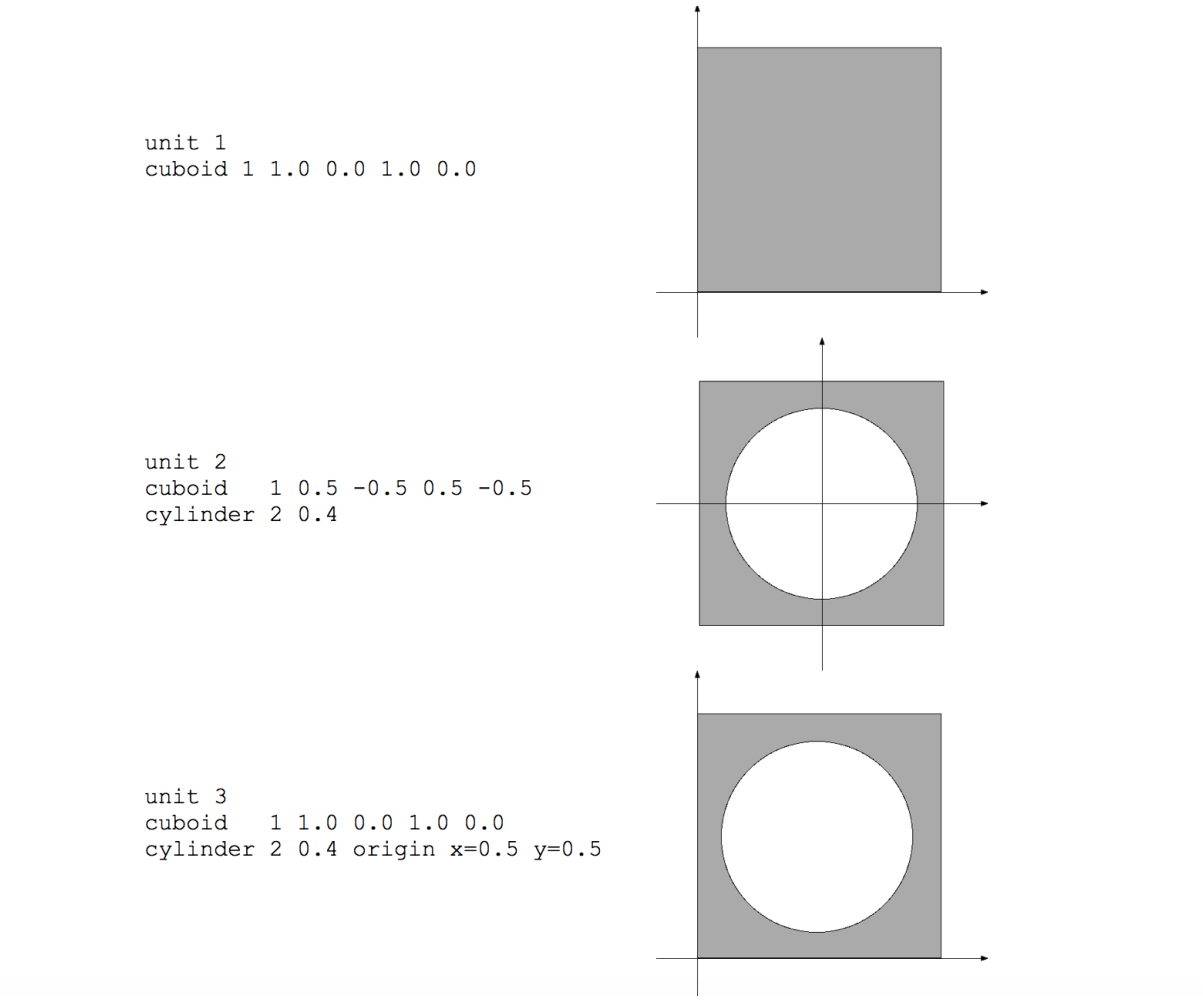

Fig. 9.2.21: Example of units to be placed in an array.

Unit 1 is a simple 1 by 1 cm cuboid with its origin located at its bottom-left corner; unit 2 is a similar-sized cuboid but with its origin located at its geometric center and with a cylinder centered in it; and unit 3 is identical to unit 1 but with a cylinder centered in it. Units 2 and 3 are identical in structure but use a different local coordinate system.

Now assume an array has been defined in the array data block and assigned *arrayid*=50. The relative positions of the units are shown in Fig. 9.2.22; unit 3 is located in row 1, column 1.

We desire to place this array within a unit 4, a 2 by 2 cm cuboid with its lower-left corner located at (0,0). Because there are four different array positions, this array has four possible placements:

```
unit 4
cuboid 10 2.0 0.0 2.0 0.0
array 50 10 place 1 1 0.0 0.0

unit 4
cuboid 10 2.0 0.0 2.0 0.0
array 50 10 place 2 1 1.5 0.5

unit 4
cuboid 10 2.0 0.0 2.0 0.0
array 50 10 place 1 2 0.5 1.5

unit 4
cuboid 10 2.0 0.0 2.0 0.0
array 50 10 place 2 2 1.0 1.0
```

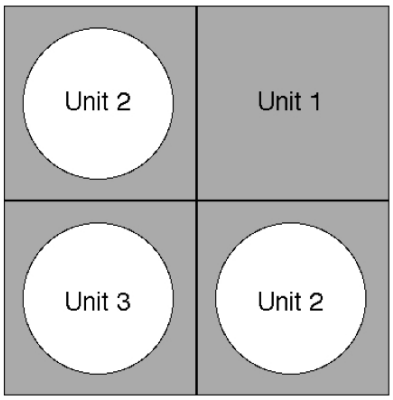

Fig. 9.2.22: Layout of units in array 50.

For the first example, the unit located in row 1, column 1 (i.e., unit 3) is placed such that its origin (its lower-left corner) is located at (0,0), which is the origin of unit 4. For the second example, the unit located in column 2, row 1, is placed such that its local origin, which is in the center of the unit, is located at x=1.5, y=0.5 in the coordinate system of unit 4.

Media specifications

A unit is only partially specified by its constituent bodies. At this point, no composition has been associated with the various regions of the problem nor has the outer boundary of the unit been defined. This section provides information on the use of *media* specifications to define the contents of each shape that has been defined.

Each shape statement defines a basic shape, with optional modifiers, which represents a spatial region within the unit. Assignment of compositions to regions is performed via *media* specifications.

As discussed earlier in the introduction to shapes, input processing in the SGGP is combinatorial. This permits intersection of shapes, and different compositions (or media) may be assigned to different portions of intersecting bodies.

The format of a media specification is as follows:

```
media  materialid  bias_placeholder  reg_def_vector
```

where *materialid* is the composition number being placed in this entry, *bias_placeholder* is a simple placeholder that is required but not used, and *reg_def_vector* is the region definition vector used to define the shape or shapes to which the mixture is assigned.

The *bias_placeholder* is used to be as consistent as possible with KENO-VI input. KENO-VI allows the user to assign biases within the media assignments to improve the Monte Carlo solution performance. Biases have no meaning in NEWT, so the field has no meaning. In KENO-VI, if no special biasing is desired, a value of 1 is assigned. If it is desired to move models between NEWT and KENO-VI format, a placeholder value of 1 is recommended. However, the value itself has no meaning within NEWT; it is simply read and ignored. (This may change in a future release.)

The region definition vector is used to describe the location of the composition within the current unit. This is done by providing a list of shapes for which the media is either "inside" or "outside." The sense of the media with respect to a shape is specified by listing the shape number with a negative sign if "outside" and with a positive (or no) sign when the media is placed "inside" the shape.

Consider a simple cylinder inside a cuboid. Assume composition 1 is to be placed inside the cylinder and composition 2 outside the cylinder but inside the cuboid. The shape and media specifications could have the following format:

```
unit 1
cylinder 10 0.5
cuboid 20 1.0 -1.0 1.0 -1.0
media 1 1 10
media 2 1 20 -10
```

In the above example, the first media record places mixture 1 inside all of shape 10 (the cylinder). The second media entry places mixture 2 in all regions that are outside shape 10 but inside shape 20. Note also that a bias placeholder value of 1 is used in each media statement.

It is necessary to specify media for all regions of the unit. If any regions remain unassigned, NEWT will stop with an error message. If the second record had been omitted, regions outside the cylinder would be unspecified and the code would stop. Note also that if the second media statement had read only

```
media 2 1 20
```

then composition 2 would have been placed inside all of cuboid 20, including inside the cylinder 10. The fact that the contents of 10 have already been specified is ignored. The above statement directs the code to put mixture 2 everywhere inside the boundaries of the cuboid.

Each region definition vector combines all specifications with a logical AND. In other words, the second media record in "`media 2 1 20`" places composition 2 in all regions that are simultaneously outside shape 10 **and** inside shape 20. Separate media specifications are required to place a composition in two independent shapes. The following represents a cuboid with two nonintersecting cylinders.

```
unit 1
cylinder 10 0.4 origin x=0.5
cylinder 20 0.4 origin x=1.5
cuboid 30 2.0 0.0 1.0 -1.0
media 1 1 10
media 1 1 20
media 2 1 30 -10 -20
```

A media statement is necessary to place composition 1 inside shape 10; a similar statement is necessary to place composition 1 inside shape 20. Finally, all space inside cuboid 30 but outside both 10 and 20 is filled with composition 2. If one attempted to fill both 10 and 20 with composition 1 in a single media record, for example,

```
media 1 1 10 20
```

then an error would occur. The code would attempt to place composition 1 in all space that is simultaneously within shape 10 **and** within shape 20-and no such space exists.

A more common example is the configuration of a fuel pin (composition 1), gas gap (composition 2), clad (composition 3), and moderator (composition 4) in a lattice. Consider a pin in a hexagonal lattice:

```
unit 1
cylinder 10 0.4
cylinder 20 0.41
cylinder 30 0.5
hexprism 40 0.8
media 1 1 10
media 2 1 20 -10
media 3 1 30 -20
media 4 1 40 -30
```

In this example, for the hexagonal moderator region outside the clad, it is sufficient to specify that mixture 4 is inside 40 **and** outside 30. Although it is true that the moderator is also outside shapes 10 and 20, it is not necessary to specify this. Logically, since 10 and 20 are inside 30, then everything outside 30 must be outside 10 and outside 20. The use of a hexprism in this example is irrelevant. If the outer body had been a cuboid, the result would have been the same.

As a final example, consider a unit with intersecting bodies. It becomes possible to assign a unique composition to each intersection of shapes (Fig. 9.2.23).

```
unit 1
cylinder 10 9.0 origin x=4.5
cylinder 20 9.0 origin x=-4.5 y=-4.5
cylinder 30 9.0 origin x=-4.5 y=4.5
cuboid 40 15.0 -15.0 15.0 -15.0
media 1 0 10 -20 -30
media 2 0 20 -10 -30
media 3 0 30 -10 -20
media 4 0 10 20 30
media 5 0 10 20 -30
media 6 0 20 30 -10
media 7 0 10 30 -20
media 8 0 40 -10 -20 -30
```

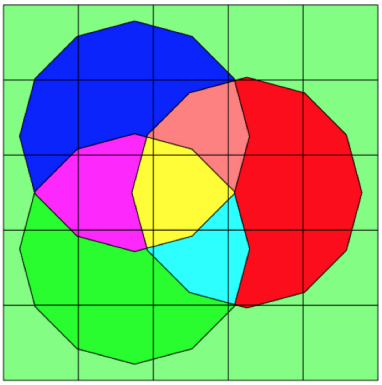

Fig. 9.2.23: Media assignments in overlapping regions.

In this model, cylinder 10 is on the right, 20 is the lower left, and 30 is the upper left. Media 1, placed inside cylinder 10 but outside 20 and 30, is represented by the partially filled right-hand side of the right cylinder. The central region of the unit is filled with composition 4 and represents all areas that are simultaneously within shapes 10, 20, and 30. The outermost region is everything that is inside 40, but outside 10, 20, and 30.

Media statements apply only to shapes, and only to those shapes within the unit. Holes and array specifications are used to define placement of one or more units in which media have already been specified in the corresponding unit definitions. Like shape statements, media statements may occur in any order. However, if one region is erroneously assigned two different compositions in two different media statements, the code will allow this and will proceed with the calculation. The last specification for a shape will always take precedence. Thus, it is important that newly developed models be visually inspected using mixture plots (files named "*.newtmatl.ps") created using *drawit=yes* in the parameter block.

Unit boundary

The final section of a unit description is the *boundary* specification. This input record serves two purposes: to specify the shape that defines the outer bounds of the unit, and hence the shape of the unit, and (optionally) to specify the underlying grid associated with the unit. The format of the boundary specification is as follows:

```
boundary  body_id  [x-discretization y-discretization]
```

where *body_id* is the identification number for the body that is to serve as the unit boundary. The *x-discretization* and *y-discretization* terms are integers (≥2) that specify the number of rectangular cells to be placed in the unit in the x-direction and y-direction, respectively. A grid specification is **required** for the global unit but is optional for other units. If a grid is specified for a grid other than the global unit, that grid replaces the base grid. (An exception to this principle is discussed later.)

In general, grid refinement should be such that cell sizes are on the order of or smaller than a mean free path for a neutron. Grid spacing can be easily varied in order to converge on the parameter of interest. Global factors, such as a system eigenvalue, can tolerate a relatively coarse grid. However, if fluxes are known to vary rapidly in space, then a more refined grid may be necessary. NEWT does provide the ability to locally refine a grid structure so that detail can be modeled where needed, without having to pay the computational penalty of refining the grid everywhere. NEWT does place one limit on grid refinement: every shape, hole, or array placed within a unit must be intersected by at least one gridline. The grid may be locally defined or part of the global grid, but it must intersect each body at least once. Thus, if small geometric shapes are modeled, a detailed grid structure is generally necessary.

Examples of boundary specifications follow, as parts of partial unit specifications. Media descriptions are omitted for simplicity. Accompanying figures illustrate the grid structure(s) associated with each specification. Fig. 9.2.24 shows a single (global) unit with a 2 by 2 base grid. Cuboid 10 serves as the boundary for the unit. This represents the minimum grid structure that can be specified for a unit. Fig. 9.2.25 shows a more complex configuration in which a unit defined with a 5 by 5 grid is placed in the center of a larger enclosing unit, specified to have a 3 by 3 grid. Note that because the first unit has its own (local) grid, the underlying grid structure is removed in favor of the local grid structure. The grid is applied to the boundary shape of the unit, which is cuboid 10.

Fig. 9.2.26 shows a similar structure; however, the cuboid was removed from unit 1 and the outer hexprism was defined as the unit boundary. Note that the grid structure applied to the nonrectangular body is the same as the one that would be assigned for a cuboid with the same minima and maxima in x and y directions. Fig. 9.2.27 illustrates the grid structure that would be applied to the same model as was used in the previous figure but with CMFD acceleration enabled. Because CMFD is normally applied to a coarse mesh defined by the base global grid (unless xycmfd=0), the global grid is always retained when CMFD acceleration is used. Finally, Fig. 9.2.28 illustrates the use of a base grid only. In this case, no grid structure is assigned for unit 1; the bodies are inlaid but are adapted to the base global grid structure.

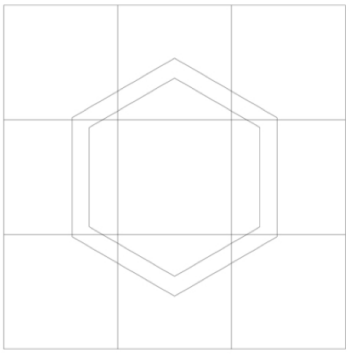

Fig. 9.2.28: Use of base grid without localized grid specification.

The following section provides examples of complete geometry specifications for various models, including bodies, media, and boundary specifications. Each will include one or more uses or boundary specifications for units.

Geometry block examples

The following three subsections present geometry block examples to show how various models may be assembled. Each listing is described briefly and is followed by a figure showing the NEWT grid structure generated for each set of geometry instructions.

Simple pin cell

The following geometry block (Fig. 9.2.29) shows the specifications necessary to define a single pin-cell. The model is reduced to a 1/4 cell to take advantage of symmetry. Mixture 1 is fuel, mixture 2 is fill gas, mixture 3 is clad, and mixture 4 is moderator. Features of this model include the use of chords to obtain 1/4 cylinders and the specification of 20 sides for each cylinder (five sides for a 1/4 cylinder).

Hexagonal assembly

The geometry block below (Fig. 9.2.30) is used to describe a hexagonal fuel assembly within a hexagonal shroud. Each cylinder is placed individually, followed by a series of media statements that fill each cylinder. The hexagonal moderator area is surrounded by a hexagonal shroud of cladding material. Note that NEWT allows only cuboid and hexprisms as outer boundaries for the global unit. This model could also have been assembled with a unit definition for a set of cylinders, which could then be placed in the global unit using holes or by defining a single pin cell and placing it using an array.

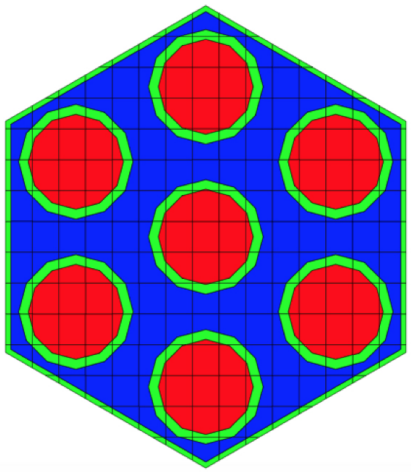

Fig. 9.2.30: Geometry model of hexagonal fuel assembly.

Advanced CANDU reactor ACR-700 assembly

This example of a geometry block (Fig. 9.2.31) is included to illustrate the complexity of design that is possible through the use of simple bodies, units, and holes. The ACR-700 design cannot be modeled using an array because pins are not placed in a repeating lattice pattern. Features of this example include use of holes; use of noncuboidal units placed in holes; and localized pin-cell grid refinement by (1) decreased mesh size in fuel elements (three outer rings) and (2) increased radial discretization (central pin).

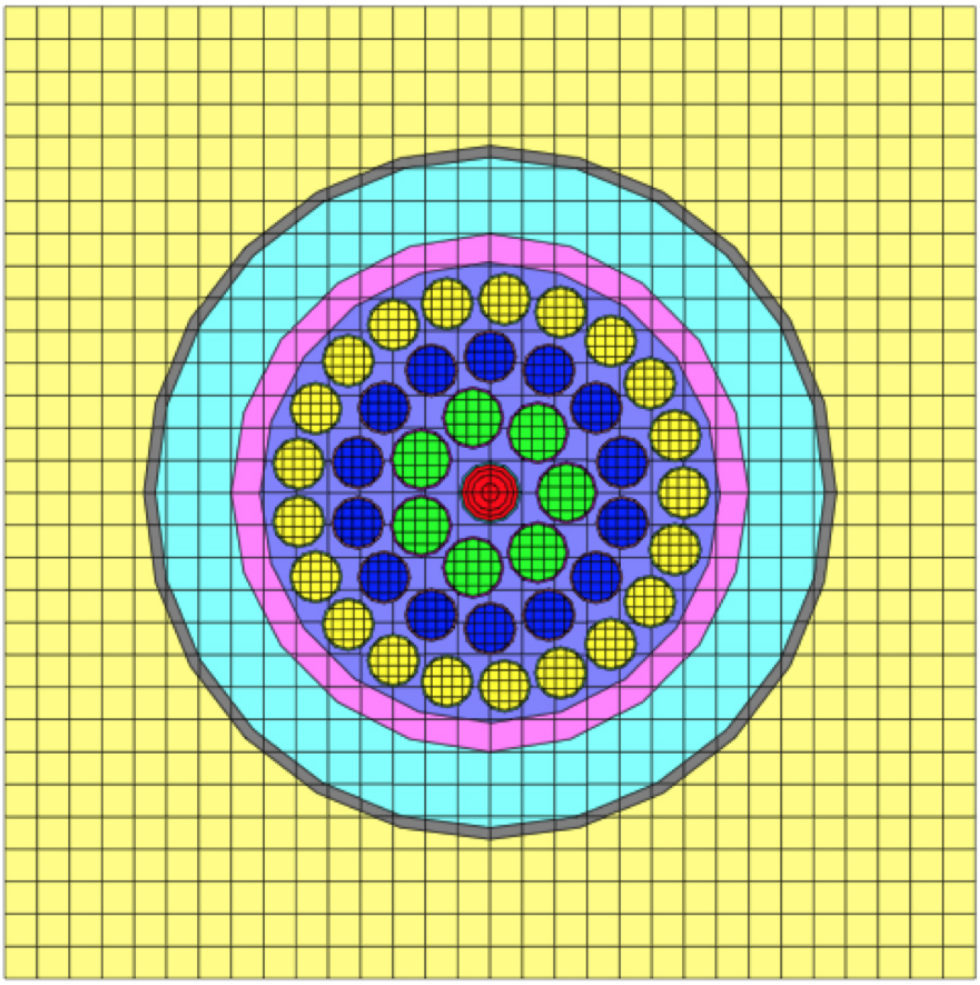

Fig. 9.2.31: ACR-700 fuel assembly model.

Summary of geometry specifications

This section is provided as a quick reference for geometry statements. Details and examples of the usage of each geometry specification are provided in previous subsections of this manual. For each definition, the lists of permitted modifiers are listed.

Unit definition statements

```
[global] unit   unit_id
```

The *unit* statement is used to initiate the definition of each unit used. *unit_id* is an integer identification label for the unit and must be unique. One (and only one) global unit is required in each geometry model. Modifiers: none.

```
cuboid  body_id  xmax xmin ymax ymin [modifier_list]
```

The *cuboid* statement is used to define a rectangular shape. *body_id* is the integer identification label for the cuboid and must be unique within the unit it is used. The rectangle is defined such that the coordinates (x_{min}, y_{min}) and (x_{max}, y_{max}) represent the lower-left and upper-right vertices of the cuboid. Modifiers: *rotate, com*.

```
cylinder body_id  radius [modifier_list]
```

The *cylinder* statement defines a circle with integer label *body_id* and radius *radius*, placed with its center at the origin (0,0) of the unit. Modifiers: *origin, rotate, chord, sides, com*.

```
hexprism  body_id  radius [modifier_list]
```

The *hexprism* statement defines a standard hexagon with integer label *body_id* and inscribed radius *radius*, placed with its center at the origin (0,0) of the unit. A standard hexagon has vertices located on north (top) and south (bottom) regions of the shape. Modifiers: *origin, rotate, chord, sides, com.*

```
rhexprism  body_id  radius [modifier_list]
```

The *rhexprism* statement defines a rotated hexagon with integer label *body_id* and inscribed radius *radius*, placed with its center at the origin (0,0) of the unit. A rotated hexagon has vertices located on east (right) and west (left) regions of the shape. Modifiers: *origin, rotate, chord, sides, com.*

```
wedge  body_id  xbase xpt ypt [modifier_list]
```

The *wedge* statement defines a triangle with integer label *body_id* placed with a vertex at (0,0), a vertex at (x_{base},0), and a vertex at (x_{pt},y_{pt}). Modifiers: *origin, rotate, com.*

```
array arrayid body_id place i j xij yij  [modifier_list]
```

The *array* placement statement specifies the placement of an array with identification number *arrayid* (defined in the array data block), within shape *body_id*. If the *place* statement is used, the array element located in row *i* (counted from the bottom) and column *j* (counted from the left) is placed such that its origin is located at spatial coordinate (*xij*, *yij*) of the unit in which it is placed. Modifiers: *com*.

```
hole unit_id [modifier_list]
```

The *hole* statement is used to place a different unit identified by label *unit_id* within the current unit. The origin of the unit being placed will be located at the origin of the current unit but can be repositioned using the *origin* modifier. Modifiers: *origin, rotate, com*.

```
media  materialid  bias_placeholder  reg_def_vector
```

The *media* statement assigns material properties associated with mixture index *materialid* to a shape region defined within a unit. The *bias_placeholder* term is not currently used but is retained for consistency with KENO-VI; typically it is assigned a value of 1. *reg_def_vector* is the region definition vector and assigns the mixture placement relative to shapes within the unit. If the index is positive, the shape region is included in the material assignment; if negative, it is excluded. Modifiers: none.

```
boundary  body_id  [x-discretization y-discretization]
```

The *boundary* statement is used to define the outer boundary of the unit, corresponding to the outer bounds of the shape *body_id* within the unit. This shape must exist and must contain all other bodies associated with the unit. The *x-discretization* and *y-discretization* terms are integers (≥2) that specify the number of cells to be placed in the unit in the x-direction and y-direction, respectively. A grid specification is required for the global unit but is optional for other units. Modifiers: none.

Geometry modifiers

```
origin x=xnew y=ynew
```

Used to relocate the origin of cylinders, hexprisms, rhexprisms, and holes to new co-ordinate (x_{new}, y_{new}). The default (if not specified) is to place the origin of the body at (0, 0).

```
rotate  a1=A
```

Causes a body to be rotated by an angle of *A* degrees (counterclockwise) around its origin. It can be applied to holes and all basic shapes; the default is 0 degrees.

```
chord  +/- x=xplane
chord  +/- y=yplane
```

Chords are used to truncate a shape at the line x=*chord* (or y=*chord*). Multiple chord commands are allowed, but only one line (either in x- or y-direction) is specified for each. If the negative keyword `-x` (or `-y`) appears, then the part of the shape to the left of (below) the chord cut is retained. Similarly, if the positive keyword (`-x` or `-y`) is used, then the portion of the shape to the right of or above the chord is retained. Chords may be applied to cylinders, hexprisms, and rhexprisms only.

```
sides=N
```

For use with the cylinder statement, the *sides* modifier specifies the number of sides on the regular polygon used to approximate the cylinder. Its default is N = 12. The radius of the polygon is adjusted such that the area of the polygon matches the area of the cylinder it is approximating. The *sides* modifier is unique to NEWT and is not used by KENO-VI.

9.2.3.7 Boundary conditions

The *geometry data* block is generally followed by the *bounds* data block, in which boundary conditions for the sides of the bounding shape in the global array are specified. NEWT supports the use of cuboid, hexprism, and wedge shapes to define outer boundaries. This results in the need to specify up to 6 surface boundaries, on up to 8 spatial orientations. In other words, a cuboid will have boundaries on +x, -x, +y, and -y faces. A regular hexprism will have boundaries on +x and -x faces; it will also have boundaries on the four sloped sides of the hex. In order to identify the sense of sides for specification of boundary conditions, NEWT applies an eight-point compass nomenclature. The four permitted rectangular boundary surfaces are identified as +x, -x, +y, and –y, corresponding to east (E), west (W), north (N), and south (S) faces, as illustrated in Fig. 9.2.32 Sloped (non-rectangular) surfaces are identified as +x+y, +x-y, -x-y, and -x+y, for northeast (NE), southeast (SE), southwest (SW), and northwest (NW) surfaces. No assumptions are made on the slope of the various non-rectangular surfaces; for the bodies available within NEWT, it is not possible to have more than one surface in each octant.

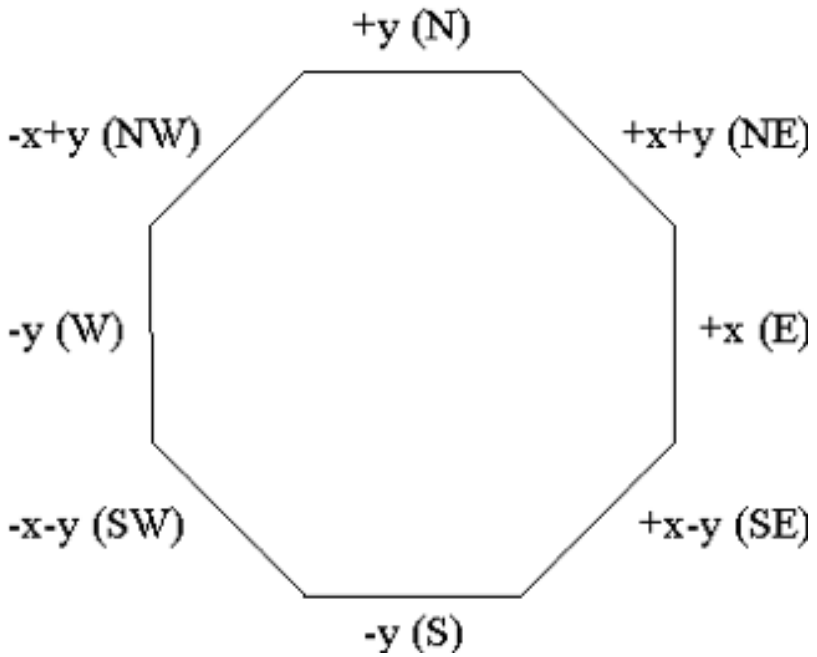

Fig. 9.2.32: Two-dimensional boundary condition surface orientations.

Currently, full specification of boundary conditions is permitted only when the boundary body for the global unit is a cuboid. Only white and vacuum boundary conditions are permitted on non-rectangular surfaces.

Boundary conditions therefore may only be specified for the ± x and ± y faces of a boundary cuboid. Four boundary conditions are currently supported:

1. reflective (default),

2. white,
3. vacuum, and
4. periodic.

Albedo boundary conditions are not yet supported but will be available in a future release. Additional information on the meaning of each boundary condition type is provided in the following section.

Boundary conditions descriptions

Boundary conditions are mathematical approximations used to describe the behavior of neutrons when they cross a problem boundary. Typically, transport methods provide for reflective (or mirror), white, vacuum, or periodic boundary conditions. The following subsections describe and illustrate these four types of boundary conditions.

Reflective boundary condition

For the reflective boundary condition, the incoming angular flux is set equal to the outgoing angular flux in the direction corresponding to mirror or specular reflection. As shown in Fig. 9.2.33, a given quantity of neutrons leaving a boundary (dotted line) in a particular direction will be returned (solid line of same color) to the system with the same quantity but at a mirrored angle to the initial leakage direction.

Note: In the following figures, a dashed arrow indicates neutrons leaving the system while a solid arrow represents those returning to the system. The length of the arrow is proportional to the number of neutrons; therefore, longer arrows represent more neutrons than do shorter arrows.

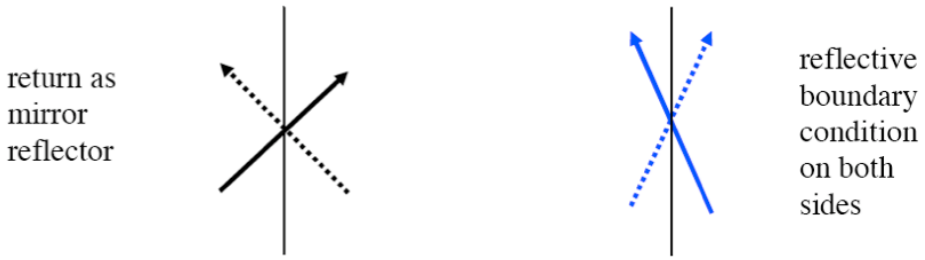

Fig. 9.2.33: Reflective boundary condition.

White boundary condition

For the white boundary condition, the incoming angular fluxes are each set equal to a single value chosen such that the net flow across the boundary is zero. The white boundary provides isotropic return (solid lines) at a boundary (Fig. 9.2.34).

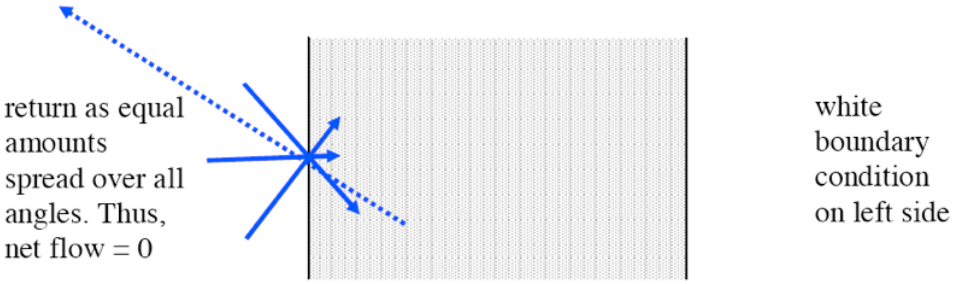

Fig. 9.2.34: White boundary condition.

Vacuum boundary condition

A vacuum boundary condition means that no neutrons will reenter the boundary. Thus, any neutron exiting the system through a boundary with a vacuum boundary condition is permanently lost to the system. This condition is illustrated in Fig. 9.2.35.

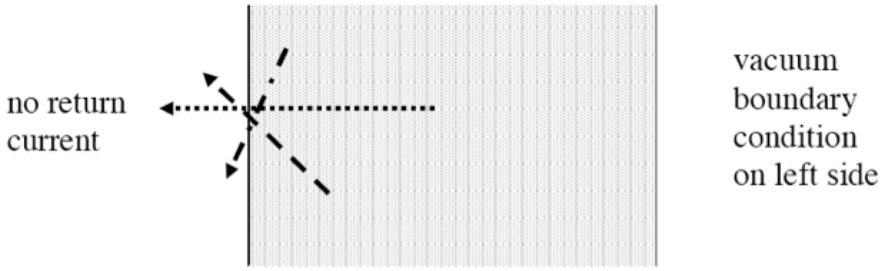

Fig. 9.2.35: Vacuum boundary condition.

Periodic boundary condition

For the periodic boundary condition, the incoming angular flux on a boundary is set equal to the outgoing angular flux on the opposite boundary. Fig. 9.2.36 shows the leakage leaving each boundary (dotted lines) being returned at the same quantity and angle on the opposite boundary (solid line of same color). When the periodic boundary condition is used, it must be applied to both opposing boundaries.

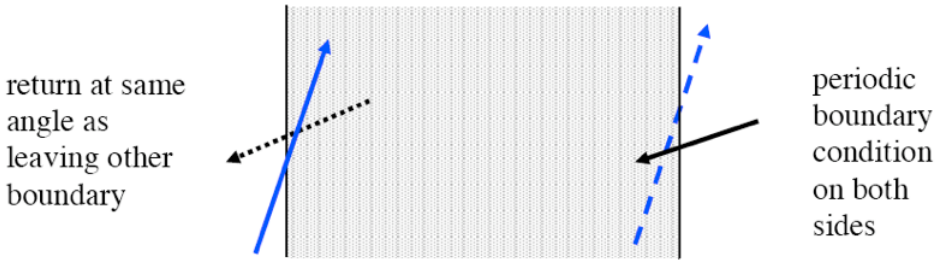

Fig. 9.2.36: Periodic boundary condition.

Boundary condition specification

The standard format for boundary condition specifications is as follows:

```
read bounds
-x=west_BC  +x=east_BC  -y=south_BC  +y=north_BC
+x+y=northeast_BC   +x-y=southeast_BC
-x+y=northwest_BC   -x-y=southwest_BC
end bounds
```

where *west_BC, east_BC, south_BC, north_BC, northeast_BC, southeast_BC, northwest_BC, southwest_BC* are each one of the eight possible boundary condition options. The name of the boundary condition requires only the number of leading characters required to make the name unique. For this set, the first letter is sufficient; that is, +x=v, +x=vac +x=vacu, and +x=vacuum are all equivalent and specify a vacuum (zero return) boundary condition on the right side of the global cuboid.

In keeping with KENO-VI, multiple shortcuts exist to simplify the specification. For example, a single boundary condition can be assigned to all four sides simultaneously with the *all*= specifier:

```
read bounds
all=refl
end bounds
```

All KENO-VI boundary face keywords that do not reference the z-dimension are allowed and are listed in Table 9.2.2.

Table 9.2.2: Boundary condition specifiers accepted by NEWT.

Keyword	**Boundary edge**
+x, +xb	East (right)
-x, -xb	West (left)
+y, +yb	North (top)
-y, -yb	South (bottom)
all, xyf, yxf	All boundaries
+xy, +yx, +fc	East (right) + north (top)
-xy, -yx, -fc	West (left) + south (bottom)
xfc	West (left) + east (right)
yfc	North (top) + south (bottom)
+x+y	Northeast (top right)
-x+y	Southeast (bottom right)
-x-y	Southwest (bottom left)
-x+y	Northwest (top left)

9.2.3.8 General cross section weighting

NEWT performs cross section weighting by mixture and optionally by homogenization zone (Sect. 9.2.3.10). Weighting is always used in conjunction with an energy collapse. Cross section weighting is performed over a spatial and energy domain; the resulting average (weighted) cross sections will preserve all reaction rates in the collapsed cross section set; that is,

$$\sigma^i_G = \frac{\int_r N^i(r)dr \int_G \sigma^i(E,r)W(E,r)dE}{\int_r N^i(r)dr \int_G W(E,r)dE}, \tag{9.2.29}$$

where

$\sigma^i_G \equiv$ average (weighted) cross section in energy group G for nuclide I,

$N^i(r) \equiv$ number density of nuclide i in region r,

$W(E,r) \equiv$ the weighting function within region r,

$\sigma^i(E,r) \equiv$ the cross section from the input library for nuclide i in region r.

Within NEWT, each collapsing region is the spatial region or regions in which a given mixture is placed. Hence, for most of the cross section types, an average cross section for the mixture associated with the spatial domain r (which may include one or more defined regions occupied by that mixture) is calculated by weighting the original problem-specific cross section data for that mixture using as a weighting function the neutron spectrum calculated within spatial domain r.

In practice, the integration of Eq. (9.2.29) is performed as a simple summation over all cells j within region r:

$$\sigma_{i,G} = \frac{N^i_r \sum_{j\in r} \sum_{g\in G} \sigma^i_{g,j} W_{g,j}}{N^i_r \sum_{j\in r} \sum_{g\in G} W_{g,j}}. \tag{9.2.30}$$

Because any region r is defined as the sum of all spatial regions containing a given mixture, is constant everywhere within r.

All multigroup cross sections and related data present on the AMPX library are weighted using appropriate weighting functions. For most basic cross sections, the multigroup flux obtained from the transport solution is the appropriate weighting function and $W_{g,r}$ in Eq. (9.2.30) becomes $\phi_{g,r}$. However, special cross sections and data need special treatment, as described in the following sections.

Scattering cross section transfer matrix weighting

In weighting scattering cross sections, the form of the weighting is slightly more complex:

$$\sigma^i_{s,G\to G'} = \frac{\int_r N^i(r)dr \int_G W(E,r)dE \int_{G'} \sigma^i(E\to E',r)\,dE'}{\int_r N^i(r)dr \int_G W(E,r)dE}, \tag{9.2.31}$$

or, in multigroup format,

$$\sigma^i_{s,G\to G'} = \frac{N^i_r \sum_{j\in r} \sum_{g\in G} W_{g,r} \sum_{g'\in G'} \sigma^i(g\to g')}{N^i_r \sum_{j\in r} \sum_{g\in G} W_{g,r}}. \tag{9.2.32}$$

In general, the scalar flux, $\phi_{\mathrm{g,r}}$ is the appropriate weighting function for scattering cross sections:

$$\sigma^i_G = \frac{N^i_r \sum_{j\in r} \sum_{g\in G} \sigma^i_{g,r}\phi_{g,r}}{N^i_r \sum_{j\in r} \sum_{g\in G} \phi_{g,r}}. \tag{9.2.33}$$

This is an approximation for the higher order moments ($l > 0$) of the scattering cross sections, which should be more properly weighted using the lth moment of the flux instead of the 0th moment (scalar) flux as used in Eq. Eq. (9.2.33). However, because flux moments are generally both positive and negative, NEWT performs higher-order-moment scattering cross section weighting using the positive scalar flux.

Weighting of the collapsed fission spectrum, χ

Weighting is not required for collapsing a fission spectrum vector; the format for a collapsed fission spectrum (χ_G) is a very straightforward summation of the fission spectra in energy groups g spanning the energy domain of the collapsed energy group G:

$$\chi_G = \sum_{g \in G} \chi_g. \tag{9.2.34}$$

Weighting of the number of neutrons per fission

Accurate weighting of ν in an energy and space domain requires weighting by the fission rate; that is,

$$W(E, r) = \sigma^i_f(E, r)\phi(E, r). \tag{9.2.35}$$

Hence, for ν, Eq. Eq. (9.2.33) has the form

$$\nu^i_G = \frac{N^i_r \sum_{j \in r} \sum_{g \in G} \nu^i_g \sigma^i_{f,g,r} \phi_{g,r}}{N^i_r \sum_{j \in r} \sum_{g \in G} \sigma^i_{f,g,r} \phi_{g,r}}. \tag{9.2.36}$$

Weighting of (n,2n), (n,3n), and (n,4n) cross sections

In creating AMPX weighted libraries with NEWT, all data on the original library are collapsed and written to a collapsed working-format library, for each reaction type and for each nuclide. Therefore, each of the (n,*X*n) libraries is collapsed independently using Eq. Eq. (9.2.30) and is written on the weighted library.

However, during NEWT transport calculations, NEWT computes and stores a single effective (n,2n) reaction rate, determined as the weighted sum of the individual reactions:

$$\sigma^{\text{effective}}_{n,2n} = \sigma_{n,2n} + 2\sigma_{n,3n} + 3\sigma_{n,4n}. \tag{9.2.37}$$

The (n,2n) reaction rates reported in NEWT output are those computed for the effective cross section. The effective (n,2n) cross section is not saved to the weighted library.

Calculation and weighting of transport cross sections

Transport cross sections are processed in a different manner from other cross sections. The transport cross section does not represent a purely measurable quantity. Introduced within the P_1 (diffusion) approximation to the neutron transport equation, it attempts to preserve a flux gradient in addition to reaction rate information. Hence, the magnitude of a microscopic transport cross section is affected by both the physics properties of the nuclide in question and the geometrical attributes of the spatial domain where the nuclide resides and the other nuclides present in the same vicinity.

Consistent with XSDRNPM, NEWT provides two options to generate a microscopic transport cross section-based on the "consistent" and "inconsistent" methods for solving the P_1 transport equations. These approximations are referred to as the "outscatter" and "inscatter" approximations because of the nature of the equations used.

Outscatter approximation (inconsistent method)

In the outscatter approximation, the following assumption is made for the transport cross section in group g:

$$\sigma_{tr}^{g} = \sigma_{t}^{g} - \bar{\mu}^{g}\sigma_{s}^{g}, \tag{9.2.38}$$

where σ_{t}^{g} and σ_{s^g} are the total and scattering cross section in group g,

$$\bar{\mu}^{g} = \frac{\sigma_{s,1}^{g}}{3\sigma_{s,0}^{g}} \tag{9.2.39}$$

and

$$\sigma_{s,N}^{g} = \sum_{g'} \sigma_{s,N}\left(g \rightarrow g'\right). \tag{9.2.40}$$

Note that the $\sigma_{s,N}\left(g \rightarrow g'\right)$ terms are the P_N coefficients of the scattering matrix, hence the origin of the term "outscatter."

Inscatter approximation (consistent method)

In the "consistent" P_1 approximation of the transport equation, the transport cross section is defined as

$$\sigma_{tr}(E) = \sigma_{t}(E) - \frac{1}{3J(E)} \int_{0}^{\infty} \sigma_{s,1}\left(E' \rightarrow E\right) J\left(E'\right) dE' \tag{9.2.41}$$

where J is the neutron current and $\sigma_{s,1}$ is the first moment (P_1 coefficient) of the scattering transfer matrix.

If one multiplies Eq. Eq. (9.2.41) by J(E), integrates over group g, and converts to a group-averaged form by dividing by $\int_g J(E)dE$, the following expression is derived:

$$\sigma_{tr}^{g} = \sigma_{t}^{g} - \frac{1}{3J_g} \sum_{g'} \sigma_{s,1}\left(g' \rightarrow g\right) J_{g'}. \tag{9.2.42}$$

This is the "inscatter" approximation. It is consistent because the transport values are explicitly derived from the P_0 and P_1 equations.

Weighting function for transport cross section

Internal investigations have shown that transport cross sections computed using the "outscatter" approximation are more robust in subsequent nodal core calculations as compared with transport cross sections computed using the "inscatter approximation." NEWT computes transport cross sections using the outscatter approximation and collapses the cross section with the scalar flux.

9.2.3.9 Array definition

Any arrays specified in unit definitions within the *read geom* block are defined in terms of form and content in the *read array* data block. The block has the form shown below:

```
read array
ara=arrayid  nux=nx  nuy=ny  typ=aratype  [pinpow=yes/no]
fill i1 i2 i3 i4 ... iN end fill
...
end array
```

where *arrayid* is a unique integer identifier for the array, *nx* is the number of array elements moving left to right (i.e., columns), and *ny* is the number of array elements moving from bottom to top (i.e., rows). The type of array is indicated by *aratype* (e.g., square, hexagonal). The optional parameter *pinpow* may be specified as either *yes* or *no* (default is no) and is used to enable/disable pin power edits for units within the array. The *fill…end fill* specifier set is used to input the elements of the array. A total of *N *entries are required, where* *N = nx*ny.

Each of these portions of the array definition statement is described in more detail below.

Array types

NEWT supports arrays of cuboids, hexprisms, and rotated hexprism elements. Four different array types may be selected. Table 9.2.3 lists the supported array types and corresponding element types. The array type given in the first column lists the keyword associated with each type, as used in the typ= specifier; in some cases, multiple keywords are associated with a specific array type. The element type in the second column provides the boundary shape that can be used in the given array type. For example, a cuboidal (square) array may only be filled with cuboidal units.

Table 9.2.3: NEWT array types with corresponding element types.

Array type	**Element type**
Cuboidal, square	Cuboid
Hexagonal, triangular	Hexprism
Shexagonal	Hexprism
Rhexagonal	Rhexprism

All arrays are filled in a 2-D *i, j* pattern, with *i* varying from 1 to *nux* and *j* varying from 1 to *nuy*. All *nux*nuy* elements of each array must be filled. Fig. 9.2.37 illustrates the layout of a conceptual 4 by 4 cuboidal array, showing the row/column index for each element of the array. Fig. 9.2.38 shows the row/column designation for a 4 by 4 hexagonal array. Because of the shape of a hexprism, the array itself is staggered. However, the row/column numbering is simple to understand.

The stacked hexagon (shexagon) layout, as shown in Fig. 9.2.39, was developed to simply allow an alternate placement algorithm for hexprisms. Any model that can be specified with *typ=hexagonal* can also be specified with *type=shexagonal*; the choice of which form to use is simply one of user preference. It is important to note that beginning with row 3, units will be placed in a physical location different from that of the hexagonal layout when the shexagonal layout is used.

Finally, the rotated hexprism (rhexprism) array is pictured in Fig. 9.2.40. This array is intended to facilitate placement of rhexprisms. The numbering of cells is somewhat irregular because of the staggered rows, but it is easy to follow if one is aware of the fill pattern as illustrated in the figure. Note that the layout of a rhexagonal array can be replicated exactly using a hexagonal or rhexagonal array, placed in a hole, and rotated 90°. Thus, the type of hexprism-based array used can always be tailored to the preferences of the user and all can be used to create the same model.

It is often the case, especially for hexagonal-type arrays, that one does not need to fill all array positions. While the array fill procedure does require that all positions be filled, NEWT provides a mechanism to fill a position with a null unit, effectively skipping that position. This is discussed further under Fill Operations.

1,4	2,4	3,4	4,4
1,3	2,3	3,3	4,3
1,2	2,2	3,2	4,2
1,1	2,1	3,1	4,1

Fig. 9.2.37: Layout of a 4 by 4 cuboidal array.

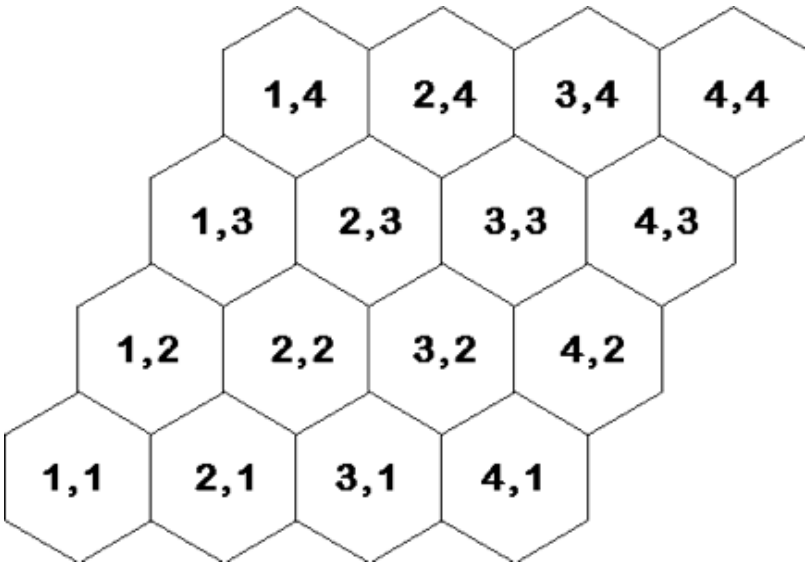

Fig. 9.2.38: Layout of a 4 by 4 hexagonal array.

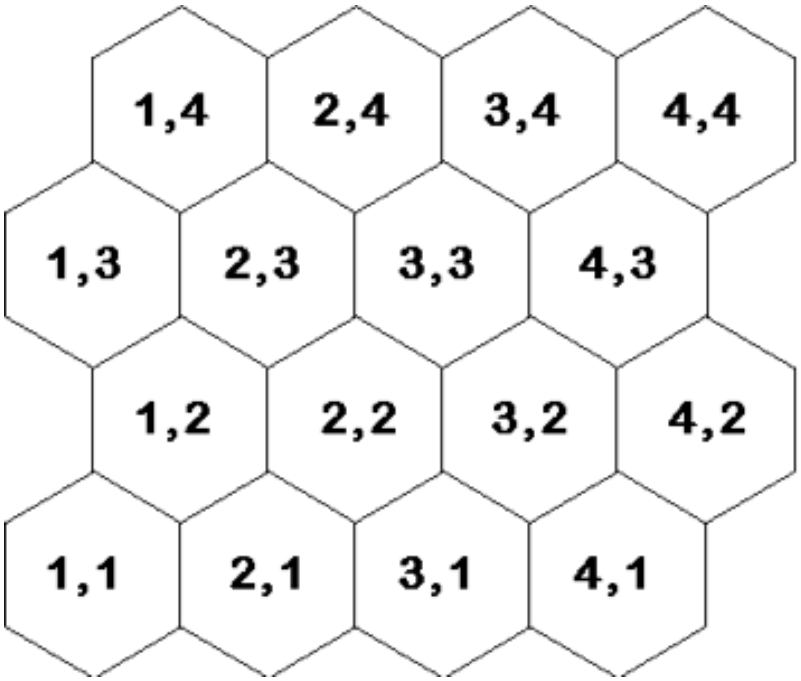

Fig. 9.2.39: Layout of a 4 by 4 stacked hexagonal (shexagonal) array.

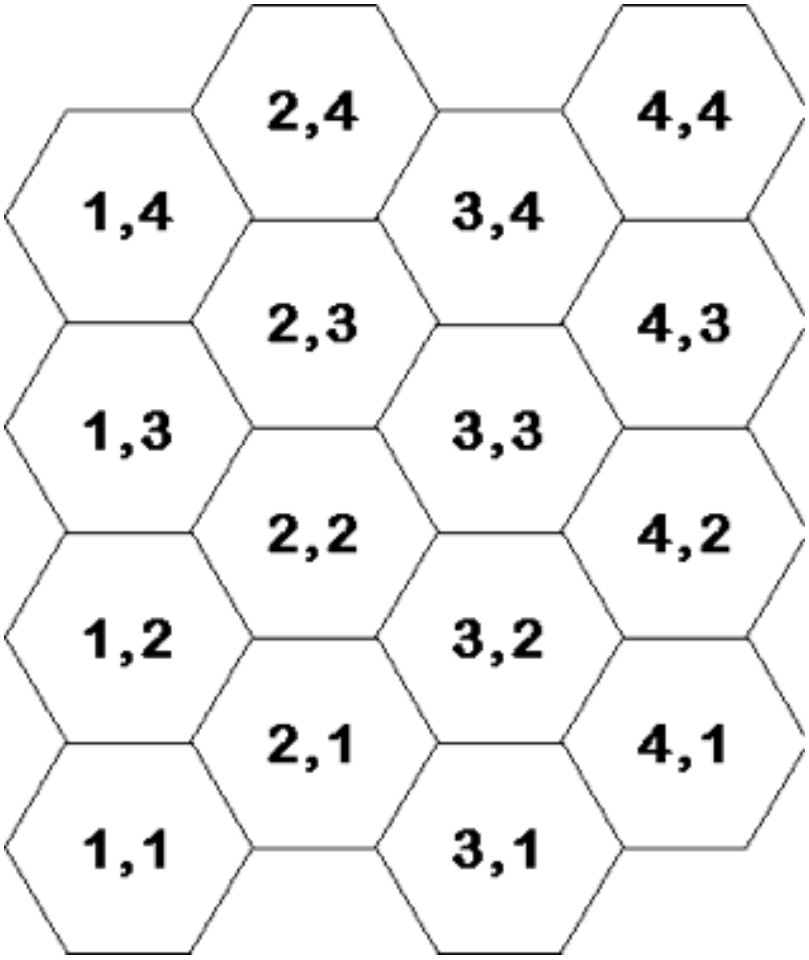

Fig. 9.2.40: Layout of a 4 by 4 rotated hexagonal (rhexagonal) array.

Although all elements of cuboidal arrays **must** be cuboids, they need not be the same size. Elements of each row must have the same height but may have varying widths. Similarly, elements of each column must be of a single common width but may vary in height. Less flexibility is available in hex-based arrays, because of their very nature. Hexagonal and stacked hexagonal arrays may contain only hexprisms, and all must be of the same outer size (although unit contents may vary as needed). Rotated hexagonal arrays likewise are limited to rhexprisms with a single boundary size.

Pin-power edits

In lattice-physics calculations, it is often necessary to obtain a pin-power edit showing the power produced in each fuel pin cell. NEWT uses the array functionality to define pin cells. When *pinpow=yes* is specified, an extra edit is produced that gives the normalized pin power in each pin cell. A pin cell is defined as any element within the array that contains a fissionable nuclide. Pin powers are normalized such that the average of all fuel-bearing array elements is 1.0. Array elements such as burnable poison rods or water holes, which produce no *fission* power, are not included in the power normalization process. The *pinpow* functionality is not available for hexagonal, shexagonal, or rhexagonal lattices.

Output provides an edit of each assembly for which *pinpow=yes* is specified. In addition, a final edit is provided for the entire system, normalized to all fuel cells in all arrays for which *pinpow=yes* is specified.

Pin-power edits are shown in the description of output in Sect. 9.2.5.

Fill operations

The final section of an array specification is the *fill* list. Delimited by *fill* and *end fill* keywords, NEWT expects a list of N=nux*nuy unit numbers, specifying the unit to be placed at each array position. Arrays are filled left to right, starting at the bottom left-hand corner and moving up a row after all columns in the current row are filled. In other words, any of the 4×4 arrays in the figures above would be filled in the following order: (1,1), (2,1), (3,1), (4,1), (1,2), (2,2), (3,2), (4,2), (1,3), (2,3), (3,3), (4,3), (1,4), (2,4), (3,4), (4,4).

The list of elements used to fill an array consists of unit numbers. Each unit used in the fill list must be defined in the geometry block and must be of the shape and size required for the array type and position. However, NEWT provides the ability to fill an array location with a null unit, which in essence skips the current array location. This is accomplished simply by entering unit number "0" (a "null" unit) at the location to be skipped.

Examples of array definitions

Consider a simple 3×3 square array with array ID 10, with unit 1 to be placed in the center of the array, surrounded by unit 2 cells. Such a specification would take the following form:

```
ara=10 nux=3 nuy=3 type=cuboidal fill 2 2 2 2 1 2 2 2 2 end fill
```

This may also be written spanning several lines to help visualize the layout:

```
ara=10 nux=3 nuy=3 type=cuboidal fill
2 2 2
2 1 2
2 2 2 end fill
```

Note that the array is being filled from the bottom so that the actual unit layout is inverted relative to the fill description. A fill specification that places unit 1 at the top center position in this array would be input as follows, where the second-to-last entry in the list is placed in the horizontal center of the top row.

```
ara=10 nux=3 nuy=3 type=cuboidal fill
2 2 2
2 1 2
2 1 2 end fill
```

Arrays may be nested within arrays. Each array must be placed in a unit, but a unit containing an array may be placed within another array. The following example demonstrates the use of nested arrays, along with the use of a null unit.

In this example, we define two units containing cells, a unit containing a smaller array and a global unit containing a larger array:

```
unit 1
'0.5/0.6 cm radius pin
cylinder 30 0.5 sides=20
cylinder 20 0.6 sides=20
cuboid 10 4p0.75
media 1 1 30
media 2 1 20 -30
media 3 1 10 -20
boundary 10 3 3

      unit 2
'0.25/0.3 cm radius pin
cylinder 30 0.25 sides=8
```

(continues on next page)

(continued from previous page)

```
cylinder 20 0.3 sides=8
cuboid 10 4p0.375
media 1 1 30
media 2 1 20 -30
media 3 1 10 -20
boundary 10 3 3

'small array
unit 3
cuboid 10 1.5 0 1.5 0
array 1 10 place 1 1 0.375 0.375
media 3 1 10
boundary 10 5 5       'large array
global unit 4
cuboid 10 3.0 0.0 3.0 0.0
array 2 10 place 1 1 0.75 0.75
media 3 1 10
boundary 10 5 5
```

Now, in a *read array* block, we define array 1, a 2 by 2 array filled with unit 2 cells, and array 2, filled with two unit 1 cells, one unit 3 cell (containing array 1), and one null unit:

```
read array
ara=1 nux=2 nuy=2 typ=cuboidal
fill 2 2
     2 2 end fill
'
ara=2 nux=2 nuy=2 typ=cuboidal
fill 1 3
     0 1 end fill
end array
```

When assembled, the model would appear as shown in Fig. 9.2.41. Note that local grids override the global grid in each array location but that the global grid is seen where the null unit is placed.

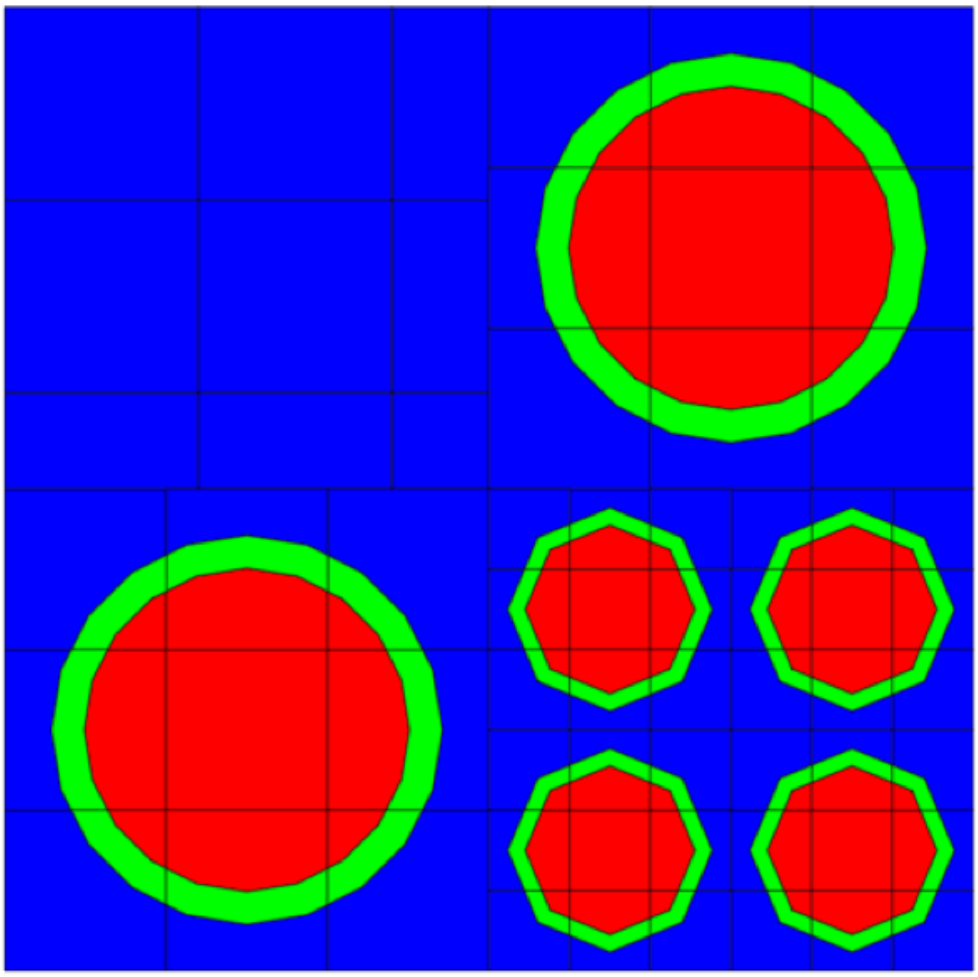

Fig. 9.2.41: Example of nested arrays and a null unit specification.

9.2.3.10 Homogenization block

Homogenization block keyword = homog, hmog, homo

As discussed earlier, NEWT can be used to collapse cross sections to a reduced broad-group format. The cross sections produced from this operation are written as microscopic cross sections for each nuclide in each mixture. NEWT also provides the ability to produce macroscopic weighted cross sections homogenized over one or more mixtures. Homogenized cross sections are created using the collapsing energy structure defined in the collapse data block or the original library's group structure if no collapsing instructions are provided. Flux-weighted collapsed cross sections are combined with number densities and added such that reaction rates in homogenized materials are conserved.

Within the homogenization block, multiple homogenization records are permitted, and the same mixtures may be repeated in different records. Each record provides a recipe defining the mixtures to be homogenized. Homogenization records have the following form:

```
Homogenized     Mixture          List of        end
Mixture ID     Description    Mixtures
```

The homogenized mixture ID is the "nuclide" number under which the mixture is saved on the homogenized cross section library. The value is arbitrary and serves only as a means to identify the cross section set on the library, although each ID must be unique. The mixture description is an alphanumeric label of up to 12 characters that is associated with the mixture; this label provides a little more descriptive ability than the ID itself. The label may not contain blanks. Finally, the label is followed by the list of mixtures to be homogenized, terminated by the end keyword. The list may contain up to 1000 unique mixtures.

A sample homogenization block is shown below. In this illustration, two homogenized mixtures are created. This first consists of five different fuel mixtures (201–205); this could be used to obtain the average fuel cross section for an assembly containing five different fuel types. The homogenized cross sections will be written to the homogenized library as nuclide 500, with label "fuel." The second instruction homogenizes mixtures 201, 210, and 220 from the original problem; this could be used, for example, to homogenize the fuel, clad, and moderator of a fuel pin cell. This cross section set would be written on the same library as nuclide 501, with the label "fuel_cell201."

```
read hmog
500   fuel  201 202 203 204 205  end
501   fuel_cell201   201 210 220 end
end hmog
```

Homogenized (macroscopic) cross sections are saved in an AMPX working-format library at the unit specified by the *hmoglib*= parameter (default=13) [ft13f001].

Instead of calculating the sometimes complicated decay chains to determine cumulative yields, nodal codes often apply simplified models for xenon and samarium. The homogenization block therefore also enables the calculation of fitted yields for ^{135}I, ^{135}Xe and ^{149}Pm for use in nodal codes. Like the Polaris sequence, NEWT relies for this calculation on a set of pre-calculated fitted yields. Up to SCALE 6.2, NEWT and Polaris used different sets of pre-calculated fitted yields. Polaris used yields that were determined based on a set of LWR Polaris calculations with subsequent yield fitting.

To improve consistency between the sequences, since SCALE 6.3, NEWT by default uses the same fitted yields as Polaris. Yield resource `lwr_yields.h5` in SCALE's data directory is used by both sequences. For backwards compatibility, the yields used by NEWT up to SCALE 6.2 are available in resource `legacy_yields.h5`.

Users can switch the yield resource or use their own resource by linking the respective resource into the temporary working directory.

Example 1: Use NEWT legacy yield data

```
read shell
  cp ${DATA}/legacy_yields.h5 ${TMPDIR}/lwr_yields.h5
end shell
```

Example 2: Use user-defined yield data

```
read shell
  cp /path/to/user-resource.h5 ${TMPDIR}/lwr_yields.h5
end shell
```

9.2.3.11 Assembly discontinuity factors

Assembly discontinuity factor (adf) block keyword = adf

Because discontinuity factors have meaning only with respect to homogenized cross sections, ADFs are calculated only if homogenized cross sections are also specified via the Homogenization data block (see Sect. 9.2.3.10). Calculation of ADFs is specified in the *read adf* data block. The three supported formats of this data block are as follows. For a single-assembly model, the following format is used:

```
read adf
1 homg_assm_id n=Y1 s=Y2 e=X1 w=X2
end adf
```

For a reflected assembly model, the following format is used:

```
read adf
2 homg_assm_id homog_refl_id w=Xi
end adf
```

```
read adf
3 homg_assm_id line1 line2 line3 ...
end adf
```

where

`hmog_assm_id` is the identifying label assigned to the homogenized assembly,

`hmog_refl_id` is the label assigned to the homogenized reflector region,

`Y1` is the y-ordinate of the north boundary of the assembly (typically this is y_{max} for the global unit),

`Y2` is the y-ordinate of the south boundary of the assembly (typically this is y_{min} for the global unit),

`X1` is the x-ordinate of the east boundary of the assembly (typically this is x_{max} for the global unit),

`X2` is the x-ordinate of the east boundary of the assembly (typically this is x_{max} for the global unit),

`Xi` is the x-ordinate for the fuel/reflector interface,

`linei` is a series of two ordered pairs (`X1`,``Y2``), (`X1`,``Y2``)that define a line segment in the NEWT grid.

In a single-assembly calculation, only a single homogenized mixture is specified. Leading index 1 indicates that ADFs for the fuel assembly are being calculated; ADFs may be calculated on any or all faces of a rectangular assembly. In a reflected assembly, the leading index is 2, followed by the homogenized mixture ID for the fuel assembly first, then the homogenized mixture ID for the reflector region. An ADF may be requested only for one location, at the fuel/reflector interface. In any configuration, ADFs may be requested for a set of arbitrary line segments defined in the NEWT geometry. In this case, the leading index is 3, followed by the homogenized mixture ID, followed by up to 12 line segments, which are defined by their beginning and ending points. ADFs along these lines are defined as the surface-averaged flux divided by the average flux defined for the associated homogenized mixture. Surface-averaged currents are also edited for each arbitrary line segment; both full and partial currents in both the x- and y- directions are provided. The

net current is also provided in the few-group cross section database file *xfile016*. The orientation of the net current across the line segment is further discussed in Appendix A of TRITON chapter.

Although any homogenized set of mixtures can be specified for each homogenized region, the ADF will have physical meaning only if the homogenized set represents all mixtures in the assembly. Similarly, if a reflector calculation is performed, the *hmog_refl_id* should represent the set of homogenized reflector mixtures. The average collapsed flux in the homogenized mixtures is used to calculate the homogeneous flux for a single-assembly ADF. In a reflector calculation, the homogenized cross sections for the reflector are used to solve the multigroup diffusion approximation (Sect. 9.2.2.5).

Examples illustrate the use of the ADF input specification. Consider a 17×17 pressurized-water-reactor (PWR) design. Because of symmetry, it can be modeled a $1/4$ assembly; therefore, we choose to model the upper right quadrant, as shown in Fig. 9.2.42. Mixtures 1, 2, 3, and 4 represent the fuel, clad, moderator, and guide tube materials, respectively. The west and south sides of the model are the assembly midplanes, so ADFs calculated on these boundaries would have no physical meaning. (These are not real assembly boundaries.) However, because of the symmetry of the assembly, fluxes would be identical on all boundaries. Therefore, selection of either the north or east boundary will yield a valid ADF for all boundaries. We choose to request an ADF calculation for the east (right) side of the assembly.

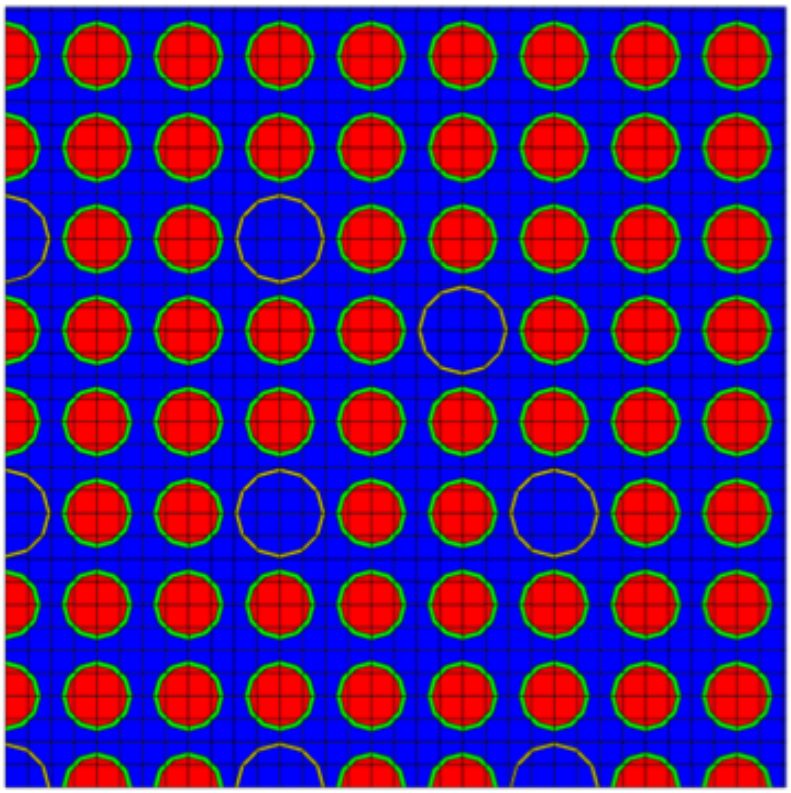

Fig. 9.2.42: Upper-right quadrant of an unreflected PWR assembly.

Assuming we are collapsing 44 energy groups to 2 energy groups, we would specify the following *collapse*, *homog*, and *adf* blocks to obtain 2-group ADFs representative of this assembly:

```
read collapse
22r1 22r2
end collapse
read hmog
500 assm   1 2 3 4 end
end hmog
read adf
1 500 e=10.752
end adf
```

Again, recall that for a single assembly, the ADF in each energy group is simply the average flux on the specified boundary divided by the average flux for the entire assembly, which in this case is the flux in homogenized mixture 500.

ADF can also be calculated using the arbitrary line-segment ADF type. Using this new ADF type, the ADF input would be the following:

```
read collapse
22r1 22r2
end collapse
read hmog
500 assm   1 2 3 4 end
end hmog
read adf
3 500 10.752 0.0 10.752 10.752
end adf
```

In this example, the east-side ADF will be calculated along the line segment starting at (10.752,0) and ending at (10.752,10.752). The values of the line segments depend on a coordinate system of the global unit.

For a reflected model, consider the same type of assembly but representing an assembly placed on the core periphery. It is bounded on one side by a 2 cm stainless steel baffle and 10 cm of water, beyond which is treated as vacuum. Because the reflector calculation is a 1-D solution, it is not possible to directly model a fuel assembly with two reflector boundaries. Typically the assumption is made that the same ADF may be applied in any assembly/reflector boundary and that a 1-D reflector model is all that is necessary. This model is pictured in Fig. 9.2.43. Notice that different mixtures are used in the reflector model. Fluxes used in homogenized mixtures and for generating homogenized cross sections are spatially averaged; thus, it is important to separate the moderator in the reflector from that in the fuel assembly such that average fluxes in each region properly characterize that region. For example, the flux in the reflector will be significantly different (far more thermal) from the flux within the assembly.

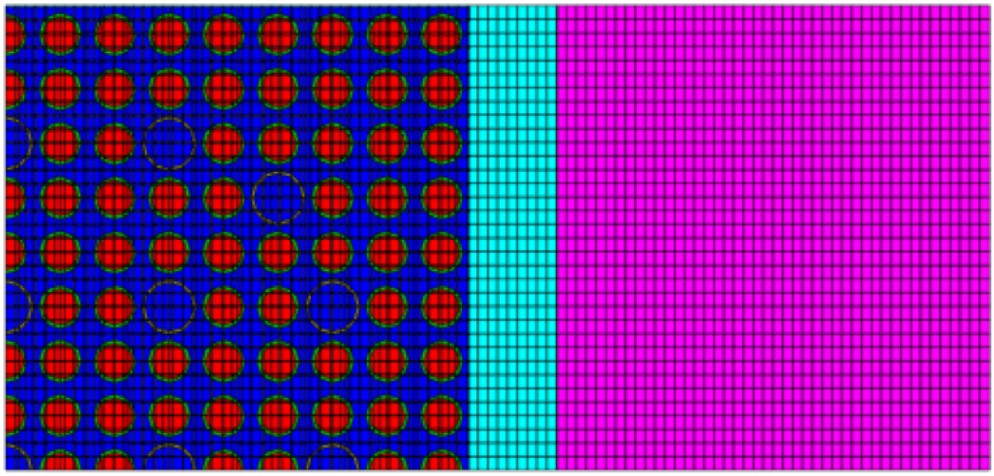

Fig. 9.2.43: Upper-right quadrant of a PWR assembly with baffle and reflector.

Assuming again a collapse from 44 energy groups to 2, the following *collapse*, *homog*, and *adf* blocks would be specified to obtain 2-group ADFs representative of the assembly and the reflector; 2-group cross sections for each homogenized region would also be prepared from the collapse and homogenization instructions:

```
read collapse
22r1 22r2
end collapse
read hmog
500 assm   1 2 3 4 end
501 reflector 5 6 end
end hmog
read adf
2 500 501 w=10.752
end adf
```

9.2.3.12 Flux planes

Fluxplane block keyword = fluxplane, fluxplan, flux, fluxplanes

The fluxplane block is a special output edit that lets one obtain the average scalar flux and currents along any line segment or any continuous set of collinear line segments. One must simply specify the start and end points of a line segment for which a linearly averaged flux is desired. This line segment must correspond to one or more line segments in the model's grid structure, which requires some knowledge of where grid lines exist in the model.

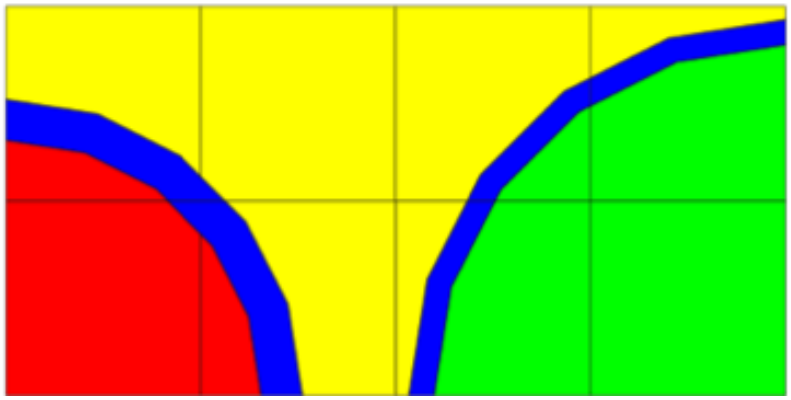
The format of a flux plane specification is as follows:

```
read fluxplane
text_label homg_assm_id xstart ystart xend yend
...
end fluxplane
```

where *text_label* is an alphanumeric description used to label the selected plane in the output, *homg_assm_id* is the identifier in the *homog* block, and *(xstart, ystart)* and *(xend, yend)* are the start and end points, respectively, for the line segment for which an average flux is desired. The *text_label* string must not contain white space and may be up to 16 characters in length.

As an example, we consider a simple model consisting of two dissimilar pin cells (1/4 cells):

```
global unit 1
cuboid 1 1.26 0.0 0.63 0.0
cylinder 2 .4750 chord +x=0 chord +y=0 sides=20
cylinder 3 .4095 chord +x=0 chord +y=0 sides=20
cylinder 4 .6030 chord +y=0 chord -x=1.26 origin x=1.26 sides=20
cylinder 5 .5630 chord +y=0 chord -x=1.26 origin x=1.26 sides=20
media 1 1 3
media 2 1 2 -3
media 10 1 5
media 2 1 4 -5
media 3 1 1 -2 -4
boundary 1 4 2
```



We know a line segment (actually, two) exists at $x = 0$, $x = 0.63$, and $x = 1.26$, between $y = 0$ and $y = 0.63$. Thus, a legitimate set of flux plane specifications would be the following:

```
read fluxplane
cell_interface 0.63 0.0 0.63 0.63
midplane_cell1 0.0 0.0 0.0 0.63
midplane_cell2 1.26 0.0 1.26 0.63
end fluxplane
```

This will provide a summary of fluxes and currents at each line segment in fine-group structure, and if a collapse is performed, in broad-group structure. Results from a calculation with a two-group collapse appear as follows:

```
Broad Group Fluxes:
 Group    cell_interface    midplane_cell1    midplane_cell2
    1      5.906586D+01      5.903113D+01      5.930420D+01
    2      7.645792D+00      7.641424D+00      6.705809D+00

Broad Group Currents (x):
 Group    cell_interface    midplane_cell1    midplane_cell2
    1     -3.481505D-01      0.000000D+00      0.000000D+00
    2      3.004759D-01      0.000000D+00      0.000000D+00

Broad Group Currents (y):
 Group    cell_interface    midplane_cell1    midplane_cell2
    1      1.081450D-01      1.652161D-01      1.120160D-01
    2     -1.031163D-01     -1.647396D-01     -9.993214D-02
```

Output also includes +x, -x, +y, and -y components of currents.

9.2.3.13 Mixing table block

Mixing table block keyword = mixt, mixtable

Generally, NEWT calculations are performed using a cross section library and mixing table prepared in advance by other SCALE modules. However, NEWT allows the user the ability to manually specify the isotopic composition of each mixture used in a NEWT model. If a mixing table block is read, any existing mixing table data file is ignored. Therefore, all mixtures specified in the material block must be mixed in the mixing table block.

The format of the mixing table is simple and straightforward. For each nuclide used, three parameters must be supplied: (1) *mixid*, the mixture ID number into which the nuclide is to be mixed; (2) *nuclideid*, the SCALE ID number for the nuclide (which must exist on the cross section library being referenced); and (3) *concentration*, the number density (atoms/b-cm) of the nuclide in this mixture. The same nuclide may appear in multiple mixtures or more than once in a single mixture if desired. Macroscopic cross sections are determined for each mixture by the following formula:

$$\Sigma^R = \sum_i \sigma_i^R N_i \tag{9.2.43}$$

where

Σ^R is the mixed macroscopic cross section for reaction R in the mixture,

N_i is the number density of nuclide i,

σ_i^R is the microscopic cross section for reaction R in nuclide i.

The form of the mixing table block is as follows:

```
read mixt
mixid1 nuclideid1 concentration1
mixid2 nuclideid2 concentration2
mixid3 nuclideid3 concentration3
...
mixidN nuclideidN concentrationN
end mixt
```

This concludes this list of input blocks available within NEWT. The following section provides a list of sample inputs used to represent a variety of configurations and use of codes. These examples are intended to provide a broader illustration of the use of NEWT in a range of potential applications.

9.2.4 EXAMPLES OF INPUTS

This section provides annotated sample input listings for three different model types, showing the use of a number of different options and approaches in model development for a variety of applications. These samples use the TRITON T-XSEC sequence to prepare cross sections for stand-alone NEWT calculations. In general, this is more easily accomplished as a TRITON T-NEWT calculation in which cross section processing and a NEWT transport solution are combined into a single calculation. However, the user is directed to the TRITON user's manual (Chapter T1.4 of the SCALE manual) for details on T-XSEC and T-NEWT calculations. The examples are intended simply to demonstrate the use of the NEWT code. The T-XSEC data are included to allow a user to observe the mixture definitions used in the NEWT input in its calculation. These problems are also available as sample problems in the SCALE distribution.

9.2.4.1 Sample 1

Sample 1 illustrates the use of a series of three consecutive stand-alone NEWT calculations. Annotated input for this problem is given in Fig. 9.2.44. The calculation begins with SCALE standard composition specifications used to prepare a problem-specific weighted cross section library and mixing table for use by NEWT. In this case the T-XSEC sequence of the TRITON control module is used. This input is described in the TRITON chapter and is not described further here.

The first NEWT case uses no parameter block; thus, all default parameters are applied. The default is an eigenvalue calculation, with cross sections read from ft04f001 (xnlib=4) and collapsed cross sections written to ft30f001 (wtdlib=30). The 238-group cross section library is collapsed to a 44-group library using mixture-weighted fluxes. The model calculates the eigenvalue for a simple 1/4 pin cell. The center of the pin is placed at the origin, the lower-left corner of the global unit boundary, inlaid into a 2 by 2 base grid. The grid structure is illustrated in Fig. 9.2.45.

The second case performs the same calculation using the collapsed cross section library created by the first case. Parameter *restart*=no is set to prevent the code from attempting a restart from the existing library. Because the first case saved 238-group fluxes and the second case uses 44 energy groups from the collapsed set, a restart is not possible.

The third NEWT case is a calculation identical to the second case, although the input is different. In this case, the flux restart file from the previous calculation is used as a first guess for fluxes. This is permitted since both cases used the same cross section library and therefore have the same energy boundaries. For this case, the "read geom" data block is omitted, telling NEWT to use the geometry restart file from the previous case. This allows a rapid restart, since no geometric data need to be recomputed. Because no other parameters are changed, this case will converge after one outer iteration to the same eigenvalue as in the first case.

Fig. 9.2.44: Sample 1 input listing (annotated).

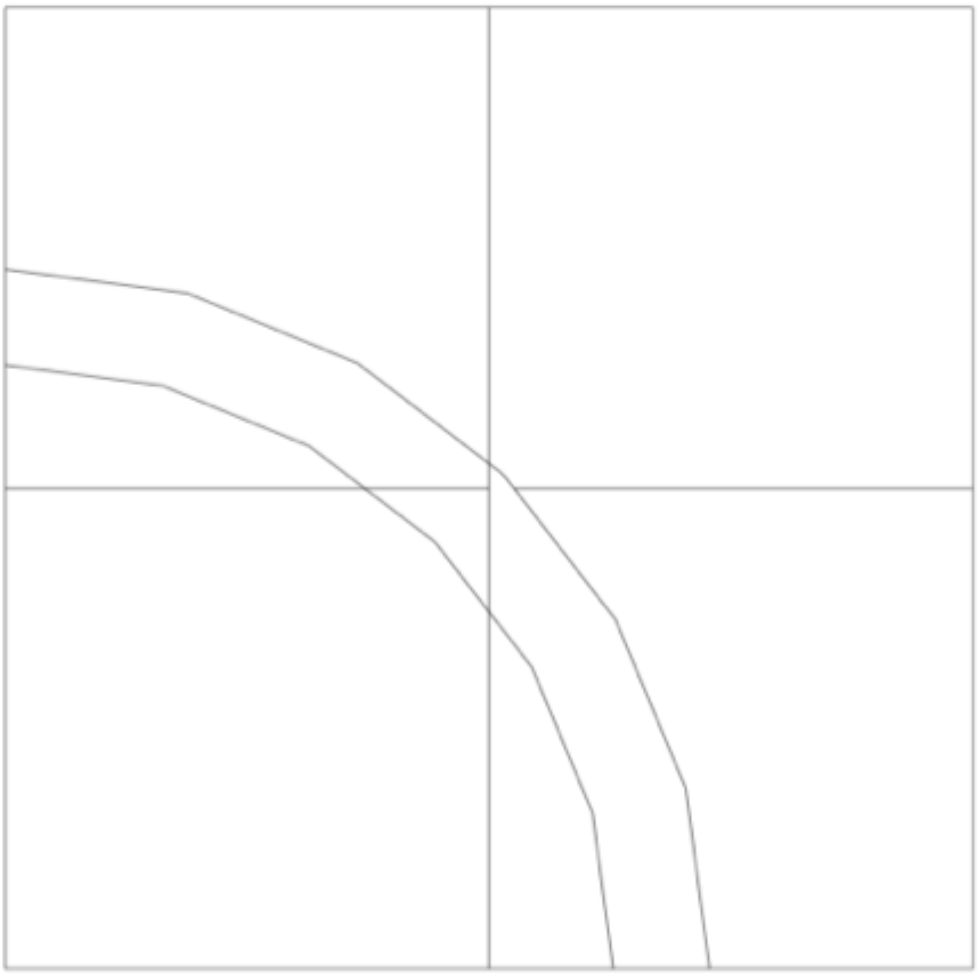

Fig. 9.2.45: Grid structure for 1/4 pin cell of Sample 1.

9.2.4.2 Sample 2

Sample 2 (shown in Fig. 9.2.46 and Fig. 9.2.47) illustrates the use of multiple bodies within a single unit. It highlights the use of media definitions to include and exclude regions when various bodies are used. Although an array can be used to place bodies, this example illustrates a method suitable for use in developing a model for a configuration with an irregular non-array-type structure. This sample problem also highlights the use of partial-current unstructured-mesh CMFD acceleration, which reduces the number of outer iterations from 35 to 21 and the CPU run time by ~25%.

Mixed-oxide fuel specification, mixture number 2

Zircaloy clad, mixture number 5

Borated water moderator, mixture number 6

Cell specification for a triangular lattice

End of T-XSEC case

Beginning of NEWT calculation

Parameter block uses product quadrature set: two polar angles with three azimuthal angles, partial-current CMFD acceleration with four fine-mesh cells per coarse-mesh cell. The echo option is turned on, as well as other convergence control options.

List of all problem materials—P_1 scattering is specified in fuel and clad; P_2 scattering, in moderator

Fig. 9.2.46: Sample 2 input listing (annotated).

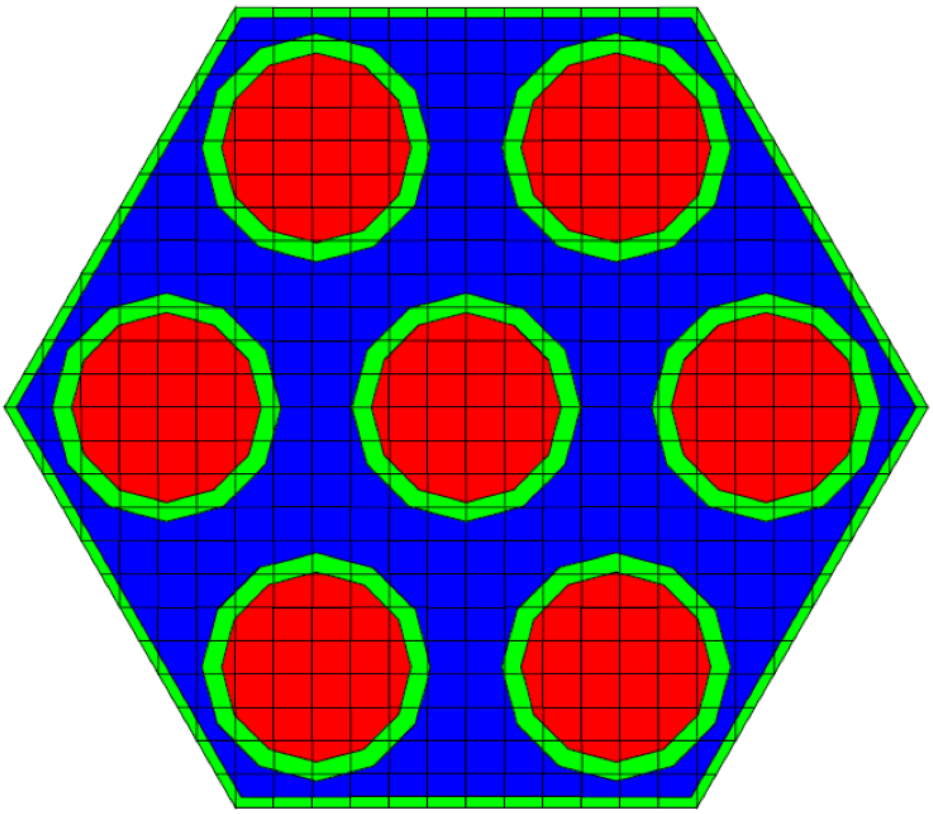

Fig. 9.2.47: Mixture placement and grid structure for model described in Sample 2.

Sample 3

Sample 3 demonstrates the development of a VVER-440 hexagonal fuel assembly. Annotated input for this problem is given in Fig. 9.2.48. The output plot for this model is shown in Fig. 9.2.49. The key attributes of this model are as follows:

1. the use of hexagonal (hexprism) units in a stacked hexagonal array,
2. the use of null units as placeholders in the array,
3. a full model within a rhexagonal outer boundary,
4. the use of white boundary conditions,
5. **the use of the new partial-current-based unstructured CMFD** acceleration for hexagonal-domain configurations, and
6. new type-3 ADF inputs.

Using CMFD acceleration, the number of outer iterations needed for convergence decreased from 21 to 8 with a run-time speedup of ~2.58.

t-xsec sequence of TRITON
title card
238-group ENDF/B-VII library

Define aliases: four fuels, four clads, and four moderators will be defined by the three aliases

Read compositions

Four different fuel mixtures are defined. Because each mixture contains different specifications (different enrichments, Gd in one rod), these cannot be defined by using an alias

Use aliases to define four identical clads with different mixture IDs

Use aliases to define four identical moderators with different mixture IDs

Aliases are used to define a single cell description that will be expanded to four different cell descriptions
End of t-sec case

Begin NEWT calculation
Title card followed by parameter block. CMFD option 3 used in the parameter block, along with four fine meshes per course mesh.

Material block specified four fuel mixtures, a clad mixture, and outer (can) clad mix—all with P-1 scattering—and a single moderator with P-2 scattering

Begin geometry description. Geometry block consists of a list of units

Unit 2 contains an annular fuel pin. Model consists of mixture 23 (moderator), fuel mixture 2, more moderator, and clad—all within a hexprism filled with moderator

Unit 3 is identical to unit 2 but places mixture 3 in the fuel region

Unit 5 is identical to unit 2 but places mixture 5 in the fuel region

Unit 6 is identical to unit 2 but places mixture 6 in the fuel region

Unit 9 is a control rod guide tube, consisting of moderator within the tube, which is, in turn, set into a hexagonal region of moderator

Unit 100 is the global unit. Three nested hexprisms are specified: filled with moderator, zirc, and more moderator. An array is placed with element 7,7 centered in the unit. The outer boundary is a hexprism. A 28 by 28 grid is specified for the unit. Therefore, a 7 by 7 coarse-mesh grid is used

All units have been specified. This completes the geometry description

A single array is used in the model and is specified here. A stacked hexagonal array format is used for a 13 by 13 array. The guide tube is place in the center (unit 9); units 2, 3, 5, and 6 are placed in appropriate positions. Null units are placed in corner regions where no array elements are needed

White BCs are specified for the horizontal outer boundaries. White BCs are always used on nonhorizontal and nonvertical boundaries

Homogenization block is used to define one new mixture ID 500—composed of all the mixtures used in the model. The string identifier for the homogenized material is "fuel"

Associated with the new homogenized mixture 500 are type 3 assembly discontinuity factors. In this case, surfaced-averaged flux and currents are provided for six line segments that correspond to the outer boundary of the assembly

A one-group collapse is provided in the Collapse block

End of this NEWT case

Fig. 9.2.48: Sample 3 input listing (annotated).

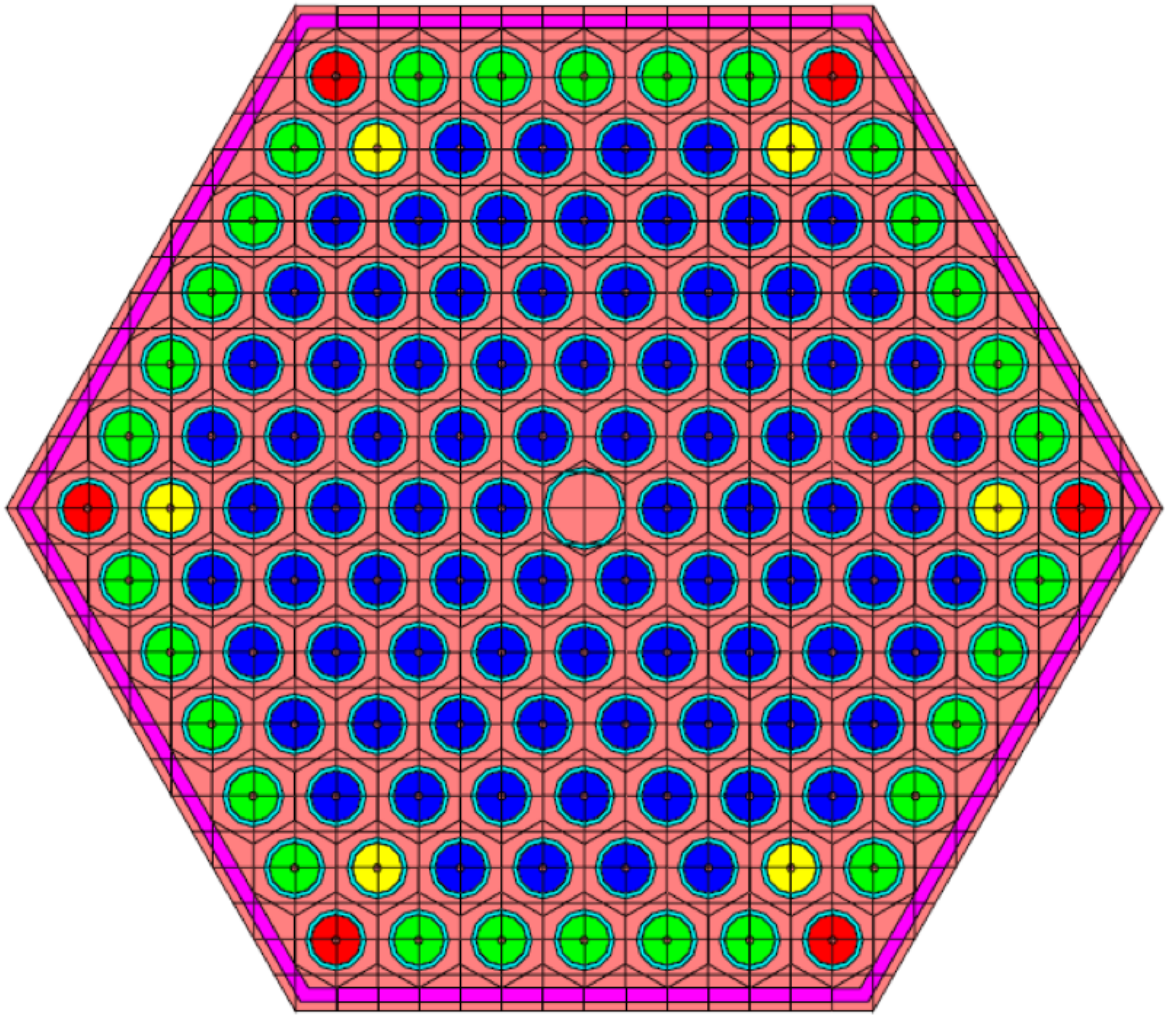

Fig. 9.2.49: Grid structure and material placement for VVER-440 model.

9.2.4.3 Sample 4

Sample 4 demonstrates the use of NEWT in modeling a larger, more complex configuration. Annotated input for this problem is given in Fig. 9.2.50. The calculation begins with the use of SCALE standard composition specifications to prepare a problem-specific weighted cross section library and mixing table for use by NEWT. In this case the T-XSEC sequence of the TRITON control module is used.

This NEWT case is used to calculate the eigenvalue of an infinite lattice of fuel assemblies. Symmetry at the assembly center is used to reduce a 15 by 15 assembly lattice to a smaller one-quarter assembly. The grid structure is illustrated in Fig. 9.2.51. A similar illustration showing media placements by color is given in Fig. 9.2.52.

This input illustrates several features of NEWT modeling capabilities. Some important features of this model are as follows.

- In this sample problem, S-6 quadrature, P-1 scattering (P-2 in the moderator), spatial convergence criteria of 0.005, and an eigenvalue convergence criteria of 0.001 are used. These are an order of a magnitude larger than the values typically used for LWR lattice calculations.

- Two sets of UO_2 cross sections are prepared in the T-XSEC calculation. These cross sections are identical with the exception of the mixture number. Since NEWT reports fluxes, reaction rates, etc., by mixture, the placement of a unique mixture at a specific location in a model allows one to determine, for example, the reaction rates at that model location. Mixture 7, placed in unit 9 in this model, occurs in only one pin location in the model. Mixture 1, placed in all other fuel rod locations, will yield reaction rates close to the average of those for all fuel in the assembly. If the flux or reaction rate was needed in each unique fuel location, a unique mixture would be needed for each location.
- The use of chords for cutting cylinders allows inclusion of one-half and one-quarter fuel cells in the quarter-assembly model. Because the fuel assembly has an odd number of rods in each dimension, use of symmetry at the assembly midplanes requires the rods to be bisected.
- In this model, local grid spacing was selected such common grid spacings occur in all cells. However, this is not a requirement. For example, a much more refined local grid could have been specified for unit 9. There is no requirement that grid lines match between different elements of an array.
- Unstructured coarse-mesh finite-difference acceleration (cmfd=2 or cmfd=yes) was employed to accelerate the convergence of the solution. For this case, 14 outer iterations were required for full spatial convergence as compared with 30 outer iterations when CMFD is disabled. The CMFD-accelerated case ran 2.5 times faster than its unaccelerated counterpart. In this sample problem, xycmfd=2 was used to define the coarse-mesh grid to have two fine-mesh cells per coarse-mesh cell.
- Two-group homogenized cross sections were generated along with single-assembly (i.e., type 1) ADFs derived from the Collapse block, ADF block, and the Homogenization block. In addition, a B1 critical spectrum search is computed after the transport calculation, which is folded into the transport solution to generated homogenized constants.

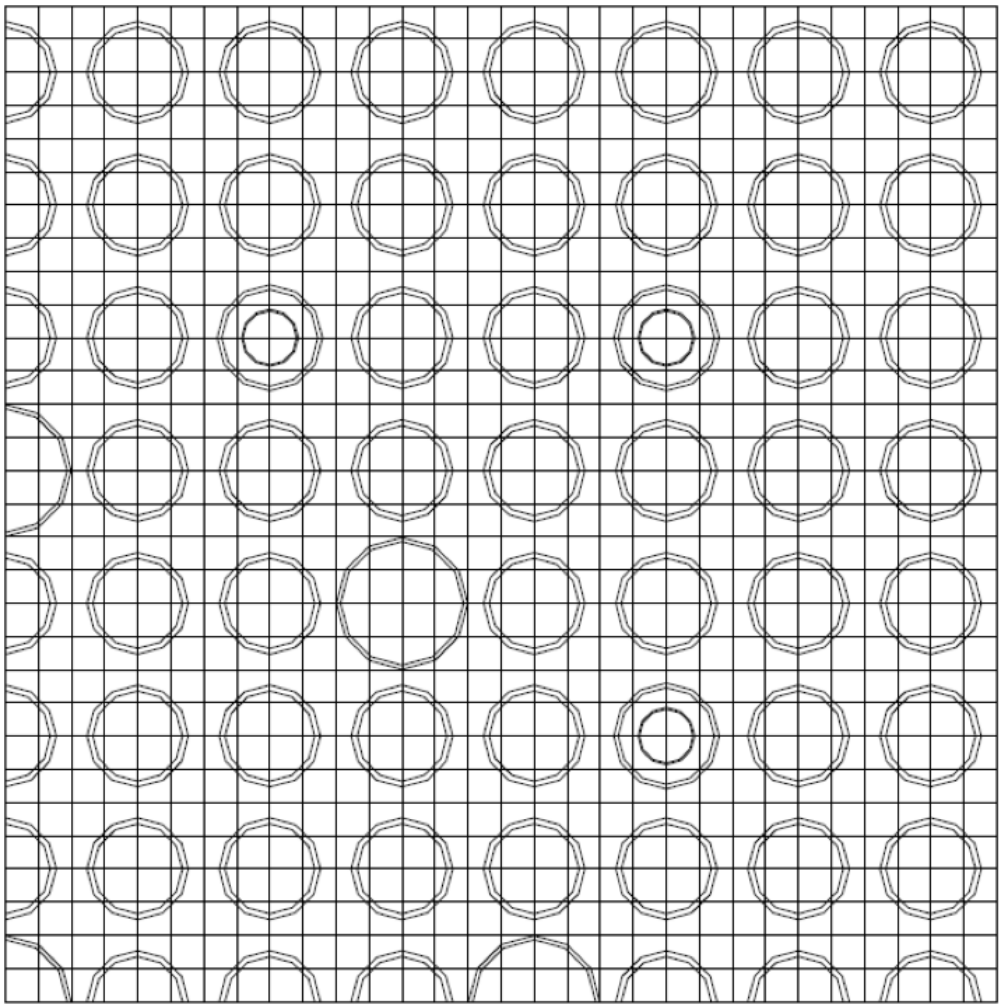

Fig. 9.2.51: Grid structure for one-quarter assembly of Sample 4.

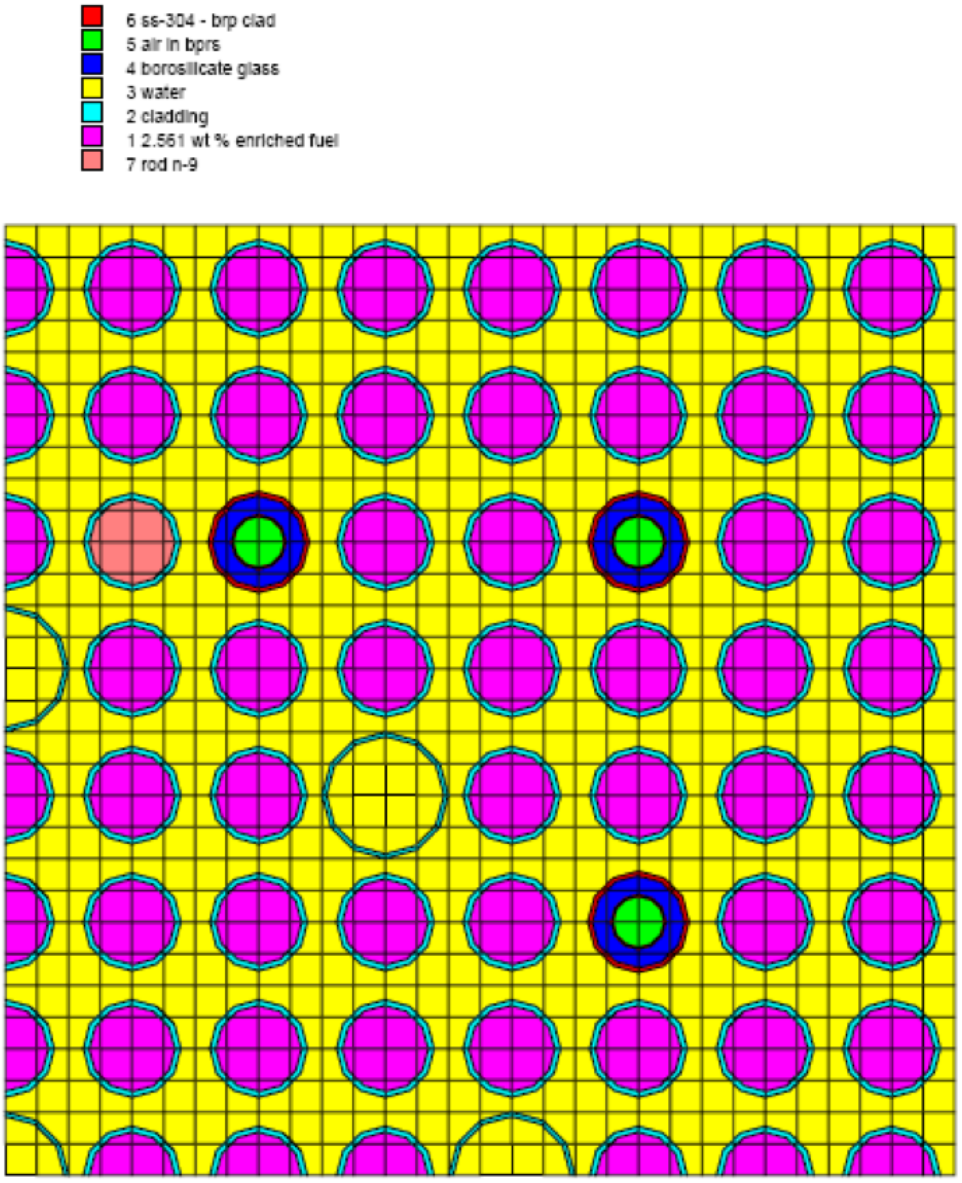

Fig. 9.2.52: Mixture placement for quarter-assembly model of Sample 4.

9.2.4.4 Sample 5

Sample 5 (Fig. 9.2.53) illustrates a calculation for a fuel assembly with a large water boundary and a vacuum boundary condition. The calculation begins with the use of SCALE standard composition specifications to prepare a problem-specific weighted cross section library and mixing table for use by NEWT.

In this model, seven UO_2 pins are adjacent to eight MOX pins, which, in turn, are adjacent to a large reflector region. The outer boundary of the reflector is vacuum. Reflection on the top and bottom boundaries makes the problem infinite in the y direction. The grid structure for this problem is illustrated in Fig. 9.2.54. This problem illustrates the use of the original CMFD acceleration scheme in NEWT (cmfd=1 or cmfd=rect). Because of the large degree of scattering within the reflector region, the problem can be relatively slow to converge. Without CMFD acceleration, 40 outer iterations are required for spatial convergence as compared

with 12 when CMFD is enabled. A total run-time speedup of ~1.4 is achieved with the CMFD acceleration scheme.

In addition to the application of CMFD, Sample 5 also illustrates the use of NEWT's reflector ADF capability. Reflector ADFs are computed along the fuel/reflector interface.

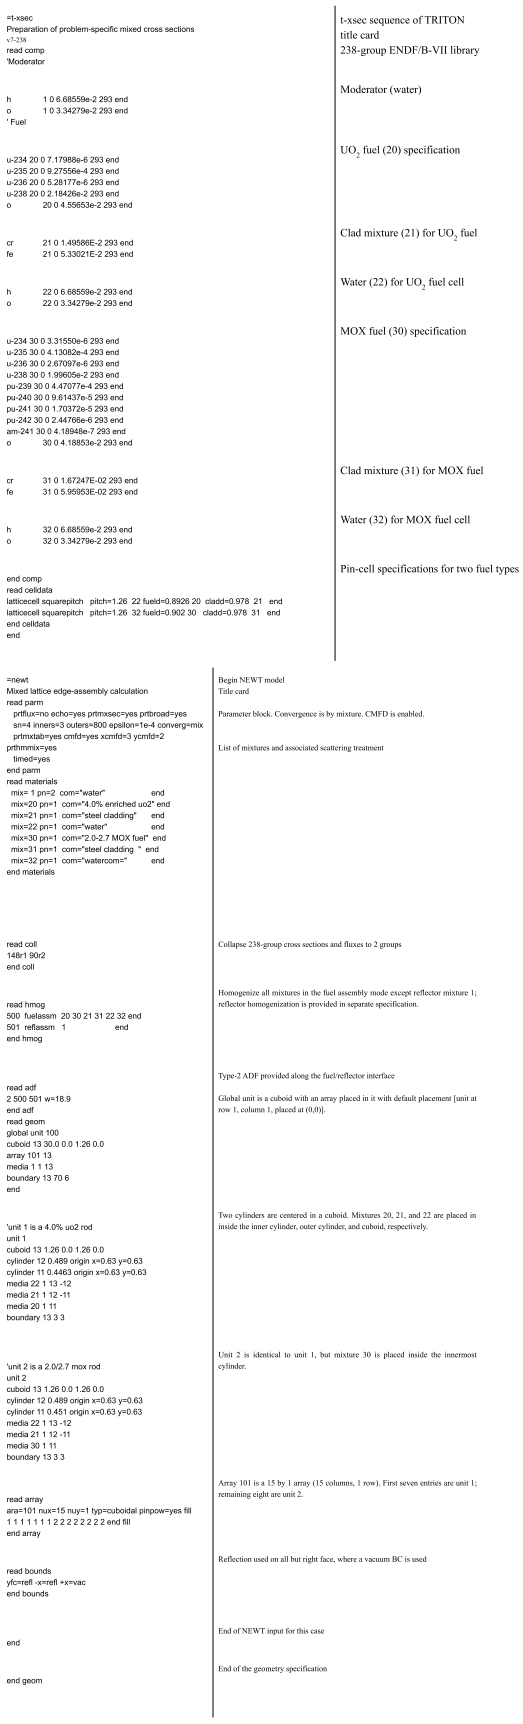

Fig. 9.2.53: Sample 5 input listing (annotated).

Fig. 9.2.54: Grid structure for 15-pin row of Sample 5.

9.2.5 DESCRIPTION OF OUTPUT

This section contains a brief description and explanation of NEWT output. Portions of the output will not be printed for every problem. Some output is optional, depending on user input specifications and is so noted in the description. As with any SCALE module, output begins with an input echo, module execution records with times and completion codes, and the program verification information banner page. These outputs are common to all SCALE modules and are not described here.

9.2.5.1 NEWT banner

Following the SCALE program verification information, the first section unique to NEWT output is the NEWT banner, which appears as shown in Fig. 9.2.55. The bottom of the banner gives the title of the case as given in input. The NEWT banner is printed only if the command line option -p is used to run SCALE.

9.2.5.2 Input summary

The next several pages of output provide a summary of input parameters. As described in Sect. 9.2.5, default parameters are used when no user specification is supplied. The input summary lists all parameters and states used in the calculation, whether user supplied or default. The following subsections describe the various blocks of output information provided in the input summary.

Control options

The Control Options block lists global control parameters that determine the type of analysis being performed. A sample Control Options page is shown in Fig. 9.2.56. Parameters are self-explanatory. More information is available in the description of the keywords in Sect. 9.2.5.2.

           Array no.   101 (   8,   8), type = cuboidal
```

Fig. 9.2.60: Pin-power edit request summary.

Geometry specifications

The Geometry Specifications block (Fig. 9.2.61) lists parameters associated with the geometric model specified by the user. The first section lists the characteristics of the global unit. This is followed by a listing of the four boundary conditions. Finally, the last section in this block lists all bodies specified for the model. The appearance and contents of this section of input depend on the nature of the input model.

Energy group structure listing

The Energy Group Structures block (Fig. 9.2.65) lists the energy and lethargy boundaries found in the cross section library. If a broad-group collapse was requested, the boundaries of the broad-group library that will be produced are also identified. This example shows the structure of the SCALE 44GROUPNDF5 library and 2-group fast/thermal collapse structure. The final entry (group 45, broad group 3) indicates the lower bound of the previous energy group.

Fig. 9.2.65: Energy Group Structure Listing page.

Quadrature parameters

The Quadrature Parameters block (Fig. 9.2.66) lists the first-quadrant angles and weights used for the specified order of quadrature. The same angles and weights are applied in the other three quadrants; however, the signs of the angles vary with the quadrant. Also listed are the P_n moments associated with the maximum P_n scattering order requested in all materials. Of course, only a subset of these moments applies to the lower-order P_n assignments.

Mixture volumes listing

The Mixture Volumes block (Fig. 9.2.67) provides a summary of the volume and volume fraction of each mixture in the problem, together with the total volume. This block can be used as a simple check of the input model by ensuring that the calculated volumes of mixtures used for a given problem match the expected volumes or volume fractions.

```

Mixing table listing

The Mixing Table block summarizes the input mixing table, whether user supplied or read from a SCALE-generated file. Number densities are in units of atoms per barn-centimeter. Although optional, the mixing table is printed by default. This default setting can be disabled by specifying *prtmxtab*=no in the Parameter block. A sample mixing table is shown in Fig. 9.2.68.

```

Fig. 9.2.68: Mixing Table Listing page.

Nuclide cross sections

The Nuclide Cross Section block is optional and is printed only when *prtxsec*=yes is specified in the Parameter Block. The volume of output generated is quite extensive, especially when a very fine group library is used and/or a large number of nuclides are included in the mixing table. The nuclide data are taken directly from the working library used for the calculation. A sample showing a partial listing for a single nuclide is shown in Fig. 9.2.69.

Following the block header, nuclide data are listed for all nuclides. For each record, the same format is used. Nuclide data begin with a listing of nuclide header information. This is followed by a listing of the 1-D cross sections that are important in NEWT calculations. The sample below shows a partial listing of the 1-D cross sections. Following the 1-D cross section listing is the scattering matrix for the nuclide. This abbreviated listing shows a portion of the P_0 matrix for this nuclide; however, in a full listing, all higher-order elements are printed as well.

As was indicated in the input description, specification of *prtxsec*=1d can be used to obtain header and 1D cross section data only, skipping the printing of scattering matrices.

Fig. 9.2.69: Partial listing of Nuclide Cross section data pages.

Mixture cross sections

The Mixture Cross Section block provides mixed macroscopic cross sections for each mixture provided in the input mixing table. The block is also optional and is printed only when *prtmxsec*=yes is specified in the Parameter Block. Although the volume of output generated is not as extensive as that of the nuclide listings, the mixture cross section print can be voluminous, especially when a very fine group library is used and/or a large number of mixtures are included in the mixing table. A sample showing a partial listing for a single mixture is shown in Fig. 9.2.70.

Following the block header, information is provided for each mixture using the same format. Mixture data begin with a listing of general mixture information, including the mixing table for that mixture. This is followed by a listing of 1-D cross sections important in NEWT calculations. The sample below shows a partial listing of the 1-D mixed macroscopic cross sections. Following the 1-D cross section listing is the scattering matrix for the nuclide for all moments requested for the mixture. This abbreviated listing shows a portion of the P_0 matrix for this nuclide; however, in a full listing, all higher-order elements are printed as well if greater than P_0 scattering was requested.

As was indicated in the input description, specification of *prtmxsec*=1d can be used to skip the printing of scattering matrices.

Fig. 9.2.70: Partial listing of Mixture Cross section data pages.

9.2.5.3 Iteration history

The next portion of NEWT output lists the iteration convergence history for the iterative solution (Fig. 9.2.71). This information can be used to track and understand the performance of the outer loop of the iterative solution. The first column provides the outer iteration count. The second column lists the system eigenvalue after each outer iteration. The third column lists the change in the eigenvalue from the last outer iteration; this is one of the parameters tested for convergence. The fourth column, "Max Flux Delta," gives the maximum change in cell flux for all cells and all energy groups; this is also used as a convergence test. The next column lists the cell number and energy group corresponding to the maximum flux change in this iteration. The next two columns list the same flux information for mixtures with fissionable nuclides. This can be used to track spatial convergence in fuel when convergence is slowed by significant scattering outside the fuel. Finally, the last column provides information on the convergence of inners in each outer iteration. Inner iterations do not need to converge within early outer iterations, but final convergence will not be achieved until all inners are converged. The maximum number of inner iterations per energy group is set by the *inners*= parameter in the

parameter input block. After convergence is achieved, the table is terminated by printing the final version of k_{eff}.

If the parameter keyword *timed=* is set to *yes*, four additional columns are introduced that give timing information on the solution process, listing real ("wall clock") time, elapsed CPU time since beginning the iteration process, elapsed CPU time per outer iteration, and an estimate of the fractional CPU usage during each outer. Fig. 9.2.72 illustrates the form of output produced when *timed=yes* is input. Additionally, a supplementary edit follows the iteration edit when *timed=yes*, giving information on average time per transport sweep (outer iteration) within different components of the solution. This edit is especially useful when coarse-mesh finite-difference acceleration is used, to assess the overhead of the CMFD accelerator.

```

Fig. 9.2.73: Four-factor formula with alternate three-group formulation.

9.2.5.5 Fine-group balance tables

Following the iteration history and flux convergence, a fine-group balance table is provided for each mixture used in the calculation. Fine group refers to the group structure of the library used for the calculation. Broad-group data, discussed later, refer to a group structure collapsed from the original fine-group structure. After tables for all mixtures are printed, a last table provides a fine-group summary for the entire problem (i.e., the volume-weighted average for all mixtures). Balance tables are printed by default but may be disabled by setting *prtbalnc=no* in the Parameter block.

Fig. 9.2.74 shows a clipped excerpt from the fine-group summary of an output listing. Similar tables are produced for each mixture in the problem for all energy groups in the problem. The header lists the NEWT mixture number; the mixture ID (i.e., the SCALE mixture number); and the mixture description, if provided in the original input specification. The header also gives the number of computational cells in which the mixture was present and the volume of the mixture in the problem.

For each mixture, two tables are printed. The first table provides a balance of all sources and loss terms: the fixed source, the fission source, in-scatter, out-scatter, absorption, leakage, n-2n production, and the net balance of all terms for each energy group. The final row lists the mixture total for all groups. The fixed source lists the user-supplied source for fixed-source problems. This field is disabled (set to zero) for eigenvalue calculations. The fission source is the number of neutrons born into each energy group in the mixture. In this example, the mixture is water, which is not fissile; hence, no fission source is present. In-scatter represents the number of neutrons scattered into each group from all other groups; conversely, out-scatter is the loss from each energy group by scattering. Absorption is the number of neutrons absorbed in reactions that do not emit a neutron (e.g., n-γ). Leakage is the net loss of neutrons from the mixture to another mixture or a nonreflective boundary, and n-2n is the effective n-2n production rate calculated from a weighted sum of all n-*x*n reactions. The balance table is the ratio of production to loss in each energy group.

The second fine-group balance table, also shown in Fig. 9.2.74, lists other reactions rates of interest. The first two columns after the group number list in-scatter broken into its upscatter and downscatter components. The subsequent two columns provide a similar breakdown for out-scatter from the energy group. Self-scatter is the amount of within-group scattering occurring within each energy group. The fission rate is the number of (n-fission) reactions occurring in each group. The next column provides the transverse leakage (i.e., the product of the flux and the DB^2 term). This column will provide only nonzero values when a nonzero buckling height is specified in input. The final column lists the total (scalar) flux for each energy group.

Fig. 9.2.74: Partial mixture fine-group balance table output.

9.2.5.6 Planar fluxes and currents

If planar fluxes are requested, an edit is printed to provide fluxes and currents on each line segment specified, identified by label (Fig. 9.2.75). Fine-group fluxes are listed for each energy group, followed by x and y net currents and partial currents (+x, -x, +y, and -y). Fluxes and currents are printed for each group in the input group structure. The example below shows only partial listings of each for simplicity. If a broad-group collapse is requested, the fine-group output is followed by the set of fluxes and currents for each broad energy group.

Note that discontinuity factors make internal use of planar fluxes to determine the flux and current on each boundary. Hence, planar flux edits will be present any time an ADF calculation is performed.

9.2.5.7 Pin-power edits

The next section of the NEWT output listing is the pin-power edit (Fig. 9.2.76). This information is printed only if *pinpow=yes* is set in one or more arrays. Two maps are provided. The first is the power of each fuel location relative to all other fuel pins in all other arrays for which *pinpow=yes*. This is useful if multiple fuel assemblies are present or if more than one array is used to describe a fuel assembly. The second power map shows the pin edit normalized to the set of pins within the single array. Both maps are identical in a relative sense; different normalization factors are applied. If *pinpow=yes* is specified for only one array, then the two edits will have the same normalization factor and will be identical. The location of each pin is identified by the (x,y) coordinate of the center of each element of the array, in centimeters. Please note that the pin-power option is available only for square (cuboidal) arrays.

Following the two maps is a one-line edit identifying the location and magnitude of the maximum pin power.

```

```

Fig. 9.2.76: Example of pin-power edit.

9.2.5.8 Broad-group collapse

Broad-group summary data

The next section of the NEWT output listing is the broad-group summary listing (Fig. 9.2.77). This is printed only if a broad-group collapse is performed. This section lists broad-group data calculated based on the collapsing scheme applied. First, the energy group structure is printed, followed by cell-averaged fluxes in each mixture, for all collapsed groups. This is followed by flux disadvantage factors for each mixture and each broad group.

Note that when NEWT is used as the transport solver within TRITON depletion calculations, a three-group collapse is always done automatically. If a second user-specified collapse is requested, broad-group summary data will be provided for both collapsing structures.

Fig. 9.2.77: Broad-group summary output.

Broad-group cross section data

The next section of data in a NEWT output listing is the broad-group cross section output (Fig. 9.2.78). This is printed only if a broad-group collapse is performed and if *prtbroad=yes* is specified in Parameter block input. This block lists the collapsed cross section data for key reactions for each nuclide used in the calculation. This is a summary form of the data that are written to the collapsed cross section library. It does not list all reactions. Such data may be read directly from the working-format library by other SCALE utilities if needed. The listing below shows the data printed for a single nuclide. Data are written in the same format for all nuclides used in the analysis.

9.2.5.9 Critical spectrum edit

When a critical buckling correction is requested (e.g., *solntype=b1* is set in the NEWT parameter block or user-defined material buckling or transverse height), the critical spectrum is computed using either the B1 approximation or the P1 approximation (Fig. 9.2.79). The output lists the buckling in $1/cm^2$, the method (B1 or P1), and the computed critical spectrum as a function of energy. Note that the spectrum is normalized "per unit lethargy" to be equal to 1.0. In addition to the critical spectrum, the critical adjoint spectrum and the zero-buckling spectra (forward and adjoint) are also edited.

```
Critical Spectra Calculated with the B1 Method
 Critical Buckling is  0.73987E-03
 Cross sections were weighted using the B1 critical flux.

9.2.5.10 Assembly discontinuity factors

When calculation of assembly discontinuity factors (ADFs) is requested, a broad-group edit is provided for each face for which an ADF was selected (Fig. 9.2.80). Up to four ADFs may be printed for the fuel region. If the model contains a reflector region in addition to the required fuel region, then ADFs are printed for a single face, typically the fuel/moderator interface. Discontinuity factors for user-input surfaces may also be edited.

```

```

Fig. 9.2.80: Output of assembly discontinuity factors.

9.2.5.11 Groupwise form factors

Whenever homogenization is performed and pin-power edits are requested, NEWT will automatically calculate groupwise form factors (GFFs). GFFs are used in pin-power reconstruction calculations for homogenized assemblies used in nodal diffusion methods (Fig. 9.2.81).

```

Homogenized cross sections

When homogenization is performed and parameter *prthmmix=yes* is set, the final output section of a NEWT calculation is the homogenized cross section edit, as shown in Fig. 9.2.82. This information is generally passed to nodal analysis codes and hence is presented in a slightly different format from other cross sections. Output includes a region-averaged k-infinity value, transport-corrected cross section, and two interpretations of absorption. The first is the directly collapsed absorption cross section, while the second (Total-Scatter) is a more consistent definition of absorption as applied in nodal calculations. The difference between the two definitions is the effective (n-2n) cross section. Both cross sections exclude contributions from ^{135}Xe and ^{149}Sm; microscopic cross sections and number densities for these two nuclides are printed explicitly elsewhere in the table. Nu*fission is the product of the fission cross section and the number of neutrons produced per fission, while Kappa*fission is the product of the fission cross section and the energy release per fission (J). Inverse velocity is the inverse (1/x) of the group neutron speed.

The table also lists the two-group isotropic scattering matrix and the prompt fission fraction distribution. Finally, NEWT lists approximate six-group decay constants (lambdas) and group fractions (betas) for each

group.

9.2.5.12 End-of-calculation banner

NEWT output listings are terminated with an end-of-calculation banner (shown in Fig. 9.2.83) upon successful completion of a calculation. If this banner is not present, then the calculation ended abnormally, and the output listing must be reviewed to determine the cause of the error. In general, the final lines of an output file describe the error condition that caused the calculation to stop.

```
*****************************************************************************************************************************
         NEWT execution completed with zero errors
*****************************************************************************************************************************
```

Fig. 9.2.83: End-of-calculation banner listing.

Postscript graphics files

Two user-selectable options within NEWT provide the ability to generate PostScript-based graphics files for visualization of both input specifications and output results. By specification of *drawit=yes* in the NEWT parameter block, NEWT will generate two PostScript-based plot files: `newtgrid.ps` and `newtmatl.ps`. The former, a grayscale plot of the line segments generated by NEWT based on the input specification, will be generated if all body placement input is valid. If input contains errors such that the code stops before grid generation routines are completed, no `newtgrid.ps` output is created.

The `newtmatl.ps` plot illustrates the same grid structure but with material placement indicated by color. At this time, no user control is provided for color assignment or plot control. This plot also requires complete grid generation; additionally, it requires completion of all media placement routines before the plot will be produced.

Figures used throughout this manual were generated from newtgrid and newtmatl PostScript plot files. Files `newtgrid.ps` and `newtmatl.ps` are automatically copied back from SCALE's temporary directory to the original location of the input case, with the names *casename*.newtgrid.ps and *casename*.newtmatl.ps.

When *prtflux=yes* is input, NEWT will generate a set of flux plots showing relative neutron number densities in each energy group. A plot file will be generated with the name fluxplot_*N*g.ps, where *N* is the number of energy groups in the problem. If an energy collapse is performed, an additional file named fluxplot_*M*g.ps is created, where M is the number of energy groups in the collapsed set. Fig. 9.2.84 is an example of a flux plot output for the fast group of a two-group flux collapse.

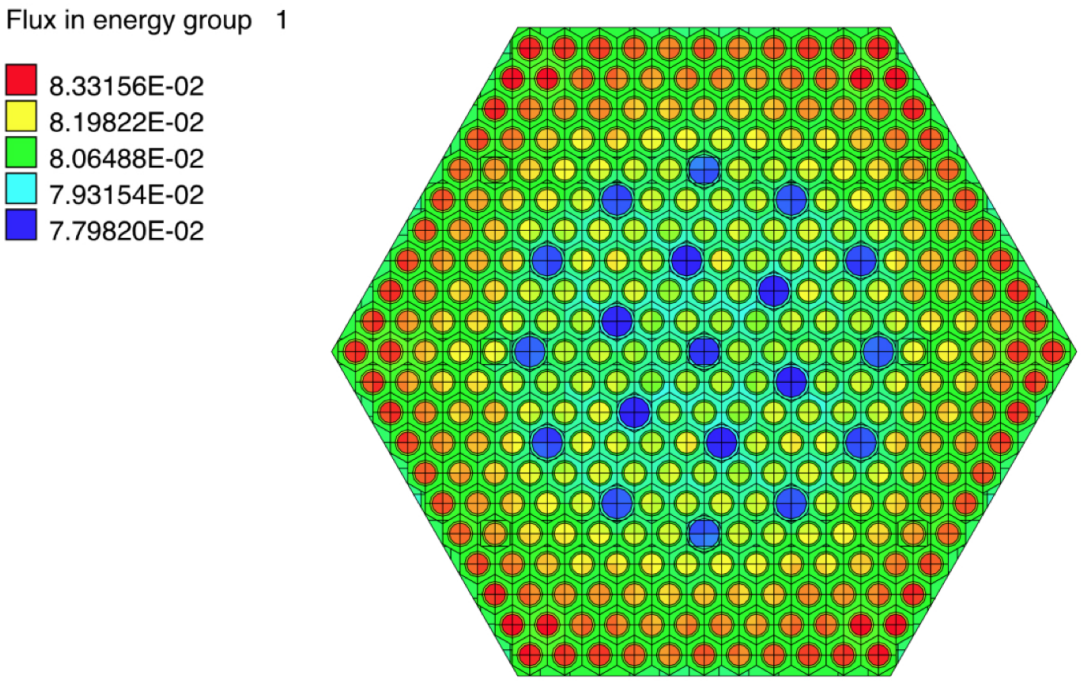

Fig. 9.2.84: Example of a flux plot image created with prtflux=yes.

9.2.5.13 Media zone edits

NEWT automatically determines "zones" representing spatially independent regions of the same media. For example, in a fuel pin cell, the fuel, clad, and moderator are all considered separate zones. In an array of such pin cells, each unique location is a unique zone. Zone numbers and the geometric location of each zone are listed in the *Geometry Specification*" in Sect. 9.2.5.2.6.

Upon completion of a calculation, NEWT provides an output edit of each zone by number, giving the mixture number, average flux, fission power, and volume, as shown in Fig. 9.2.85.

Zone data

Zone No.	Mix No.	Relative Flux	Relative Fission Power	Zone Volume
1	31	3.33874E-01	0.00000E+00	2.19695E-01

10. SCALE NUCLEAR DATA LIBRARIES

Introduction by A. Holcomb, D. Wiarda and M. L. Williams

Chapter 10 describes the SCALE cross section data libraries for use with deterministic and Monte Carlo radiation transport modules. All cross section libraries were processed from ENDF/B-VII.1 or -VIII.0 evaluated data files using the AMPX code system [SCALE-DATA-WWCD15]. SCALE includes continuous-energy libraries, as well as multigroup libraries with several group structures. Libraries are available for neutron, gamma, and coupled neutron-gamma transport calculations. The fine and broad multigroup libraries provided for reactor physics and criticality safety applications in SCALE 6.3 include intermediate resonance parameters (lambdas) and improved Bondarenko data for self-shielding calculations using the Bondarenko method, or the traditional CENTRM-based procedures in SCALE can be used for self-shielding. Section 10.1 in this chapter describes the available cross section libraries.

Fine and broad group covariance libraries containing cross section uncertainties and correlations are also distributed with SCALE for sensitivity/uncertainty analysis with the Sampler and TSUNAMI modules. The covariance libraries include a comprehensive collection of data for all nuclides included in the SCALE cross section libraries. New 252-group and 56-group covariances based on ENDF/B-VII.1 and other data sources are available, along with the older 44-group covariance library distributed with earlier releases of SCALE. The Covariance Libraries chapter describes the contents of the SCALE 6.3 covariance libraries and explains how they were processed.

Additional libraries used for transmutation calculations with ORIGEN are described in the ORIGEN Data Resources section of the ORIGEN chapter. These libraries include fission product yields, decay data, decay gamma spectra, etc., as well as supplemental cross section data not available in ENDF/B.

10.1 SCALE CROSS SECTION LIBRARIES

A. Holcomb, D. Wiarda, C. Celik, K. S. Kim, M. L. Williams, M. E. Dunn, B. T. Rearden

ABSTRACT

The cross section data libraries available in the SCALE code system are briefly described in this section. All libraries were processed from ENDF/B-VII.1 and -VIII.0 evaluated data files using the AMPX code system. Continuous-energy libraries as well as several multigroup libraries for a variety of applications are included in SCALE. Several fine-group and broad-group structures are available so that a user may select the nuclear data library based on considerations of application, accuracy, and execution time.

ACKNOWLEDGMENTS

We would like to acknowledge all those who participated in developing and implementing the SCALE cross section libraries for their assistance in preparing previous versions of this document. Special thanks go to S. Goluoglu, N. M. Greene, and L. M. Petrie for their contributions to SCALE data processing efforts, and to C. R. Daily and W. J. Marshall for their extensive validation testing of the libraries described here.

10.1.1 INTRODUCTION

SCALE includes both multigroup (MG) and pointwise continuous energy (CE) nuclear data libraries, which were processed using the AMPX code system [XSLibWWCD15]. Libraries are available for neutron and for coupled neutron-photon transport calculations. The CE libraries are used for Monte Carlo calculations with CE-KENO (criticality) and CE-Monaco (shielding), and are also used by the pointwise (PW) discrete ordinates code CENTRM to obtain PW flux spectra for computing self-shielded MG cross sections. The MG libraries are used in the MG-KENO and MG-Monaco Monte Carlo codes, and in the deterministic transport codes XSDRNPM, NEWT, and DENOVO. All cross section libraries in SCALE 6.3 and later versions are based strictly on ENDF/B-VII.1 [XSLibCHO+11] and ENDF/B-VIII.0 [XSLibDAB18], while earlier SCALE releases included libraries processed from ENDF/B-VI.8, V, and IV. The ENDF/B-VII.1 CE and MG libraries include the 423 nuclides shown in Table 10.1.1, and the ENDF/B-VIII.0 CE and MG libraries contain data for 556 nuclides (Note that while ENDF/B-VIII.0 contains data for neutron-as-a-target, this data is not useful for SCALE calculations and is thus the processed data is not released with SCALE.). ENDF does not have evaluated data for several isotopes in the SCALE Standard Composition Data; therefore the libraries do not include cross sections for these nuclides, which are listed in Table 10.1.2. If one of these isotopes is explicitly requested or if the natural element containing the isotope is requested in the SCALE input, a warning message is written saying that the nuclide is being omitted from the calculations. The most commonly encountered example of this is O-18 which has an abundance of approximately 0.2% in elemental oxygen (Note that O-18 data are available in ENDF/B-VIII.0, but not ENDF/B-VII.1.).

The ENDF/B-VII.1 libraries include 21 thermal-scattering moderators for which bound-scattering kernels [e.g., S(α,β)] are provided as given in Table 10.1.3. This table also lists the temperatures available in MG and CE libraries for the materials with bound kernels. The ENDF/B-VIII.0 libraries include 34 thermal-scattering moderators for which bound-scattering kernels are provided; of particular interest are updated thermal scatter laws for HinH2O and multiple graphite compositions. The thermal scattering kernels for all other materials are based on the free-gas kernel. On the MG libraries, these nuclides have 2D scattering matrices processed from the free-gas kernel evaluated at the temperatures of 293 K, 565 K, 600 K, 900 K, 1200 K, 2000 K, and 2400 K. SCALE 6.3 includes routines that automatically interpolate the CE cross section data, as well as thermal scattering kernels to any arbitrary temperature for Monte Carlo calculations [XSLibHCML16]. Analogous procedures are available for MG data. The CE libraries do not include free gas kernel data because the transport codes internally evaluate the free gas scattering information at the specified temperature.

For each reaction and nuclide, CE data were processed from ENDF/B in the manner described in Sect. 10.1.2.5. The CE data were further processed into several generic MG libraries focused on different applications. CE data are stored as individual files for each nuclide, and an associated cross section directory file contains the names of the individual files. Furthermore, the MG libraries each contain data for all nuclides. AMPX master libraries are very general and contain essentially all reaction data available in ENDF/B, as well as several specialized cross sections used in SCALE. The master libraries also include Bondarenko shielding factors tabulated as a function of background cross section and temperature for all nuclides and groups, and the master libraries may contain intermediate resonance parameters for self-shielding. A much improved methodology in AMPX was used to process more accurate shielding factors for the most important resonance absorbers.[1]

The CE and MG libraries available in SCALE 6.3 are given in Table 10.1.4, which also lists the main source of data for each library. The desired MG or CE library for a computation is typically selected by specifying the appropriate mnemonic name from Table 10.1.4. The CE library mnemonic corresponds to the actual name of the cross section directory file, and the MG mnemonic is an alias for the file containing the actual master library, shown in the third column of Table 10.1.4. SCALE control modules recognize the mnemonics in the first column, or the standard MG library name in the third columns of the table. Users also may supply

their own MG library by specifying the file name as the library name in the control module input (only lower case alphanumeric characters are allowed in the filename, and the filename must be eight characters or less in length). The library must be an AMPX master library and must be located in the SCALE data directory or the temporary working directory where the problem is run.

The CE data libraries do not require additional processing prior to their use in transport computations. However the MG libraries distributed with the SCALE code system contain problem-*independent* cross sections processed with generic weighting functions appropriate for a specified type of application (e.g., criticality safety, shielding, etc.). These data must be further processed into problem-*dependent* libraries by performing resonance self-shielding and other modifications. This is done by the XSProc module during the execution of a SCALE control sequence prior to executing a transport solver.

Table 10.1.1: Nuclides in CE and MG ENDF/B-VII.0 and -VII.1 libraries.

[a] Yield data are only available in coupled MG libraries and in the CE libraries.

[b] Narrow and/or intermediate resonance factors are only available on MG libraries.

[c] Incident gamma cross sections are only available on coupled MG libraries. A separate incident gamma CE library is available

Table 10.1.2: Isotopes with no ENDF/B-VII.0 or -VII.1 nuclear data.

Element	SCALE standard composition ID	Missing Isotopes	ZA numbers	% Abundance
oxygen	8000	18	8018	0.20
neon	10000	21, 22	10021, 10022	0.27, 9.25
ytterbium	70000	All(1)	(1)	
osmium	76000	All(2)	(2)	
platinum	78000	All(3)	(3)	
tantalum	73000	180m	1073180	0.01

(1) no data for any of the 7 naturally-occurring ytterbium isotopes

(2) no data for any of the 7 naturally-occurring osmium isotopes

(3) no data for any of the 6 naturally-occurring platinum isotopes

10.1.2 DESCRIPTION OF THE SCALE CROSS SECTION LIBRARIES

10.1.2.1 The 238-group and 252-group ENDF/B-VII libraries (V7-238, v7-252)

SCALE includes a fine group structure for criticality safety and reactor physics applications: a 252-group library structure based on either ENDF/B-VII.1 or ENDF/B-VIII.0 is available for either criticality safety or reactor physics. Table 10.1.8, shows the group structure for the 252 fine-group libraries. The 252-group structure was developed to adequately capture spectral and temperature effects important for reactor systems and was processed with newer, improved procedures.

The SCALE control sequences for criticality safety and reactor physics applications normally perform self-shielding of the fine-group libraries using the BONAMI module for the unresolved resonance range; and the CENTRM/PMC modules for the resolved resonance/thermal range. However the 252-group libraries include Bondarenko self-shielding factors for the entire energy range, which provides the option of using the Bondarenko method to self-shield both the resolved and unresolved resonance ranges, as an alternative to the more rigorous (and computationally intensive) CENTRM/PMC approach. As discussed in the following section, one objective of the ENDF/B-VII.1 and ENDF/B-VIII.0 252-group and 56-group libraries was to provide a more accurate Bondarenko treatment for the resolved resonance range.

Differences in the 238-group and 252-group libraries

The standard weighting function described in Table 10.1.6 is typically used to create MG data for all materials in a library, and Bondarenko shielding factors can be computed using the narrow resonance (NR) approximation for the flux spectrum: $\sigma_t + \sigma_0$)*C(E) where σ_0 is the background cross section, and C(E) is the standard weight function. Bondarenko factors are tabulated at temperatures of at 293 K, 565 K, 600 K, 900 K, 1200 K, 2000 K, and 2400 K in the 252-group library.

Table 10.1.6: Standard weighting function for processing MG data.

Energy Range	Standard Weight Function
10^{-5} eV - 0.1 eV	Maxwellian, with peak at 0.025 eV
0.1 eV - 80 keV	1/E
80 keV - 10 MeV	Watt Fission spectrum at temperature of 1.273 MeV
10 MeV -20 MeV	1/E

Several enhancements were made in the MG processing procedures used to produce the 252-group library so that it would be more applicable to reactor physics as well as criticality safety applications. Some of the improvements in the 252-group library compared to the SCALE-6.2 238-group library are given below

(a) The base weighting function for processing MG data of actinide materials (Z>89) was computed by the PW transport code CENTRM for a PWR lattice at 300 K. This approach provides more representative weighted 2D scattering matrices for most cases of interest. The standard weighting function is still used for materials with Z<90.

(b) The thermal energy range which includes up-scattering reactions was extended to 5 eV, compared to 3 eV in the SCALE 6.2 238-group library

(c) Temperature-dependent thermal-scattering matrices for water-bound H, O-16, and actinide materials were processed with temperature-dependent thermal flux spectra obtained from CENTRM calculations for a PWR pincell. Actinide and O-16 MG thermal scattering kernels were weighted with the fuel zone flux at temperatures of 293 K, 600 K, 900 K, 1200 K, and 2400 K, and the water scatter kernels were weighted with the moderator flux at 293 K, 500 K, 600 K, 650 K, 900 K, and 1200 K. In the SCALE 6.2 238-group library,

thermal scattering matrices at all temperatures were weighted with a temperature-independent Maxwellian spectrum.

(d) Group-dependent IR parameters ("lambdas") were calculated for all materials and are included in the 252-group libraries. This allows the Bondarenko self-shielding method in SCALE to use the IR approximation for the 252-group libraries, while the SCALE 6.2 238-group library was limited to the NR approximation.

(e) A number of improvements were made in processing of Bondarenko self-shielding data.

- The number of temperatures for the Bondarenko factors was increased. Shielding factors are tabulated at temperatures 292 K, 600 K, 900 K, 1200 K, and 2400 K for the 252-group libraries.
- In addition to the Bondarenko factors normally included for capture, fission, elastic, and total cross sections, self-shielding factors are also included for the multigroup elastic within-group cross section to address the impact of resonance reactions on the scattering distribution.
- In the unresolved resonance range, self-shielding factors were calculated using probability tables.
- Bondarenko factors for nuclides with atomic masses Z>39 were calculated with CENTRM PW flux spectra rather than the analytical NR approximation. Two types of CENTRM models were used. Heterogeneous models of water-moderated lattices spanning the range of expected self-shielding were used to calculate shielding factors for ^{235}U, ^{238}U, ^{239}Pu, ^{240}Pu, ^{241}Pu, ^{90}Zr, and ^{96}Zr. The CENTRM transport calculations were performed using the method of characteristics method for 2D unit cell models. Homogeneous models were used to compute shielding factors for the remaining nuclides with Z>39. These CENTRM calculations were performed for homogeneous media containing the absorber material mixed with hydrogen, and the hydrogen concentration was varied to obtain the desired set of background cross sections. Table 10.1.7 summarizes the processing options for the 252-group library.

Table 10.1.7: Standard weighting functions for processing 252-group library data library.

Nuclide	**Base Weight Function**	**Bondarenko Factor**
U-238, -235; Pu-239, -240, -241	PWR spectrum	CENTRM heterogeneous calculations
Other actinides Z>90	PWR spectrum	CENTRM homogeneous calculations
39<Z<90	standard	CENTRM homogeneous calculations
Z<40	standard	NR analytical spectrum

10.1.2.2 The 56-group library

An ENDF/B-VII.1 and an ENDF/B-VIII.0 broad group library with 56 energy groups are available mainly for light water reactor physics calculations. The group structure is shown in Table 10.1.9. This library was processed using the same PW flux spectra used to generate the 252-group libraries (i.e., for a PWR fuel lattice). This library includes the same materials and properties as the 252-group library, and the data were computed in the same manner, except for several specially weighted nuclides which have heterogeneous Bondarenko shielding factors (in addition to those given in Table 10.1.4) computed for specific LWR components. These are summarized in Table 10.1.10.

Table 10.1.9: 56-Group energy structure (5 eV thermal boundary).

10.1.2.3 The test-8grp library for code testing

The library named test-8grp is used for code testing and verification of reproducibility. It was collapsed from the fine-group v7-252 library, using the standard weight functions in Table 10.1.6. This library has all the nuclides and same types of nuclear data as in the v7-252 library; but the eight energy-group structure provides capability to test codes and input in shorter times than with the standard production libraries. Table 10.1.11 gives the eight group structure, which has four thermal groups below 3 eV, and four fast groups.

The library can also be used with the CENTRM/PMC resonance shielding methodology.

Important: THIS LIBRARY SHOULD NOT BE USED FOR REAL APPLICATIONS.

10.1.2.4 The 200N-47G (V7-200N47G) library for shielding

A coupled fine-group neutron-gamma library based on ENDF/B-VII.1 is available for radiation transport calculations with SCALE shielding modules. The 200 neutron and 47 gamma energy group structures are provided in Table 10.1.12 and Table 10.1.13, respectively. The neutron group structure is identical to the 199-group VITAMIN-B6 [XSLibWDP+09] structure except that an additional group has been added to extend the top energy boundary to 20 MeV. The MG neutron data were generated using the standard weighting function described in Table 10.1.6, and the MG photon data were weighted with a flat spectrum with roll-offs. Full-range Bondarenko factors are provided for all nuclides, and the default self-shielding method for this library is to use BONAMI for all energy groups, enabling faster neutron resonance self-shielding calculations. The Bondarenko shielding factors for all nuclides are computed with the NR approximation. If the Bondarenko approach is not appropriate, self-shielding calculations can be done with the CENTRM module. The 200n-47g libraries have dose factor and response function data shown in Table 10.1.14 which are consistent with previous SCALE shielding libraries.

The fine-group coupled libraries were validated by performing radiation transport calculations with the SCALE shielding sequence MAVRIC for several shielding benchmark calculations [XSLibWDP+09]. The calculated results for transmission/attenuation values and spectral results matched experimental measurements well. Overall, the results obtained with using the 200n-47g coupled library demonstrate the effectiveness of the SCALE methods and data for shielding applications.

10.1.2.5 The 28N-19G shielding libraries (V7.1-28N19G)

In addition to the fine-group shielding library, SCALE has a broad-group ENDF/B-VII.1 library. The ENDF/B-VII.1 library has 28 neutron and 19 gamma groups. The change in the neutron group structure (as compared with the SCALE 6.2 27 group structure) was necessary to allow for thermal up-scatter up to 5 eV; the gamma groups are identical in both libraries. The broad-group library was primarily developed to perform adjoint discrete ordinates calculations needed to prepare importance maps and biased source distributions for biasing forward Monte Carlo shielding calculations with the fine-group libraries in the MAVRIC shielding analysis sequence. The constituents of the 278n-19g library and the processing methods are the same as the 200n-47g library. The 28 neutron and 19 gamma group structures are provided in Table 10.1.15 and Table 10.1.16, respectively. The broad-group library has the same dose factor information described in Table 10.1.14 for the fine group library.

Table 10.1.15: Energy boundaries for the 28 neutron group structure.

10.1.2.6 The continuous-energy libraries

The ENDF/B-VII.1 and ENDF/B-VIII.0 CE libraries are general-purpose libraries used for both criticality calculations and shielding calculations, although the former do not use the photon data in the libraries. These libraries have CE data for the same nuclides as the MG libraries. CE data for each nuclide are stored in individual files contained in the SCALE data directory. The CE libraries were generated using AMPX to an energy-mesh tolerance of 0.1%; i.e., the data value at any intermediate energy point can be interpolated linearly within an error of 0.1%. Cross section data and kinematic data are provided for all reactions given in the ENDF evaluations and are identical to the reactions available on the MG libraries. Kinematic data are given for a range of incident energies as marginal probability distributions over the exit angles and conditional probability distributions over the exit energies in the laboratory system. Usually, 32 equiprobable exit angle bins are used for the conditional probability distribution, except if the distribution is isotropic or can be described with fewer exit angles. For elastic and discrete inelastic reaction, a larger number of exit angles are used as needed to accurately describe the kinematic in the laboratory system. Gamma production kinematic data are provided if available for nuclides that provide gamma production kinematic data. If gamma production data are present, sections for each discrete photon and the continuum are given along with the yield for each of the section. The incident neutron CE libraries are generated at temperature 293 K, 565 K, 600 K, 900 K, 1200 K, 200 K, and 2400 K. The kinematic data are not temperature dependent except for thermal moderators, which are included at the temperatures provided by the evaluator (see Table 10.1.3 for a list of thermal moderator nuclides and the list of available temperatures). Probability tables for the unresolved resonance range are provided, if the evaluations included unresolved resonance data [XSLibDL04]. Probability tables are available at 293 K, 565 K, 600 K, 900 K, 1200 K, and 2400 K. For neutron transport calculations, the CE cross sections and thermal kernels are automatically interpolated to the specified temperature using the methods described in [XSLibWDP+09].

For use in CE_MONACO, CE libraries for incident gammas are also available, based on ENDF/B-VII.1 ENDF/B-VIII.0 data, respectively. Only temperature independent cross section and kinematic data are available in the incident gamma libraries.

10.1.2.7 Gleaning Data from the Multigroup Libraries

As mentioned in Section 11.1, "AMPX LIBRARY UTILITY MODULES," the AMPX module rade can be used to print useful information, such as the available neutron targets, neutron energy group structure, and gamma energy group structure (when present). Please see the AMPX manual :cite: *XSL-wiarda_ampx-2000_2015* for more detailed instructions explaining the input for the relevant AMPX modules.

10.1.3 APPENDICES

10.1.3.1 MT Reaction Types on SCALE Cross-Section Libraries

ENDF reaction types (MT) are identified by an integer number from 1 through 999. Table 10.1.17 includes a copy of information taken from Ref. 8. Within SCALE, MT numbers are used to identify reactions on various input and output arrays.

MT numbers greater than 999 are additional SCALE-specific identifiers that may appear in SCALE cross-section libraries. These reaction types are not ENDF reaction types but may be added by various preprocessing codes in the SCALE and/or AMPX systems.

These reactions are listed in Table 10.1.18.

The dose conversion factors and their corresponding MT numbers in the SCALE shielding cross-section libraries can be found in Table 10.1.14.

Table 10.1.17: ENDF MT Reaction Types.

MT	Reaction	Description
1	(n,total)	Neutron total cross sections. Sum of MT=2, 4, 5, 11, 16-18, 22-26, 28-37, 41-42, 44-45, 102-117.
2	(z,z_0)	Elastic scattering cross section for incident particles.
3	(z,nonelastic)	Nonelastic neutron cross section. Sum of MT=4, 5, 11, 16-18, 22-26, 28-37, 41-42, 44-45, 102-117.
4	(z,n)	Production of one neutron in the exit channel. Sum of the MT=50-91.
5	(z,anything)	Sum of all reactions not given explicitly in another MT number. This is a partial reaction to be added to obtain MT=1.
6-9		Not allowed in version 6.
10	(z,continuum)	Total continuum reaction; includes all continuum reactions and excludes all discrete reactions.
11	(z,2nd)	Production of two neutrons and a deuteron, plus a residual.
12-15		(Unassigned)
16	(z,2n)	Production of two neutrons and a residual [XS1]. Sum of MT=875-891, if they are present.
17	(z,3n)	
18	(z,fission)	
19	(n,f)	
20	(n,nf)	Second-chance fission [XS2].
21	(n,2nf)	Third-chance fission[XS2].
22	(z,nα)	Production of a neutron and an alpha particle, plus a residual.
23	(n,n3α	Production of a neutron and three alpha particles, plus a residual.
24	(z,2nα)	Production of two neutrons and an alpha particle, plus a residual.
25	(z,3nα)	Production of three neutrons and an alpha particle, plus a residual.
26		Not allowed in version 6.
27	(n,abs)	Absorption; sum of MT=18 and MT=102 through MT=117.
28	(z,np)	Production of a neutron and a proton, plus a residual.
29	(z,n2α)	Production of a neutron and two alpha particles, plus a residual.
30	(z,2n2α)	Production of two neutrons and two alpha particles, plus a residual.
31		Not allowed for version 6.
32	(z,nd)	Production of a neutron and a deuteron, plus a residual.
33	(z,nt)	Production of a neutron and a triton, plus a residual.
34	(z,n^{3}He)	Production of a neutron and a ^{3}He particle, plus a residual.
35	(z,nd2α)	Production of a neutron, a deuteron, and 2 alpha particles, plus a residual.
36	(z,nt2α)	Production of a neutron, a triton, and 2 alpha particles, plus a residual.
37	(z,4n)	Production of 4 neutrons, plus a residual.
38	(n,3nf)	Fourth-chance fission cross section[2].
39		Not allowed for version 6.
40		Not allowed for version 6.
41	(z,2np)	Production of 2 neutrons and a proton, plus a residual.
42	(z,3np)	Production of 3 neutrons and a proton, plus a residual.
43		(Unassigned)
44	(z,n2p)	Production of a neutron and 2 protons, plus a residual.

Table 10.1.17 – continued from previous page

45	(z,npα)	Production of a neutron, a proton, and an alpha particle, plus a residual.
46-49		Not allowed in Version 6.
50	(y,n_0)	Production of a neutron, leaving the residual nucleus in the ground state.
51	(z,n_1)	Production of a neutron, with residual in the 1st excited state.
52	(z,n_2)	Production of a neutron, with residual in the 2nd excited state.
	...	
	...	
90	(z,n_{40})	Production of a neutron, with residual in the 40th excited state.
91	(z,n_c)	Production of a neutron in the continuum not included in the above discrete representation.
92-100		(Unassigned)
101	(n,disap)	Neutron disappearance; equal to sum of MT=102-117.
102	(z,:math:*gamma*)	Radiative capture.
103	(z,p)	Production of a proton, plus a residual. Sum of MT=600-649, if they are present.
104	(z,d)	Production of a deuteron, plus a residual. Sum of MT=650-699, if they are present.
105	(z,t)	Production of a triton, plus a residual. Sum of MT=700-749, if they are present.
106	(z,^{3}He)	Production of a ^{3}He particle plus a residual. Sum of MT=750-799, if they are present.
107	(z,α)	Production of an alpha particle, plus a residual. Sum of MT=800-849, if they are present.
108	(z,2α)	Production of 2 alpha particles, plus a residual.
109	(z,3α)	Production of 3 alpha particles, plus a residual.
110		(Unassigned)
111	(z,2p)	Production of 2 protons, plus a residual.
112	(z,pα)	Production a proton and an alpha particle, plus a residual.
113	(z,t2α)	Production of a triton and 2 alpha particles, plus a residual.
114	(z,d2α)	Production of a deuteron and 2 alpha particles, plus a residual.
115	(z,pd)	Production of proton and a deuteron, plus a residual.
116	(z,pt)	Production of proton and a triton, plus a residual.
117	(z,dα)	Production of deuteron and an alpha particle, plus a residual.
118-119		(Unassigned)
120		Not allowed for version 6.
121-150		(Unassigned)
151	(n,RES)	Resonance parameters that can be used to calculate cross sections at different temperatures in the resolved and unresolved energy regions.
152-200		(Unassigned)
201	(z,Xn)	Total neutron production.
202	(z,X γ)	Total gamma production.
203	(z,Xp)	Total proton production.

continues on next page

Table 10.1.17 – continued from previous page

204	(z,Xd)	Total deuteron production.
205	(z,Xt)	Total triton production.
206	(z,X ^{3}He)	Total ^{3}He production.
207	(z,Xα)	Total alpha particle production.
208	(z,X π^+)	Total π^+ production.
209	(z,X π^0)	Total pi^0 production.
210	(z,X π^-)	Total π^- production.
211	(z,X :math:mu^+`)	Total μ^+ production.
212	(z,X μ^-)	Total μ^- production.
213	(z,Xκ^+)	Total κ^+ production.
214	(z,Xκ^0_{long})	Total κ^0_{long} production.
215	(z,Xκ^0_{short})	Total κ^0_{short} production.
216	(z,Xκ^-)	Total κ^- production.
217	(z,Xp)	Total anti-proton production.
218	(z,Xn)	Total anti-neutron production.
219-250		(Unassigned)
251	(n,...)	$\bar{\mu}_L$, average cosine of the scattering angle (laboratory system) for elastic scattering of neutrons.
252	(n,...)	ξ, average logarithmic energy decrement for elastic scattering of neutrons.
253	(n,...)	γ, average of the square of the logarithmic energy decrement divided by twice the average logarithmic energy decrement, for elastic scattering of neutrons.
254-300		(Unassigned)
301-450	(z,...)	Energy release parameters,$E * \sigma$, for total and partial cross sections; MT= 300 plus the reaction MT number, *e.g.*, MT=302 is the elastic scattering kerma.
451	(z,...)	Heading or title information; given in File 1 only.
452	(z,...)	$\bar{V}_T$, average total (prompt plus delayed) number of neutrons released per fission event.
453		(Unassigned)
454	(z,...)	Independent fission product yield data.
455	(z,...)	$\bar{V}d$, average number of delayed neutrons released per fission event.
456	(z,...)	$\bar{V}p$, average number of prompt neutrons released per fission event.
457	(z,...)	Radioactive decay data.
458	(n,...)	Energy release in fission for incident neutrons.
459	(z,...)	Cumulative fission product yield data.
460-464		(Unassigned)
465-466		Not allowed in version 6.
467-499		(Unassigned)

1115	Flux moment (P_5) weighted total cross section
1116	Flux moment (P_6) weighted total cross section
1117	Flux moment (P_7) weighted total cross section
1118	Flux moment (P_8) weighted total cross section
1119	Flux moment (P_9) weighted total cross section
1452	Product of $\bar{V}T$ times the fission cross section
1456	Product of $\bar{V}_p$ times the fission cross section
1455	Product of $\bar{v}_d$ times the fission cross section
1500-1501	Same as 1000, 1001 except for gamma-ray cross sections
1527	Gamma-ray energy absorption coefficient factors
2006	Non-absorption collision probability (CE libraries only)
2016	Probability of emitting two neutrons (CE libraries only)
2017	Probability of emitting three neutrons (CE libraries only)
2018	Fission probability (CE libraries only)
2022	Within-group scattering cross section
2027	Absorption probability (CE libraries only)
4561	$\bar{V}_p$ for first chance fissions
4562	$\bar{V}_p$ for second chance fissions
4563	$\bar{V}_p$ for third chance fissions
4564	$\bar{V}_p$ for fourth chance fissions

10.2 ORIGEN DATA RESOURCES

ORIGEN data resources include nuclear decay data, multigroup neutron reaction cross sections, neutron-induced fission product yields, and decay emission data for photons, neutrons, alpha particles and beta particles. The nuclear decay data are based primarily on ENDF/B-VII.1 evaluations. The multigroup nuclear reaction cross section libraries now include evaluations from the JEFF-3.0/A neutron activation file containing data for 774 target nuclides, more than 12,000 neutron-induced reactions, and more than 20 different reaction types below 20 MeV, provided in various energy group structures. Energy-dependent ENDF/B-VII.0-based fission product yields are available for 30 fissionable actinides. Gamma-ray and x-ray emission data libraries are based on ENDF/B-VII.1. The photon libraries contain discrete photon line energy and intensity data for decay gamma and x-rays emission for 1,132 radionuclides, prompt and delayed continuum spectra for spontaneous fission, (α, n) reactions in oxide fuel, and bremsstrahlung from decay beta (electron and positron) particles slowing down in either a UO_2 fuel or water matrix. Methods and data libraries used to calculate the neutron yields and energy spectra for spontaneous fission, (α, n) reactions, and delayed neutron emission are adopted from the SOURCES4C code. Capabilities to calculate the beta and alpha particle emission source and spectra have also been added.

10.2.1 ACKNOWLEDGEMENTS

Development and testing of ORIGEN data resources, libraries, and methods have been sponsored by many organizations including the US Nuclear Regulatory Commission (NRC), the US Department of Energy (DOE), and nuclear power and research institutions.

10.2.2 VERSION INFORMATION

Following is a description of the data resources available for use with ORIGEN in different SCALE versions. Methodologies and algorithms used in applying the data are described in the ORIGEN chapter.

10.2.2.1 Version 6.3 (2021)

Data lead(s): A. Holcomb and W. Wieselquist

Nuclear data in ORIGEN has had minor updates for SCALE 6.3. The old ENDF/B-VII.0 libraries have been removed. There are new libraries for 302-groups (for fast-spectrum systems) and 1597-groups as an very fine group option for any spectrum. Data for recoverable energy per capture for Gd-155 and Gd-157 has been updated from 5 MeV to 8.5360 and 7.9370 MeV, respectively.

10.2.2.2 Version 6.2 (2016)

Data lead(s): I. C. Gauld, D. Wiarda, M. Pigni, and W. Wieselquist

Nuclear data in ORIGEN are unchanged from SCALE 6.1.3 except for the modification of independent fission yields for thermal fission of ^{235}U and ^{241}Pu and fast fission of ^{238}U to provide greater compatibility between the direct and cumulative fission yields when using the updated decay data from ENDF/B-VII.1. Additionally, ORIGEN no longer has its own independent source of nuclide mass and abundance data and now relies on the SCALE Standard Composition library so that there is consistency in this data across SCALE. D. Mueller and W. Wieselquist are acknowledged for testing of the new yield data. W. Wieselquist and S. Hart are acknowledged for the revision of this chapter.

10.2.2.3 Version 6.1.3 (2011)

Data lead (s): I. C. Gauld and D. Wiarda

SCALE 6.1 represented a complete revision and update of the nuclear data available in ORIGEN. The following is a summary from the SCALE 6.1 manual.

> The ORIGEN data libraries include nuclear decay data, neutron reaction cross sections, neutron induced fission product yields, delayed gamma-ray emission data, and neutron emission data. The nuclear decay data libraries have been updated based on ENDF/B-VII evaluations and expanded to include 903 activation products and structural materials, 174 actinides, and 1149 fission products. The cross section libraries have been revised using evaluations from the JEFF-3.0/A neutron activation file, containing data for 774 target nuclides, more than 12,000 neutron-induced reactions, and more than 20 different reaction types below 20 MeV. The JEFF-3.0/A activation file is processed into several multigroup cross section libraries, from 44 groups to 238 groups, that can be used to determine the neutron reaction transition rates in ORIGEN. Energy-dependent ENDF/B-VII fission product yields are provided for 30 fissionable actinides. Photon yield data libraries have been updated based on the most recent ENSDF nuclear structure evaluations processed using the NuDat program. The photon libraries contain discrete photon line energy and intensity data for decay gamma and x-rays emission for 982 radionuclides, prompt and equilibrium continuum fission product spectra from spontaneous fission, (α, n) reactions in oxide fuel, and bremsstrahlung from decay beta (negatron and positron) particles

slowing down in either UO_2 fuel or water matrix. Methods and data libraries used to calculate the neutron yields and energy spectra for spontaneous fission, (α, n) reactions in any matrix, and delayed neutron emission are adopted from the SOURCES code. The libraries used by ORIGEN can be coupled directly with detailed and problem-dependent physics calculations to obtain self-shielded problem-dependent cross sections based on the most recent evaluations of ENDF/B-VII. In addition, the library formats allow multiple sets of cross section data to be stored on a library to represent the changes in cross sections during irradiation.

10.2.3 INTRODUCTION

ORIGEN data resources include nuclear decay data, multigroup neutron reaction cross sections, neutron-induced fission product yields, and decay emission data for photons, neutrons, alpha particles and beta particles. The available resources are summarized in Table 10.2.1 and described in greater detail in the subsequent sections. The "Unit" column shows the corresponding unit number for use with FIDO input systems (e.g. with COUPLE).

10.2.4 DECAY RESOURCE

The nuclear data stored on the decay resource is based on ENDF/B-VII.1 evaluations [Origen-Data-ResourcesCHO+11], including half-lives, decay modes and branching fractions, and recoverable energy per disintegration. Decay modes include beta (β^-), positron (β^+) and electron capture (EC), isomeric transition (IT), alpha (α), spontaneous fission (SF), delayed neutron (β^- n) emission, neutron emission (n), double beta decay ($\beta^-\beta^-$), and decay by beta and alpha emission ($\beta^-\alpha$). The decay resource also includes radiotoxicity factors based on the radioactivity concentration guides (RCGs) for air and water as defined in Part 10, Title 20, of the Code of Federal Regulations (10CFR20) [Origen-Data-Resources10c]. RCGs specify the maximum permissible concentrations of an isotope in soluble and insoluble forms for both ingestion and inhalation and for occupational and unrestricted exposure. The radiotoxicity is calculated as the dilution volume of a nuclide for cases of direct ingestion or inhalation. The values are defined to be the smaller (i.e., more toxic) of the values for soluble and insoluble forms of the isotope. The maximum permissible RCGs for air and water are the public exposure limits for adult ingestion and inhalation dose coefficients of ICRP Publication 72 [Origen-Data-ResourcesInternationalCoRPICRP77]. External exposure dose coefficients for noble gases were obtained from the Environmental Protection Agency (EPA) Federal Guidance Report 12 [Origen-Data-ResourcesUEPAEPA93]. Recoverable energy includes the delayed energy from all electron-related radiations (e.g., β^-, β^+, Auger electrons), all gamma rays, x-rays, annihilation radiations, and the average energy of all heavy charged particles and delayed neutrons. The average alpha energy includes the energy of the recoil nucleus. A part of the recoverable energy per decay not included in the ENDF/B-VII.1 values is the additional contribution from spontaneous fission. This energy was calculated as the product of the spontaneous fission branching fraction and recoverable energy per fission using a value of 200 MeV per fission and then added to the ENDF/B-VII.1 recoverable Q energy. A value of 12.56 MeV gamma energy per fission was used in computing the fraction of recoverable spontaneous fission energy from gamma rays. External Bremsstrahlung radiation is **not** included in the Q-value since the Bremsstrahlung spectrum depends on electron interactions with the medium that contains the decay nuclide. The energy from capture gamma rays accompanying (α, n) reactions is not included either since it also depends on the medium.

Appendix A describes the decay resource file format. It is important to note that the decay resource not only defines fundamental decay data, but also the complete ORIGEN nuclide set, including the "duplicates" of nuclides across sublibraries. For example, a version of ^{155}Gd is contained in both the light nuclide/activation product and fission product sublibraries. Appendix D includes the full list of the nuclides on the ORIGEN decay library "end7dec" created by COUPLE based on the current decay resource, including duplicates.

Appendix E contains a list of the fundamental decay data only, without duplicates. To consider a different set of nuclides in an ORIGEN calculation, the current process is to alter the decay resource and then regenerate the "end7dec" decay library with COUPLE. By default, all subsequent libraries created from COUPLE using problem-dependent reaction transitions are based on the "end7dec" decay library and will therefore include the modified nuclide set.

10.2.5 NEUTRON REACTION RESOURCE

The neutron cross sections defining the nuclear reaction transmutation rates use a comprehensive collection of nuclear data evaluations compiled from the JEFF-3.0/A neutron activation files [Origen-Data-ResourcesSKFK03]. The JEFF-3.0/A files contain continuous energy neutron data for 774 target nuclei, including ground and metastable excited states, and 12,617 neutron-induced reactions below 20 MeV. The JEFF-3.0/A cross section data are developed directly from the European Activation File (EAF-2003) [Origen-Data-ResourcesFKS02] formatted as standard ENDF-6 format data. JEFF-3.0/A cross sections are stored using File 3, multiplicities on File 10, and isomeric branching to different metastable levels using File 9. The evaluations include many reactions that may be important for modeling fast fission and other high-energy systems. Neutron reactions are available for 23 reaction types, including (n,n'), $(n,2n)$, $(n,3n)$, (n,f), $(n,n'\alpha)$, $(n,2n\alpha)$, $(n,3n\alpha)$, $(n,n'p)$, $(n,n2\alpha)$, $(n,n'd)$, $(n,n't)$, $\left(n,n'^{3}He\right)$, $(n,4n)$, $(n,2np)$, (n,γ), (n,p), (n,d), (n,t), $\left(n,^{3}He\right)$, (n,α), $(n,2\alpha)$, $(n,2p)$, and $(n,p\alpha)$.

The JEFF-3.0/A evaluations also include extensive compilations of energy-dependent branching fractions that define neutron reaction transitions to ground and metastable energy states. Energy-dependent branching is fully implemented in the ORIGEN cross section libraries. Implementation of the JEFF-3.0/A cross sections as ORIGEN multigroup data was accomplished by processing and collapsing the JEFF-3.0/A pointwise cross sections into a standard multigroup AMPX format using ENDF data-processing modules of the AMPX [Origen-Data-ResourcesDG02] cross section processing code system. The collapse is performed using a thermal Maxwellian-1/E-fission-1/E weighting spectrum (see Fig. 10.2.1) to provide infinite dilution multigroup cross sections.

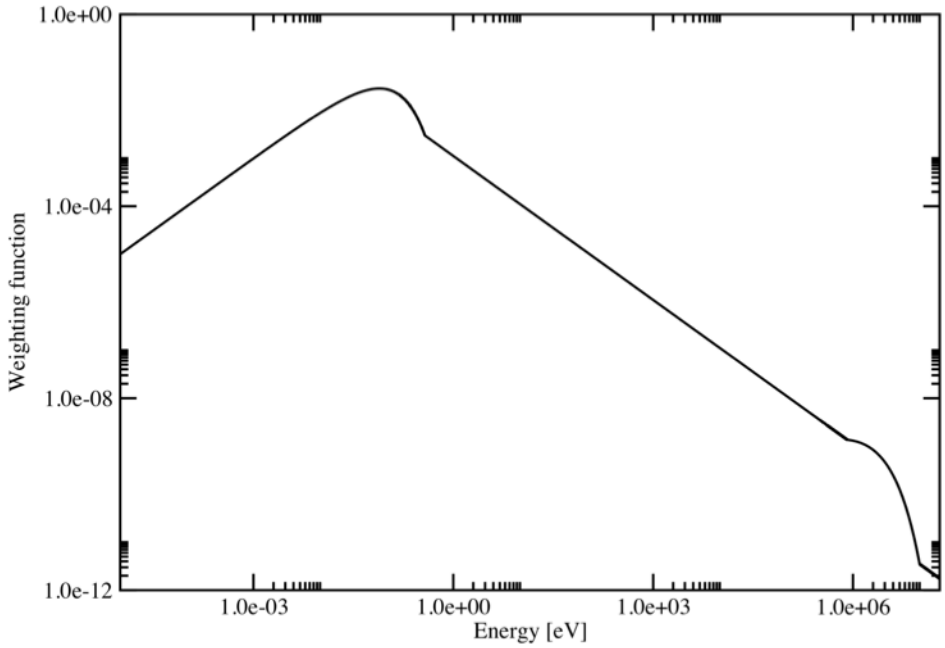

Fig. 10.2.1: Pointwise flux spectrum used to generate collapsed cross section libraries.

Neutron reactions with transitions to multiple states of the daughter product are represented using separate cross sections to the ground and metastable states. A special reaction identifier (MT') is defined for this implementation of metastable transitions as

$$\mathrm{MT}' = \mathrm{MT} * 10000 + 100 * \mathrm{LP} + \mathrm{LT} \tag{10.2.1}$$

where MT is the reaction identifier, LP is the product metastable state, and LT is the target metastable state. Using the ^{187}W(n,3n)^{185}W cross section (MT=17) as an example, the reaction identifier 170000 defines the partial cross section to the ground state of ^{185}W, and 170100 defines the cross section to metastable ^{185m}W.

Cross section data from the JEFF-3.0/A neutron activation file are first converted to point-wise cross section data, are Doppler broadened to 900K, and then they are collapsed to different group structures. The following group strucures are available in SCALE:

- 238-group neutron (thermal applications),
- 252-group neutron (thermal applications),
- 56-group neutron (thermal applications),
- 200-group neutron (fast applications and shielding),
- 47-group neutron (applications using the BUGLE shielding transport library),
- 49-group neutron (collapsed version of 238 groups),
- 44-group neutron (collapsed version of 238 groups), and
- 999-group neutron (multipurpose).

Several minor modifications were made to the JEFF-3.0/A data:

- The ^{239}Np radiative neutron capture cross section was replaced with data from ENDF/B-VII.0. Neutron capture using JEFF-3.0/A cross sections was significantly larger than ENDF/B-VII.0 due to differences in the resonance cross section region. Although experimental resonance parameters are not available for ^{239}Np, comparisons of ^{240}Pu production during irradiation [Origen-Data-ResourcesGum54] obtained using the two evaluations showed that better agreement with the experiment was obtained using the ENDF/B-VII.0 evaluation.
- The $^{241}Am(n,\gamma)$ branching fraction to the ^{242}Am ground and metastable states was replaced by the evaluation from ENDF/B-VII.0 to yield better agreement with the results of destructive radiochemical assay measurements of irradiated fuels. The branching fraction of ^{241}Am to ^{242m}Am for thermal neutron capture changed from 8.2% in JEFF-3.0/A to 10.0% in ENDF/B-VII.0.

The cross section library header record information and a complete list of nuclides in JEFF-3.0/A libraries developed for ORIGEN are provided in Appendix E.

Because JEFF-3.0/A-based libraries are formatted as standard AMPX working libraries, they can be accessed and/or manipulated using standard AMPX utility modules in SCALE. For example, multigroup cross sections may be listed using the PALEALE module. Additionally, the data may be visualized using the Fulcrum user interface. Cross section plots of the 238-group JEFF-3.0/A library are illustrated in Fig. 10.2.2 for (n,γ), (n,α), (n,2n), and (n,3n) cross sections to the ground and metastable states.

Before the cross sections in ORIGEN can be used, they must be collapsed with a user-defined multigroup flux to a one-group cross section and added to the ORIGEN binary library (see the COUPLE input description).

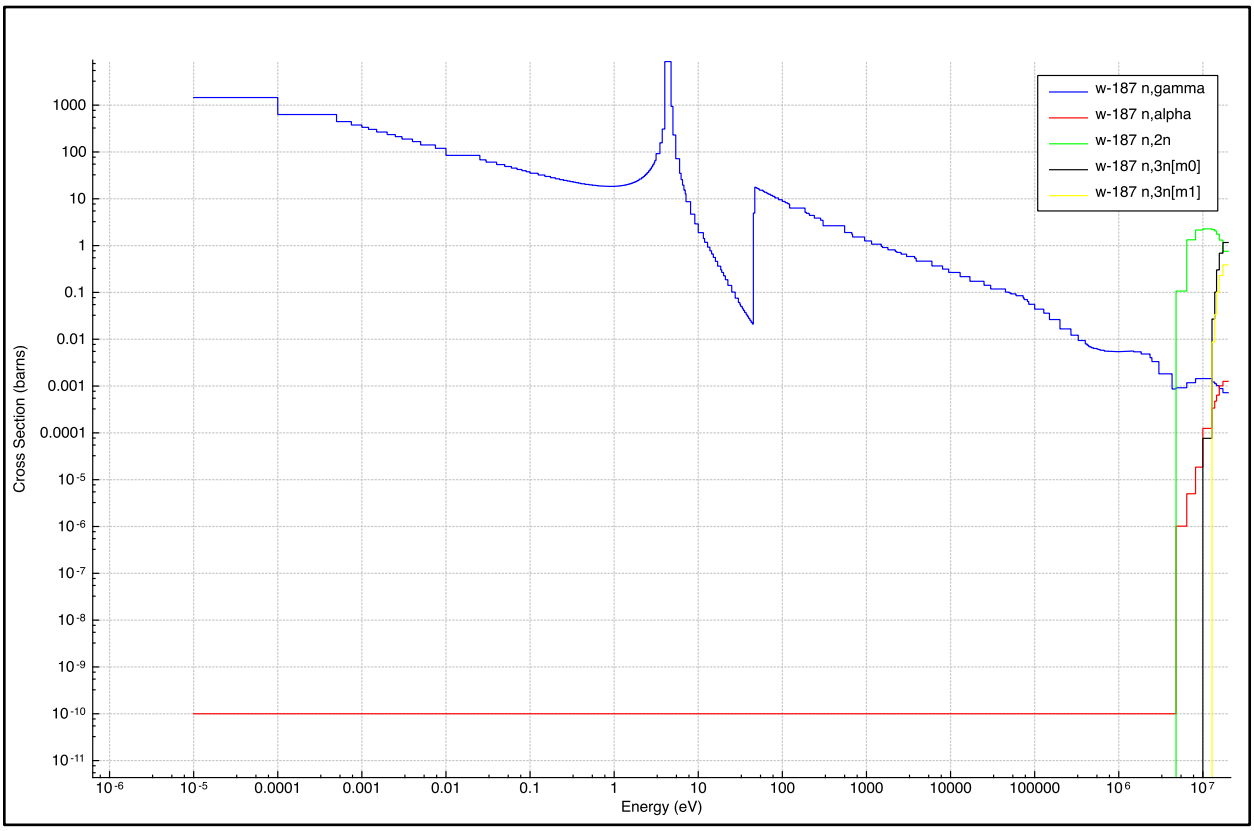

Fig. 10.2.2: 238-group JEFF-3.0/A cross sections for ^{187}W.

10.2.6 FISSION YIELD RESOURCE

The fission-yield resource contains the energy-dependent direct yields of each fission product for 30 fissionable actinides, including ^{227,228,232}Th, ^{231}Pa, $^{232–238}$U, $^{238\text{-}242}$Pu, ^{241,242m,243}Am, ^{237,238}Np, $^{242\text{-}246,248}$Cm, ^{249,252}Cf, and ^{254}Es. Independent (direct) fission product yields are stored as atom percent per fission, and except for ^{235}U(thermal), ^{238}U(fast), and ^{241}Pu(thermal), they are obtained from ENDF/B-VII.0 [Origen-Data-ResourcesCOH+06] File 8 and MT=454.

Revised independent fission product yields for ^{235}U(thermal), ^{238}U(fast), and ^{241}Pu(thermal) were adopted to address inconsistencies between the direct and cumulative fission yields in ENDF/B-VII.0 caused by the use of updated nuclear decay schemes in the decay sublibrary [Origen-Data-ResourcesFWP15, Origen-Data-ResourcesPFG15]. Namely, recent changes in the decay data, particularly the delayed neutron branching fractions, result in calculated fission product concentrations that do not agree with the cumulative fission yields in the ENDF/B-VII.0 library. These issues were particularly evident for the three cited isotopes because their fissioning systems result in a preferential formation of fragments that are sensitive to the changes in the decay data. For example, a study on ^{239}Pu(thermal) showed negligible differences between cumulative yields calculated (using the recent decay data sublibrary) and the cumulative yields in ENDF/B-VII.0. Energy-dependent product yields are available for thermal, fast, and high-energy incident neutron energies. For fast fission, the value of the energy of incident neutron was modified from the value of 500 keV tabulated in ENDF/B-VII.0 to more accurately represent the relationship between the energy distribution of the neutrons causing fission and the and the fission neutron spectrum energy. For this implementation of the yield data, the effective incident neutron energy for fast fission was adjusted from 500 keV to 2.0 MeV to better reflect the average fission energy of most nuclides. The neutron energies for thermal fission (0.0253 eV) and high energy fission (14 MeV) are unchanged.

The fission product yields also include cumulative ternary yields from the JEF-2.2 fission yield library [Origen-Data-ResourcesNuclearEAgency00] for ^{3}H and ^{4}He. The nuclide ^{3}He was also added to the fission product library since it is a decay product of tritium.

Note that inclusion of fission yields for each actinide in an ORIGEN library can be controlled by the user through COUPLE. Actinides not assigned with explicit yields do not produce fission products during fission.

10.2.7 ENERGY RESOURCE

The energy resource is a set of data defined internally to ORIGEN to compute the total power during irradiation if the flux is known, or the total flux if the power is known. The data include the energy contributed by fission and capture. The recoverable energy values taken primarily from ENDF/B evaluations are listed in Table 10.2.3 and Table 10.2.4. The recoverable energy for fission and neutron capture for nuclides not listed in the tables are assumed to be 200 MeV and 5.0 MeV, respectively.

Table 10.2.3: Recoverable energy (MeV) values for actinides

Nuclide	Fission	Capture
^{230}Th	190.00	5.010

10.2.8 EMISSION RESOURCES

The two main groups for emission resources are the photon (gamma) resource, which includes beta particle emission data, and the neutron resource, which includes alpha emission data.

10.2.8.1 Gamma Emission

The resources for gamma emission are stored as separate files (see Table 10.2.5) containing the photon data associated with different modes of decay or photon production. The photon data sets include decay gamma and x-ray line-energy data, gamma rays accompanying spontaneous fission, gamma rays accompanying (α, n) reactions in oxide fuels, and Bremsstrahlung spectra from decay electrons/positrons slowing down in UO_2 and water. The photon energy spectra can be generated in any energy group structure for all activation products, actinides, and fission product nuclides with photon yield data.

Table 10.2.5: Photon data files

File name	Description
MPDKXGAM	x-ray and gamma emissions line data
MPSFANGM	spontaneous fission and (α, n) reactions
MPBRH2OM	bremsstrahlung from beta particles slowing down in water
MPBRH2OP	bremsstrahlung from positrons slowing down in water
MPBRUO2M	bremsstrahlung from beta particles slowing down in UO_2
MPBRUO2P	bremsstrahlung from positrons slowing down in UO_2

All photon data sets are constructed with the same format (see Appendix C). The majority of the photon emissions are discrete energy lines. Photon continuum data, used to represent Bremstrahlung and some other gamma-ray emission spectra, are stored at discrete energies and approximately expanded to a continuum, as needed. Gamma and x-ray yields are directly from ENDF/B-VII.1 decay files containing spectral data for decay transitions of 1,132 nuclides. A separate file contains emission spectra for gamma rays accompanying spontaneous fission and for gamma rays accompanying (α, n) reactions in oxide fuels [Origen-Data-ResourcesCHG79]. The spontaneous fission spectra combine prompt and equilibrium fission product gamma-ray components. The prompt spectrum is similar to that of ^{235}U, and the delayed fission product gamma intensity at equilibrium is about 0.75 of that from the prompt fission gamma rays. Based on measured prompt fission gamma spectra from ^{235}U, spontaneous fission spectra are computed from the following approximation:

$$N(E) \cong \begin{cases} 11.5 & 0.1 \leq E \leq 0.6\ MeV \\ 35.4e^{-1.78E} & 0.6 \leq E < 1.5\ MeV \\ 12.6e^{-1.09E} & 1.5 \leq E \leq 10.5\ MeV \\ 0 & \text{otherwise.} \end{cases} \tag{10.2.2}$$

where

N(E) = number of photons per unit energy per fission (photons/MeV per fission) at energy E, where E is the photon energy (MeV).

For medical and industrial spontaneous fission source applications, a more accurate simulation of the source may be desirable. Work has been performed on ^{252}Cf source modeling to explicity represent the fission

product generation from fission and the delayed gamma emission. In this application, the equilibrium spontaneous fission gamma spectrum was replaced with an evaluation of the ^{252}Cf prompt gamma spectrum, and the delayed fission product gamma rays was modeled explicitly in ORIGEN by generating the time-dependent fission products using ^{252}Cf spontaneous fission product yields from ENDF/B-VII.0 [Origen-Data-ResourcesIGW11]. This was performed by adding decay transitions to the ORIGEN library from the actinides to the fission products. The spectrum of gamma rays accompanying (α, n) reactions is based on reaction data for alpha interactions on ^{18}O and from studies for $^{238}PuO_2$ systems. The spectrum is computed from the approximation:

$$N(E) \cong 2.13 \cdot 10^{-8}\ e^{-1.38E} \tag{10.2.3}$$

where

> N(E) = number of photons per unit energy per alpha decay (photons/MeV per disintegration) at energy E (MeV).

The photon yields in this data set are continuum spectra represented by discrete lines with an energy width of 500 keV and range from 250 keV to 10.25 MeV.

Two photon data sets contain bremsstrahlung spectra from decay electrons and positrons slowing down in a UO_2 fuel matrix. The yields are in the form of continuum spectra represented in the data sets as discrete lines using up to 70 quasi-logarithmic spaced energy points over the energy range between 0 and 13.5 MeV. Two libraries contain bremsstrahlung spectra from decay electrons and positrons slowing down in water. Bremsstrahlung spectra were calculated using a computer program developed by Dillman *et al.* [Origen-Data-ResourcesDSF73] using beta spectra derived from **Evaluated Nuclear Structure Data Files (**ENSDF) decay data with a computer program written by Gove and Martin [Origen-Data-ResourcesGM71].

10.2.8.2 Neutron Emission

There are four neutron emission resources used by ORIGEN to calculate the neutron intensities and spectra: (1) neutron decay data, (2) an alpha-particle stopping power, (3) a target (α, n) cross section, and (4) a target (α, n) product level branching. All of the neutron data are stored in a text format with names and descriptions given in Table 10.2.6. The neutron decay data contain basic decay information for decay processes that lead to direct and indirect emission of neutrons, including spontaneous fission branching fractions, alpha decay branching fractions, delayed neutron branching fractions, alpha-particle decay energies, Watt fission spectrum parameters, and delayed neutron spectra. The stopping cross sections, (α, n) target cross sections, and product-level branching data are used in calculating the neutron yield and spectra from (α, n) reactions.

The neutron data were obtained directly from the updated SOURCES-4B code package. The sources of the neutron data are described by Shores [Origen-Data-ResourcesSho00]. An update was made to correct an error in the ^{250}Cf spontaneous fission neutron branching fraction in the neutron source decay data distributed with the SOURCES code. The ^{250}Cf branching fraction was incorrectly assigned the value from ^{252}Cf of $3.092 \cdot 10^{-2}$. A corrected value of $7.700 \cdot 10^{-4}$ from ENDF/B-VII.1 is used.

Table 10.2.6: Neutron source data libraries

File name	Description
ALPHDEC	Neutron source decay data
STCOEFF	Stopping cross section expansion coefficients
ALPHYLD	Target (α, n) product level branching
ALPHAXS	Target (α, n) cross section

The neutron source decay contains spontaneous fission data for the 49 actinides listed in Table 10.2.7. These data include the spontaneous fission branching fraction, the number of neutrons per fission (*nu*), and the watt spectrum parameters for spontaneous fission. The spontaneous fission neutron energy spectrum is approximated using spectral parameters A and B, such that

$$N(E) \cong \mathrm{C}\, e^{-\frac{E}{A}} \sinh \sqrt{\mathrm{BE}} \tag{10.2.4}$$

where E is the neutron energy and C is a normalization constant.

Neutron yields from alpha-particle interaction are available for 19 (α, n) target nuclides: ^{7}Li, ^{9}Be, ^{10}B, ^{11}B, ^{13}C, ^{14}N, ^{17}O, ^{18}O, ^{19}F, ^{21}Ne, ^{22}Ne, ^{23}Na, ^{25}Mg, ^{26}Mg, ^{27}Al, ^{29}Si, ^{30}Si, ^{31}P, and ^{37}Cl. The neutron decay data contain discrete alpha-particle energies and branching fractions for 89 actinides and 7 fission products listed in Table 10.2.9. The sources of the level branching fraction data and the (α, n) cross section data are listed in Table 10.2.10. The stopping cross sections and (α, n) target cross section and product level branching libraries are used in calculating the neutron yield and spectra from Ziegler [Origen-Data-ResourcesZie77] for all elements with Z < 93, and from Wilson [Origen-Data-ResourcesWPS+83] for all elements geq 93.

10.2.8.3 Beta Emission

Beta emission rates and energy spectra are calculated using an analytic expression for the kinetic energy of the emitted β^- particles [Origen-Data-ResourcesGM71]:

$$N(Z,W) = \frac{g^2}{2\pi^3} F(Z,W)\,\rho W\,(W_0 - W)^2\,S_n(W)\,dW \tag{10.2.5}$$

where

Z = atomic number of the daugher nucleus

g = weak interaction coupling constant

W = kinetic energy of beta particle (in $m_e c^2$ units)

$F(Z,W)$ = Fermi function

W_0 = endpoint beta energy

$\rho = \sqrt{W^2 - 1}$ = electron momentum

$S_n(W)$ = spectral shape factor based on transition type

n = classification of the transition type

Internal conversion electron emission is not considered.

The calculation requires nuclear data on the fraction of the beta transition to each exicited state of the daughter nucleus, the maximum endpoint energy of the transition (W0), and a classification of the beta transition (n) defined by the spin and parity change of the transition which defines the spectral shape factor. The transition classification uses n=0 for allowed and forbidden non-unique transitions, n=1 for first forbidden unique transitions, n=2 for second forbidden unique transitions, and n=3 for third forbidden unique transitions. These data are not stored in the decay data resource but are included in a separate beta decay resource used only for the beta calculation.

The beta decay data are stored in the formatted file origen.rev00.ensdf95beta.data. The data are derived from ENSDF as compiled in 1995. The file includes beta decay information for 715 beta decay nuclides and has 8486 beta transition branches.

10.2.8.4 Alpha Emission

Calculation of the alpha emission intensity and spectrum requires detailed information that is not available on the decay resource. The calculation requires the alpha particle energy and branching fraction for each transition branch. Unlike the beta spectrum, the alpha particles are emitted with discrete energies, and the source spectrum may be generated by straightforward binning into the user-defined group structure. Alpha particle emission data are also used in the (α, n) neutron source calculation. Therefore, the alpha emission spectra are calculated using the same alpha decay library in the neutron emission resource: origen.rev01.alphdec.data.

10.2.9 DECAY RESOURCE FORMAT

The decay resource is a simple text format file that can be processed by COUPLE to create a binary decay-only library that can be used directly by ORIGEN. In general, this is not necessary, as the decay resource distributed with SCALE has already been processed with COUPLE to produce the end7dec ORIGEN decay-only binary library file. Modifying the decay data or the set of nuclides ORIGEN tracks requires modification of the decay resource file. The format is described in Table 10.2.11. Note that as of the SCALE 6.2 release, ORIGEN now uses the SCALE Standard Composition resource for abundance data and the "ABUND" field shown below is ignored by COUPLE when reading the decay resource.

Table 10.2.11: Definitions of data in the decay resource

Data name	Definition
LIB	Nuclide sublib (used by COUPLE)
NUC1	Nuclide identifier
IU	Units for the half life value (see numref:*tab-origen-hl-units*)
HALFL	Value of the half life in IU units
FB1	Beta decay transition leading to a daughter in the metastable state
FP	Positron emission decay fraction or orbital electron capture to the ground state
FP1	Positron emission decay fraction or orbital electron capture to a metastable state
FA	Alpha particle emission decay fraction
FT	Isomeric transition decay fraction
LIB1	Nuclide type in the library
FSF	Spontaneous fission decay fraction
FBN	Delayed neutron decay (beta particle and a neutron) fraction

continues on next page

Table 10.2.11 – continued from previous page

Q	Recoverable energy per decay (MeV)
ABUND	Natural atom isotopic abundance in percent (**no longer used**)
AMPC	Maximum permissible concentration in air
WMPC	Maximum permissible concentration in water
LIB1	Nuclide type in the library (used by COUPLE)
FG	Fraction of recoverable decay energy Q associated with gamma rays
FB	Beta decay transition leading to a daughter in the ground state
FBB	Double beta decay fraction
FN	Neutron decay fraction
FBA	Beta decay plus an alpha particle emission decay fraction

The variable LIB (and LIB1)defines the nuclide sublibrary (1/2/3=activation product/actinide/fission product). Variable LIB1 is included for formatting purposes only.

The nuclide identifier is read in variable NUC1 and is subsequently stored in array NUCL. The nuclide identifier is given by

$$\text{NUCL} = \text{Z} * 10000 + \text{A} * 10 + \text{I} \tag{10.2.6}$$

where Z is the atomic number, A is the atomic mass number, and I is the isomeric state, where $I = 0$ designates a ground state, and $I = 1$ is the first metastable state.

The variable HALFL is the physical half-life in units designated by the variable IU, as shown in Table 10.2.12. The definitions of 11 variables representing the different decay mode branching fractions are given in Table 10.2.11. The decay branching fractions are used in constructing the transition matrix.

Table 10.2.12: Units of half-life indicated by the variable IU

IU	**Units of half-life**
1	seconds
2	minutes
3	hours
4	days
5	years
6	stable
7	10^3 years
8	10^6 years
9	10^9 years

The variable Q is the total amount of recoverable energy (MeV) per disintegration released by radioactive decay used for decay heat calculations. It does not include the energy of neutrinos emitted during beta decay transitions. The variable FG is the fraction of recoverable energy per disintegration that comes from gamma rays and x-rays. The value of Q is obtained directly from ENDF/B-VII.1 as the sum of the average beta, gamma, and alpha decay energy values. The quantity includes the energy from all electron- related radiations such as β^-, β^+, Auger electrons, etc., all gamma rays, x-rays, and annihilation radiations, and the average energy of all heavy charged particles and delayed neutrons. The contribution from alpha decay energy includes the energy of the recoil nucleus. A part of the recoverable energy per decay not included in the ENDF/B-VII.1 values is the additional contribution from spontaneous fission. This energy was calculated

as the product of the spontaneous fission branching fraction and recoverable energy per fission using a value of 200 MeV per fission and added to the ENDF/B-VII.1 recoverable Q energy. A value of 12.56 MeV gamma energy per fission was used in computing the fraction of recoverable spontaneous fission energy from gamma rays.

External bremsstrahlung radiation is **not** included in the values of FG since the bremsstrahlung spectrum depends on electron interactions with the medium that contains the decay nuclide. The energy from capture gamma rays accompanying (α, n) reactions is also not included since it also depends on the medium. The variable ABUND is the atom percent abundance of naturally occurring isotopes.

An example of the decay resource content for selected fission products is presented as Example 10.2.1.

Example 10.2.1: Example of the ENDF/B-VII.1 decay data resource entries for selected fission products.

10.2.10 FISSION YIELD RESOURCE FORMAT

The independent fission product yields are stored as a formatted text file. The header record for each set of fission product yields includes the fissionable nuclide ID and an unused entry (0.0), followed by the number of incident neutron energies included for this nuclide. The fission yields for each energy are preceeded by a single record containing the incident neutron energy (eV), an unused entry (0.0), an index for the incident energy, the number of data entries per fission product, the total number of entries for each incident energy, and the number of fission products. The fission product yields for each fissionable nuclide and incident neutron energy are then listed as pairs of entries for the fission product nuclide ID and the independent (direct) fission yield as atom percent per fission. An example of the format is shown below in Example 10.2.2 for ^{227}Th.

The number and order of the fission product yields must be the same for all fissionable nuclides and must correspond to the fission products in the nuclear decay data. The fission product yields for each fissionable nuclide, excluding the yields for the terniary fission products ^{3}H, ^{3}He, and ^{4}He, sum to 200.

The fissionable nuclides and the tabulated incident neutron energies for which yields are available are listed in Table 10.2.2.

Example 10.2.2: Fission yield format example showing a portion of ^{227}Th.

10.2.11 GAMMA RESOURCE FORMAT

An example of the photon data entries for the emissions from ^{140}La decay is shown below in Example 10.2.3. The header record for each nuclide contains the nuclide ID, the total number of emission lines in the evaluation, as well as the number of discrete x-ray lines, discrete gamma lines, and number of pseudo lines used to represent continuum data if present in an evaluation used to reconstruct continuous energy emission spectra from the discrete representation. The last entries in the header record include the total gamma energy (MeV), and the character nuclide name. The emission spectrum is listed using pairs of entries for the photon energy (MeV) and photon emission (photons per disintegration).

Example 10.2.3: Gamma resource format example showing ^{140}La decay photon emission.

10.2.12 ORIGEN "END7DEC" NUCLIDE SET

Table 10.2.13 shows a list of the 2,237 nuclides on the origen.rev04.end7dec ORIGEN binary decay-only library, and because this library provides the basis for all other libraries, effectively the set of nuclides tracked by ORIGEN in any decay or irradiation calculation. The "index" column is the index of that nuclide in the set (internally every ORIGEN isotopics vector has this order), the "sublib" column is the sublibrary (LT=light nuclide, AC=actinide, FP=fission product) in which the nuclide resides, the "nuclide" column is the nuclide identifier, the "mass" column is the mass of the nuclide in grams per mole, the "abundance" column is the natural abundance in atom percent for the nuclide (note only light nuclides have abundances), and the "decay" column is the decay constant. Note that the mass and abundance data are embedded on the library with the values from the current SCALE Standard Composition Library.

Table 10.2.13: Nuclide listing for "end7dec" ORIGEN library

index	sublib	nuclide	mass (g/mol)	abundance (atom%)	decay (1/s)
1	LT	1-H-1	1.0078	1.00E+02	0.00E+00
2	LT	1-H-2	2.0141	1.15E-02	0.00E+00

10.2.13 DECAY RESOURCE CONTENTS

A concise representation of the data contained in the decay resource (i.e., the first 500 lines) is shown below in Example 10.2.4. Note that the actual decay resource file currently also defines the complete ORIGEN nuclide set, including the multiple versions of some nuclides by sublibrary, e.g., ^{155}Gd-155, as both a light nuclide/activation product and a fission product. The content list below contains no such duplication.

Example 10.2.4: Contents of decay resource.

```
---------------
ind: index
izzzaaa: 7-digit id composed of
i: 1-digit isomeric (metastable) state
zzz: 3-digit atomic number
aaa: 3-digit mass number
symbol: element-aaa(m) where m is first metastable state
dk: decay constant in 1/s
```

(continues on next page)

(continued from previous page)

```
Q: recoverable decay energy in MeV
fQphot: fraction of Q decay energy associated with gamma rays
mode: decay mode and yield pairs in the form
decay_mode1(isomeric_states1) yield1
decay_mode2(isomeric_states2) yield2
...

10.2.14 REACTION RESOURCE CONTENTS

A concise representation of the data contained in the reaction resource is shown below in Example 10.2.5. This type of output may be generated from any AMPX multigroup library using the PALEALE utility.

Example 10.2.5: Contents of reaction resource.

```

10.3 SCALE NUCLEAR DATA COVARIANCE LIBRARY

A. Holcomb, D. Wiarda, M. L. Williams, G. Arbanas, and B. L. Broadhead

ABSTRACT

An updated cross section covariance library has been created for use with the sensitivity and uncertainty modules in SCALE 6.3. The data have been assembled from a variety sources, including high-fidelity covariance evaluations from ENDF/B-VIII.0 as well as approximate uncertainties obtained from a collaborative project performed by Brookhaven National Laboratory, Los Alamos National Laboratory, and Oak Ridge National Laboratory. This document describes the assumptions in generating the data, the library contents, and processing procedure for the SCALE 56-group and 252-group covariance libraries. The ENDF/B-VII.1 covariance libraries provided with SCALE 6.3 are identical to the libraries released with SCALE 6.2. The SCALE 44-group covariance library distributed with SCALE 6.0 and SCALE 6.1 is retained for backwards compatibility.

ACKNOWLEDGMENT

We gratefully acknowledge the sponsorship of the US Department of Energy Nuclear Criticality Safety Program in the development of the SCALE 6.3 covariance libraries.

10.3.1 INTRODUCTION

The SCALE 6.3 covariance library suite contains covariance libraries based on ENDF/B-VIII.0, ENDF/B-VII.1, and pre-ENDF/B-VII.0. For each ENDF release, if uncertainty information is not available for all neutron targets, then the corresponding SCALE covariance library is patched such that each library has some estimate of the uncertainty data for every neutron target in the library. The ENDF/B-VIII.0 covariance library [XSLibDAB18] contains at least some covariance data for 252 nuclides and the ENDF/B-VII.1 library [COVLIBCHO+11] has data for 187 nuclides. Both the ENDF/B-VIII.0 and ENDF/B-VII.1 covariance libraries have been supplemented by the previous SCALE 6.1 covariance data for the ~305 nuclides missing covariance data in ENDF/B-VIII.0 and ~215 nuclides missing covariance data in ENDF/B-VII.1. The ENDF/B-VII.1 uncertainties were modified for a few nuclides, as described in Sect. 10.3.2.3. The ENDF/B-VIII.0 covariance data are available in a 56-group format, and the ENDF/B-VII.1 covariance library is in both a 56-group and 252-group format. These covariance libraries were generated for compatibility with the ENDF/B-VII.1 cross section libraries distributed with SCALE 6.3, and they may also be applied for the 238-group ENDF/B-VII.0 library provided with SCALE 6.2. The previous SCALE 6.0 and SCALE 6.1 44-group library (44groupcov) was based on older covariance data and is retained in SCALE 6.3 for backwards compatibility. However, the 56- and 252-group covariance libraries (56groupcov7.1 and 252groupcov7.1) are now recommended for all applications. The 56-group library-which is default for SCALE uncertainty analysis-and the 252 fine-group library generally produce similar results, except for some threshold reactions such as (n,2n). The 252-group library may be used to improve uncertainty estimates from these types of data, but it takes more execution time than the default 56-group library. Because the 56- and 252-group covariance data in many cases are based on newer uncertainty evaluations than the previous 44-group library, some differences will occur between these sets of results.

The covariance data correspond to relative uncertainties assembled from a variety of sources, including evaluations from ENDF/B-VIII.0, ENDF/B-VII.1, ENDF/B-VI, and approximated uncertainties from a collaborative project performed by Brookhaven National Laboratory (BNL), Los Alamos National Laboratory (LANL), and Oak Ridge National Laboratory (ORNL). Because SCALE uncertainty data come from several different sources, the application of a single generic covariance library to all multigroup cross section libraries raises questions about consistency with any given data evaluation. In reality, much of the approximate uncertainty data in the library is based on simplifying approximations that do not depend on specific ENDF evaluations and thus can be applied to all cross section libraries within the limitations of the assumed methodology. In other cases in which a covariance evaluation has been taken from a specific nuclear data file (e.g., ENDF/B-VIII.-,ENDF/B-VII.1, ENDF/B-VI, or JENDL), it is assumed that the same *relative* (rather than *absolute*) uncertainties can be applied to all cross section libraries, even if these are not strictly consistent with the nuclear data evaluations. The assumption is partially justified by the fact that different evaluations often use many of the same experimental measurements since there is a limited amount of this information available. In some cases, older data evaluations have been carried over into the newer ENDF versions. Also, because many important nuclear data are now known rather well, newer evaluations in many instances correspond to rather modest variations from previous ones and are expected to lie within the earlier uncertainties.

No inherently "true" uncertainty can be defined for nuclear data. For example, in theory, two independent evaluations could produce similar nuclear data with very different uncertainties. Differences in nuclear data evaluations directly impact calculations that can be affirmed by comparisons with benchmark experiments;

but there is no established procedure to quantify the reliability of uncertainty estimates. In general, the SCALE covariance library should be viewed as a best-estimate assessment of data uncertainties based upon the specific methodology described in the following section. While this methodology is not unique and other approaches could have been used, the SCALE covariance library is a reasonable representation of the nuclear data uncertainties for most applications given the current lack of information. Furthermore, it is the only available comprehensive library that has been created in a well-defined, systematic manner.

10.3.2 COVARIANCE DATA DESCRIPTION

10.3.2.1 Evaluated covariances from nuclear data files

A rigorous, modern evaluation of nuclear data typically uses a regression algorithm that adjusts parameters in a nuclear physics model (e.g., Reich-Moore resonance formula, optical model, etc.), to fit a set of differential experimental measurements that have various sources of statistical and systematic uncertainties [COVLIBLLD+06]. Information from the regression analysis of the model parameters can be propagated to uncertainties and correlations in the evaluated differential data. In this manner, the differential nuclear data and covariances are consistent and are coupled together by evaluation processes. Unfortunately, only a limited number of cross section evaluations have produced high-fidelity covariances in this rigorous manner. All other nuclear data uncertainties must be estimated from approximations in which the uncertainty assessment is decoupled from the original evaluation procedure.

The SCALE covariance library is based on several different uncertainty approximations with varying degrees of fidelity relative to the actual nuclear data evaluation. The library includes high-fidelity evaluated covariances obtained from the latest ENDF releases whenever available. As discussed in Sect. 10.3.1, it is assumed that covariances taken from one data evaluation, such as ENDF/B-VII.1, can also be applied to other evaluations of the same data, such as ENDF/B-VIII.0. If this is done judiciously for cases in which the nuclear data evaluations are similar, then the covariances taken from one source should be a reasonable representation of uncertainties for the other evaluations.

10.3.2.2 Approximate covariance data

At the other end of the spectrum from high fidelity data, low-fidelity (lo-fi) covariances are defined to be those estimated independently of a specific data evaluation. The approximate covariance data in SCALE are based on results from a collaborative project funded by the US Department of Energy Nuclear Criticality Safety Program to generate lo-fi covariances over the energy range from 10^{-5} eV to 20 MeV for materials without covariances in ENDF/B-VII.1. Nuclear data experts at BNL, LANL, and ORNL devised simple procedures to estimate data uncertainties in the absence of high fidelity covariance evaluations. The result of this project is a set of covariance data in ENDF/B file 33 format that can be processed into multigroup covariances [COVLIBLKH+08]. Some of these data were later revised and included in ENDF/B-VII.1, while others were carried over from SCALE 6.1 to the SCALE 6.3 library. In this documentation, these data are known as BLO (BNL-LANL-ORNL) uncertainty data, which were generated as described below.

ORNL used uncertainties in integral experiment measurements of thermal cross sections, resonance integrals, and potential cross sections to approximate the standard deviations of capture, fission, and elastic scattering reactions for the thermal (<0.5 eV) and resonance ranges (0.5 eV- 5 keV). Full energy correlation was assumed for the covariances within each of these respective ranges [COVLIBWBDR07, COVLIBWR08] This procedure was originally introduced for the approximate uncertainty data in SCALE 5.1. However, the current version includes updated integral measurement uncertainties, using the more recent values tabulated by Mughabghab in the *Atlas of Neutron Resonances* [COVLIBMug06]. The lo-fi relative uncertainty is computed as the absolute uncertainty in the integral parameter (i.e., thermal cross section or resonance

integral) taken from the *Atlas*, divided by the average of the measured parameter and the calculated value computed from ENDF/B-VII differential data:

$$U = \frac{\Delta_I}{0.5 \times (X_I + X_D)}, \tag{10.3.1}$$

where:

U is the relative lo-fi uncertainty included in SCALE,

Δ_I is the absolute uncertainty in the integral measurement (obtained from Mughabghab), and

X_I and X_D are the measured and computed (from ENDF/B differential data) integral parameter values, respectively.

In some cases the integral measurement value from the Mughabghab *Atlas*[6] and the corresponding value computed from the ENDF/B-VII differential evaluation are inconsistent-defined here as having a difference greater than two standard deviations in the measured and computed integral parameters. In these cases, the lo-fi relative standard deviation is defined as half the difference relative to the average of the measured and calculated values:

$$U = \frac{|X_I - X_D|}{X_I + X_D};\ \text{for}\ |X_I - X_D| > 2\Delta_I. \tag{10.3.2}$$

In some instances this expression may exceed 100%. For these cases, a 100% uncertainty was assigned. Also, the *Atlas* does not include uncertainties in integral measurements for several isotopes, which typically are not of great interest for most applications. In this case the integral uncertainty was defined as a +/-5 in the least significant digit for these materials; e.g., 1.23 is assign an uncertainty of +/- 5E-3.

BNL and LANL provided estimates in the fast energy range from 5 keV to 20 MeV for covariances of capture, fission, elastic, inelastic, (n,2n) cross sections, and prompt nubar. BNL used optical model calculations with estimated uncertainties in model parameters to compute covariances in the fast range for about 300 structural isotopes, fission products, and non-fissionable heavy nuclei. Estimated uncertainties in model parameters were based on previous work and expert judgment [COVLIBPHO09]. Covariances for 14 actinide isotopes were obtained from earlier work performed by BNL for Subgroup-26 (SG-26) [COVLIBRHOM07]. The SG-26 actinide covariances cover the full energy range, including thermal, resonance, and fast regions. If the thermal data uncertainties estimated by the SG-26 approach exceed the thermal uncertainty given in reference 6, the thermal data covariances are represented by ORNL's integral uncertainty technique.

LANL produced covariances in the fast range for an additional 47 actinide materials. The LANL actinide covariances were based on empirical estimates of nuclear reaction models [COVLIBKTY+08]. Full energy range covariances were also produced by LANL for 16 light isotopes ranging from hydrogen to fluorine [COVLIBHal08]. These included high fidelity covariances from R-matrix analyses for ^{1}H, ^{6}Li, and ^{10}B, along with lo-fi uncertainties for the other materials, based on approximations such as least-squares fitting to experimental data, statistical model calculations at higher energies, or sometimes simply best-judgment estimation [COVLIBLKH+08].

10.3.2.3 Modifications to covariance data

In generating earlier covariance libraries, some omissions or inconsistencies were identified and corrected in the current covariance library:

- If the absolute correlation is larger than 1, it is set to 1.
- If a relative uncertainty is larger than 1, it is set to 1.

- If cross section data exist but covariance data do not span the entire range, then the diagonal element for the higher energy groups is repeated for the lower energy groups.
- If total inelastic scattering covariance is not supplied, it is calculated from the uncertainties in the discrete level inelastic data.
- If total nubar covariance is not supplied, it is calculated from the the prompt and delayed nubar uncertainties

A few inconsistencies were found in the ENDF/B-VII.1 uncertainty data, and these were modified for the SCALE 6.3 covariance library [COVLIBWIMR14]. The corrections were also conveyed to the National Nuclear Data Center, where they were added to the ENDF/A file for possible inclusion in the future release of ENDF/B-VIII.1. These modifications are summarized below:

(a) ^{235}U thermal nubar: standard deviation was decreased from 0.7% to 0.3% in energy range from 0.0 to 0.5 eV, consistent with JENDL-3.3.

(b) ^{239}Pu thermal nubar: standard deviation was increased from 0.01% to 0.15% in energy range from 0.0 to 0.01 eV, consistent with ENDF/B-VII.1 uncertainty at 0.01 eV.

(c) H thermal capture: standard deviation reduced from 2.5% to 0.2%, consistent with Williams and Rearden 2008 [COVLIBWR08],

(d) ^{103}Rh thermal capture: reduced from ~4% to 1.04%, consistent with Williams and Rearden 2008 [COVLIBWR08].

(e) ^{151}Sm thermal capture: modified to ~1.8%, consistent with Williams and Rearden 2008 [COVLIBWR08].

(f) ^{147}Pm: standard deviation was reduced from 24% to 5% in the energy range 0.5–5000 eV, consistent with the quoted resonance integral uncertainty in Williams and Rearden 2008 [COVLIBWR08].

Several modifications were also made to the uncertainties obtained from the original BLO data used in SCALE 6.1. The energy boundary between the thermal and resonance covariance blocks was modified from 0.5 to 0.625 eV in order to coincide with a 56-group boundary. The BLO lo-fi data do not include thermal or resonance range uncertainties for isotope reactions that do not have integral uncertainties given in the Mughabghab text [COVLIBMug06]. These occur mainly for relatively unimportant data such as elastic cross sections of several fission products. Therefore in these cases the uncertainties were estimated using different approaches. For example, the thermal data uncertainty was sometimes used to represent the epithermal uncertainty if it was not available in the Mughabghab tabulation, and sometimes the high-energy uncertainty was extended to lower energies. The uncertainty in the ^{149}Sm resonance capture integral is not provided in the 2006 edition of Mughabghab's text, so it was set to the value of 5.7%, which was obtained from an earlier tabulation by Mughabghab [COVLIBMug03].

10.3.2.4 Covariance data for fission spectra

As of ENDF/B-VII.1, covariance matrices are now provided for the fission exit energy distribution. The data are given as a function of incident energy. The incident energy grid is very broad, and the exit energy distribution is constant over a given incident energy group. Since the COVERX library file only allows one multigroup fission spectrum (χ) covariance matrix per nuclide, the exit energy spectrum is used for the average energy of fission. If ν is nubar, f is fission, and w is the appropriate flux, then the average energy of fission is calculated as:

$$10^7 \exp\left(-\frac{\sum \nu f w \frac{1}{2}\left(\log\left(\frac{10^7}{E_{g1}}\right)+\log\left(\frac{10^7}{E_{g2}}\right)\right)}{\sum \nu f w}\right) \tag{10.3.3}$$

where the sum is over all groups and E_{g1} and E_{g2} are the group boundaries for group g. ENDF/B-VII.1 provides covariance data for exit energy distributions for 64 nuclides. This includes all nuclides for which fission spectrum (χ) covariance matrices where provided in the previous covariance library. Some additional χ-covariance matrices were taken from JENDL-4.0. The new 56-group and 252-group fission spectrum covariances are more complete and significantly improved compared to the earlier 44-group chi uncertainty data, which were based on the Watt fission spectrum in ENDF/B-V. (see Sect. 10.3.5).

10.3.3 MULTIGROUP COVARIANCE PROCESSING

Covariance data were processed with the AMPX code PUFF-IV [COVLIBWD06]. PUFF-IV has major improvements in the treatment of the resolved and unresolved resonance parameter uncertainties over previous code versions [COVLIBWALD08]. All nuclides with resonance parameter uncertainty files were processed with the full sensitivity option in PUFF-IV.

10.3.4 CONTENTS OF THE SCALE 6.3 COVARIANCE LIBRARY

The SCALE covariance library provides uncertainty data in 56- and 252-group formats for a total of 456 materials in ENDF/B-VII.1 and 587 materials in ENDF/B-VIII.0, including some duplication for materials with multiple thermal scattering kernels. Table 10.3.1 describes the contents of the library using the following nomenclature:

1. ENDF/B-VII.1: evaluated covariance data released with ENDF/B-VII.1
2. ENDF/B-VII.2-prelim: recently evaluated data proposed for future release of ENDF/B-VII.2
3. ENDF/B-VI: evaluated covariance data released with ENDF/B-VI
4. BLO approximate data: lo-fi covariances from BLO project
5. SG-26: approximate covariances from WPEC Subgroup-26
6. JENDL-4.0: evaluated covariance data released with JENDL-4.0

Several covariance evaluations include cross correlations between reactions. These are summarized in Table 10.3.2.

Table 10.3.1: Contents of SCALE 6.3 covariance libraries.

10.3.5 SCALE 6.1 44-GROUP COVARIANCE LIBRARY

The older 44-group covariance library distributed with SCALE 6.0 and SCALE 6.1 is included with this distribution for backwards compatibility. The 44-group covariance library provides uncertainty data for a total of 401 materials, including some duplication for materials with multiple thermal scattering kernels. However, the 44-group library was created prior to the official release of ENDF/B-VII.1. Therefore, it is recommended that the 56- or 252-group covariances be used rather than the 44-group. As discussed in Sect. 10.3.1, it is assumed that covariances taken from one data evaluation such as ENDF/B-VI or JENDL-3.3 can also be applied to other evaluations of the same data, such as ENDF/B-VII. If this is done judiciously for cases in which the nuclear data evaluations are similar, then the covariances taken from one source should be a reasonable representation of uncertainties for the other evaluations. Among the materials in the SCALE 44-group library with covariances taken from high-fidelity nuclear data evaluations are the following:

a) ENDF/B-VII evaluations *(includes both VII.0 and pre-release covariances proposed for VII.1, but no official ENDF/B-VII.1)*:

Au, ^{209}Bi, ^{59}Co, ^{152,154,155,156}Gd, ^{191,193}I, ^{7}Li, ^{23}Na, ^{93}Nb, ^{58}Ni, ^{99}Tc,^{232}Th, ^{48}Ti, ^{239}Pu, ^{233,235,238}U,V

(b) ENDF/B-VI evaluations:

Al, ^{241}Am, ^{10}B, ^{12}C, ^{50,52,53,54}Cr, ^{63,65}Cu, ^{54,56,57}Fe, In, ^{55}Mn, ^{60,61,62,64}Ni, ^{206,207,208}Pb, ^{242}Pu, ^{28,29}Si

(c) JENDL-3.3 evaluations:

^{11}B, ^{1}H, ^{16}O, ^{240,241}Pu

Two modifications were also made to the ENDF/B-VII evaluated nubar covariances. These nubar uncertainties are believed to be more realistic. The ENDF/B-VII.0 ^{235}U thermal nubar uncertainty of 0.71% was revised to the JENDL-3.3 value of 0.31%. In addition, the thermal nubar certainty in the pre-released ENDF/B-VII.1 ^{233}U evaluation was modified to the value in a recent ORNL data evaluation [COVLIBLWRD08]. This ORNL ^{233}U cross section evaluation also provided the thermal and resonance cross sections for the prereleased

ENDF/B-VII.1 data. The ENDF/B-VII.1 pre-release nubar data for ^{239}Pu was incomplete when the 44-group covariance library was generated, so ^{239}Pu nubar data are included from ENDF/B-V, the most current data available at that time. This value is much higher than the current estimated uncertainty in ^{239}Pu nubar. The basic ENDF/B uncertainty files that were changed are described in Table 10.3.3.

Several modifications were also made to the uncertainties obtained from the BLO data. The BLO thermal uncertainties for ^{1}H capture and elastic and for ^{16}O elastic were modified to the JENDL-3.3 values of 0.5% and 0.1%, respectively. Similarly, the uncertainty in the ^{10}B (n,alpha) thermal cross section was modified to the ENDF/B-VI value of about 0.2%, since this is more consistent with the Mughabghab integral uncertainty. The uncertainty in the ^{149}Sm resonance capture integral is not provided in the 2006 edition of Mughabghab's text; therefore it was set to the value of 5.7% which was obtained from an earlier tabulation by Mughabghab [COVLIBMug03].

Table 10.3.3: Summary of changes made to covariance evaluations for the 44-group library.

ENDF/B-VII.1 pre-release ^{239}Pu	Data were incomplete at time of library generation, so ENDF/B-V data were used for nubar.
ENDF/B-VII ^{235}U	Thermal nubar modified to JENDL-3.3 value
ENDF/B-VII ^{233}U	Thermal nubar modified to value from ORNL internal evaluation
ENDF/B-VI ^{241}Am	Thermal uncertainties were added to total cross section (set equal to capture uncertainties)
ENDF/B-VI ^{28}Si, ^{29}Si, ^{30}Si, ^{206}Pb, ^{57}Fe	In elastic scatter uncertainty, corrected cross reference to MT=102 from original value of MT=1.02
ENDF/B-VI ^{208}Pb, ^{207}Pb	Removed MT=3 due to inconsistency with other MT values, resulting in very large uncertainty predictions

At the time of the preparation of the 44-group covariance library, ENDF/B did not provide fission spectra uncertainty estimates. The methodology used to construct these data for the 44-group covariance library is described in Broadhead and Wagschal [COVLIBBW04]. In this approach, the fission spectrum is represented as either a Watt or Maxwellian distribution. These energy distributions are widely used to represent fission spectra and have been commonly employed in many ENDF/B evaluations. For example, Watt and Maxwellian expressions were used almost exclusively to describe fission spectra in ENDF/B-V and also for many ENDF/B-VI evaluations. More recent evaluations for some important fissionable nuclides have replaced the simple Watt and Maxwellian analytical expressions by distributions such as the Madland-Nix spectrum obtained from more phenomenological nuclear fission models. However, it is assumed here that uncertainties based on an appropriate Watt or Maxwellian representation of the fission spectrum can be transferred to the actual fission spectra contained in the different multigroup cross section libraries.

The methodology in Broadhead and Wagschal [COVLIBBW04] determines energy-dependent covariances from uncertainties and correlations in the *a* and *b* parameters for the Watt spectrum or the *T* parameter for a Maxwellian spectrum, appearing the analytical expressions given below:

Watt Spectrum: $\chi(E) = \frac{e^{-E/a}}{I} \sinh(\sqrt{bE})$

Maxwellian Spectrum: $\chi(E) = \frac{\sqrt{E}e^{-E/T}}{I}$

In these expressions, the parameter "I" is the normalization factor required to normalize the integrated spectrum to unity. The value of "I" is fixed by the values of the other parameters. Due to the normalization

constraint, the fission spectrum covariance includes anti-correlations. The assumed fission spectra parameters and uncertainties are given in Maerker, Marable, and Wagschal 1980 [COVLIBMMW80] and in Howerton and Doyas 1971 [COVLIBHD71].

Table 10.3.4 shows that fission spectra covariances are not provided for all fissionable materials in the SCALE multigroup cross sections. Table 10.3.5 lists the fissionable nuclides without fission spectra covariances on the 44-group covariance library.

Table 10.3.4: Source of fission spectrum parameters and uncertainties

Watt spectrum	a or T	b	Source of parameters	σ_a or σ_T (%)	σ_b (%)	Source of uncertainty

Table 10.3.6 describes the contents of the library using the following nomenclature:

1. ENDF/B-VII.0: evaluated covariance data released with ENDF/B-VII.0
2. ENDF/B-VII-p: recently evaluated data proposed for future release of ENDF/B-VII.1
3. ENDF/B-VI: evaluated covariance data released with ENDF/B-VI
4. JENDL-3.3: evaluated covariance data in JENDL-3.3
5. BLO approximate data: lo-fi covariances from BLO project

6. BLO LANL evaluation: LANL R-matrix evaluation from BLO project
7. SG-26: approximate covariances from WPEC Subgroup-26

11. UTILITY MODULES FOR SCALE LIBRARIES

M.L. Williams

Historically the SCALE Code System has included a number of standalone, executable utility modules developed mainly for performing operations on various types of multigroup nuclear data libraries and on the standard composition library used in SCALE. In legacy versions of SCALE, some utility modules were directly executed during computational sequences; but in the modern version of SCALE the standalone executables are no longer used in computation sequences — their functions have been incorporated into a more unified and integrated framework. Several of the earlier utility modules were deprecated in the SCALE 6.2 release; but others are retained and are still quite useful for nuclear data manipulations, editing, and checking. Most of these utilities are taken directly from the AMPX code system. Sect. 11.1 provides a listing of the AMPX modules distributed with SCALE, along with a brief description of each module's function. User input for these modules can be found in the AMPX documentation that accompanies SCALE. Several additional utility modules included in the SCALE code package are also described in this section. Finally, many AMPX and SCALE utility modules use the FIDO input processing procedure, and this is described in the FIDO chapter.

11.1 AMPX LIBRARY UTILITY MODULES

D. Wiarda, A. Holcomb, L. M. Petrie

Abstract

The purpose of this section is to document selected AMPX modules that can benefit the analyst interested in editing, converting, or combining cross-section libraries normally used by the SCALE system modules. The input description for these codes is provided in the documentation of the AMPX nuclear data processing code system that is distributed with SCALE package.

11.1.1 INTRODUCTION

AMPX is a modular system [UTILS-WWCD15] that generates continuous energy (CE) and multigroup (MG) cross section data from evaluated nuclear data files such as ENDF/B. All the nuclear data libraries distributed with SCALE have been processed using AMPX. In addition to data processing modules, AMPX also includes a number of useful utility modules for checking, manipulating, and editing the libraries in SCALE. This section lists and briefly describes some of the AMPX utility codes that may be useful to SCALE users. Input instructions for these codes can be found the AMPX code documentation, which is distributed with the SCALE code package. Additional AMPX modules of interest may also found in the documentation.

11.1.2 AJAX: MODULE TO MERGE, COLLECT, ASSEMBLE, REORDER, JOIN, AND/OR COPY SELECTED DATA FROM AMPX MASTER LIBRARIES

AJAX (**A**utomatic **J**oining of **A**MPX **X**-Sections) is a module to combine data from different AMPX libraries. Options are provided to allow merging from any number of files.

11.1.3 ALPO: MODULE TO CONVERT AMPX LIBRARIES INTO ANISN FORMAT

ALPO (**A**NISN **L**IBRARY **P**RODUCTION **O**PTION) is a module for converting AMPX working libraries into the library format used by the legacy discrete ordinates transport codes ANISN and DORT/TORT contained in the DOORS package cite:*rhoades_doors_1998*.

11.1.4 CADILLAC: MODULE TO MERGE MULTIPLE COVARIANCE DATA FILES

CADILLAC (**C**ombine **A**ll **D**ata **I**dentifiers **L**isted in **L**ogical **A**MPX **C**overx-format) is a module that can be used to combine multiple covariance data files in COVERX format into a single covariance data file. The material IDs can be changed as needed by the user.

11.1.5 COGNAC: MODULE TO CONVERT COVARIANCE DATA FILES IN COVERX FORMAT

COGNAC (**C**onversion **O**perations for **G**roup-dependent **N**uclides in **A**MPX **C**overx-format) is a module that can be used to convert a single COVERX-formatted data file from bcd format to binary. Also, COGNAC can be used to convert from binary to bcd, binary to binary, and bcd to bcd.

11.1.6 LAVA: MODULE TO MAKE AN AMPX WORKING LIBRARY FROM AN ANISN LIBRARY

LAVA (**L**et **A**NISN **V**isit **A**MPX) is a module that can convert an ANISN formatted library (neutron, gamma, or coupled neutron-gamma) to an AMPX working library that can be used in XSDRNPM.

11.1.7 MALOCS: MODULE TO COLLAPSE AMPX MASTER CROSS-SECTION LIBRARIES

MALOCS (**M**iniature **A**MPX **L**ibrary **O**f **C**ross **S**ections) is a module to collapse AMPX master cross-section libraries. The module can be used to collapse neutron, gamma-ray, or coupled neutron-gamma master libraries.

11.1.8 PALEALE: MODULE TO LIST INFORMATION FROM AMPX LIBRARIES

PALEALE lists selected data by nuclide, reaction, data-type from AMPX master and working libraries.

11.1.9 RADE: MODULE TO CHECK AMPX CROSS-SECTION LIBRARIES

RADE (**R**ancid **A**MPX **D**ata **E**xposer) is provided to check AMPX- and ANISN-formatted multigroup libraries. It will check neutron, gamma, or coupled neutron-gamma libraries.

11.1.10 TOC: MODULE TO PRINT AN AMPX LIBRARY TABLE OF CONTENTS

Program TOC is a utility program to print a sorted table of contents of an AMPX cross section library. It is designed to be run interactively, with the cross section library specified as the argument.

11.2 WORKER: SCALE SYSTEM MODULE FOR CREATING AND MODIFYING WORKING-FORMAT LIBRARIES

L. M. Petrie

ABSTRACT

WORKER is a standalone utility module used to convert AMPX master-formatted or working-formatted multigroup cross section libraries into a single working library for SCALE transport calculations performed by XSDRNPM, KENO V.a and KENO-VI, and other modules. Beginning with SCALE 6.2, WORKER is no longer used for calculations performed with SCALE sequences because this function has been absorbed into

the XSProc module. This document gives instructions on how to use the WORKER program as a standalone module.

ACKNOWLEDGMENTS

Several former ORNL staff made valuable contributions to the WORKER development. The authors acknowledge the contributions of former ORNL staff members S. Goluoglu, N. M. Greene, and D. F. Hollenbach.

11.2.1 INTRODUCTION

Historically the AMPX nuclear data processing system [WORKER1] has defined two formats for the multigroup (MG) libraries used in SCALE. The "master" formatted library contains more general information than normally required for radiation transport calculations. A master library includes such information as 2D transfer arrays for all inelastic levels, temperature-dependent thermal-scattering kernels, and Bondarenko self-shielding data. A "working" formatted library contains only the subset of these data needed for radiation transport calculations. A working library contains only a single, combined 2D transfer array [i.e., sum of elastic, all discrete inelastic levels, (n,2n), etc.], and the temperature-dependent data normally have been interpolated to the appropriate temperatures. In SCALE 6.2, more general formats for nuclear data libraries are supported, and the MG libraries distributed with SCALE are no longer restricted by the inflexible Master library format. However the WORKER module is retained in SCALE 6.2 for manipulation of legacy formatted libraries.

WORKER is a standalone program that reads input nuclear data library files and produces a single working library file that can be read by transport modules such as XSDRNPM, KENO-VI, NEWT, CENTRM, and Monaco. Prior to SCALE 6.2, the distributed MG libraries were stored in master format, and WORKER was executed during every MG sequence to read the master library file and write an output working library file subsequently read by the transport codes run by the sequence. In modern versions of AMPX and SCALE (e.g., SCALE 6.2 and later), the differences in the master and working formats are superfluous, and the functions of WORKER are now performed in memory by the XSProc module. Nevertheless, WORKER may still be useful for manipulation of external library files and for standalone execution of SCALE modules such as CENTRM and XSDRNPM.

11.2.2 AMPX LIBRARY FORMAT CONVERSION

The primary function of WORKER is to convert data from an initial AMPX MG library file, with any format supported by SCALE, into the AMPX working library format. The nuclear data files distributed with SCALE provide MG data that are truly problem-independent and that can be tailored at runtime for a particular application. These library files must carry data at a sufficient level of detail to allow satisfying many of the less-common but very powerful analyses such as cross section sensitivity studies and coupled neutron-gamma transport calculations. The nuclear data libraries include shielding factors used by the Bondarenko self-shielding method. Temperature dependence of the shielding factors and the thermal scattering kernel data is allowed. Any number of scattering processes [e.g., elastic, discrete-level inelastic, continuum inelastic, (n,2n), etc.] can be included to any degree of anisotropic representation. In short, there is too much detail to require transport codes to process this library.

WORKER processes and combines the data mentioned above into a form ready for use by MG particle transport programs. The final output is an AMPX working library file containing two types of data: group-averaged 1D cross sections for an arbitrary number of processes for neutrons and/or gamma rays, and total 2D transfer matrices (i.e., summed over the scattering types) for neutrons and/or gamma rays. In some cases, the transfer matrices on the master library are temperature-dependent. WORKER performs linear interpolation to the temperature specified for the nuclide, but it does not extrapolate outside the range of the data. WORKER also has the option of producing an AMPX master library of the selected nuclides interpolated to the specified

temperature(s). For resonance nuclides, the elastic scattering matrix is scaled uniformly to make the matrix consistent with the self-shielded 1D values. The $P_\ell(\ell > 0)$ matrices are scaled by the amount required for the P_0 matrix. For processes involving multiple-exit neutrons [e.g., (n,2n), (n,3n), etc.], WORKER multiplies by the appropriate multiplicity before adding to the total transfer matrix. In the case of coupled neutron-gamma libraries, gamma yields are sometimes expressed in "yield" units, thereby requiring a multiplication by a cross section before their introduction into the total transfer matrix. (This scheme allows one to produce self-shielded gamma production cross sections.)

11.2.3 WORKER INPUT SPECIFICATIONS

The following is a description of WORKER input requirements and input-output device requirements.

11.2.3.1 Input parameters

WORKER uses FIDO-type input. The number of items to be input in an array is shown in brackets, and default values are given in parentheses. If N1 and/or N7 are negative, a *direct access* master file will be assumed on that unit. Note that direct access master files may use up to five different units. The initial values of N1 or N7 will be used to determine the starting unit number for the first file, and the unit number will be incremented by 1 for each additional file.

Data block 1

-1$$ Option [1]

1. NFISFOT – No Fission Photon Option (0)

   0 – add fission photons to the transfer array

   1 – do not add fission photons to the transfer array

0$ Logical Assignments [6]. This array is input only if a user needs to modify default values.

1. N1 – Input Master Cross section Library (1)
2. N2 – Input Working Cross section Library (2)
3. N4 – Output Working Cross section Library produced by WORKER (4)
4. N5 – Scratch (18)
5. N6 – Scratch (19)
6. N7 – Output Temperature Interpolated Master Library (0)

1$ Integer Parameters [8]

1. NUCM – Number of nuclides to be read from the input library, N1. (0)
2. NUCW – Number of nuclides to be read from the input working library, N2. (0)
3. IPRT – Output print option trigger. (2)

   -2 – no cross section edits

   -1 – edit reaction cross sections

   >-1 – edit reaction cross sections and transfer arrays through order IPRT
4. IMST – Flag to copy entire Master Library. (0) (0 / >0 = only listed nuclides/all nuclides)
5. IWRK – Flag to copy entire Working Library. (0) (0 / >0 = only listed nuclides/all nuclides)

6. N1A – Sequence number of the filename for unit N1. (1)
7. N2A – Sequence number of the filename for unit N2. (1)
8. N4A – Sequence number of the filename for unit N4. (1)

Data block 2

WORKER can combine data from multiple input libraries to make the merged output working library on logical Unit N4. This output working library contains either the entire library specified or only those nuclides selected on the specified library. If IMST is set greater than ZERO, the entire input library is copied to the output working library. If IWRK is set greater than ZERO, the entire input working library is copied to the output working library. If there is no data in the `4$$` or `5$$` arrays, the nuclide ID numbers listed in the `2$$` and `3$$` arrays remain unchanged. For selected master libraries, nuclides are by default selected at 300 K unless data is provided in the 6** array.

2$$

ID numbers from the input library on N1 of nuclides to be placed on the output working library. If this array is not present and N1 is specified or if IMST > 0, then all nuclides on N1 will be copied to the output working library.

3$$

ID numbers from the input library on N2 of nuclides to be placed on the output working Library. If this array is not present and N2 is specified or if IWRK > 0, then all nuclides on N2 will be copied to the output working library.

4$$

New ID numbers for nuclides from the input master library on N1 to be placed on the output working Library. If this array is not present and N1 is specified, then all nuclides on N1 that are to be copied to the output working library will retain their original ID numbers. These correspond on a one-to-one basis with the ID numbers entered in the 2$$ array.

5$$

New ID numbers for nuclides from the input library on N2 to be placed on the output working library. If this array is not present and N2 is specified, then all nuclides on N2 that are to be copied to the output working library will retain their original ID numbers. These correspond on a one-to-one basis with the ID numbers entered in the $$ array.

6**

Thermal-Scattering kernel temperatures (K) for nuclides selected. Scattering kernels are sometimes provided at several temperatures for a nuclide on a master library. To get data at the specified input temperature, WORKER will interpolate between temperature data. For temperatures above the maximum or below the minimum temperature, WORKER will not extrapolate but instead will use the maximum or minimum temperature data. This array has no effect for sets of data with zero or one thermal kernel.

7$$

MT number of the incoherent thermal-scattering kernel. These allow selecting a thermal-scattering kernel with an MT (identifying) number other than the default (1007).

8$$

Mixture numbers associated with the ID numbers in the 2$$ array.

9$$

Mixture numbers associated with the ID numbers in the 3$$ array.

T - Terminate Block 2.

11.2.3.2 Abbreviated input description

Users who become familiar with the values required by WORKER will become dissatisfied with having to use a detailed input description. The description that follows is intended to serve as a "skeleton" guide for these users:

Data Block 1

-1$$ Option (1)

1. NFISFOT – Fission photon flag

0$$ Logical Assignments (6)

1. NT1 – Input library (1)
2. NT2 – Working In (2)
3. NT4 – Working Out (4)
4. NT5 – Scratch (18)
5. NT6 – Scratch (19)
6. NT7 – Master Out (0)

1$ Integer Parameters [5]

1. NMT – number from master

T Terminate Block 2

11.2.3.3 Input/output assignments

WORKER typically requires the following input-output devices during an execution.

Logical Number	Purpose
NT1 (1)	Input Cross section Library
NT2 (2)	Previously Prepared Working/Weighted Library
NT4 (4)	New Working Library
NT5 (18)	Scratch Unit
NT6 (19)	Scratch Unit
NT7 (0)	Temperature Interpolated Master Library
5	Record Input (when run outside of SCALE)
6	Printed Output

11.2.4 SAMPLE PROBLEM

A sample problem includes two calls to WORKER to represent different capabilities. The input assumes there is a master library available on Unit 84 that contains at least the following five nuclides-1001, 8016, 13027, 92235, and 92238-and a working library that contains the same nuclides on Unit 70.

11.2.4.1 Sample problem input

Example 11.2.1 shows the input for the sample problem. The first call to WORKER copies five nuclides from the master library on Unit 84 to the working library on Unit 75. The `0$$` array specifies reading a master library on Unit 84 and writing a working library on Unit 75. The `1$$` array specifies selecting five nuclides that are read from the master library. The `2$$` array lists the five nuclides requested from the master library: hydrogen (1001), oxygen (8016), aluminum (13027), ^{235}U (92235), and ^{238}U (92238). The `4$$` array specifies the new nuclide ID numbers. In this problem, the `4$$` array is not needed since the ID numbers do not change. The 6** array specifies selecting the thermal scattering kernel at 300 K for any nuclide having multiple-scattering kernels.

The second call to WORKER combines a master and working library. The `0$$` array specifies reading a master library on Unit 70 and a working library on Unit 75 and writing a new working library on Unit 79. The `1$$` array specifies selecting five nuclides that are read from the master library and five nuclides that are read from the working library. The `2$$` array lists the five nuclides requested from the master library: hydrogen (1001), oxygen (8016), aluminum (13027), ^{235}U (92235), and ^{238}U (92238). The `4$$` array specifies the new nuclide ID numbers for the master library nuclides. The `3$$` array lists the five nuclides requested from the working library: hydrogen (1001), oxygen (8016), aluminum (13027), ^{235}U (92235), and ^{238}U (92238). The `5$$` array specifies the new nuclide ID numbers for the working library nuclides. The 6** array specifies selecting the thermal scattering kernel at 600 K for any nuclide from the MASTER library having multiple-scattering kernels.

Example 11.2.1: Sample problem input.

```
=WORKER
  0$$ 84  0  75  E
  1$$  5  0  -2  -1  -1   E   T
  2$$ 1001 8016 13027 92238 92235  E
  4$$ 1001 8016 13027 92238 92235  E
  6** 300  300  300   300   300    E   T
END
```

11.3 COMPOZ DATA GUIDE

J. R. Knight[1] *and L. M. Petrie*

ABSTRACT

The COMPOZ program used to create the Standard Composition Library is described. Of particular importance is documentation of the COMPOZ input data file structure. Knowledge of the file structure allows users to edit the data file and subsequently create their own site-specific composition library.

ACKNOWLEDGMENT

This work was originally funded by the Office of Nuclear Material Safety and Safeguards of the U.S. Nuclear Regulatory Commission.

11.3.1 INTRODUCTION

COMPOZ is the program that creates (writes) the SCALE Standard Composition Library. Data are input in free form. A text data file containing the input to COMPOZ (and the Standard Composition Library) is available with the SCALE system. Execution of COMPOZ using this data file creates the Standard Composition Library currently available with the SCALE package. This section provides documentation of the data file structure. Knowledge of the data file structure allows users to edit the data file and subsequently create their own site-specific or user-specific composition library.

COMPOZ is intended to create or make *permanent changes* to and/or to print the composition library and should not be used for any other purpose. To avoid confusion with the Standard Composition Library provided with SCALE, it is strongly recommended that only *new* keywords and compositions be used in any site-specific or user-specific library.

11.3.2 INPUT DATA DESCRIPTION

COMPOZ input data are entered in free form. All data must be followed by at least one blank. The COMPOZ input data file contains *five* data records or blocks:

1. COMPOZ mode flag selects whether a new standard composition library will be created, or an old standard composition library will be listed. Only if a new library is being created are the following data records entered. A new library is created with a filename of "xfile089". If an old library is being dumped as an ASCII file, it will be named "_sclN...N" where N...N is an 18 digit sequence number that is incremented starting from 0 for each library dumped in the same directory.
2. The header record contains the library identification, a set of parameters describing the size of the library, and library title with 80 characters per line.

[1] Formerly with Oak Ridge National Laboratory.

3. The standard composition table contains the name, theoretical density, number of elements, and other information about each standard composition. Individual nuclides, mixtures, and compounds are all included in the table.
4. The nuclide information table contains the nuclide identification number, atomic mass, and resonance energy cross sections.
5. The isotopic distribution table contains the nuclide identification number and the atom percent of each isotope used in specifying the default enrichment.

Note: For executing COMPOZ via SCALE, an =COMPOZ is required in the first eight columns of a record preceding the mode flag, and an END is required in the first three columns of a record inserted after the last data record. If debug output is desired, then use =COMPOZ PRINTDEBUG to execute compoz.

11.3.2.1 COMPOZ mode selector

1. LGEN =

   0 – create a new library and list it

   1 – list an existing library

   >1 – list an existing library and write an ASCII input file.

If LGEN is 0, then input the following data to create a new standard composition library.

11.3.2.2 Library heading information

1. IDT – library identification number
2. TITLE – 1 line of 80 characters used to identify the library

11.3.2.3 Standard composition table

1. SCID – Composition name, maximum of 12 characters.
2. ROTH – Theoretical density, gm/cm^3.
3. ICP –

   0 for a mixture,

   1 for a compound.
4. NCZA – Element or nuclide ID
5. ATPM – Weight percent if ICP = 0. Number of atoms per molecule if ICP = 1.
6. END – Keyword END to terminate this standard composition.

For each composition, items 4 and 5 are repeated until all components of the composition are described. Items 1 through 6 are entered in a similar fashion for all compositions. After all the standard compositions are read, terminate the table with an END [label], where [label] represents an optional label.

11.3.2.4 Nuclide information table

1. NZA – Nuclide ID. This should be the mass number + 1000 * the atomic number.
2. AM – Atomic mass, C-12 scale.
3. SIGS – Resonance energy scattering cross section, barns.
4. SIGT – Resonance energy total cross section, barns.
5. NU*SIGF – Resonance energy nu*sigf cross section, barns.

The resonance energy cross sections are averaged over the appropriate energy range for the nuclide. Items 1–5 are repeated for all nuclides. After all nuclides are entered, terminate the nuclide table with an END [label].

11.3.2.5 Isotopic distribution table

1. NZN – 1000 * atomic number of variable isotope elements.
2. ISZA – Isotope ID.
3. ABWP – Default abundance, atom percent.
4. END – Keyword END to terminate this isotopic specification.

The default abundance is generally the naturally occurring abundance. For each element, items 2 and 3 are repeated until 100% total abundance is described, making a set for this element. The next element is described in the same fashion in the next set, etc. After all isotopic distributions are entered, terminate the isotopic distribution table with an END [label].

11.3.3 SAMPLE PROBLEM

The following sample problem first lists the SCALE standard composition library, then creates a new, short standard composition library, then lists and outputs an ASCII copy of this new library, and finally copies this new copy back to the output directory.

```
  =compoz
'  print the current standard composition library
    1
end
=compoz

11.4 ICE: MODULE TO MIX MULTIGROUP CROSS SECTIONS

N. M. Greene,[*] *L. M. Petrie, S. K. Fraley*[*] [ice1]

ABSTRACT

ICE is a legacy SCALE utility program that reads microscopic cross sections from an AMPX working library and uses input mixture number densities to produce macroscopic cross sections, which are written to an output file in the AMPX working library format. User input is entered with the FIDO procedures.

11.4.1 INTRODUCTION

ICE (**I**ntermixed **C**ross Sections **E**ffortlessly) is a legacy SCALE utility program that reads microscopic cross sections from an AMPX working library and uses input mixture number densities to produce macroscopic cross sections, which are written to an AMPX working library output file. The code was originally developed to allow efficient cross section mixing with minimum user effort and with reduced core storage requirements. The SCALE version of ICE is the latest in a series [UTILS-Fra76] of versions of the program.

In previous versions of SCALE several sequences employed the ICE module as a component in the self-shielding procedure; however in modern sequences the functionality of ICE has been replaced by new routines in the XSProc module. The ICE module is retained in the modern version of SCALE mainly for use as a standalone executable module to compute macroscopic cross sections and to provide backward compatibility with legacy inputs.

11.4.2 CROSS SECTION MIXING EXPRESSIONS

The mixing operations in ICE use the simple expressions presented below.

11.4.2.1 Cross-section mixing for AMPX libraries

For the options that produce AMPX working libraries, the mixing of cross sections involves a very simple summing of constituent values times a number density for the constituent, that is, Σ, a macroscopic value, is determined by

$$\Sigma = \sum_j N_j \sigma_j \tag{11.4.1}$$

where the j are the individual nuclides in the mixture whose number density and microscopic cross sections are N_j and σ_j, respectively.

The only exceptions to the above rule are for fissionable mixtures where the number of neutrons per fission, ν_g, or a fission spectrum, χ_g, is required:

$$\nu_g = \frac{\sum_j N_j \nu_{gj} \sigma_{gj}}{\sum_j N_j \sigma_{fgj}} \tag{11.4.2}$$

χ_g is defined as the fraction of the fission neutrons produced by the mixture which fall in group g. By definition,

$$\sum_g \chi_g = 1.0 \tag{11.4.3}$$

ICE uses the following scheme to determine χ. First, terms F_g are determined by

$$F_g = \sum_j N_j \chi_{g,j} \sum_{g'} \overline{\nu\sigma}_{fg',j} \hat{\phi}_{g'}, \tag{11.4.4}$$

where VO fg, j is the average of the product of ν times $\sigma 0_f$ for the nuclide, $\chi_{g,j}$ is the nuclide fission spectrum, and $\hat{\phi}_g$ is an estimate for the integrated flux in group g'. Once the F_g are determined, χ_g is determined by normalizing the sum of F_g to unity.

In many AMPX libraries, the integrals of the spectrum used to determine the multigroup values are carried on the library for each nuclide. ICE uses this nuclide-dependent spectrum to determine χ_g. This option should be exercised with caution, however, for no attempt is made to ensure that the individual spectra are consistently normalized.

11.4.3 INPUT INSTRUCTIONS

The input to ICE uses the FIDO schemes described in the FIDO chapter. In the descriptions, the number of entries expected in an array is given in square brackets.

11.4.4 SAMPLE PROBLEM

A simple case has been selected to demonstrate the use of ICE. In this case, it is desired to produce mixture cross sections for UO_2 and H_2O using basic data from ENDF version 7 238 group SCALE library. Information pertinent to the basic data is given in the following table:

Nuclide	Identifier	Order of Scattering
^{235}U	92235	5
^{238}U	92238	5
O	8016	5
H	1001	5

The atom densities to be used are:

UO_2

N(^{235}U) = 0.01 atoms/(barn-cm)

N(^{238}U) = 0.04 atoms/(barn-cm)

N(O) = 0.08 atoms/(barn-cm)

Water

N(H) = 0.06 atoms/(barn-cm)

N(O) = 0.03 atoms/(barn-cm)

In the sample case, we have elected to make an AMPX working library on logical 61,

We have selected further to identify UO_2 with a 111 on the AMPX working library.

CSAS-MG PARM=CHECK is run to set up the master library, then WORKER is run to produce a working library for ICE.

A listing of the input follows:

```

11.5 FIDO INPUT SYSTEM

L. M. Petrie

ABSTRACT

This document provides a description of the FIDO input system being used in conjunction with several SCALE functional modules. The FIDO system is a widely used method of entering or modifying large data arrays with minimum effort. Special advantage is taken of patterns of repetition or symmetry whenever possible.

ACKNOWLEDGMENTS

This document was funded by the Office of Nuclear Material Safety and Safeguards, U.S. Nuclear Regulatory Commission, for inclusion within the SCALE manual.

11.5.1 INTRODUCTION

The FIDO input method is specially devised to allow entering or modifying large data arrays with minimum effort. Advantage is taken of patterns of repetition or symmetry wherever possible. The FIDO system was patterned after the input method used with the FLOCO coding system at Los Alamos and was first applied to the DTF-II code. Since that time, numerous features requested by users have been added, a free-field option has been developed, and the application of FIDO has spread to innumerable codes. Starting with SCALE 5, the FIDO routines have been converted to Fortran 90, and the requirement that arrays be held in a large container array has been removed.

The data are entered in units called "arrays." An array comprises a group of contiguous storage locations that are to be filled with data at the same time. These arrays usually correspond on a one-to-one basis with Fortran arrays used in the program. A group of one or more arrays read with a single call to the FIDO package forms a "block," and a special delimiter is required to signify the end of each block. Arrays within a block may be read in any order with respect to each other, but an array belonging to one block must not be shifted to another. The same array can be entered repeatedly within the same block. For example, an array could be filled with "0" using a special option, and then a few scattered locations could be changed by reading in a new set of data for that array. If no entries to the arrays in a block are required, the delimiter alone satisfies the input requirement.

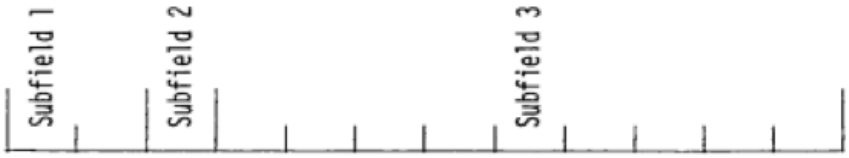
Three major types of input are available: fixed-field input, free-field input, and user-field input.

11.5.2 FIXED-FIELD INPUT

The fixed-field input option is documented here for completeness.

Note: The use of fixed-field input is NOT recommended. Use the free-field input option documented in Sect. 11.5.3.

Each record is divided into six 12-column data fields, each of which is divided into three subfields. The following sketch illustrates a typical data field. The three subfields always comprise 2, 1, and 9 columns, respectively.



To begin the first array of a block, an array originator field is placed in any field on a record:

Subfield 1: An integer array identifier < 100 specifying the data array to be read in.

Subfield 2: An array-type indicator:

"$" if the array is integer data

"*" if the array is real data

"#" if the array is double-precision data

Subfield 3: Blank

Data are then placed in successive fields until the required number of entries has been accounted for.

In entering data, it is convenient to think of an "index" or "pointer" as a designator that is under the control of the user and which specifies the position in the array into which the next data entry is to go. The pointer is always positioned at array location #1 by entering the array originator field. The pointer subsequently moves according to the data operator chosen. Blank fields are a special case in that they do not cause any data modification and do not move the pointer.

A data field has the following form:

Subfield 1: The data numerator, an integer <100. We refer to this entry as N_1 in the following discussion.

Subfield 2: One of the special data operators listed below.

Subfield 3: A nine-character data entry, to be read in F9.0 format. It will be converted to an integer if the array is a "$" array or if a special array operator such as Q is being used. Note that an exponent is permissible but not required. Likewise, a decimal is permissible but not required. If no decimal is supplied, it is assumed to be immediately to the left of the exponent, if any; and otherwise to the right of the last column. This entry is referred to as N3 in the following discussion.

A list of data operators and their effect on the array being input follows:

"Blank"

indicates a single entry of data. The data entry in the third subfield is entered in the location indicated by the pointer, and the pointer is advanced by one. However, an entirely blank field is ignored.

"+" or "-"

indicates exponentiation. The data entry in the third field is entered and multiplied by $10^{\pm N_1}$ where N_1 is the data numerator in the first subfield, given the sign indicated by the data operator itself. The pointer advances by one. In cases where an exponent is needed, this option allows the entering of more significant figures than the blank option.

"&"

has the same effect as "+."

"R"

indicates that the data entry is to be repeated N_1 times. The pointer advances by N_1. The entry 5R1 is equivalent to 1 1 1 1 1.

"I"

indicates linear interpolation. The data numerator, N_1, indicates the number of interpolated points to be supplied. The data entry in the third subfield N_3 is entered, followed by Nj interpolated entries equally spaced between that value and the data entry found in the third subfield of the next nonblank field. The pointer is advanced by $N_1 + 1$. The field following an "I" field is than processed normally, according to its own data operator. The "I" entry is especially valuable for specifying a spatial mesh. For example, the entry 3I 10 50 is equivalent to 10 20 30 40 50. In "$" arrays, interpolated values will be rounded to the nearest integer.

"L"

indicates logarithmic interpolation. The effect is the same as that of "I" except that the resulting data are evenly separated in log-space. This feature is especially convenient for specifying an energy mesh. For example, the entry 3L 1 1+4 is equivalent to 1 10 100 1000 10000.

"Q"

is used to repeat sequences of numbers. The length of the sequence is given by the third subfield, N_3. The sequence of N_3 entries is to be repeated N_1 times. The pointer advances by $N_1 * N_3$. If either N_1 or N_3 is 0, then a sequence of $N_1 + N_3$ is repeated one time only, and the pointer advances by $N_1 + N_3$. This feature is especially valuable for geometry specification.

The "N" option

has the same effect as "Q," except that the order of the sequence is reversed each time it is entered. This feature is valuable for the type of symmetry possessed by S_n quadrature coefficients.

"M"

has the same effect as "N," except that the sign of each entry in the sequence is reversed each time the sequence is entered. For example, the entries

1 2 3 2M2

would be equivalent to

1 2 3 -3 -2 2 3.

This option is also useful in entering discrete ordinates angular quadrature coefficients.

"Z"

causes $N_1 + N_3$ locations to be set at 0. The pointer is advanced by $N_1 + N_3$.

"C"

causes the position of the last array entered to be printed. This is the position of the pointer, less 1. The pointer is not moved.

"O"

causes the print trigger to be changed. The trigger is originally off. Successive "O" fields turn it on and off alternately. When the trigger is on, each record is listed as it is read.

"S"

indicates that the pointer is to skip N_1 positions leaving those array positions unchanged. If the third subfield is blank, the pointer is advanced by N_1. If the third subfield is nonblank, that data entry is entered following the skip, and the pointer is advanced by $N_1 + 1$.

"A"

moves the pointer to the position, N_3 specified in the third subfield.

"F"

fills the remainder of the array with the datum entered in the third subfield. For example, F9 will fill all positions of the array with a value of 9.

"E"

skips over the remainder of the array. The array length criterion is always satisfied by an E, no matter how many entries have been specified. No more entries to an array may be given following an "E," except that data entry may be restarted with an "A."

The reading of data to an array is terminated when a new array origin field is supplied, or when the block is terminated. If an incorrect number of positions has been filled, an error edit is given; and a flag is set which will later abort execution of the problem. FIDO then continues with the next array if an array origin was read. Otherwise, control is returned to the calling program.

A block termination consists of a field having "T" in the second subfield. Entries following "T" on a record are ignored, and control is returned from FIDO to the calling program.

Comment records can be entered within a block by placing an apostrophe (') in column 1. Then columns 2–80 will be listed, with column 2 being used for printer carriage control. Such records have no effect on the data array or pointer.

11.5.3 FREE-FIELD INPUT

With free-field input, data are written without fixed restrictions as to field and subfield size and positioning on the record. The options used with fixed-field input are available, although some are slightly restricted in form. In general, fewer data records are required for a problem, the interpreting print is easier to read, a record listing is more intelligible, the records are easier to enter, and certain common data entry errors are tolerated without affecting the problem. Data arrays using fixed- and free-field input can be intermingled at will within a given block.

The concept of three subfields per field is still applicable to free-field input; but if no entry for a field is required, no space for it need be left. Only columns 1–72 may be used, as with fixed-field input. A field may not be split across records.

The array originator field can begin in any position. The array identifiers and type indicators are used as in fixed-field input. The type indicator is entered twice to designate free-field input (i.e., "$$," "**," or "##"). The blank third subfield required in fixed-field input is not required. For example,

31**

indicates that array 31, a real-data array, will follow in free-field format.

Data fields may follow the array origin field immediately. The data field entries are identical to the fixed-field entries with the following restrictions:

1. Any number of blanks may separate fields, but at least one blank must follow a third subfield entry if one is used.

2. If both first- and second-subfield entries are used, no blanks may separate them (i.e., 24S, but not 24 S).

3. Numbers written with exponents must not have imbedded blanks (i.e., 1.0E+4, 1.0-E4, 1.0+4, or even 1+4, but *not* 1.0 E4). A zero should never be entered with an exponent. For example, 0.00 - 5 or 0.00E - 5 will be interpreted as $- 5 \times 10^{-2}$.

4. In third-subfield data entries only 9 digits, including the decimal but not including the exponent field, can be used (i.e., 123456.89E07, but *not* 123456.789E07).

5. The Z entry must be of the form: 738Z, *not* Z738 or 738 Z.

6. The + or - data operators are not needed and are not available.

7. The Q, N, and M entries are restricted: 3Q4, 1N4, M4, but *not* 4Q, 4N, or 4M.

11.5.4 USER-FIELD INPUT

If the user follows the array identifier in the array originator field with the character "U" or "V," the input format is to be specified by the user. If "U" is specified, the FORTRAN FORMAT to be used must be supplied in columns 1–72 of the next record. The format must be enclosed by the usual parentheses. Then the data for the entire array must follow on successive records. The rules of ordinary FORTRAN input as to exponents, blanks, etc., apply. If the array data do not fill the last record, the remainder must be left blank.

"V" has the same effect as "U," except that the format read in the last preceding "U" array is used.

11.5.5 CHARACTER INPUT

If the user wishes to enter character data into an array, at least three options are available. The user may specify an arbitrary format using a "U" and reading in the format. The user may follow the array identifier by a "/." The next two entries into subfield 3 specify the beginning and ending indices in the array into which data will be read. The character data are then read starting with the next data record in an 18A4 format if going to a real or integer array, and 9AB if going to a double precision array.

Finally, the user may specify the array as a free-form "*" array and then specify the data entries as "nH" character data where n specifies how many characters follow H.

11.6 MALOCS2: MODULE TO COLLAPSE AMPX MASTER CROSS SECTION LIBRARIES

L.M. Petrie

11.6.1 INTRODUCTION

MALOCS2 (**M**iniature **A**MPX **L**ibrary **O**f **C**ross **S**ections) is a module to collapse AMPX master cross-section libraries. The SCALE MALOCS2 module is an extension of the AMPX module MALOCS. MALOCS2 provides capability to read the collapsing spectrum from the output flux file produced by XSDRNPM, and also has extended options for collapsing Legendre moments of the 2D elastic scattering matrix. The module can be used to collapse neutron, gamma-ray, or coupled neutron-gamma master libraries.

11.6.2 MALOCS INPUT DATA

broadfilename
filename of the collapsed library [no default]

crosssectionprint
cross section printing option [none]

none - don't print any cross sections

onedxsecs - print the 1D cross sections

twodxsecs N - print the 2D cross sections through Legendre order N

epsilon
epsilon for when to print invalid moment messages[0.05]

finefilename
filename of the input library [no default]

fluxfilename
filename of an xsdrn flux file to be used in the collapse [no default]

numgammagroups
the number of fine gamma groups [no default]

gammacollapse
the broad group by fine group collapse structure for the gammas

must come after "numgammagroups"

latticezones
identifies the zones to be used as fuel, gap, clad, and moderator [1,2,3,4]

max2dweightorder
maximum Legendre order to be collapsed [max Legendre order of the nuclide]

numneutrongroups
the number of fine neutron groups [no default]

neutroncollapse
the broad group by fine group collapse structure for the neutrons

must come after "numneutrongroups"

printepsilon
not used [2.0D-6]

problemfilename
filename of the xsdrn data file that corresponds to the flux file [no default]

sigmatotalpl
flag to turn on doing a within group correction using the Pl weighted sigma total

'y' or 'yes' is true, anything else is false [true]

updatechi
flag to turn on updating the total chi

'y' or 'yes' is true, anything else is false [true]

validate2ds
flag to validate the Legendre moments of the collapsed 2D cross sections

'y' or 'yes' is true, anything else is false [true]

weighttype
type of weighting to be done

innercell - cell weight over a subset of the zones

innercell is followed by the largest zone number in the innercell

cell - cell weight over the whole cell

zone - weight each zone independently

region - cell weight each nuclide over only the zones it is in

default is region

wgtsource
source of the weighting flux

nuclideflux - use the flux from the nuclide on the fine group library

inputflux - read a flux from input

[default is to use an xsdrn flux]

end
terminates input stream

11.6.3 MALOCS EXAMPLE PROBLEM

The following problem shortens the 56 group library to just the nuclides that will be used to run a fixed source, 1-D discrete ordinates calculation of a void sphere with a neutron source in it, surrounded by a sphere of water, and then surrounded by an iron sphere. The flux from the discrete ordinates problem is then used to collapse the short library to 14 groups using a zone collapse method. Finally, the collapsed library is listed showing the nuclides on it, and copied back to the input directory.

12. INSTALLING AND BUILDING SCALE

12.1 SYSTEM REQUIREMENTS

12.1.1 SUPPORTED OPERATING SYSTEMS

- Linux 64-bit (RHEL 6 or newer)
- Mac OS X (Darwin) 10.11.6 or newer
- Windows 7, 64-bit or newer

12.1.2 DISK SPACE REQUIREMENTS

You must have at least 180 GB free on your computer when you begin a SCALE 6.3 install! Once setup files are removed, the final disk usage for SCALE 6.3 will be ~110 GB.

You will need to download ~62 GB of data to begin the SCALE install:

- SCALE data pak installer (61 GB)
- SCALE code installer for your operating system (<1 GB)

Once these files are available locally on your machine, proceed with the installation instructions below.

Note: Once unpacked and installed, the SCALE data and code will be ~110 GB, which will increase the total disk space usage to ~171 GB. After verifying the install was successful, you may delete the data pak and code installers to free your disk of the ~62 GB in setup files, bringing the final install size to ~110GB.

12.1.3 MEMORY

Minimum: 8 GB (per CPU for parallel calculations).

Note: SCALE calculations vary widely with the amount of memory required. It is always possible to increase the complexity of a model and exceed the amount of memory available. Large TRITON-KENO 3D models can easily require 32 GB of memory.

12.1.4 JAVA REQUIREMENTS

Java 1.8 or newer.

12.2 INSTALLATION INSTRUCTIONS

The SCALE 6.3.0 installation has been divided into three components: 64-bit pre-compiled binaries, source code, and the data. The precompiled binaries are available in platform-familiar installers: NSIS on Windows, Drag-N-Drop bundle on Mac, and Tar GZip on Linux. For deployments that include source code, it is available as a zip file, and the data are available as a self-extracting IzPack installer. Other systems may require a custom build of SCALE from source code using the build instructions provided below.

Pre-Compiled Binaries

Note: After the Binaries are installed, the nuclear data still must be installed. After completing the binary installation according to the instructions in this section, please follow the instructions for SCALE 6.3 Data.

Windows

Double-click the Windows installation file "SCALE-6.3.0-setup.exe", agree to the terms, and the following "Welcome" dialog will be shown.

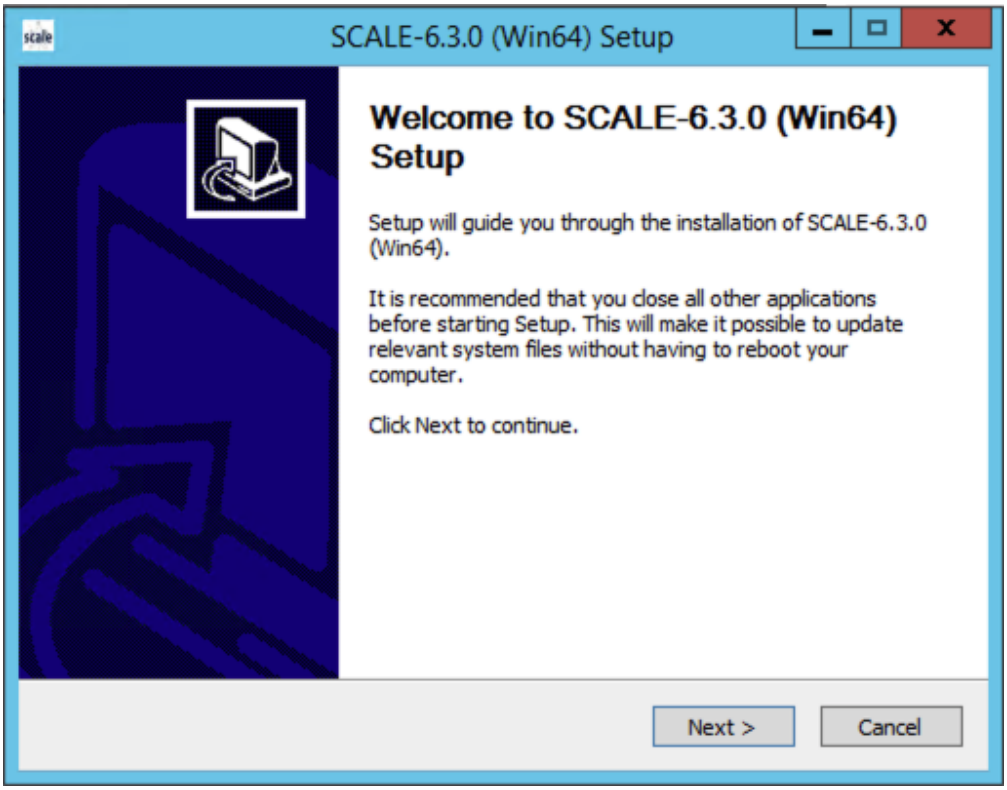

Fig. 12.2.1: Example Windows installation start screen.

Follow the prompts through the install. There are two user decisions. The first is regarding the install location, as shown below. Generally, the "C:SCALE-6.3.0" is sufficient. (Do not install SCALE to the "Program Files" directory, as it has insufficient default privileges.)

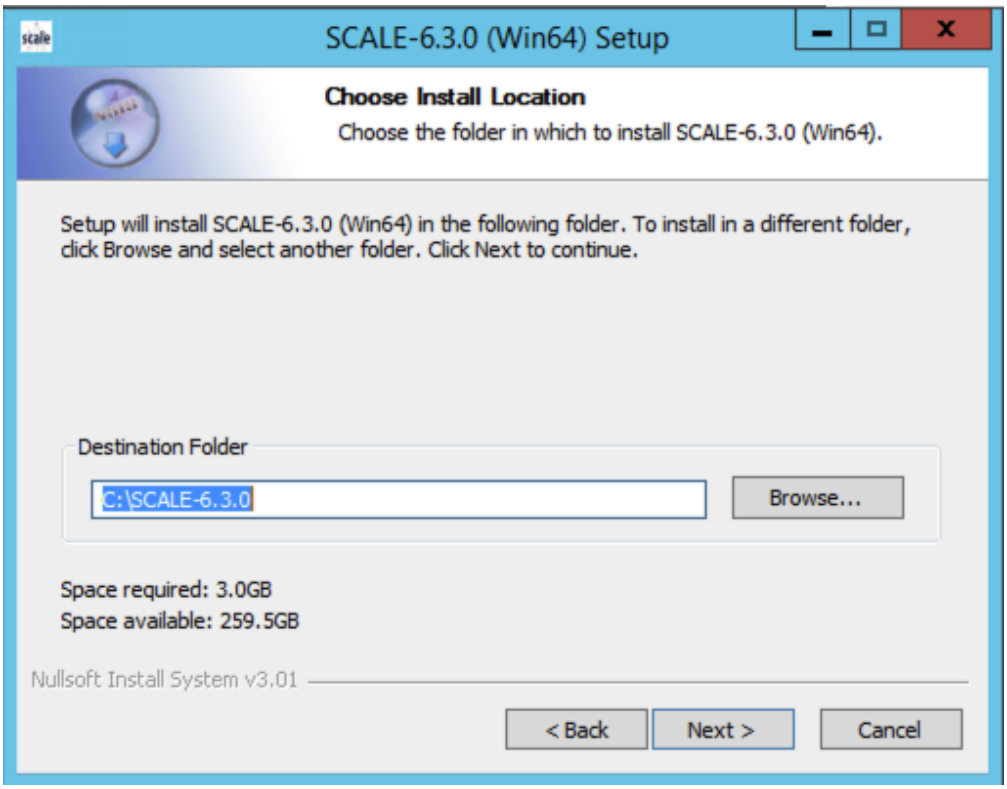

Fig. 12.2.2: Example Windows install location.

The next user decision is to designate the name of the SCALE 6.3.0 application folder within the Windows start menu. The default is “SCALE 6.3.0 (Win64)”; however, changing this name will not affect the installation in any way.

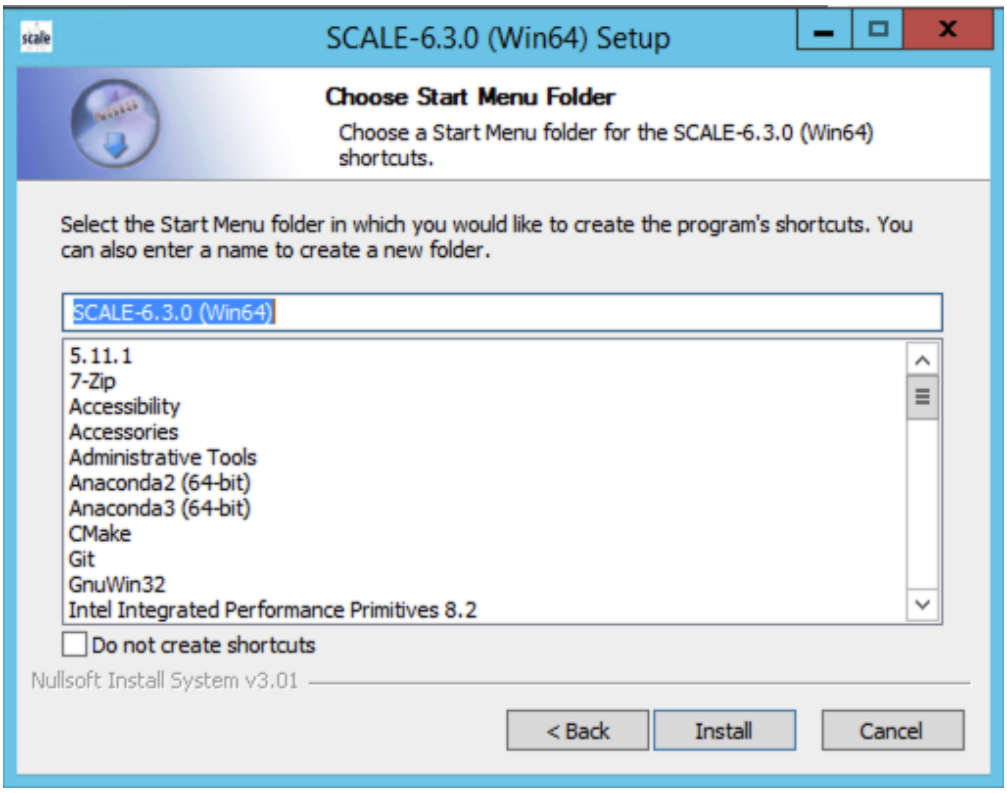

Fig. 12.2.3: Example Windows start menu folder selection.

The installation can take several minutes. Note that Norton Antivirus on Windows requires an exception for the SCALE Runtime Environment program, scalerte.exe. If using Norton Antivirus, please establish this exception prior to testing; otherwise, SCALE 6.3.0 will not be able to execute. Once installation is complete, follow the instructions given below to install SCALE 6.3 Data.

Mac OSX

Double click the Mac OSX installation file “SCALE-6.3.0-setup.dmg”; after a few moments, the following screen will open.

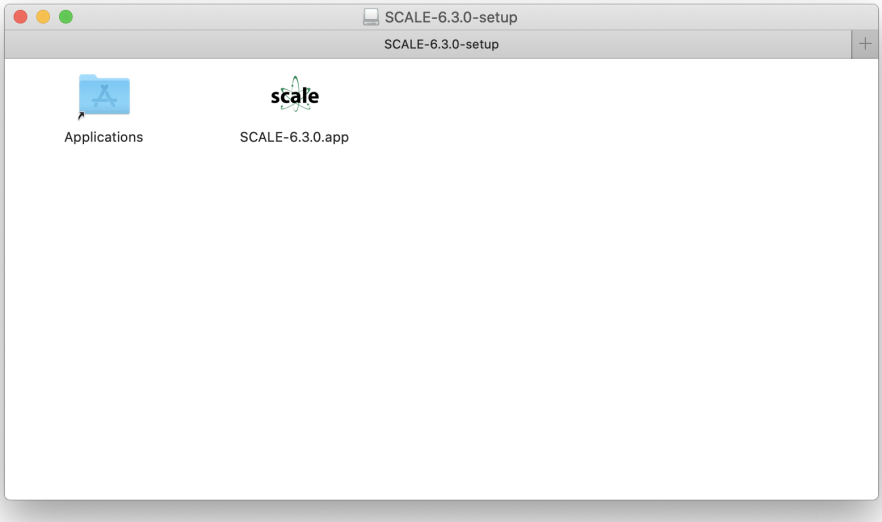

Fig. 12.2.4: Example Mac OS X bundle contents.

Drag the "SCALE-6.3.0.app" icon onto "Applications" to install SCALE-6.3.0. Once installation is complete, follow the instructions given below to install SCALE 6.3 Data.

Linux

Copy the SCALE-6.3.0.tar.gz to the installation directory. Invoke 'tar -xzf SCALE-6.3.0.tar.gz' to create the SCALE-6.3.0 directory.

```
[hts@hts-rhel-pc] ~/codes $ ls *.tar.gz
SCALE-6.3.0.tar.gz
[hts@hts-rhel-pc] ~/codes $ tar xf SCALE-6.3.0.tar.gz
[hts@hts-rhel-pc] ~/codes $ cd SCALE-6.3.0/
[hts@hts-rhel-pc] ~/codes/SCALE-6.3.0 $ ls
Ampx             bin                 cmds  etc                 help    include   lib      Meshview        plugins  regression    samples               uslstats
AmpxRunResources.xml  CentrmOptions.xml  docs  FileNameAliases.txt  images  Javapeno  LICENSE  MoreOptions.xml  python   release-info  ScaleRunResources.xml  vibe
```

Fig. 12.2.5: Example Linux Tar GZip.

Once installation is complete, follow the instructions given below to install SCALE 6.3 Data.

Source Code

If you received the source code version, you can unzip SCALE-6.3.0-Source.zip file to any location on your computer.

For example, on a Windows platform, double click the SCALE-6.3.0-Source.zip file. This will extract the files into the "SCALE-6.3.4-Source" directory.

On Linux and Mac OS X, create a destination directory for the source and copy the SCALE-6.3.0-Source.zip into that directory.

Change to the directory and invoke unzip `SCALE-6.3.0-Source.zip` to deploy the source code.

12.2.1 SCALE 6.3 DATA

Note that if you have SCALE 6.3 data installed from a prior SCALE 6.3 installation, you can copy or link the data into the SCALE 6.3.0 directory. To link preinstalled SCALE 6.3 data, open a command prompt and change the directory to the SCALE 6.3.0 installation directory:

```
(C:\SCALE-6.3.0, /Applications/SCALE-6.3.0/Contents/Resources, etc.).
```

On Windows, the following will link the SCALE 6.3 data into the SCALE 6.3.0 installation. (This may require administrative privileges.)

```
mklink /D data C:\SCALE-6.3\data
```

On OS X, the following will link the SCALE 6.3 data into the SCALE 6.3.0 installation:

```
ln -s /Applications/SCALE-6.3.app/Contents/Resources/data data
```

On Linux, the following will link the SCALE 6.3 data into the SCALE 6.3.0 installation:

```
ln -s /scale/scale6.3/data data
```

To begin installation of SCALE 6.3 data**, copy the scale-6.3-data-setup.jar to your local disk. Double-click this jar file. If the installer does not start**, then bring up a command prompt or terminal window and issue the following command: `java -jar scale-6.3-data-setup.jar` in the location where the installer jar file was copied.

After launching the installer, a dialog should appear as shown below.

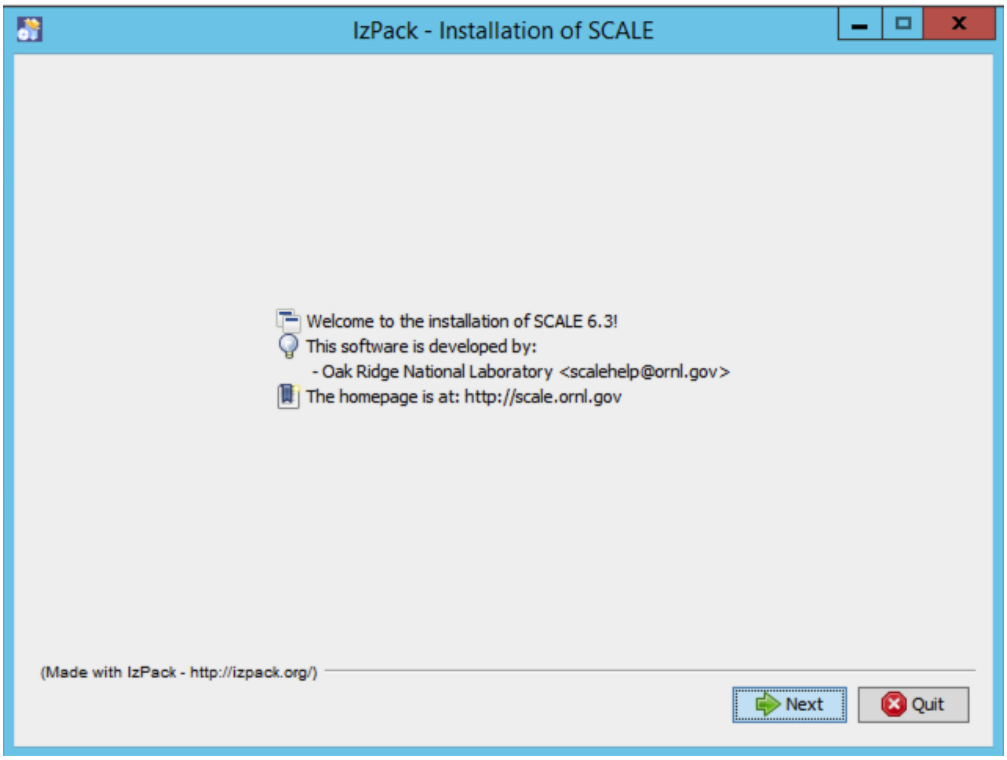

Fig. 12.2.6: SCALE 6.3 data installer welcome dialog.

Continue by pressing *Next*.

You will be prompted to review and accept the terms of the license agreement.

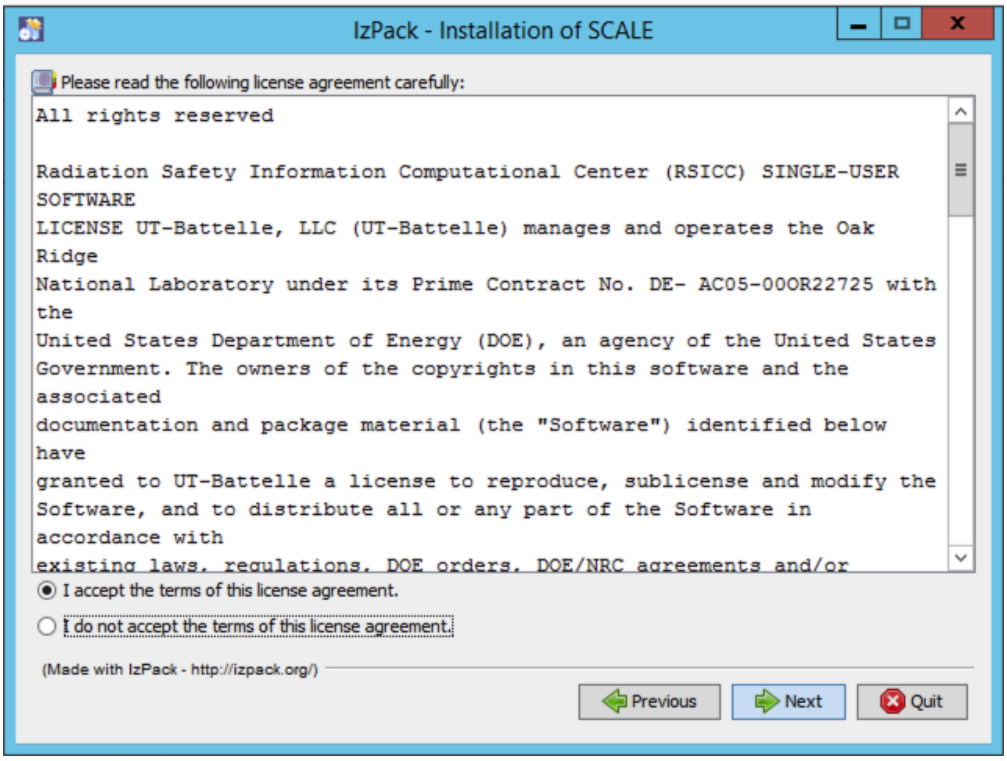

Fig. 12.2.7: SCALE license agreement.

To proceed, check to indicate your acceptance of the terms, and press next. You will be prompted to choose the destination of your installation.

For Windows users, the recommended installation path is inside your SCALE-6.3.0 directory:

```
c:\SCALE-6.3.0
```

For Linux, a typical location is:

```
/scale/scale6.3.0
```

For Mac, a typical location is:

```
/Applications/SCALE-6.3.0.app/Contents/Resources
```

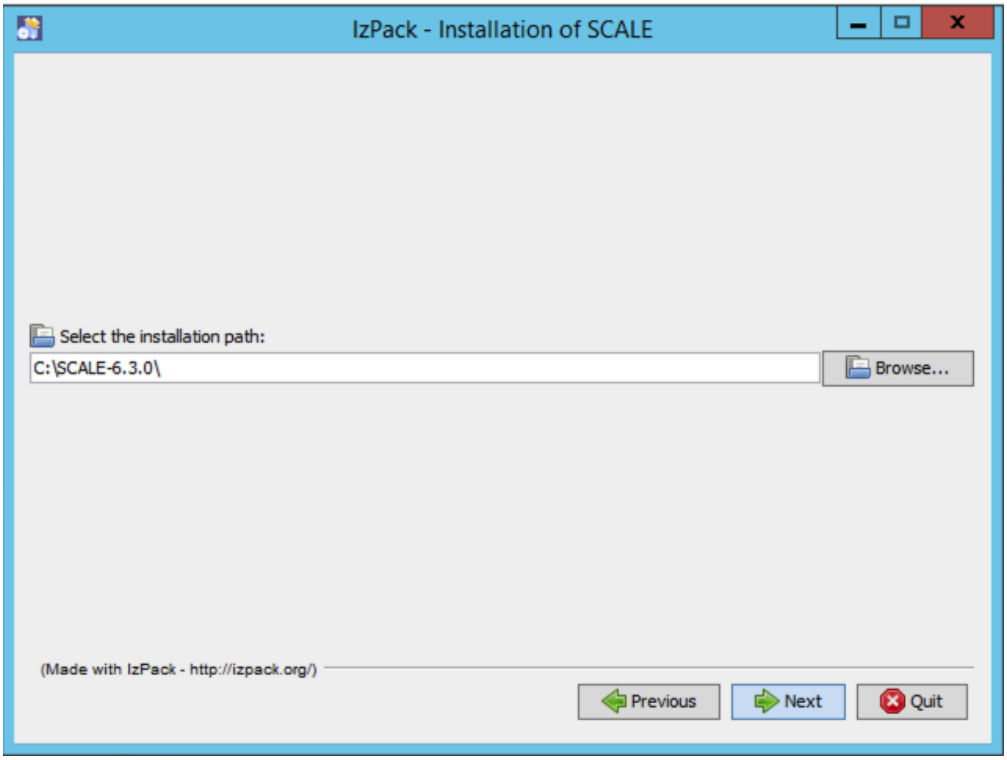

Fig. 12.2.8: Example setting typical data installation path on Windows.

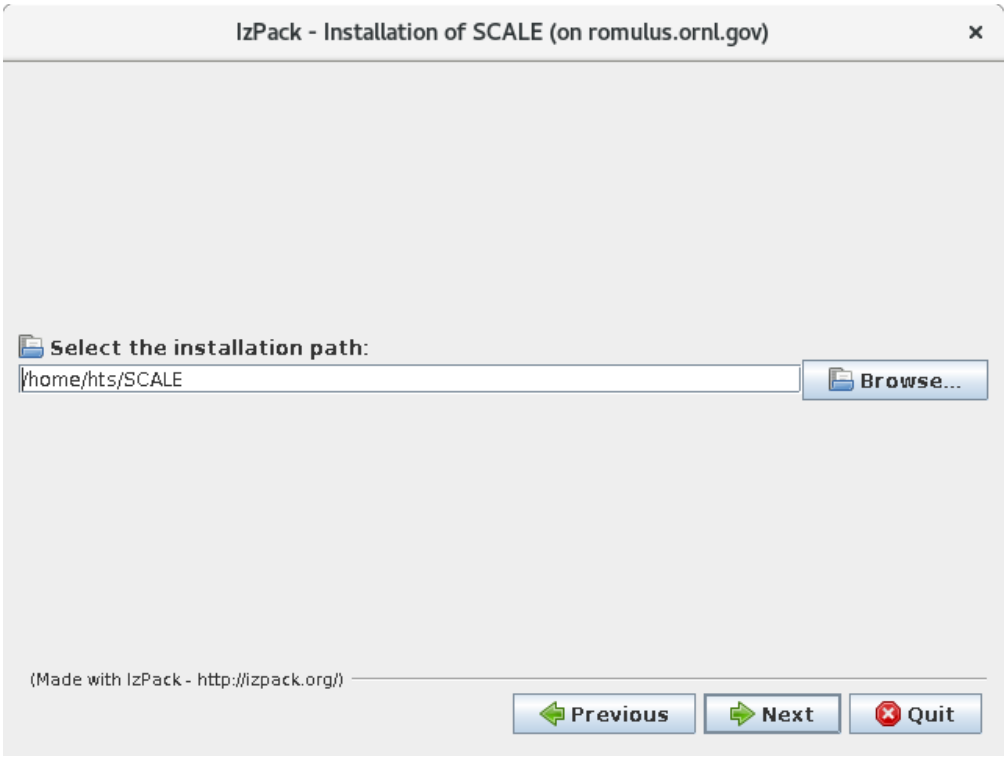

Fig. 12.2.9: Example setting a typical data installation path on Linux.

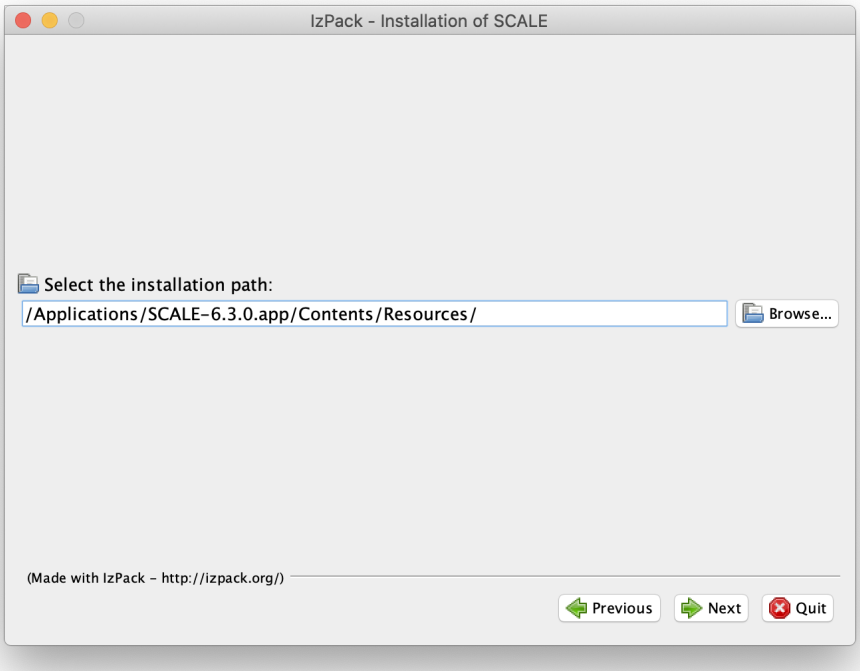

Fig. 12.2.10: Example setting a typical data installation path on Mac OS X.

For some systems, the installer will not be allowed to create a new directory. If you encounter a message like the one shown below, simply create the directory manually (e.g., using Windows Explorer), and then return to the installer and continue.

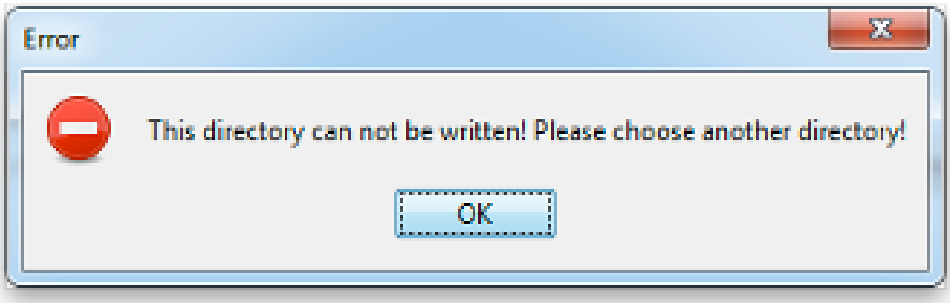

Fig. 12.2.11: Data installer directory creation error message.

In most cases, the installer will present a prompt to confirm the creation of a new directory; if that target directory is correct, then you can simply press *OK*. If the directory was manually created, the installer will notify you that it is about to overwrite any previous contents. Press *Yes* to continue.

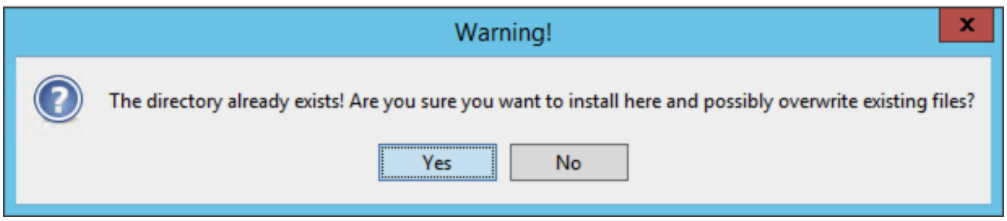

Fig. 12.2.12: Directory overwrite dialog.

The installer then presents a dialog for available data sets you may wish to install.

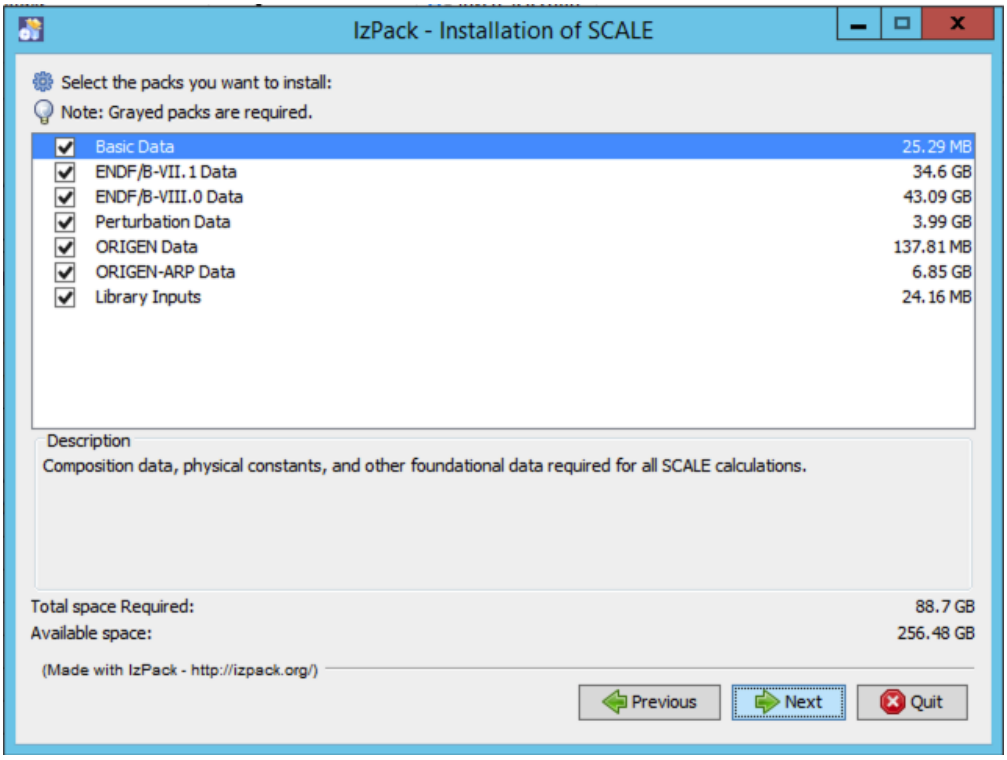

Fig. 12.2.13: Data selection dialog.

Please select the data needed to perform your desired SCALE calculations.

- Basic Data — Composition data, physical constants, and other foundational data required for all SCALE calculations
- ENDF/B-VII.1 Data — Nuclear Data from ENDF/B-VII.1 for CE and MG calculations, coupled n-gamma data from ENDF/B-VII.1 for MG calculations, and ENDF/B-VII.1 neutron covariance data (recommended for most calculations; required to run the SCALE sample problems)
- ENDF/B-VIII.0 Data — Nuclear Data from ENDF/B-VIII.0 for CE and MG calculations
- Perturbation data — 1,000 samples of data each for ENDF/B-VII.1 neutron covariance data, fission product yield covariance data, and radioactive decay covariance data (required for Sampler calculations perturbing nuclear data)

- ORIGEN Data — Activation, depletion and decay data from ENDF/B-VII.1 and JEFF 3.0/A (required for activation, depletion and decay calculations)
- ORIGEN reactor libraries — Pre-generated ORIGEN reactor libraries for many fuel types (required for spent fuel characterization and source terms calculations)

Next, the installer may ask for the location of the data .pak files that are unpacked during the installation process. Please direct the installer to the location of these data files, which are part of the SCALE distribution and may be on the distribution media or copied to a local directory as shown below.

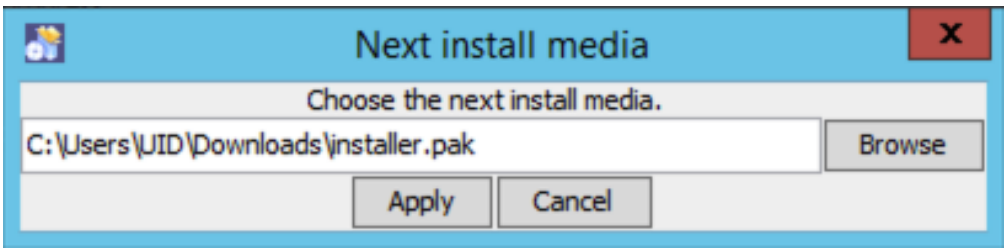

Fig. 12.2.14: Media selection dialog.

The installer will display the progress of the installation. If installing from a DVD set, part way through the installation, you will be prompted for `installer.pak.1`. Please insert the PAK.1 disk and click *Apply*.

The installation from PAK.1 will complete and prompt for `installer.pak.2`. Please insert the PAK.2 disk and click *Apply*.

PAK.2 will finish. Proceed with all DVDs or files in the delivery until you have completed your installation of SCALE 6.3 data.

12.3 RUNNING SCALE

SCALE is run by using the Fulcrum user interface or by invoking the SCALE Runtime Environment, *scalerte*, from the command line. Note that this release does not include the previous interfaces GeeWiz or OrigenArp for running SCALE on Windows, as Fulcrum should be used instead. Additionally, previous shortcuts like *runscale* are not implemented.

12.3.1 RUNNING SCALE FROM FULCRUM

The most convenient way to run SCALE from a desktop is by launching Fulcrum. The Fulcrum executable is provided in the *bin* directory where SCALE was installed (e.g., `C:\SCALE-6.3.0\bin\Fulcrum.exe`). Fulcrum includes an online help document to assist users with its many features, and it includes links to the user manual and primers.

12.3.1.1 Windows

For a Windows installation, launch Fulcrum from either the start menu or the shortcut provided in the *SCALE-6.3.0* folder on the desktop.

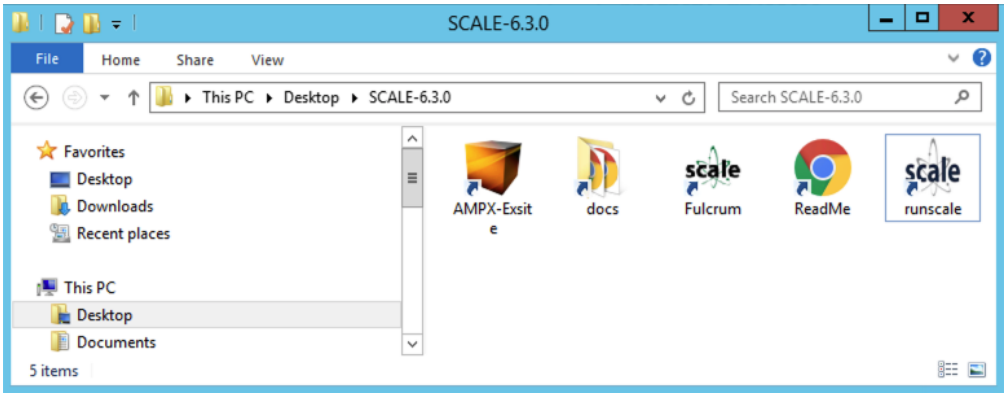

Fig. 12.3.1: Example Windows desktop SCALE shortcuts folder.

12.3.1.2 Linux

For a Linux installation, launch Fulcrum directly from the bin directory of the SCALE installation (e.g., `/scale/scale6.3.0/bin/Fulcrum`).

12.3.1.3 Mac OS X

For a Mac installation, launch Fulcrum by executing the *SCALE-6.3.0* app in the Applications directory.

12.3.2 RUNNING SCALE FROM THE COMMAND LINE

Using the command line, SCALE can be executed using the *scalerte* command from the *bin* directory inside the SCALE installation. Paths for each platform are shown below based on recommended installation directories. Your directory may differ based on the installation.

12.3.2.1 Windows

```
C:\\SCALE-6.3.0\bin\scalerte.exe
```

Note: Note that Norton Antivirus may require an exception for scalerte.exe on Windows to prevent the executable from being quarantined.

12.3.2.2 Linux

```
/scale/scale6.3.0/bin/scalerte
```

12.3.2.3 Mac

```
/Applications/SCALE-6.3.0.app/Contents/Resources/bin/scalerte
```

The SCALE runtime environment provides several command line options. The usage is as follows.

```
scalerte [options] inputfile(s) [options] [inputfile(s)]
```

Where `inputfile(s)` are one or more files or file patterns (`test.inp`, or `test*.inp`, etc.).

Where *options* are:

`-a`: Specify alias file.

```
-a path/to/aliasesfile
```

-f: Add hostname to output filename. Produces inputfile.hostname.out

-h: Print this information as a help message.

-I: Number of threads to use for MPI/OpenMP directives. -I 4

-m: Print information messages as SCALE executes.

-M: Specify a machine names file for SCALE parallel capabilities.

```
-M /path/to/machine/names/file
```

-n: Nice level on Nix systems, ignored on Windows. Default: -n 2

-N: Number of MPI processes to run. -N 20

-o: Overrides the default *inputfile.out* output name. The *.out* extension is appended by scalerte, so there is no need to specify the extension.

```
-o path/to/outputfile
```

Note: If the *path/to/outputfile* already exists, it will be deleted. If this option is specified while in stack mode (multiple input files), the value provided is prepended to the inputfile's basename.

```
scalerte triton* -o myout results in output names myout.triton*.out
```

-z: Add date to the output filenames.

Produces output files in the form of

```
inputfile.yyyy.MM.ddThh.mm.ss.out
inputfile.yyyy.MM.ddThh.mm.ss.msg
inputfile.yyyy.MM.ddThh.mm.ss.etc
```

Where:

- yyyy- is the year of execution.
- MM- is the month of execution.
- dd- is the day of execution.
- hh- is the hour of execution.
- mm- is the minute of execution.
- ss- is the second of execution.

12.3.3 EXAMPLE INVOCATION

For users familiar with previous invocations of the SCALE batch script, this usage is no longer valid. The only valid entry point is scalerte. Scalerte can be executed from anywhere with a fully qualified path such as `C:\SCALE-6.3.0\bin\scalerte` or `/scale/scale6.3.0/bin/scalerte`, for example.

Invoke SCALE on a single input file named *HelloWorld.inp.*

```
scalerte HelloWorld
```

or

```
scalerte HelloWorld.inp
```

Invoke SCALE on all input files patterned *HelloWorld*.inp.*

```
scalerte HelloWorld*.inp
```

Invoke SCALE on all input files patterned *HelloWorld*.inp* and print runtime messages to the console.

```
scalerte HelloWorld*.inp -m
```

Invoke SCALE on all input files patterned *HelloWorld*.inp* and include hostname and date/time in the output file's name.

```
scalerte HelloWorld*.inp -fz
```

or

```
scalerte HelloWorld*.inp -f -z
```

Invoke SCALE on *HelloWorld.inp* and rename output to be *MyHello.out.*

```
scalerte HelloWorld -o MyHello
```

or

```
scalerte HelloWorld.inp -o MyHello
```

Invoke SCALE on all files patterned *HelloWorld*.inp* and rename output to be *MyHelloWorld*.out*.

Note: When SCALE is run in stack mode (multiple inputs), the output override is prepended to the input file's name.

```
scalerte HelloWorld*.inp -o My
```

Invoke SCALE on *HelloWorld.inp* and keep the working directory.

```
scalerte HelloWorld.inp -r
```

Invoke SCALE on *HelloWorld.inp* and override and keep the working directory.

```
scalerte HelloWorld.inp -r -T myHelloWorldTempDir
```

Invoke SCALE on *HelloWorld.inp* and specify the number of threads to be 4.

```
scalerte HelloWorld.inp -I 4
```

12.3.4 SCALE VARIABLES

This section describes the environment variable used within *scalerte*. These variables can be accessed through SCALE's *shell* module to populate the working directory and/or to return SCALE-generated files that were not returned by *scalerte*.

Shell is used to perform system commands inside a problem before, after, or between explicitly called modules. It is usually used in SCALE to link a file from one name and place to another name and place, to delete files or directories, and to move or copy files. The use of shell in an input has the following form:

```
=shell
 *** System Commands ***
end
```

where *System Commands* are any UNIX or DOS command(s). This is particularly useful in tandem with the following environment variables when files not automatically returned are desired. The following example shell command copies the x16 file back alongside the output file.

```
=shell
cp x16 ${OUTBASENAME}.x16
end
```

Please note the syntax of Nix and Windows environment variables, ${VAR} and %VAR% respectively, are interchangeable, as *scalerte* and *shell* understand both.

Below are the seven primary locations known by *scalerte*:

- The user's home directory, HOME

  *Nix systems, ${HOME}, /home/uid

  *Windows, %HOME%, C:Usersuid

- The directory of SCALE, SCALE

  *Nix systems, ${SCALE}, location of user's installation—typically `/scale/scale#`

  *Windows, %SCALE%, location of user's installation—typically C:SCALE#

- The directory of the input file, INPDIR

  *Nix systems, ${INPDIR}

  *Windows, %INPDIR%

- The directory of the output file, OUTDIR, which by default is the same as INPDIR, because the output file is written next to the input file

  *Nix systems, ${OUTDIR}

  *Windows, %OUTDIR%

- The directory from which SCALE was invoked, the return directory, RTNDIR, which is the directory your console will return to upon completion

  *Nix systems, ${RTNDIR}

  *Windows, %RTNDIR%

- The directory that contains the SCALE data, DATA

  *Nix systems, ${DATA}

  *Windows, %DATA%

- The working directory for a given input file, TMPDIR, or shorthand TMP

  *Nix systems, ${TMPDIR}, ${TMP}

  *Windows, %TMPDIR%, %TMP%

There are several secondary locations in the SCALE directory tree. These are as follows:

- The directory containing the platform-specific compiled programs, PGMDIR, or legacy PGM_DIR:

  *Nix systems, ${PGMDIR}, ${PGM_DIR}

  *Windows, %PGMDIR%, %PGM_DIR%

Lastly, there are several environment variables provided for convenience and/or that are associated with output data that can be useful.

- The directory containing the ORIGEN data files, ORIGENDIR

  *Nix systems, ${ORIGENDIR}

  *Windows, %ORIGENDIR%

- The base name of the input file, BASENAME, which is the name of the input file without both absolute path and extension

  *Nix systems, ${BASENAME}, or ${CASE_NAME}

  *Windows, %BASENAME%, or %CASE_NAME%

- The base name of the output file, OUTBASENAME, or legacy CASE_NAME, which is the name of the output file without both absolute path and extension

  *Nix systems, ${OUTBASENAME}, or ${CASE_NAME}

  *Windows, %OUTBASENAME%, or %CASE_NAME%

- The base name of the output file, OUTBASE, which is the absolute name of the output file without file extension

  *Nix systems, ${OUTBASE}

  *Windows, %OUTBASE%

- The absolute path to the input file, INPUTFILE

  *Nix systems, ${INPUTFILE}

  *Windows, %INPUTFILE%.

- The absolute path to the output file, OUTFILE.

  *Nix systems, ${OUTFILE}

  *Windows, %OUTFILE%

- The directory containing USLSTATS output, USLDIR (If USLSTATS data were output, then these data would be located in OUTDIROUTBASENAME.uslstats directory.)

  *Nix systems, ${USLDIR}

  *Windows, %USLDIR%

- The directory containing CENTRM output, CENTRMDIR (If CENTRM data were output, then these data would be located in OUTDIROUTBASENAME.centrmfiles directory.)

  *Nix systems, $CENTRMDIR

  *Windows, %CENTRMDIR%

- The directory containing XSDRNPM output, XSDRNDIR (If XSDRNPM data were output, then these data would be located in OUTDIROUTBASENAME.xsdrnfiles directory.)

  *Nix systems, $XSDRNDIR

  *Windows, %XSDRNDIR%

- The platform-specific file separator, FS, which is either backslash () on Windows, or forward slash (/) on Nix systems

  *Nix systems, ${FS}

  *Windows, %FS%

12.3.5 PARALLEL EXECUTION CAPABILITY

SCALE 6.3 contains four modules and sequences that have distributed memory (MPI) parallelism: KENO V.a, KENO-VI, Sampler, and ORIGAMI. However, the binary executable files distributed with SCALE do not have MPI enabled. To run one of these codes in parallel, the user must first build SCALE with MPI enabled (see build instructions in this guide). Control modules like CSAS6, T6-DEPL, and TSUNAMI-3D-K6 automatically initiate the parallel version of KENO–VI in a parallel SCALE build if the user provides the required arguments as summarized below. When running a standalone code in parallel (such as KENO-VI), a "%" prefix is required on the sequence specification record in the input file (e.g., =%keno-vi). Parallel code execution is available on Linux and Mac systems but is not available on Windows PCs.

The executable binary code distributed with SCALE only enables serial calculations. If MPI parallelism is desired, then the source code must be compiled with MPI support enabled for the platform and configuration where the code will be executed in parallel. The SCALE build configuration sets some variables (*SCALEMPI*, *SCALECMDS*, and *MPIRUN*), depending on the third-party MPI package for the SCALE driver, which prepares two different execution environments with these variable sets for both serial and parallel code execution.

Executing SCALE in parallel is initiated by *scalerte* when the user provides the necessary MPI command line arguments with the two options, *–N* and *–M*, which specify the number of MPI processes and machine names, respectively. To run an input called `HelloWorld.inp` from an MPI build on SCALE on two nodes specified in the machine file *mach*, use the following command:

```
scalerte -N 2 -M mach HelloWorld.inp
```

With these options, *scalerte* sets *NTASKS* and *MACHINEFILE* variables, depending on the user request, and passes them to the SCALE driver. During the parallel code execution process, the driver invokes the MPIRUN wrapper to run the parallel functional module across MPI processes. An environment variable *MPIARGS* is available for the driver to pass some user-defined MPI options to MPIRUN wrapper.

12.4 SCALE SAMPLE PROBLEMS

The SCALE sample problems are designed by the SCALE developers to verify the installation and functionality of SCALE relative to the expected results. Users are urged to run the sample problems to verify the proper installation of SCALE. ORNL has provided a set of reference results from each sample problem against which the results of each installation can be compared.

The sample problems are most easily run through Fulcrum by selecting *Run SCALE Verification* from the *Run* menu on the main menu bar. This will run all of the sample problems sequentially and will present any differences from the ORNL-generated results.

The SCALE runtime environment, *scalerte*, which is described in the subsequent section, has a built-in scripting interface to allow for invocation of several groupings of sample problems, including individual problems, problems for a specific module, subsets of modules, or all samples. The sample problems will print a message indicating the sample problem currently running, followed by the differences between ORNL-generated results and the newly generated results for the sample problem(s). Note that there may be up to an hour's delay before messages are printed to the console. The final message will indicate that the "Process finished with a 0 return code . . . ." If no differences or minimal differences are noted for a particular sample problem, then SCALE has been properly installed for the tested functionality.

The set of sample problems is located in the samples directory of the SCALE installation.

To run all sample problems, execute the following command:

```
scalerte @samples/samples
```

To invoke sample problems for a particular module or sequence, use

```
scalerte @samples/samples modulename
```

where `modulename` is the name of the module or sequence to test, e.g., *centrm*.

To invoke a single sample problem, do the following.

```
scalerte @samples/samples problemname
```

where `problemname` is the name of the specific sample problem to test, e.g., `centrm-pwr.inp`.

The above *modulename* and *problemname* examples can be combined and repeated to exercise sets of sample problems of interest. For example, run *csas* and *origen* sequence sample problems in addition to the *centrm-pwr.inp* sample.

```
scalerte @samples/samples csas centrm-pwr.inp origen
```

As the sample problems execute, feedback will be provided to the screen such as that shown in the example below. If no differences or only small differences are reported between the ORNL results and the currently generated results for each sample, then SCALE has been properly installed and configured for the tested functionality.

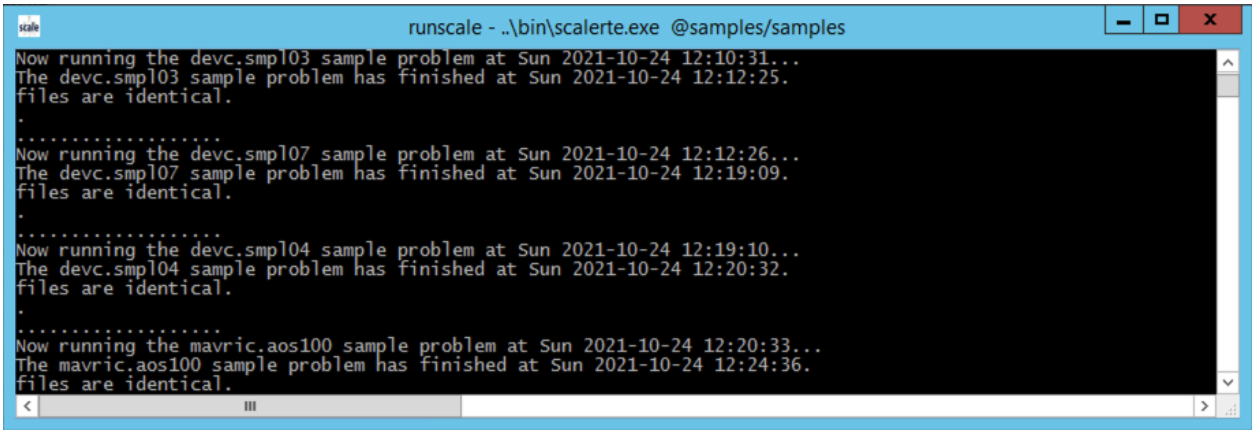

Fig. 12.4.1: Sample problem output messages.

For any problems or questions, please contact scalehelp@ornl.gov.

12.5 BUILD INSTRUCTIONS

These instructions are only for those who wish to recompile their SCALE binaries. If you are running SCALE using the precompiled binary executable files distributed with SCALE, then please disregard this section.

For SCALE 6.3 and subsequent updates, the build configuration has been completely renewed relative to all previous versions. The SCALE build is now based on CMake from KitWare, which supports a consistent experience on Linux, Mac, and Windows.

12.5.1 OVERVIEW

There are four main steps to create and install SCALE binaries

1. Install compilers and third-party libraries (TPLs).
2. Configure CMake to generate a native build tree.
3. Compile all executables and libraries.
4. Install to deploy all executables into a configuration ready for execution.

12.5.2 REQUIRED RESOURCES

SCALE requires the following programs in order to compile:

1. Fortran Compiler
    i. Windows – Intel Fortran compiler 15.0
    ii. Linux - Intel Fortran compiler 14.1+/GNU gfortran 4.8.3+ compiler
    iii. Mac OS – GNU gfortran 4.8.5+ compiler
2. C/C++ Compiler
    i. Windows – Intel C/C++ compiler 15.0.=
    ii. Linux – Intel C/C++ compiler 14.1+ / GNU g++/gcc 4.8.3+ compiler
    iii. Mac OS – GNU g++/gcc 4.8.5+ compiler

3. CMake 3.13+ - Platform independent build configuration for Linux, Darwin, and Windows

SCALE requires the following libraries, which are not distributed with SCALE:

LAPACK libraries:module

a. lapack

b. blas

You must modify the LAPACK variable in configure_scale_gnu.sh to point to your installation of LAPACK prior to configuration.

The following optional package is required by SCALE if MPI support is desired:

> OpenMPI-1.8.1+ - Optional for SCALE build with MPI support on Linux and Mac OS (currently, SCALE does not support MPI for Windows)

12.5.3 MAC OSX RESOURCES

Mac OSX does not come preloaded with the necessary resources for compiling SCALE. Macports provides a simple mechanism for retrieving almost all of the required resources necessary to compile SCALE on a Mac. This process has only been tested on Mac OSX 10.11.6.

You can download the latest macports from http://www.macports.org/. You will need XCode (free from the App Store) with commandline tools installed for macports to work.

Important: You will need administrative privileges to install macports and the necessary resources.

Please see macports instructions for xcode installation/requirements. http://guide.macports.org/#installing.xcode

After installing these resources, a new shell session is necessary to access the new tools.

..note:: If your rsync port is blocked by the firewall (as is the case at ORNL), you may synchronize over http by updating your */opt/local/etc/macports/sources.conf* file to change the line:

```
rsync://rsync.macports.org/release/tarballs/ports.tar [default]
```

to

```
http://www.macports.org/files/ports.tar.gz [default]
```

The following commands will install all necessary resources.

If the rsync port is blocked, use

```
$> sudo port -d sync
```

If the rsync port is open, use

```
$>sudo port selfupdate
```

Regardless of rsync status, execute the following commands:

```
$>sudo port install gcc48
$>sudo port select gcc mp-gcc48
$>sudo port install qt4-mac
```

These commands upgrade the default compilers from gcc 4.2.2 to gcc 4.8.3, and they install qt4.8.6.

12.6 CMAKE CONFIGURATION

CMakeLists.txt files can be found throughout SCALE. From the SCALE root directory, these CMakeLists.txt files create a tree of included directories called the SOURCE TREE. Namely, the source directories are

```
packages/AmpxLib

XSProc

ScaleLib

etc.
```

To configure a build, call cmake on the root CMakeLists.txt file, namely `scale_dir/CMakeLists.txt`. CMake takes your source tree and creates a BUILD TREE. The build tree contains or will contain the build configuration, the Make or NMake files, and all compilation output: object files, archive libraries, and binary executables.

SCALE requires several TPLs, specifically, QT and Lapack. These TPLs must be specified at the time of configuration. For ease of use, configuration scripts for every supported platform are available in the scripts directory of the source code. These scripts describe the necessary variables to define. A user's modifications to these scripts should be limited to the path to the root directories for the TPLs.

12.6.1 RECOMMENDED CONFIGURATION PROCEDURE

After unpacking the source code, navigate to the root scale directory (<SCALE_SRC_ROOT>. You will see CMakeLists.txt, PackagesList.cmake, and CTestConfig.cmake. This is the root of the source tree, to which you will point CMake. This example demonstrates creating build trees for multiple configurations for your working copy.

12.7 LINUX AND MAC CONFIGURATION

- **Make Build Directory**

```
mkdir build

mkdir -p build/intel \**this could be any directory

or

mkdir -p build/gcc
```

- **CMake Initialization**

  Copy the cmake script from the scripts directory to your build directory. Update the cmake script with your TPL specifications.

  - Serial SCALE (without MPI support)

```
cp <SCALE_SRC_ROOT>/script/configure_scale_gnu.sh
build/gcc

chmod u+x build/gcc/configure_scale_gnu.sh
```

- Parallel SCALE (with MPI support)

```
cp script/configure_scale_mpi.sh build/gcc

chmod u+x build/gcc/configure_scale_mpi.sh
```

- **Create Your Configuration**

  Create your configuration by pointing this script at the source tree root

```
cd build/gcc
```

  Edit the CMakelists.txt file in <SCALE_SRC_ROOT>/Trilinos/packages/anasazi/src/ so as to comment out the following lines:

```
ASSERT_DEFINED(Anasazi_ENABLE_ThyraEpetraAdapters)

ASSERT_DEFINED(Anasazi_ENABLE_ThyraCore)

ASSERT_DEFINED(Anasazi_ENABLE_Tpetra)
```

  – Serial SCALE (without MPI support)

```
./configure_scale_gnu.sh ../..
```

  – Parallel SCALE (with MPI support)

```
./configure_scale_mpi.sh ../..
```

/* **Configuration Output….** */

**If you add or remove source files from the source tree, CMake will NOT see these modifications unless a CMake file is modified (CMakeLists.txt,PackagesList.cmake,etc…).

CMake will re-evaluate the entire source tree when any CMake file has been modified. If CMake does not pick up the addition/removal of sources files, then the easiest way to update the build tree is to "touch" any CMake file in the source tree.

12.7.1 WINDOWS CONFIGURATION

Instructions are not documented here. Please contact scalehelp@ornl.gov for assistance.

12.7.2 COMPILATION

Every library and executable is a TARGET. Calling make on Linux and Mac and nmake on Windows from the root of your build tree (<SCALE_SRC_ROOT>/build/gcc from the previous example) will build ALL targets. There are two options when building specific targets. For example, MavricUtilities contains a number of executables: mtadder, mtaverager, and so on.

You may invoke make mtadder to build mtadder alone. Alternatively, you can build it from build/gcc, cd packages/MavricUtilities and make to compile ALL targets in mavricUtilities.

12.7.3 COMPILATION FLAGS

You may modify `CMAKE_Fortran_FLAGS`, `CMAKE_C_FLAGS`, and `CMAKE_CXX_FLAGS` on the cmake command invocation line.

12.7.4 INSTALLATION

CMake provides the install target, which installs all binaries from the current directory down. For example, `make install'` from `build/gcc` will install any targets, which would install aim, mavric, mtadder, mtaverager, etc., while `cd packages/Mavric` and `make install` will only install targets declared in the Mavric directory.

***Note that `make install` re-evaluates the build for all dependencies. For example, package A depends on packages B and D. Package D depends on package E. Therefore, `make install` for package A would result in packages E, D, and B being re-evaluated and rebuilt if necessary. Thus, if you know you want to build and install, you can save time building by simply doing a `make install`. An alternative is `make install/fast`, which will skip. . . ..
