$$\left[A - \lambda B\right] \left(\frac{d\phi}{d\alpha}\, \delta\alpha \right) \;=\; -\left[\left(\frac{\partial A}{\partial \alpha} - \lambda \frac{\partial B}{\partial \alpha} \right) \delta\alpha \right] \phi \;+\; \delta\lambda\; B\phi \,. \tag{6.6.51}$$

An equation called the generalized adjoint equation is introduced as follows

$$\left[A^{\dagger} - \lambda B^{\dagger}\right]\, \Gamma^{*} \;=\; \frac{1}{R}\, \frac{\partial R}{\partial \phi} \;=\; Q^{*} \,, \tag{6.6.52}$$

where Γ^{*} is known as the generalized adjoint, or generalized importance, function. The adjoint source term in Eq. (6.6.52) is equal to the functional derivative of the response ratio with respect to the neutron flux, which corresponds to

$$\frac{1}{R}\frac{\partial R}{\partial \phi} = \frac{H_N}{\langle H_N \phi\rangle} - \frac{H_D}{\langle H_D \phi\rangle} \tag{6.6.53}$$

Taking the inner product of Γ^* with Eq. (6.6.51), and the inner product of $\left(\frac{d\phi}{d\alpha}\delta\alpha\right)$ with eq:*eq6-3-53*, and then applying the property of adjoint operators and rearranging, gives:

$$\left\{\left\langle \left(\frac{\partial R}{\partial \phi}\frac{d\phi}{d\alpha}\right)\ \delta\alpha\right\rangle = -\left\langle \Gamma^*\ \left(\frac{\partial A}{\partial \alpha} - \lambda\frac{\partial B}{\partial \alpha}\right)\ \phi\ \delta\alpha\right\rangle\ +\ \delta\lambda\,\langle\Gamma^* B\phi\rangle\ . \tag{6.6.54}$$

The left side of Eq. (6.6.54) is identical to the indirect component defined in Eq. (6.6.49). As shown in the next section, the generalized adjoint function is calculated such that the term $\langle\Gamma^* B\phi\rangle$ is equal to zero; thus

$$\delta R^{(\text{indirect})} = -\left\langle \Gamma^*\left(\frac{\partial A}{\partial \alpha} - \lambda\frac{\partial B}{\partial \alpha}\right)\phi\delta\alpha\right\rangle. \tag{6.6.55}$$

Combining Eq. (6.6.50) and Eq. (6.6.55) gives the response perturbation due to both direct and indirect components:

$$\delta R \equiv \left\{\frac{R}{\langle H_N\phi\rangle}\left\langle\frac{\partial H_N}{\partial\alpha}\delta\alpha\right\rangle - \frac{R}{\langle H_D\phi\rangle}\left\langle\frac{\partial H_D}{\partial\alpha}\delta\alpha\right\rangle\right\} - \left\langle\Gamma^*\left(\frac{\partial A}{\partial\alpha} - \lambda\frac{\partial B}{\partial\alpha}\right)\phi\delta\alpha\right\rangle \tag{6.6.56}$$

Calculation of the Generalized Adjoint Function

The forward flux ϕ and adjoint function $\phi^*$are fundamental eigenfunctions of the homogeneous equations in Eq. (6.6.1) and Eq. (6.6.3), respectively. In contrast, the generalized adjoint function Γ^* obeys an inhomogeneous equation. Furthermore, the operator $\left(A^\dagger - \lambda B^\dagger\right)$ in Eq. (6.6.52) is singular, since by definition λ is an eigenvalue. Taking the inner production of ϕ with Eq. (6.6.52) and applying the property of adjoint operators gives

$$\langle\phi Q^*\rangle = \left\langle\phi\frac{1}{R}\frac{\partial R}{\partial\phi}\right\rangle = 0. \tag{6.6.57}$$

The above relation is necessary for the singular inhomogeneous equation to have a solution; i.e., the adjoint source must be orthogonal to the forward flux. It is easily shown that the terms in Eq. (6.6.53) satisfy this condition. However a solution to Eq. (6.6.52) is not unique—the general solution for Γ^* is the sum of a particular and a homogeneous solution. If Γ^*_{p} is any particular solution, then the function $\left(\Gamma^*_{\text{p}} + a\,\phi^\dagger\right)$ is also a solution, where "a" is any constant. This can be proved by direct substitution into Eq. (6.6.52). For GPT calculations it is convenient to define an auxiliary condition that "normalizes" the generalized fission source $B^\dagger\,\Gamma^*$ to contain no fundamental mode; i.e.,

$$\left\langle\phi B^\dagger\,\Gamma^*\right\rangle = \langle\Gamma^* B\phi\,\rangle\ \ =\ \ 0\,. \tag{6.6.58}$$

The above relation is satisfied by defining the constant to be $\text{a}\ =\ \frac{\left\langle\phi\ B^\dagger\,\Gamma^*_{\text{p}}\right\rangle}{\left\langle\phi\ B^\dagger\,\phi^\dagger\right\rangle}$, so that:

$$\Gamma^* \rightarrow\ \ \Gamma^*_{\text{p}}\ -\ \ \frac{\left\langle\phi\,B^\dagger\,\Gamma^*_{\text{p}}\right\rangle}{\langle\phi B^\dagger\,\phi^\dagger\,\rangle}\ \phi^\dagger\,. \tag{6.6.59}$$

The normalization in Eq. (6.6.58) is done for two reasons. First, the 2nd term on the right side of Eq. (6.6.54) vanishes, so that the indirect effect is stationary with respect to eigenvalue perturbations introduced by $\delta\alpha$. The second reason is due to numerical difficulties in converging the generalized fission source. During outer iterations the fundamental mode component multiplies like a resonance frequency compared to other harmonics. This can lead to loss of numerical significance in the general solution. Theoretically, if the initial outer iteration has no fundamental mode in $B^\dagger\,\Gamma^*$, then subsequent outer iterations also will not. However in practice numerical approximations and incomplete convergence of inner iterations tend to re-introduce the fundamental mode. Therefore the operation in Eq. (6.6.59) is applied after each outer iteration to remove fundamental mode "contamination."

Analogous to the eigenvalue sensitivities, the response sensitivity coefficient at phase space coordinate $\vec{\xi}$ is defined as the relative change in R due to a relative change in $\alpha(\vec{\xi})$:

$$S_{R,\alpha}(\vec{\xi}) \equiv \frac{\delta R/R}{\delta\alpha/\alpha}, \tag{6.6.60}$$

The total response perturbation is obtained by summing over the response perturbations due to arbitrary α-variations throughout phase space

$$\frac{\delta R}{R} \cong \left\langle S_{R,\alpha}(\vec{\xi})\frac{\delta\alpha}{\alpha}(\vec{\xi})\right\rangle \tag{6.6.61}$$

Comparing Eq. (6.6.46) and Eq. (6.6.56) shows that the sensitivity coefficient is equal to

$$\begin{aligned} &S_{R,\alpha}(\vec{\xi}) = \\ &\underbrace{\left\{\frac{1}{\langle H_N\,\phi\rangle}\frac{\partial H_N}{\partial\alpha} - \frac{1}{\langle H_D\,\phi\rangle}\frac{\partial H_D}{\partial\alpha}\right\}}_{S^{(direct)}} - \underbrace{\frac{1}{R}\;\Gamma^*\left(\frac{\partial A}{\partial\alpha} - \lambda\frac{\partial B}{\partial\alpha}\right)\phi}_{S^{(indirect)}}. \end{aligned} \tag{6.6.62}$$

As in the case for eigenvalue sensitivity theory, the response perturbations introduced by $\delta\alpha$ may include explicit as well as implicit effects caused by changes in self-shielded cross sections $\tilde{\alpha}$ that are impacted by the value of parameter α. This can be treated by extending the partial derivative operator with respect to α to be a total derivative, so that

$$\frac{\partial}{\partial\alpha} \;\rightarrow\; \frac{d}{d\alpha} \;=\; \frac{\partial}{\partial\alpha} + \sum_{\tilde{\alpha}}\left(\frac{\partial\tilde{\alpha}}{\partial\alpha}\right)\frac{\partial}{\partial\tilde{\alpha}}. \tag{6.6.63}$$

When the above substitution is made into Eq. (6.6.62), the complete sensitivity coefficient is obtained

$$\begin{aligned} S^{(\text{complete})}_{R,\alpha} = &\left\{\frac{1}{\langle H_N\phi\rangle}\frac{\partial H_N}{\partial\alpha} - \frac{1}{\langle H_D\phi\rangle}\frac{\partial H_D}{\partial\alpha}\right\} + \left\{\sum_\alpha\left(\frac{1}{\langle H_N\phi\rangle}\frac{\partial H_N}{\partial\alpha} - \frac{1}{\langle H_D\phi\rangle}\frac{\partial H_D}{\partial\alpha}\right)\left(\frac{\partial\alpha}{\partial\alpha}\right)\right\} \\ &+ \left\{\frac{1}{R}\Gamma^*\left(\frac{\partial A}{\partial\alpha} - \lambda\frac{\partial B}{\partial\alpha}\right)\phi\right\} + \left\{\sum_\alpha\left(\left\{\frac{1}{R}\Gamma^*\left(\frac{\partial A}{\partial\alpha} - \lambda\frac{\partial B}{\partial\alpha}\right)\phi\right\}\right)\left(\frac{\partial\alpha}{\partial\alpha}\right)\right\} \end{aligned} \tag{6.6.64}$$

It can be seen that for GPT there are four distinct contributions to the complete sensitivity coefficient:

$$S^{(\text{complete})}_{R,\alpha} = S^{(\text{direct})}_{\text{explicit}} + S^{(\text{direct})}_{\text{implicit}} + S^{(\text{indirect})}_{\text{explicit}} + S^{(\text{indirect})}_{\text{implicit}} \tag{6.6.65}$$

The SAMS code evaluates sensitivity coefficients for GPT as well as eigenvalue perturbation theory. Direct sensitivity coefficients for GPT are easily determined since they depend only on the response functions and do not require an adjoint calculation. On the other hand, the expressions for indirect explicit sensitivities are very similar to those presented in Sect. 6.6.2.1 for eigenvalue responses. The detailed expressions in Eq. (6.6.10) through Eq. (6.6.23) for eigenvalue sensitivity coefficients with respect to each type of nuclear data are also valid for general responses, by replacing the fundamental mode adjoint function $\phi^\dagger$ with the generalized adjoint Γ^*, and setting the value of the denominator D equal to the response R. The treatment of implicit effects described in Section Sect. 6.6.2.2 for eigenvalue responses is also the same for general responses.

6.6.3 SAMS INPUT DESCRIPTION

The input to SAMS consists of a SCALE Analytical Sequence Specification Record, a single block of data that contains keyword input that controls the code execution, and a SCALE input termination END record. Very little input is required to obtain sensitivity and uncertainty results, given the availability of appropriate data files, as the default values are suitable for a basic analysis. The input data for SAMS are entered using the SCALE free-form reading routines. The input is not case sensitive, so either upper- or lowercase letters may be used. A maximum of 252 columns per line may be used for input.

6.6.3.1 Analytical sequence specification record

The analytical sequence specification begins in column 1 of the first line of the input file and must contain the following line.

=SAMS5 (for XSDRN or KENO V.a calculations)

=SAMS6 (for KENO-VI calculations)

This signals the SCALE driver to execute the appropriate SAMS functional module. Input data following the Analytical Sequence Specification Record and preceding the END record are passed to SAMS as input.

6.6.3.2 SAMS input data

SAMS input data consists of a single SCALE input data block, the INITIAL block. The input must begin with the keywords **READ INITIAL** and end with the keywords **END INITIAL**. The keyword entries summarized in Table 6.6.2 and Table 6.6.3 are allowed between the **READ INITIAL** and **END INITIAL** keywords. Keywords ending with '=' must be followed by the value to be assigned to the corresponding variable. Default values listed in Table 6.6.2 and Table 6.6.3 may be set or altered if SAMS is executed as part of a sequence, such as TSUNAMI-3D-K5 or TSUNAMI-3D-K6; in these cases, the sequence manual for that sequence should also be consulted for default variable values.

Table 6.6.2: SAMS input keywords

Keyword	Default value	Description
binsen	F	Produces SENPRO formatted binary sensitivity data file on unit 40
coverx=	56group-cov7.1	Name of covariance data file to use for uncertainty analysis
kenova	Kenova	Indicates whether KENO V.a or KENO-VI data files are present on logical unit number kunit and kunita
kenovi	kenova	Indicates whether KENO V.a or KENO-VI data files are present on logical unit number kunit and kunita
kunit=	35	Logical unit number of the binary data file from the forward calculation
kunita=	36	Logical unit number of the binary data file from the adjoint case
largeimp=	100.0	Value for the absolute value of implicit sensitivities, which if exceeded, will be reset to 0.0 and print a warning message.
makeimp	F	Flag to cause implicit sensitivity coefficients to be generated.
newt	Kenova	Indicates that NEWT data files are present on logical unit number kunit and kunita

continues on next page

Table 6.6.2 – continued from previous page

nocovar	T	Flag to cause uncertainty edit to be turned off (sets print_covar to F)
nohtml	F	Flag to cause HTML output to not be produced.
nomix	F	Flag to cause the sensitivities by mixture to be turned off
pmeshvol	F	Flag to print mesh volumes
pn=	3	Legendre order for moment calculations
pltp	F	Flag to cause a Javapeño 3D file containing $\phi\phi^*$ matrices to be written inside the .htmd directory of the output.
prtgeom	F	Flag to cause the sensitivities to be output for each geometry region
prtimp	F	Prints explicit sensitivities coefficients, implicit sensitivity coefficients and complete sensitivity coefficients
prtp	F	Flag to cause $\phi\phi^*$ matrices to be written to the output file.
prtvols	F	Flag to cause the volumes of the regions to be printed by SAMS
useang	F	Flag to cause the angular flux calculated in KENO to be used to calculate flux moments for sensitivity calculations. If angular fluxes were not computed by KENO, *useang* is set to false internally.
usemom	T	Flag to cause the flux moments calculated with KENO to be used to in sensitivity coefficient generation. If flux moments were not computed by KENO, *usemom* is set to false internally.
xsdrn	kenova	Indicates that XSDRN data files are present on kunit and kunita logical unit numbers
xunit=	4	Logical unit number of the AMPX working formatted cross-section library
xunitm=	42	Logical unit number for master sensitivity library
shortx=	11	Logical unit number of the AMPX short master formatted cross-section library.
unconstrained-chi	F	Flag to generate pre-SCALE 6 unconstrained chi (fission spectrum) sensitivities
sensitivity_format=	txt	Specifies desired format for the resulting sensitivity data file (SDF). May be 'txt' for text-based format or 'hdf5' for HDF5-based format.

Due to differences in the continuous-energy and multigroup sensitivity coefficient calculation methods, SAMS input files that use continuous-energy TSUNAMI do not use most of the input parameters that are described in Table 6.6.2. In fact, continuous-energy TSUNAMI calculations will only use the nomix, unconstrainedchi, and sensitivity_format input parameters; all other parameters that are input will be ignored.

Table 6.6.3: SAMS input keywords for default covariance data.

Keyword	**Default value**	**Description**
use_dcov	F	Use default covariance data

continues on next page

Table 6.6.3 – continued from previous page

use_icov	F	Use user-input covariance data
cov_fix	F	Correct covariance data if the uncertainty is large >1000% or zero
large_cov	10.0	Relative Standard deviation to apply cov_fix
return_work_cov	F	Create a new covariance data file with only the cross section covariance data used in the analysis
udcov=	0.05	User-defined default value of standard deviation for all energy groups
udcov_corr=	1.0	User-defined default correlation value
udcov_corr_type=	zone	User-defined default correlation type; allowed values are long, zone, and short
udcov_therm=	0.0	User-defined default value of standard deviation for thermal energy groups
udcov_inter=	0.0	User-defined default value of standard deviation for intermediate energy groups
udcov_fast=	0.0	User-defined default value of standard deviation for fast energy groups

Additionally, user-defined covariance data can be specified for individual nuclides and reactions using the *COVARIANCE* data block. This data begins with the keywords **READ COVARIANCE** and ends with the keywords **END COVARIANCE**. Any of the optional *COVARIANCE* input data may be entered in free form format between the **READ COVARIANCE** and **END COVARIANCE** keywords. The specifications for the *COVARIANCE* data block are described in the "User Input Covariance Data" section of the TSUNAMI Utility Modules chapter of the SCALE manual.

As the SAMS module generates HTML output, the optional *HTML* data block will provide user control over some formats of the output. This data begins with the keywords **READ HTML** and ends with the keywords **END HTML**. Any of the optional *HTML* input data may be entered in free form format between the **READ HTML** and **END HTML** keywords. The specifications for the *HTML* data block are described in the *HTML Data* section of the TSUNAMI Utility Modules chapter of the SCALE manual.

6.6.3.3 Data files required by SAMS

SAMS requires a number of data files to be available in the directory in which in the program executes to calculate MG sensitivities. These files are summarized in Table 6.6.4, but are not needed for CE sensitivity calculations.

Table 6.6.4: Data files required by SAMS.

Filename	When required	Description
ft*kunit*f001	Always	Data from forward transport solution
ft*kunita*f001	Always	Data from adjoint transport solution
ft*xunit*f001	Always	AMPX working formatted cross-section data library containing resonance self-shielded cross-section data used in transport calculations

continues on next page

Table 6.6.4 – continued from previous page

ft*xunitm*f001	Always	Master sensitivity cross-section data library; this library contains resonance self-shielded data for more reactions than are available on the working formatted library
ft*xunitsx*f001	Implicit Sensitivities	Short master cross-section data library containing infinitely dilute cross-section data
senlib.sen	Implicit Sensitivities	Sensitivity data file produced by SENLIB; contains sensitivity of values input to resonance self-shielding codes to input material number densities
bonamist.sen	Implicit Sensitivities	Sensitivity data file produced by BONAMIST; contains the sensitivity of shielded group-wise cross sections to data input to BONAMIST
coverx	Uncertainty Analysis	COVERX formatted cross-section-covariance data file

6.6.3.4 Example input

An example input file is given in Example 6.6.1. In this example, XSDRNPM was used as the transport solver (*xsdrn*), the data file from the forward transport solution is read from file ft33f001 (*kunit=33*), and the data file from the adjoint transport solution is read from file ft32f001 (*kunita=32*). SAMS will generate implicit sensitivity coefficients (*makeimp*) and print them in detail (*prtimp*). SAMS will compute and print sensitivity coefficients by region (*prtgeom*) and print the fluxes (*prtflx*).

Example 6.6.1: Example SAMS input.

```
=sams5
read initial
xsdrn
kunit=33 kunita=32
makeimp prtimp prtgeom
end initial
end
```

6.6.4 SAMPLE PROBLEMS AND OUTPUT DESCRIPTION

6.6.4.1 Example problem using XSDRNPM

This sample problem is the Flattop-25 metal system from the Cross-Section Evaluation Working Group benchmark specifications [SAMSNationalNDCenter74]. The system consists of a 6.116-cm sphere of 93%-enriched uranium with a natural uranium reflector. The outer radius of the reflector is 24.13 cm.

Prior to running SAMS, the data files listed in Table 6.6.4 were generated for this system. It is recommended that users perform sensitivity analyses on 1-D systems using the TSUNAMI-1D control module, which executes the appropriate codes to generate the required data files in an automated manner from a single input. SAMS is executed automatically as a part of the TSUNAMI-1D control sequence. However, given appropriate data files SAMS can be run as stand-alone program.

Input and text output

The SAMS input is shown in Example 6.6.2 and the output is shown in Example 6.6.3. Each section of the output is described below. Note that output shown in this section is intended only to represent the format of output that the user will encounter. The actual computed results may vary.

1. Parameter Table and Summary of Transport Calculation

In the output listing, the SAMS Parameter Table gives the values of the SAMS input data. Next, the title from the XSDRNPM input file is given and a brief summary of the transport solution is given.

2. Energy-, Region-, and Mixture Integrated Sensitivity Coefficients

Next the energy-, region-, and mixture integrated sensitivity coefficients are given for each reaction of each nuclide. The nuclide symbol and reaction name are given. The data given in the Sensitivity column represents the expected change in k_{eff} of this system due to a uniform fractional change in the cross section of the given nuclide and reaction in all energy groups for all regions and mixtures that contain this nuclide. For example, a uniform fractional change of 0.01 (or 1%) in the fission cross section of ^{235}U would produce a fractional change in k_{eff} of $5.7367 \cdot 10^{-1} \times 0.01$ or $5.7367 \cdot 10^{-3}$ (0.57367% $\Delta k/k$). Because the keyword PRTIMP was entered in the SAMS input, the explicit, implicit and complete sensitivity coefficients are listed in separate columns. If PRTIMP were not entered, only the complete sensitivity would be given in the Sensitivity column.

3. Energy- and Region-Integrated Sensitivity Coefficients

Next the energy- and region-integrated sensitivity coefficients are given for each reaction of each nuclide. The mixture number, nuclide symbol and reaction name are given. The data given in the Sensitivity column represents the expected change in k_{eff} of this system due to a uniform fractional change in the cross section of the given nuclide and reaction in all energy groups for all regions that contain the particular mixture. For example, a uniform fractional change of 0.01 (or 1%) in the fission cross section of ^{235}U in mixture 1 would produce a fractional change in k_{eff} of $5.6594 \cdot 10^{-1} \times 0.01$ or $5.6594 \cdot 10^{-3}$ (0.56594% $\Delta k/k$). Because the keyword PRTIMP was entered in the SAMS input, the explicit, implicit and complete sensitivity coefficients are listed in separate columns. If PRTIMP were not entered, only the complete sensitivity would be given in the Sensitivity column.

4. Total Sensitivity Coefficients by Nuclide

The next section of the output summarizes the total sensitivity by nuclide and mixture. The sensitivity values given here are the same as the values given in the previous section for the sensitivity of k_{eff} to the total cross section. Also included in this edit are the atom densities for each nuclide in each mixture.

5. Total Sensitivity Coefficients by Mixture

The next output edit gives the total sensitivity of k_{eff} to the mixture. Here, the sensitivity of k_{eff} to the total cross section is summed over each nuclide in a given mixture.

6. Problem Characterization (MG Calculations Only)

The next output edit is for the problem characterization data. This section includes the median group of neutrons causing fission, capture and scattering; average group for fission, capture and scattering; the average energy causing fission, capture and scattering; and the energy of the average lethargy causing fission, capture and scattering.

7. Sensitivity Coefficients by Material Zone

Because the keyword PRTGEOM was entered in the input, the next output edit gives the energy-integrated sensitivity coefficients for each material zone defined in the XSDRNPM criticality model. First, the zone number, material number and volume of the zone are given. Next, the sensitivity coefficients are given in the same format as for the region-integrated data. The edit is repeated for each material zone in the XSDRNPM criticality model.

8. Uncertainty Information

The next output edit contains the uncertainty information. First, the percent relative standard deviation in k_{eff} ($\Delta k_{\text{eff}}/k_{\text{eff}} \times 100\%$) due to cross-section-covariance data is given. Next, a listing of the uncertainty terms as produced by Eq. (6.6.58) are given. The nuclide-reaction to nuclide-reaction covariance matrix responsible for the uncertainty contribution is given followed by the contribution to the uncertainty in terms of % Δk/k. The total uncertainty can be computed from individual values by adding the square of the values with positive signs and subtracting the square of the values with negative signs, then taking the square root. The negative values are the result of anti-correlations in the cross-section-covariance data.

9. Execution Complete

The final edit produced simply states that the execution is complete and gives the elapsed time.

Example 6.6.2: SAMS input for Flattop-25 sample problem.

```
=sams5
read initial
xsdrn kunit= 31 kunita= 32 xunit=   4 xunitm=  42 makeimp prtgeom prtimp largeimp=   1.0000E+03
end initial
end
```

Note: relative standard deviation in k-eff can be computed from
individual values by adding the square of the values with positive signs and
subtracting the square of the values with negative signs, then taking the square root

Sensitivity data file

The energy-dependent sensitivity data computed by SAMS is written to a sensitivity data file (SDF), which SCALE returns to the same directory as the output file with the extension ".sdf". The SDF is generated directly in KENO in CE TSUNAMI-3D calculations. When XSDRNPM is used for the transport solution, the data file is presented in the TSUNAMI-A format described in Appendix A. This data file is suitable for visualization with the Fulcrum SCALE user interface or for system comparison with the TSUNAMI-IP code, which is described in section 6.5. A sample section of the TSUNAMI-A formatted sensitivity data file is show in Example 6.6.4.

Example 6.6.4: Sample of sensitivity data file for Flattop-25 sample problem.

Sample plots of the energy-dependent sensitivity profiles from the SDF are shown below. Fig. 6.6.1 and Fig. 6.6.2 depict the region-dependent sensitivity profiles for ^{235}U fission and ^{238}U capture, respectively, in zones 1 and 2 of the Flattop-25 sample problem, which are the core and the reflector regions, respectively.

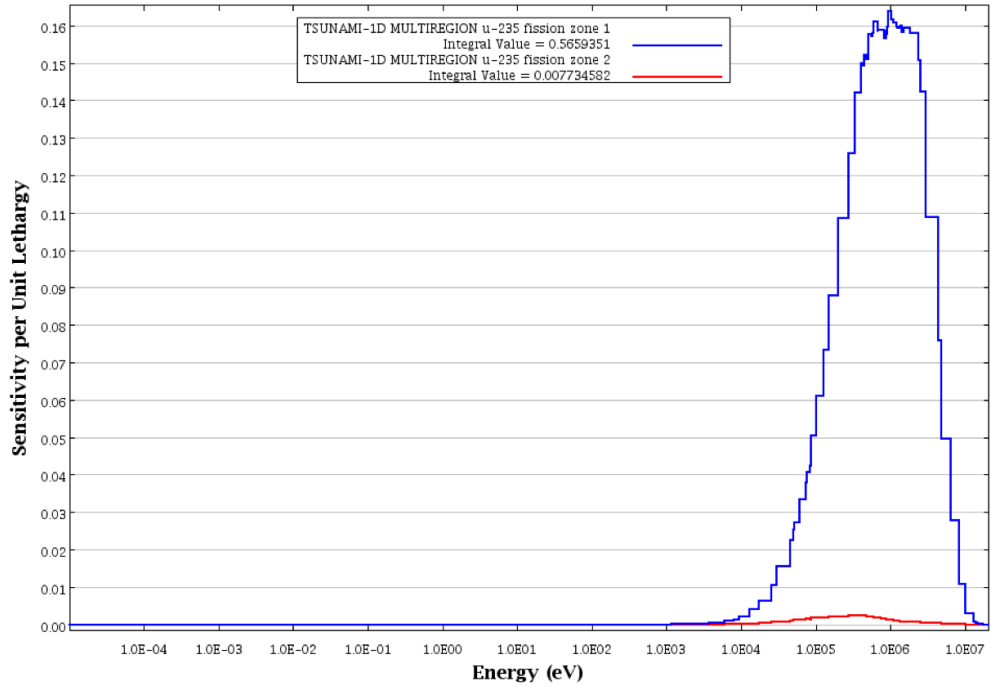

Fig. 6.6.1: Region-dependent fission sensitivity profiles for Flattop-25 sample problem.

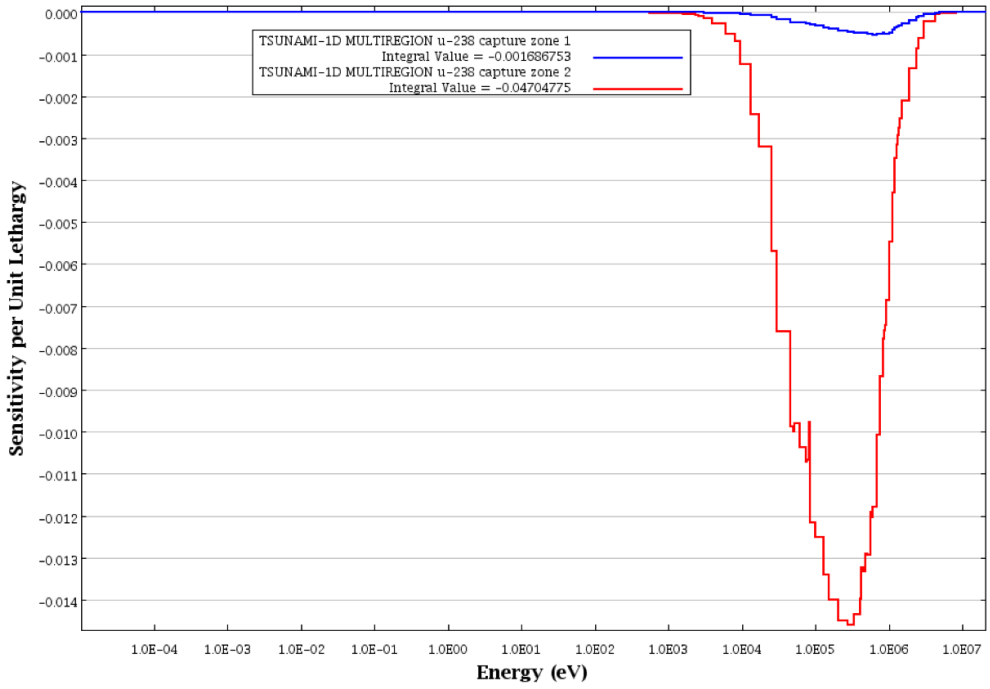

Fig. 6.6.2: Region-dependent capture sensitivity profiles for Flattop-25 sample problem.

HTML formatted output

SAMS will, by default, present the sensitivity results in HTML formatted output for interactive viewing in a web browser. SCALE will return an HTML file to the users' directory with the same name as the output file, but with the extension ".html". Opening this file in a web browser will allow the user to begin viewing the output. Other files necessary for the HTML output are stored in the ".htmd" directory associated with the output file and some utilities for data visualization are stored in the applet_resources directory, which is created in the same directory as the output file.

When the .html file is opened, an index page like the one in Fig. 6.6.3 will be shown. In this example, only one SCALE module with HTML output, SAMS, was executed from the input file. If more than one set of HTML output was available, additional modules would be listed on this page. To begin viewing the HTML output, click on the word *SAMS* in the middle of the page. Once SAMS is selected, the program verification information page is displayed, as shown in Fig. 6.6.4. The output data is sorted into four sections, three of which are shown on the left side of the window in this example. *General Information* consists of the *Program Verification Information* and the *Elapsed Time* for program execution. *Input Data* lists data input to the calculation including user input and data read from the required forward and adjoint transport calculations. *Results* contains the computed results, and an additional *Messages* section, not shown, would contain any error or warning messages generated during the SAMS calculation.

Clicking on the *Input Data* menu item reveals the menu of pages containing input data. Clicking on the *Input Parameters* item reveals the page shown in Fig. 6.6.5. Clicking on the *Summary of Transport Calculations* item reveals the page shown in Fig. 6.6.6.

Clicking on the *Results* menu item reveals the results available for viewing. Clicking on *Energy, Region and Mixture Integrated Sensitivity Coefficients for this Problem* under the results menu reveals the energy-, region- and mixture integrated sensitivity coefficients for this problem, as shown in Fig. 6.6.7. As with most of the tables in the HTML output, the table of sensitivity coefficients on this page can be sorted in ascending and

descending order by clicking on the heading of the column for which the sorting is desired. When clicking twice on the sensitivity column, the sensitivity results are sorted in descending order as shown in Fig. 6.6.8.

Skipping several output edits for brevity and selecting the *Sensitivity Data Plot* item will open a page with an applet version of Javapeño with the sensitivity data file preloaded as shown in Fig. 6.6.9. To create a plot of sensitivity data, double-click on the desired information on the right side of the window. Multiple items can be simultaneously selected in the list using standard platform specific modifier keys such as shift or control. Right-clicking on an item in the list will present a menu with various options for plotting. For more information on the use of Javapeño, please select Help from the Javapeño help menu.

6.6.4.2 Example problem using KENO V.a

This sample problem is critical experiment number 10 from evaluation LEU-COMP-THERM-009 of the ICSBEP Handbook [SAMSCom99]. The critical assembly consists of three 8 × 15 fuel-rod arrays separated by 6.46 mm thick copper plates. The U(4.31)O_2 fuel rods are 92.075-cm long. A KENO3D rendering of the KENO V.a geometry model with the water moderator removed is shown in Fig. 6.6.10.

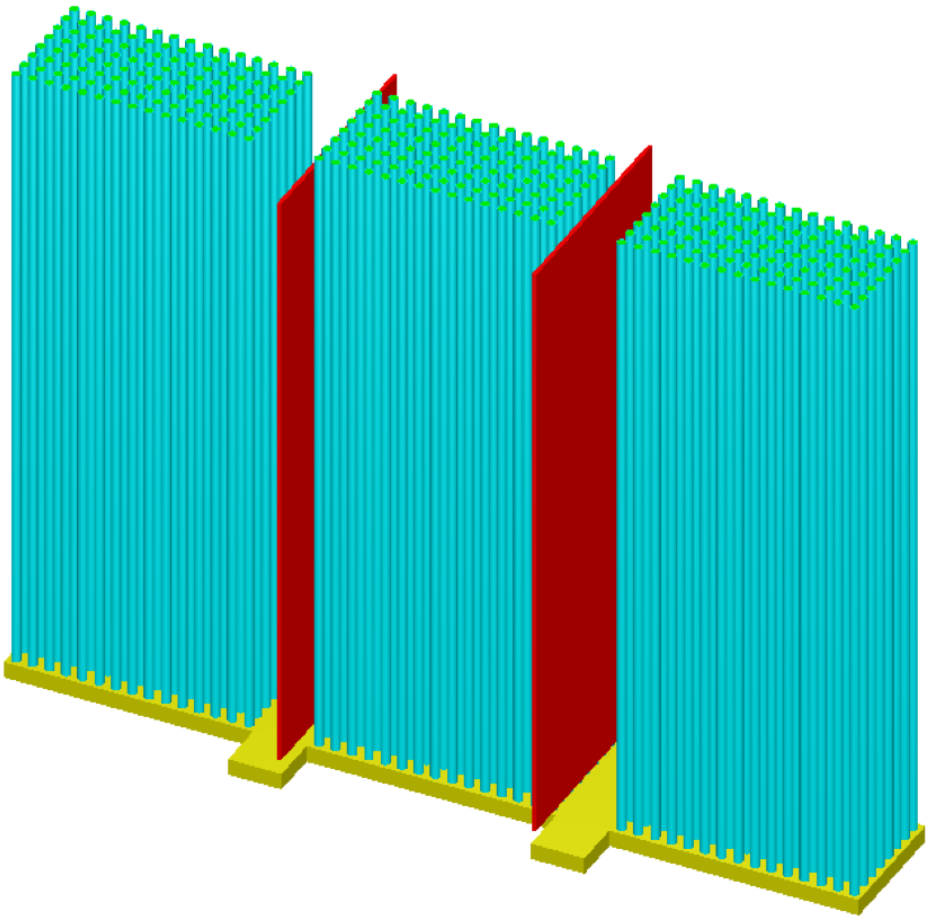

Fig. 6.6.10: KENO3D rendering of KENO V.a model of LEU-COMP-THERM-009 case 10.

Prior to executing SAMS, the data files listed in Table 6.6.4 were generated for this system. It is recommended that users perform sensitivity analyses on 3-D systems using the TSUNAMI-3D control module, which executes the appropriate codes to generate the required data files in an automated manner from a single input. SAMS is executed as a part of the TSUNAMI-3D control sequence. However, given appropriate data files SAMS can be run as a stand-alone program.

Input data and text output

The SAMS input is shown in Example 6.6.5 and the output is shown in Example 6.6.6. Each section of the output is described below. Note that output shown in this section is intended only to represent the format of output that the user will encounter. The actual computed results may vary.

1. Parameter Table and Summary of Transport Calculation

In the output listing, the SAMS Parameter Table gives the values of the SAMS input data. Next, the title from the KENO V.a input file is given and a brief summary of the transport solution is given.

2. Energy-, Region-, and Mixture Integrated Sensitivity Coefficients

Next the energy-, region-, and mixture integrated sensitivity coefficients are given for each reaction of each nuclide. The nuclide symbol and reaction name are given. The data given in the Sensitivity column represents the expected change in k_{eff} of this system due to a uniform fractional change in the cross section of the given nuclide and reaction in all energy groups for all regions and mixtures that contain this nuclide. The standard deviations represent stochastic uncertainties from the Monte Carlo calculation. For example, a uniform fractional change of 0.01 (or 1%) in the fission cross section of ^{235}U would produce a fractional change in k_{eff} of $3.2433 \cdot 10^{-1} \times 0.01$ or $3.2433 \cdot 10^{-3}$ (0.32433% $\Delta k/k$). Because the keyword PRTIMP was not entered in the SAMS input, only the complete sensitivity would be given in the Sensitivity column. If PRTIMP was entered, the explicit, implicit and complete sensitivity coefficients are listed in separate columns. Region-integrated sensitivity profiles for ^{1}H elastic scattering, ^{238}U capture and ^{235}U fission are shown in Fig. 6.6.11.

3. Energy- and Region-Integrated Sensitivity Coefficients

Next the energy- and region-integrated sensitivity coefficients are given for each reaction of each nuclide. The mixture number, nuclide symbol and reaction name are given. The data given in the Sensitivity column represents the expected change in k_{eff} of this system due to a uniform fractional change in the cross section of the given nuclide and reaction in all energy groups for all regions that contain the particular mixture. The standard deviations represent stochastic uncertainties from the Monte Carlo calculation. Because the keyword PRTIMP was not entered in the SAMS input, only the complete sensitivity would be given in the Sensitivity column. If PRTIMP was entered the explicit, implicit and complete sensitivity coefficients are listed in separate columns.

4. Total Sensitivity Coefficients by Nuclide

The next section of the output summarizes the total sensitivity by nuclide. The sensitivity values given here are the same as the values given in the previous section for the sensitivity of k_{eff} to the total cross section. Also included in this edit are the atom densities for each nuclide in each mixture.

5. Total Sensitivity Coefficients by Mixture

The next output edit gives the total sensitivity of k_{eff} to the mixture. Here, the sensitivity of k_{eff} to the total cross section is summed over each nuclide in a given mixture.

6. Problem Characterization (MG Calculations Only)

The next output edit is for the problem characterization data. This section includes the median neutron energy group causing fission, capture and scattering, average group for fission, capture and scattering, the average energy causing fission, capture and scattering, and the energy of the average lethargy causing fission, capture and scattering.

7. Sensitivity Coefficients by Region

If the keyword, PRTGEOM was entered in the SAMS input, the next output edit would give the energy-integrated sensitivity coefficients for each region of each unit defined in the KENO V.a geometry input. Note that for brevity, this output edit was not requested.

8. Uncertainty Information

The next output edit contains the uncertainty information. First, the percent relative standard deviation in k_{eff} $\left(\Delta k_{eff}/k_{eff} \times 100\%\right)$ due to cross-section-covariance data is given. Next a listing of the uncertainty terms as produced by Eq. (6.6.38) are given. The nuclide-reaction to nuclide-reaction covariance matrix responsible for the uncertainty contribution is given followed by the contribution to the uncertainty in terms of % $\Delta k/k$. The total uncertainty can be computed from individual values by adding the square of the values with positive signs and subtracting the square of the values with negative signs, then taking the square root. The negative values are the result of anti-correlations in the cross-section-covariance data.

9. Execution Complete

The final edit produced simply states that the execution is complete and gives the elapsed time.

 ------------------------------
    Problem Characterization
 ------------------------------

 median fission group is 222    5.000E-02 to 4.000E-02(eV)
                           average fission group   2.077E+02 +/- 3.212E-01
              average energy(eV) causing fission   1.115E+05 +/- 2.059E+02
  energy(eV) of average lethargy causing fission   1.128E-01 +/- 1.749E-04

 median capture group is 223    4.000E-02 to 3.000E-02(eV)
                           average capture group   2.072E+02 +/- 1.110E-01
              average energy(eV) causing capture   3.771E+04 +/- 4.509E+01
  energy(eV) of average lethargy causing capture   8.751E-02 +/- 4.773E-05
```

Figure 6.3.16. SAMS output for LEU-COMP-THERM-009 case 10 sample problem. (continued)

```
 median scatter group is 221    6.000E-02 to 5.000E-02(eV)
                           average scatter group   1.903E+02 +/- 5.331E-02
              average energy(eV) causing scatter   6.721E+04 +/- 2.875E+01
  energy(eV) of average lethargy causing scatter   3.839E-01 +/- 1.069E-04

 Generating working covariance matrix ...

6.6.5 ERROR AND WARNING MESSAGES

SAMS will display a message when a predetermined condition is encountered. Error messages are displayed prior to code termination. Warning messages are displayed when a potentially abnormal condition is encountered, but code execution continues.

6.6.5.1 Error Messages

SAMS Error 001: Selected calculation type _____ is not valid.
This message is displayed by VIP when the user enters a calculation type other than kenova or xsdrn.

SAMS Error 002: There was a zero response value.
This message is displayed by SENSITIVITY_SUMMATION when there was no fissile material in the problem or the forward or adjoint flux in all regions containing fissile material was zero. This message can be encountered when the adjoint solution fails to proceed far enough to accumulate active generations for flux accumulation in TSUNAMI-3D models.

SAMS Error 003: Error reading covariance data io=___ mat1=____ mt1=____ mat2=____ mt2=____ nblok=____ ngroup=____
This error is displayed by SAMCAVA when a non-zero return code is obtained when reading from the covariance data library.

SAMS Error 004: Adjoint flux file from KENO was not found on unit ____
This error is displayed by GET_FLUXES when the adjoint flux unit cannot be opened.

SAMS Error 005: Forward flux file from KENO was not found on unit ____
This error is displayed by GET_FLUXES when the forward flux unit cannot be opened.

SAMS Error 006: Adjoint fluxes were not calculated in the source case
This error is displayed by GET_FLUXES when an adjoint data file is found, but it does not contain flux data. The adjoint case should be rerun with flux accumulation turned on.

SAMS Error 007: Only the scalar fluxes were calculated. Execution is stopping.
This message is displayed by GET_FLUXES when the KENO calculation was run with both PNM=0 and NQD=0. The KENO case does not contain sufficient information to produce sensitivity coefficients.

SAMS Error 008: Error reading the forward restart file, record type ____
This message is displayed by GET_FLUXES when an unknown record type from the KENO forward solution is encountered.

SAMS Error 009: Error reading the adjoint restart file, record type ____
This message is displayed by GET_FLUXES if an unknown record type from the KENO adjoint solution is encountered.

SAMS Error 010: Invalid read key ____
This message is displayed by GET_INPUT when an invalid word is encountered in the input before a "read" card is encountered.

SAMS Error 011: Invalid block key ____. The first block must be initial.
This message is displayed by GET_INPUT when the first word after the first "read" is not "initial".

SAMS Error 012: End of input data reached. Expecting more data.
This message is displayed by GET_INPUT when the end of the input stream is unexpectedly encountered.

SAMS Error 013: Ending block keyword ___
does not equal the beginning block keyword ___
This message is displayed by GET_INPUT when the word following "END" does not match the word after "READ" for the current input block.

SAMS Error 014: Unknown read return flag ____
This message is displayed by GET_INPUT when a reading error occurs. This is likely due to an input error.

Error allocating ______
This message is displayed by GET_FLUXES when insufficient computational resources exist to allocate memory for processing the problem. If this message is encountered, try reducing the size of the calculation by reducing the number of mesh intervals (e.g., increase the mesh size, MSH in KENO), reducing the order of flux moments or angular fluxes accumulated (PNM and NQD in KENO), or using a cross-section data library with fewer energy groups.

6.6.5.2 Warning Messages

SAMS Warning 001: Use of mesh flux was requested (mfx=yes), but a mesh size of ____ was requested. Please enter a positive value for msh= in the KENO parameter data. SAMS will continue its calculation with the region fluxes, equivalent to mfx=no.
This message is displayed by GET_FLUXES when MFX=YES is entered in KENO parameter data, but the mesh size MSH is not entered or is non-positive. However, if the user specifies another mesh in a different section of a TSUNAMI-3D input (i.e. in the read GridGeometry block), then TSUNAMI will default to use that mesh.

SAMS Warning 002: The k-eff values for the forward and adjoint calculations differ by more than one percent.
This message is displayed by PRINT_TRANS when the k-eff values from the forward and adjoint calculations differ by more than one percent. This typically indicates poor convergence of the adjoint Monte Carlo calculation. The calculation should be rerun with more histories to improve agreement between the forward and adjoint k-eff values.

SAMS Warning 003: Implicit sensitivities were requested but no implicit datafiles were found. Proceeding with explicit sensitivity coefficients only.

This message is displayed by IMPLICIT_SENSITIVITIES when MAKEIMP is present in the SAMS input, but no datafiles from SENLIB or BONAMIST are found. The calculation will continue with explicit sensitivity coefficients only.

SAMS Warning 004: Implicit sensitivity of ____ ____ to ____ group ____ from ____ had a value of ____ and has been reset to 0.0.

This message is displayed by IMPLICIT_SENSITIVITIES when an implicit sensitivity value greater than that set by LARGEIMP is encountered. The large implicit value is likely due to an inconsistency between the CELLDATA specification for the material identified in the message and the use of that material in the geometry of the model.

SAMS Warning 005: Implicit sensitivity for mixture ____ ____ ____ exceeds the explicit sensitivity by more than an order of magnitude. Implicit sensitivity: ____Explicit sensitivity: ____ Please check for appropriate resonance self-shielding models in celldata.

This message is displayed by IMPLICIT_SENSITIVITIES when the implicit sensitivity value exceeds the explicit sensitivity value by more than an order of magnitude. The large implicit value is possibly due to an inconsistency between the CELLDATA specification for the material identified in the message and the use of that material in the geometry of the model.

SAMS Warning 006: An implicit sensitivity was generated by the resonance self-shielding calculation in ____ for mixture ____ ____ ___ with mixture ____ ____ which was not found in the model. This potentially important information will be skipped. Please check the celldata input.

This message is displayed by IMPLICIT_SENSITIVITIES when implicit data is generated by the resonance self-shielding codes, but a material needed for the calculation is not present in the geometry model. Please check for consistent use of materials in the CELLDATA input and in the geometry model.

SAMS Warning 007: USEANG was requested in the input, but angular fluxes were not computed. USEMOM has been set to true, and flux moments will be used to compute sensitivity coefficients.

This message is displayed by GET_FLUXES when USEANG is true but angular fluxes were not computed in the transport solution. In this case the flux moments computed in the transport solution are used to compute sensitivity coefficients. If neither angular fluxes nor flux moments are found, SAMS Error 007 will stop code execution prior to reaching this warning.

SAMS Warning 008: USEMOM was requested in the input, but flux moments were not computed. USEANG has been set to true, and angular fluxes will be used to compute sensitivity coefficients.

This message is displayed by GET_FLUXES when USEMOM is true but flux moments were not computed in the transport solution. In this case the angular fluxes computed in the transport solution are used to compute sensitivity coefficients. If neither angular fluxes nor flux moments are found, SAMS Error 007 will stop code execution prior to reaching this warning.

6.7 TSAR: TOOL FOR SENSITIVITY ANALYSIS OF REACTIVITY RESPONSES

M. L. Williams and M. A. Jessee

ABSTRACT

TSAR (Tool for Sensitivity Analysis of Reactivity Responses) is a SCALE functional module that computes nuclear data sensitivity coefficients for eigenvalue-difference responses such as reactor reactivity and worth coefficients. Examples include void reactivity, Doppler coefficients, and control rod worths. TSAR reads previously computed sensitivity coefficients for the k-eigenvalues at two states of a reactor system (or for two different systems) and combines them to obtain sensitivity coefficients for the difference. The k-eigenvalue sensitivities are typically obtained using the TSUNAMI-3D or -1D control sequences in SCALE. The reactivity sensitivity coefficients are combined with nuclear data covariance information to determine the uncertainty in the reactivity response.

ACKNOWLEDGMENT

Development of the TSAR code was funded by the U. S. Nuclear Regulatory Commission Office of Research.

6.7.1 INTRODUCTION

The TSUNAMI-1D, -2D, or -3D control sequences in SCALE compute multigroup sensitivity coefficients and uncertainties for the critical multiplication factor k, the reciprocal of the λ-eigenvalue of the neutron transport equation for a multiplying medium. The TSAR module in SCALE performs sensitivity/uncertainty (S/U) calculations for responses represented by the *difference* of two eigenvalues. These types of responses are often of interest in reactor physics applications. For example, TSAR can compute data sensitivities and uncertainties of reactivity responses such as control rod worths, fuel and moderator temperature coefficients, and void coefficients for two defined states of a power reactor [TSARWGC06]. Another potential application is in the analysis of benchmark critical experiments for nuclear data testing and validation studies. Data and methods deficiencies can introduce a computational bias manifested as a trend in calculated critical eigenvalues versus experiment parameters. TSAR can be applied to the *difference* in the computed eigenvalues of two benchmarks to establish the sensitivity of the bias trend to various nuclear data used in the calculations.

TSAR builds upon capabilities of other SCALE modules. TSUNAMI is first used to calculate sensitivities for the multiplication factors of the reference and altered states of the reactor, respectively. TSAR reads the sensitivity data files (.sdf file) produced by TSUNAMI *keff* calculations and uses them to compute relative or absolute sensitivities of an eigenvalue-difference response. The reactivity sensitivities are written to an output file for subsequent applications or visualization. TSAR also combines the calculated reactivity sensitivity coefficients with input nuclear data covariance matrices included in SCALE to determine the uncertainty of the reactivity response.

6.7.2 METHODOLOGY

A detailed description of the S/U methodology for reactivity responses is given in Reference D D; thus, only a brief overview is presented here. The lambda-eigenvalue form of the neutron transport equation for a multiplying medium is given by

$$(\mathbf{L} - \lambda\mathbf{P})\Phi = 0 \tag{6.7.1}$$

where L and P are the loss and production operators, respectively, for the Boltzmann equation describing a multiplying medium and $\lambda = \frac{1}{k}$ is the fundamental lambda-eigenvalue. It is assumed that the system is initially in a well-defined state 1 having a lambda- eigenvalue of λ_1. The reactivity for state 1 is defined as $\rho_1 = 1 - \lambda_1$. Suppose that changes in L and/or P transformed the original system into a new distinct

configuration designated as state 2, with the lambda eigenvalue of λ_2 and static reactivity of $\rho_2 = 1 - \lambda_2$. For example, the configuration change could be caused by moving a control rod or by voiding of the coolant. The reactivity insertion/withdrawal associated with the designated change in conditions is defined as

$$\rho_{1\to 2} = \rho_2 - \rho_1 = \lambda_1 - \lambda_2. \tag{6.7.2}$$

Eq. (6.7.2) defines the eigenvalue-difference (i.e., reactivity) response addressed by TSAR. The code edits the eigenvalues for the two reactor states and the value of the reactivity obtained from Eq. (6.7.2).

6.7.2.1 Reactivity sensitivity coefficients

The relative k-sensitivity coefficient for an arbitrary data parameter α appearing in the transport equation is equal to

$$\mathrm{S}_{\mathrm{k},\alpha} = \frac{\alpha \partial \mathrm{k}}{\mathrm{k} \partial \alpha} = -\frac{\alpha \partial \lambda}{\lambda \partial \alpha} \tag{6.7.3}$$

An analogous expression defines the relative sensitivity coefficient of the reactivity response:

$$\mathrm{S}_{\rho,\alpha} = \frac{\alpha \partial \rho_{1\to 2}}{\rho_{1\to 2} \partial \alpha} \tag{6.7.4}$$

Unlike the multiplication factor, the reactivity response can be negative. This can be source of confusion when interpreting the relative sensitivity coefficient; hence, by convention TSAR defines sensitivities relative to the *absolute value* of the reactivity; thus,

$$\mathrm{S}_{\rho,\alpha} \to \frac{\alpha}{|\rho_{1\to 2}|} \frac{\partial \rho_{1\to 2}}{\partial \alpha}. \tag{6.7.5}$$

In this way, a positive value for the relative sensitivity coefficient means that increasing the value of α always increases the value of the reactivity (i.e., a positive :math:` ho` becomes more positive, and a negative :math:` ho` becomes less negative). Conversely, a negative relative sensitivity coefficient means that increasing α always decreases the reactivity (i.e., a positive :math:` ho` becomes less positive, and a negative :math:` ho` becomes more negative). This convention is used in TSAR for all relative quantities involving the reactivity.

From the definitions in Eq. (6.7.2) and Eq. (6.7.3), Eq. (6.7.4) is simplified to the following expression used in TSAR:

$$\mathrm{S}_{\rho,\alpha} = \frac{\lambda_2 \, \mathrm{S}_{\mathrm{k2},\alpha} - \lambda_1 \, \mathrm{S}_{\mathrm{kl},\alpha}}{|\rho_{1\to 2}|}, \tag{6.7.6}$$

where $\mathrm{S}_{\mathrm{k1},\alpha}$ and $\mathrm{S}_{\mathrm{k2},\alpha}$ are the k-sensitivities for the two states. The relative change in the reactivity response due to an arbitrary relative variation (or uncertainty) in parameter α can be found very easily once the :math:` ho`-sensitivities are determined that is,

$$\frac{\Delta \rho_{1\to 2}}{|\rho_{1\to 2}|} \sim \mathrm{S}_{\rho,\alpha} \frac{\Delta \alpha}{\alpha}. \tag{6.7.7}$$

In cases where the net reactivity change is very small, the denominator of Eq. (6.7.6) approaches zero; thus, the relative sensitivity coefficient can increase without bound. For this reason TSAR provides an input option to compute U*absolute*U rather than U*relative*U sensitivity coefficients. Absolute quantities are indicated here by the presence of a tilde (~), while relative quantities have no tilde. The absolute sensitivity coefficient is

defined in TSAR as the absolute change in the reactivity, expressed in pcm (percent-milli), due to a fractional change in data:

$$S_{\rho,\alpha} = (\lambda_2 \, S_{k2,\alpha} - \lambda_1 \, S_{k1,\alpha}) \times 10^5, \tag{6.7.8}$$

so that

$$\Delta\rho_{1\to 2}(pcm) \sim S_{\rho,\alpha} \frac{\Delta\alpha}{\alpha}. \tag{6.7.9}$$

Prior to executing TSAR, it is necessary to perform TSUNAMI calculations for each reactor state, in order to evaluate the relative k-sensitivity coefficients in Eq. (6.7.3). These are written out in the SDF sensitivity file format and saved for input to TSAR. TSAR reads the two previously prepared files and uses them to evaluate Eq. (6.7.6) or Eq. (6.7.8) for the reactivity sensitivities. The :math:` ho`-sensitivities are then output to another SDF file. As discussed in Sect. 6.1 of the SCALE documentation, the complete sensitivities calculated by TSUNAMI include implicit effects associated with perturbations in resonance self-shielding; hence, the reactivity sensitivities also account for these effects, which can be significant.

TSAR prints the number of different sensitivity profiles that are computed and optionally can edit the input k-sensitivities corresponding to each reactor state, as well the calculated :math:` ho`-sensitivities. Sensitivities may be edited by a sum over group for each nuclide-reaction pair. In addition, the TSAR output SDF file containing multigroup :math:` ho`-sensitivities for each nuclide-reaction pair can be read by Fulcrum to produce plots of the energy-dependent sensitivities. The filename of the reactivity sensitivity data file is given as *job_name.react.sdf*, where *job_name* is the name of the TSAR input file (i.e., *job_name.inp*, *job_name.input*, or simply *job_name*). Additionally, if the user requests edits of the input k-sensitivities using the *print=all* option, the k-sensitivity data files are copied to the return directory as *job_name.kstate1.sdf* and *job_name.kstate2.sdf*. The *print* keyword is further described in the TSAR input section.

6.7.2.2 Reactivity uncertainty analysis

TSAR performs uncertainty analysis for eigenvalue-difference responses in much the same manner as the TSUNAMI sequences for the multiplication factor, except that either absolute or relative uncertainties may be computed. Assume that the transport calculations for the eigenvalues of the two reactor states use "N" input parameters, consisting of nuclear data for all groups, reaction types, and nuclides. The relative sensitivity coefficients for these data can be expressed as components of the N-dimension column vector $\mathbf{S}_\rho$ and similarly for the absolute sensitivities $\mathbf{S}_\rho$. The relative and absolute reactivity variances-indicated as σ_ρ^2 and σ_ρ^2, respectively-are calculated in TSAR as

$$\sigma_\rho^2 = \frac{\sigma_\rho^2}{\rho^2} = \mathbf{S}_{\boldsymbol{\rho}}^{\mathbf{T}} \mathbf{C}_{\boldsymbol{aa}} \mathbf{S}_{\boldsymbol{\rho}} \quad \text{and} \quad \sigma_\rho^2 = \mathbf{S}_{\boldsymbol{\rho}}^{\mathbf{T}} \mathbf{C}_{\boldsymbol{a\alpha}} \mathbf{S}_{\boldsymbol{\rho}}, \tag{6.7.10}$$

where $\mathbf{C}_{\boldsymbol{aa}}$

is the relative covariance matrix describing nuclear data uncertainties and correlations, which are read from the SCALE covariance libraries. Due to the manner in which the absolute sensitivity coefficient is defined in Eq. (6.4.8), the absolute variance of the reactivity still uses the relative covariance matrix of the nuclear data.

The reactivity variance is related to the uncertainties and correlations in the calculated eigenvalues of the two reactor states. It can be shown that expression in Eq. (6.7.10) for the relative variance in an eigenvalue-difference response is equivalent to

$$\sigma_\rho^2 = \frac{\lambda_1^2}{(\lambda_1 - \lambda_2)^2} \sigma_{k1}^2 + \frac{\lambda_2^2}{(\lambda_1 - \lambda_2)^2} \sigma_{k2}^2 - 2c_{1\to 2} \frac{2\lambda_1\lambda_2}{(\lambda_1 - \lambda_2)^2} \sigma_{k1}\sigma_{k2}. \tag{6.7.11}$$

In the above equations, σ_{k1} and σ_{k2} are relative standard deviations of the multiplication factors and the correlation coefficient between the two reactor states is designated as $c_{1\rightarrow 2} \in [-1, 1]$. The eigenvalue calculations of the two states are correlated because they both use the same nuclear data libraries; therefore, the variance in the eigenvalue-difference is not simply the sum of the variances of the eigenvalues. A positive correlation (i.e., $c_{1\rightarrow 2} > 0$) reduces the uncertainty in the reactivity because common uncertainties tend to cancel from the eigenvalue difference. On the other hand, negative correlations increase the reactivity uncertainty. It also can be seen from Eq. (6.7.11). that whenever the difference in the eigenvalues of the two states is small, the relative variance of the reactivity is substantially greater than the individual eigenvalue variances because the coefficients of σ^2_{k1} and σ^2_{k2} are large. Since this is usually the case for reactivity changes in a reactor, relative uncertainties in reactivity responses tend to be much larger than those for eigenvalues. If the reactivity response is close to zero, it is usually preferable to consider absolute rather than relative uncertainties. Whenever the eigenvalue difference is less than 10^{-10}, TSAR will abort the calculation if a relative uncertainty is specified.

TSAR calculates the variance in the reactivity response using the expressions in Eq. (6.7.10). The square root of the variance corresponds to the standard deviation, which indicates the reactivity uncertainty. TSAR edits this value, as well the individual contributions of each nuclide-reaction pair (including cross correlations) to the overall uncertainty.

6.7.2.3 Cross-section-covariance data

The cross-section-covariance data are read from the COVERX-formatted covariance library identified by *coverx=* in the *PARAMETER* data block on the TSAR input file. Cross-section-covariance data files distributed with SCALE are discussed in Sect. 10.3, and the format of the COVERX data file is presented in Sect. 6.3.4.1.6. The recommended SCALE covariance libraries include uncertainty data for all materials in ENDF/B-VII. These data were obtained from a variety of sources, including ENDF/B-VI and VII, JENDL, and approximate values based on uncertainties in measured integral parameters. [TSARWR08]. The *COVARIANCE* data block can be used to override and/or supplement the library uncertainty values for specified nuclide-reaction pairs. The keyword *use_icov* is entered in the *PARAMETER* data block to utilize the covariance data defined in the *COVARIANCE* data block. Additionally, a default uniform standard deviation value can be assigned for any missing covariance data. This default value is defined by the *udcov=* keyword in the *PARAMETER* data block, and the keyword *use_dcov* is entered to activate the option. Warning messages are printed to identify substituted covariance matrices.

When *use_dcov* and/or *use_icov* and *cov_fix* are specified in the *PARAMETER* data block, and a reaction has zero or large (standard deviation > 1000%) values on the diagonal of the covariance matrix, the diagonal elements and off-diagonal terms are replaced according to the user-input criteria. Warning messages are printed to identify the replaced values. Additional options for user-specified covariance data are given in Sect. 6.7.3.2.

In the reactivity-uncertainty-analysis edit, a single asterisk ("*") identifies uncertainty contributions from nuclide-reaction pairs for which the default cross-section-covariance data is applied. Likewise, the markers ("**"), ("**"), ("**"), denote (a) user-input covariance data, (b) covariance library data replaced by default values, and (c) covariance library data replaced by user-input values, respectively. In the HTML output, these uncertainty contributions are distinguished by using unique HTML colors. The different HTML colors are specified by the HTML block keywords *ud_clr=*, *ui_clr=*, *udfix_clr=*, and *uifix_clr=*. The HTML block keyword options are discussed in more detail in Sect. 6.7.3.3.

TSAR computes a problem-specific covariance library that contains cross-section covariances only for the nuclide-reaction pairs (including cross correlations) listed on the k_1-and k_2-sensitivity data files. This covariance library, referred to as the working covariance library, is written in COVERX format like the

SCALE covariance library. The working covariance library contains any default or user-input covariance data for nuclide-reaction pairs that were not on the input covariance library as well as any modified cross-section-covariance data. The working covariance library can be read by the Javapeño plotting tool to visualize the cross-section-covariance data used in the reactivity uncertainty analysis.

6.7.3 INPUT DESCRIPTION

The user input for TSAR consists of a SCALE Analytic Sequence Specification Record (i.e., *=tsar*), an optional title followed by three blocks of data in free-form keyword format, and a SCALE input termination END record. The data blocks begin with **READ KEYNAME**and end with **END KEYNAME**, where **KEYNAME** is the name of an individual data block. The *PARAMETER* data block is the only required block of data, while the *HTML* and *COVARIANCE* data blocks are optional. The data blocks can be entered in any order.

6.7.3.1 Parameter data

The *PARAMETER* block of data is used to specify the name of the previously prepared k-sensitivity data files, the name of the :math:` ho`-sensitivity data file, and other keyword options that control the code execution. The keyword options are listed in Table 6.7.1 along with their default values and description. A keyword that ends with "=" must be followed by additional data. Keywords that do not end with "=" are Boolean flags that are used to turn on certain features of the code, such as the computation of certain data or certain output edits. If the keyword is present for a Boolean entry, the value is set to true. Otherwise, the value is set to false.

Table 6.7.1: Input data for parameter block of TSAR input.

Keyword	Default value	Description
cov_fix (optional)	False	Replace zero and large (standard deviation > *large_cov*) values on diagonal of cross-section-covariance data with user-input values or default values.
coverx= (optional)	44groupcov	Name of cross-section-covariance data file to use in analysis.
large_cov= (optional)	10.0	Cutoff fractional standard deviation value for *cov_fix*. Covariance data with uncertainties larger than *large_cov* are replaced with user-defined or default values. Default =10, which is 1000% uncertainty.
nocovar (optional)	False	If *nocovar* is present, the reactivity uncertainty calculation is bypassed.
`nohtml` (optional)	False	If `nohtml` is present, HTML-formatted output is not generated.
`print=` (optional)	rho	Available options are `rho*`, `*all`, or `none`. If `print=rho`, *rho*−sensitivities edits are generated. If `print=all`, *rho* − k_1, k_2-, sensitivity edits are generated. The `print=none` option turns off all sensitivity edits.
return_work_cov (optional)	False	If *return_work_cov* is present, the working covariance library is copied to the return directory with the file name *job_name.wrk.cov,* where *job_name* is the name of the input file. If *return_work_cov* is not present, the working covariance library remains in the temporary working directory with the file name *job_name.wrk*.

Table 6.7.1 – continued from previous page

Keyword	Default value	Description
sdf_file_1= (required)	n/a	The file name of the initial state k_1-sensitivity data file.
sdf_file_2= (required)	n/a	The file name of the final state k_2-sensitivity data file.
type= (optional)	relative	Available options are *relative* (or *rel*) and *absolute* (or *abs*). If *type=relative*, the output reactivity sensitivity data file contains relative *rho*−sensitivities. If `type=absolute`, the output reactivity sensitivity data file contains absolute *rho*−sensitivities (i.e., pcm units).
udcov= (optional)	0.05	User-defined default value of standard deviation in cross-section data to use for all groups for nuclide-reaction pairs for which cross section covariance data are too large or not available on the input covariance library.
udcov_corr= (optional)	1.0	User-defined default correlation value to use for nuclide-reaction pairs for which cross section covariance data are not available on the input covariance library.
udcov_corr_type= (optional)	zone	User-defined default correlation in cross-section data to use for nuclide-reaction pairs for which cross-section covariance data are not available on the input SCALE covariance library. Allowed values are *long*, *zone*, and *short*. See Table 6.7.2 for details on *long*, *zone*, and *short.*
udcov_therm= (optional)	0.0	User-defined default value of standard deviation in cross-section data to use for thermal data for nuclide-reaction pairs for which cross-section covariance data are too large or not available on the input covariance library. If input, the *udcov_therm* value overrides the *udcov* value in the thermal range (i.e., neutron energies below 0.625 eV).
udcov_inter= (optional)	0.0	User-defined default value of standard deviation in cross-section data to use for intermediate data for nuclide-reaction pairs for which cross section covariance data are too large or not available on the input covariance library. If input, the *udcov_inter* value overrides the *udcov* value in the intermediate range (i.e., neutron energies above 0.625 eV and below 25 keV).
udcov_fast= (optional)	0.0	User-defined default value of standard deviation in cross-section data to use for fast data for nuclide-reaction pairs for which cross section covariance data are too large or not available on the input covariance library. If input, the *udcov_fast* value overrides the *udcov* value in the fast range (i.e., neutron energies above 25 keV).
use_dcov (optional)	False	Use user-defined default cross-section covariance data for nuclide-reaction pairs not included on the input covariance library.

Table 6.7.1 – continued from previous page

Keyword	Default value	Description
use_icov (optional)	False	Use user-defined cross section covarianc data input in the *COVARIANCE* input data block in place of the default values for user-input nuclide-reaction pairs that are not on the input covariance library.

6.7.3.2 User-input covariance data

The *COVARIANCE* data block described in Table 6.7.2 allows the user to specify a covariance matrix for specific nuclide-reaction pairs for which covariance data are not present on the input covariance library or that have zero or large values on the diagonal. The *COVARIANCE* data block must begin with *READ COVARIANCE* and end with *END COVARIANCE*.

Table 6.7.2: Input data for covariance block of TSAR input.

Input parameter	Requirement	Default value	Allowed values	Description
Nuclide	Required	none	Nuclide name or ZA number	Nuclide for which covariance data are to be entered
Reaction	Required	none	Reaction name or ZA number	Reaction for which covariance data are to be entered. See the TSUNAMI-IP manual for available reaction types.
all=	Optional	0.0	any number	Fractional standard deviation value to be applied to all groups
fast=	Optional	0.0	any number	Fractional standard deviation value to be applied to fast groups. If input, the *fast* value overrides the *all* value in the fast range (i.e., neutron energies above 25 keV).
therm=	Optional	0.0	any number	Fractional standard deviation value to be applied to thermal groups. If input, the *therm* value overrides the *all* value in the thermal range (i.e., neutron energies below 0.625 eV).
inter=	Optional	0.0	any number	Fractional standard deviation value to be applied to intermediate groups. If input, the *inter* value overrides the *all* value in the intermediate range (i.e., neutron energies above 0.625 eV and below 25 keV).
corr=	Optional	1.0	any number from -1.0 to 1.0	Correlation between groups

continues on next page

Table 6.7.2 – continued from previous page

Input parameter	Requirement	Default value	Allowed values	Description
corr_type=	Optional	*zone*	*long, short, zone*	Type of correlation applied from group-to-group covariance values *long* - correlation is applied between all groups *short* - correlation is applied only between adjacent groups *zone* - correlation is applied within fast, intermediate, and thermal groups, but no correlation is applied between zones
end	Required			Denotes end of input for current nuclide/reaction

Any MT number or reaction name will be treated as a valid input, but only those present on the k_1- or k_2-sensitivity data files will impact the results. The reaction sensitivity types computed by SAMS from TSUNAMI-1D and TSUNAMI-3D are described in the TSUNAMI-IP manual. An energy-covariance matrix is created for the specified nuclide-reaction pair with the square of the entered standard deviation for the diagonal terms for all groups using the *all*= value. Groups in the fast, intermediate, and thermal energies are then set to the square of the standard deviation value entered for *fast*=, *inter*=, and *therm*=, respectively. The off-diagonal terms of the energy matrix are generated according to the input for *corr*=, and *corr_type*=, with default settings of *1.0* and *zone.* Data entered in this block are used only for missing data and do not override values on the input covariance data file. The SCALE 5.1 input format is supported where data are entered in triplets with the nuclide name (e.g., u-235), then the reaction MT number or name (e.g., 18 or fission), and then a standard deviation value. In this case, the *end* keyword must not be entered. The standard deviation value is applied to all groups with default setting for correlations. These data are only used if *use_icov* is specified in the *PARAMETER* data block. When both *use_icov* and *cov_fix* are specified in the *PARAMETER* data block, and a reaction has zero or large (standard deviation > 1000%) values on the diagonal of the covariance matrix, these values are replaced with the square of the user input standard deviation value, and the corresponding off-diagonal terms are substituted according to the values of *corr* and *corr_type*.

6.7.3.3 HTML data

The optional *HTML* data block is used to customize HTML-formatted output. The *HTML* data block must begin with *READ HTML* and end with *END HTML*. The data input to the *HTML* data block consists of several keywords that are shown, along with their default values and descriptions, in Table 6.7.3. A keyword that ends with "=" must be followed by text data. For color entries, any valid html color name can be entered or the hexadecimal representation can be used if preceded by a # sign. For example, to change the background color of the html output to white, *bg_clr=white* and *bg_clr=#ffffff* have the same effect, because ffffff is the hexadecimal representation of white. An extensive list of available colors for customized output is shown in Sect. 6.3.4.1.7. Please note that not all features are supported by all browsers.

Table 6.7.3: Input data for html block of TSAR input.

Keyword	Default value	Description
bg_clr=	papayawhip	Background color
h1_clr=	maroon	Color used for major headings
h2_clr=	navy	Color used for sub-headings
txt_clr=	black	Color for plain text
lnk_clr=	navy	Color for hyperlinks
lnk_dec=	none	Decoration for hyperlinks. (none, underline, overline, line-through, blink)
vlnk_clr	navy	Color for visited hyperlinks
ud_clr=	blue	Color for values in tables that use default covariance data
ui_clr=	red	Color for values in tables that use user-input covariance data
udfix_clr=	royalblue	Color for values in tables that use default corrected covariance data
uifix_clr=	green	Color for values in tables that use user-input corrected covariance data

6.7.4 SAMPLE PROBLEM AND OUTPUT DESCRIPTION

6.7.4.1 Input and text output

An example of TSAR input is given in Example 6.7.1 Each section of the text output, not shown, is described in order below.

1. Input Listing and Summary of Calculations - The TSAR input data is printed for each data block. Both user-specified and default values for the various keywords are edited.

2. k1-Sensitivity Data File Summary and Sensitivity Coefficients — The header information for the k_1-sensitivity data files follows the input data. This includes the title on the sensitivity data file, the number of energy groups, the number of sensitivity profiles, and the values of k_1 and λ_1. If `print=all` is specified in the *PARAMETER* data block, the energy, region, and mixture-integrated k_1-sensitivity coefficients are edited for each nuclide-reaction pair.

3. k2-Sensitivity Data File Summary and Sensitivity Coefficients — The header information for the k_2-sensitivity data files follows the k_1-sensitivity data file edit. This includes the title on the sensitivity data file, the number of energy groups, the number of sensitivity profiles, and the values of k_2 and λ_1. If *print=all* is specified in the *PARAMETER* data block, the energy, region, and mixture-integrated k_2-sensitivity coefficients are edited for each nuclide-reaction pair.

4. Reactivity Value and Optional ρ-Sensitivity Coefficients — After the k_1 and k_2 sensitivity edits, the reactivity between the two states is edited in pcm units. If *print=all* or *print=rho* is specified in the *PARAMETER* data block, the energy, region, and mixture-integrated ρ-sensitivity coefficients are edited for each nuclide-reaction pair.

5. Reactivity Uncertainty Analysis — Following the edit of the reactivity value and the optional ρ-sensitivity edit, the reactivity uncertainty analysis is printed on the text output. First, a message is printed that states that the working covariance library is being generated. If *PARAMETER* block keywords `use_dcov`, `use_icov`, and/or `cov_fix` are specified, covariance warnings are printed whenever user-input covariance data are included in the reactivity uncertainty analysis. Following the covariance warnings, the total reactivity uncertainty is printed along with the reactivity uncertainty contributions from individual energy covariance matrices. The reactivity uncertainty contributions are sorted in descending order.

6.7.5 HTML OUTPUT

The input file for the TSAR sample problem shown in Example 6.7.1 is named tsar1.input. In this case, the HTML-formatted output is stored in a file called tsar1.html and additional resources are stored in directories called tsar1.htmd and applet_resources. This section contains example TSAR HTML-formatted output only for demonstration of the interface. The problem does not correspond to the sample problem distributed with SCALE and is included for illustrative purposes only. When tsar1.html is opened in a web browser, the information shown in Fig. 6.7.1 is displayed.

Fig. 6.7.1: Initial screen from TSAR HTML output.

The title of the input file is displayed between the two SCALE logos. Clicking on the SCALE logo will link the user directly to the SCALE website, if Internet access is available. Because this SCALE input file only executed TSAR, only a single output listing is available. The text "1. TSAR" is a hyperlink to view the output from TSAR. Clicking on the "1. TSAR" hyperlink will bring up the information shown in Fig. 6.7.2.

The initial page of output from TSAR is shown in Fig. 6.7.2. Program verification information is shown in the table under the TSAR logo. This table includes information about the code that was executed and the date and time it was run. The menu on the left side of the screen contains hyperlinks to specific portions of the code output. Echoes of the input data are available in the Input Data section. Any errors or warning messages are available in the Messages sections. Results from the code execution are shown in the results section.

Fig. 6.7.2: Program verification screen from TSAR HTML output.

Selecting Input Parameters will reveal the menu of available input data. Selecting Input Parameters causes the table shown in Fig. 6.7.3 to be displayed. Other input data can also be displayed by selecting the desired data from the menu.

PARAMETER	VALUE	DESCRIPTION
cov_fix	true	Replace zero and large values on diagonal of cross-section covariance data with user input values and dcov value.
large_cov=	10.0000	Cutoff fractional standard deviation value for cov_fix.
nocovar	false	Flag to cause the reactivity uncertainty edit to be turned off.
nohtml	false	Flag to cause HTML output to not be produced.
print=	all	If print=all (or nprt=2), Sensitivity edits are generated forthe initial state, final state, and reactivity. If print=rho (or nprt=1), reactivity sensitivities are editted. If print=none (or nprt=0), Sensitivity edits are not produced.
return_work_cov	true	Option to copy the working covariance data file back to the return directory.
type=	Relative	Format of the reactivity sensitivity data file.
udcov=	0.0500	User-defined default value of standard deviation in cross-section data to use for nuclide-reaction pairs for which covariance data are not available on the selected data file.
udcov_corr=	1.0000	User-defined default correlation value to use for nuclide-reaction pairs for which covariance data are not available on the selected data file.
udcov_corr_type=	zone	User-defined default correlation in cross-section data to use for nuclide-reaction pairs for which covariance data are not available on the selected data file. (long, zone, short)
udcov_fast=	0.1000	User-defined default value of standard deviation in cross-section data to use for fast data for nuclide-reaction pairs for which covariance data are not available on the selected data file.
udcov_inter=	0.1500	User-defined default value of standard deviation in cross-section data to use for intermediate data for nuclide-reaction pairs for which covariance data are not available on the selected data file.
udcov_therm=	0.0800	User-defined default value of standard deviation in cross-section data to use for thermal data for nuclide-reaction pairs for which covariance data are not available on the selected data file.
use_dcov	true	Use user-defined default covariance data, udcov, for nuclide reaction pairs not included on the covariance data file.
use_icov	true	Use user-defined data input in COVARIANCE input data block in place of udcov value for user input nuclide-reaction pairs that are not on the covariance data file.
sdf1=	41	Logical unit number for the initial state SDF file (lun1).
sdf2=	42	Logical unit number for the final state SDF file (lun2)

Fig. 6.7.3: Input parameters from TSAR HTML output.

Selecting Results causes a menu of available results to be revealed. From this menu, selecting Reactivity Sensitivities causes a submenu to be revealed. From the submenu, the Reactivity Sensitivities can be visualized in tabular format or plot format. Selecting Energy, Region, and Mixture Integrated Sensitivity Coefficients from this submenu causes the information shown in Fig. 6.7.4 to appear.

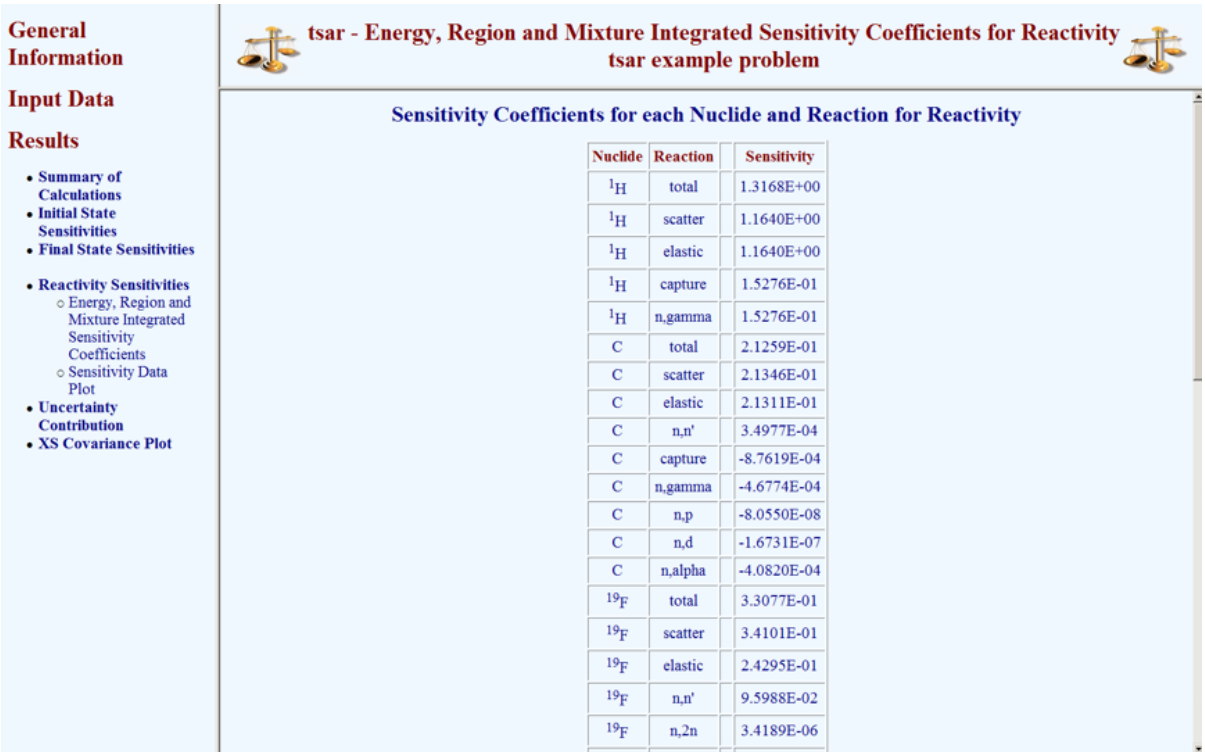

Fig. 6.7.4: Global integral indices from TSAR HTML output.

Plots of sensitivity data from the initial and final states as well as the reactivity sensitivities are available for viewing in the TSAR HTML output. If the *return_work_cov* keyword option is included in the PARAMETER block on the TSAR input file, then the covariance data can be viewed by selecting “XS Covariance Plot” in the results submenu. A Java applet version of Javapeño will appear in the browser window with the working covariance library preloaded. Data can be added to the plot by double-clicking on the list of available data on the right side of Javapeño. The plot shown in Fig. 6.7.5 was produced with this procedure.

6.8 TSURFER: AN ADJUSTMENT CODE TO DETERMINE BIASES AND UNCERTAINTIES IN NUCLEAR SYSTEM RESPONSES BY CONSOLIDATING DIFFERENTIAL DATA AND BENCHMARK INTEGRAL EXPERIMENTS

M. L. Williams, B. L. Broadhead, M. A. Jessee, J. J. Wagschal1, and R. A. Lefebvre

ABSTRACT

The TSURFER code uses the generalized linear least-squares method to consolidate a prior set of measured integral responses (such as k_{eff}) and corresponding calculated values obtained using the SCALE nuclear analysis code system. The initial estimates for the computed and measured responses are improved by adjusting the experimental values and the nuclear data used in the transport calculations-taking into account their correlated uncertainties-so that the most self-consistent set of data is obtained. This procedure makes the refined estimates of the calculated and measured responses agree within first-order accuracy, while constraining the data variations to minimize a generalized chi-square parameter. Consolidation of the original integral experiment data and calculated results reduces the prior uncertainty in the response estimates because additional information has been incorporated. The method can also address one or more "*application responses*" for which no experimental measurements are available. TSURFER computes an updated estimate for the application responses and provides an estimate for the computational bias and application uncertainty. The methodology is useful in validation studies for criticality safety and reactor analysis.

ACKNOWLEDGMENTS

The authors would like to acknowledge R. L. Childs, formerly of ORNL, for his contributions. Development of the TSURFER code was funded by the U.S. Department of Energy Nuclear Criticality Safety Program.

6.8.1 INTRODUCTION

This report describes the TSURFER code (**T**ool for **S**ensitivity/**U**ncertainty analysis of **R**esponse **F**unctionals using **E**xperimental **R**esults-pronounced "*surfer,*" with silent "T" like TSUNAMI), which is a functional module in the SCALE sensitivity and uncertainty (S/U) analysis methodology (see the TSUNAMI-1D chapter). The main functions of the code are to (a) compute uncertainties in calculated integral responses such as k_{eff}, due to uncertainties in the input nuclear data; (b) reduce discrepancies between the measured and calculated responses by adjusting the nuclear data and experimental values such that the overall consistency is maximized; (c) analyze measured responses from benchmark experiments to establish the bias and associated uncertainty in some application response that has been calculated.

TSURFER utilizes the generalized linear least-squares (GLLS) methodology based on S/U techniques originally developed in the 1970's and 1980's for a variety of applications, including nuclear data evaluation, [TSURFER-PRR+74] fast reactor design studies, [TSURFER-PC88, TSURFER-WML+76] and reactor pressure vessel damage predictions [TSURFER-MWB81]. A recent GLLS application has been in the area of criticality safety analysis, in which critical benchmarks are used to validate the computational methodology for predicting subcritical quantities and configurations of fissile materials [TSURFER-BRH+04]. Similar validation procedures also could be performed for other integral responses of interest for nuclear reactor analysis. These include responses such as reactivity coefficients associated with coolant voiding or Doppler broadening, peak power values, or in-core instrumentation readings. Although not limited to this area, the application of TSURFER to criticality safety validation studies is emphasized here.

6.8.1.1 Application to validation studies

Historically the validity of a calculation performed for some application has been established by considering how well the same calculational methods and nuclear data perform for a set of representative benchmark experiments. While a simple comparison of the computed and experimental results is very informative, it does not fully take advantage of the valuable information provided by the measured integral responses. If the original sets of calculated and experimental responses are consolidated in a consistent manner (i.e., correctly accounting for uncertainties), then the "adjusted" results should be a better estimate for the true responses, since the revised response values are based upon more information than was available in either the original calculations or measurements alone. This is essentially a statement of Bayes Theorem from probability theory, which indicates how prior information (calculated responses) can be evolved by incorporating additional information (integral measurements) into more reliable posterior results (the adjusted responses). The equations used for the GLLS methodology are equivalent to those obtained from Bayes Theorem [TSURFER-Hwa88].

Cross-section libraries for neutron transport calculations are processed from fundamental evaluated nuclear data files such as ENDF/B. Because the "true" values of the nuclear data are not known precisely, it is reasonable to view the ENDF data as being selected from a probability distribution of allowable values. Nuclear data uncertainties are described by covariance matrices that contain variances in the group cross sections for a given nuclide and reaction type, as well as covariances arising from correlations between energy groups, and possibly between reactions and materials. Discrepancies in the ENDF nuclear data caused by uncertainties in the evaluation process propagate to errors in group cross sections, which in general cause computed responses to disagree with the corresponding measured values. The GLLS approach considers potential variations in data parameters and measured integral responses that minimize the differences in measured and calculated integral responses (such as k_{eff}) for a set of benchmark experiments, *taking into account uncertainties and correlations in the ENDF data and in the integral measurements*. Since there are generally many more cross-section values than measured integral responses, the determination of the data modifications is an under-determined problem. If the data variations are not performed in a reasonable

manner, non-physical changes may be obtained. Data adjustments in the GLLS methodology are constrained by the magnitude of the nuclear data uncertainties and their correlations. TSURFER also accounts for uncertainties and correlations in the integral response measurements, arising from experimental uncertainties in parameters such as enrichment, density, impurities, etc. As long as realistic data covariances are used, the resulting data adjustments may be considered the "best estimates"-within the limitations of the GLLS linearity approximation-for realistic data alterations that improve the computed integral responses. It can be shown that the GLLS equations provide the maximum likelihood estimator for the correct nuclear data if the evaluated nuclear data and system parameters obey a multivariate normal probability distribution [TSURFER-Hwa88].

Some previous studies have applied the GLLS methodology to produce an adjusted nuclear data library in order to improve calculations of nuclear reactors with similar characteristics as the experiments used in the adjustment [TSURFER-TTYS88]. In criticality safety analysis this procedure runs the risk of applying the adjusted library to systems beyond the limits for which the data modifications are appropriate. The usual function of TSURFER is not to output an adjusted nuclear data library but rather to obtain an adjusted application response (k_{eff}) and to provide a quantitative estimate for its accuracy. Hence, it is more appropriate to view TSURFER as a tool to establish biases and uncertainties in calculated responses. Nuclear data adjustments are a by-product of this procedure.

Traditional validation of criticality safety calculations estimates the computational bias based on trends in the calculated k_{eff} values versus system parameters such as hydrogen-to-fissile ratios (H/X) or energy of average lethargy causing fission (EALF). These trending parameters are frequently used as measures of "similarity" between critical systems, hence their use as bias-predictors. Recent studies have shown that data sensitivity coefficients, either alone or in combination with cross-section uncertainty information, are good indicators of system similarity. Thus S/U-based indices have also been used in trending analyses, analogously to the commonly used physical parameters.[5] The input data for S/U trending analysis (i.e., calculated and measured responses, sensitivity coefficients, cross-section and experimental uncertainties) are almost identical to those needed for GLLS analysis; therefore, it is not surprising that some aspects of the TSURFER calculations are also used for trending results. However, TSURFER provides an alternative to the trending approach to determine the bias and can address other validation issues. For example, TSURFER is useful when there are few or no existing experiments that are similar to a particular application area, since the GLLS technique can include individual experiments that separately validate portions of the application area, even though none can be considered entirely similar to the application [TSURFER-Gol04].

6.8.1.2 Types of responses

A response corresponds to a particular integral response *type* (e.g., k_{eff}, reaction rate ratio, material worth, radiation dose, etc.) in a particular *nuclear system* (e.g., a benchmark experiment or a proposed storage arrangement of reactor fuel assemblies or a reactor core). In the TSURFER input, responses may be classified either as "*experiments*" or "*applications*" or "*omitted*."

An *experiment* response has both calculated and measured values input to TSURFER, and these play an active role in the GLLS procedure, which minimizes the difference between the two results. A value for the uncertainty in the measured response and any correlations with other experiments are also input for experimental responses. Examples of experimental integral responses are the multiplication factor for the GODIVA critical benchmark experiment, the measured ρ^{28} (ratio of epithermal to thermal capture rate for ^{238}U) in the TRX-1 critical benchmark lattice, or the coolant voiding reactivity in a power reactor.

Applications are responses for which a calculated value is known but no measured value is available. Applications often correspond to hypothetical systems being considered within the context of a design study or a criticality safety analysis for which the computational bias and uncertainty are desired. Examples of application responses are the multiplication factor (subcritical) for a proposed fuel assembly storage rack

or for a shipping cask. An application response plays a passive role in the GLLS procedure. Since the application has no experimental results, it does not impact the active responses included in the consolidation procedure; conversely, the GLLS procedure may modify the calculated application value if it is "similar" to some of the experimental responses. In this case the application response shares similar data sensitivity characteristics with one or more of the active responses and hence will be indirectly affected by the same data adjustments that impact the similar experimental responses. This provides a systematic, well-defined method for utilizing experimental benchmark measurements to establish a bias and uncertainty in the calculation of application response.

A response designated as *omitted* in the TSURFER input neither affects other responses nor is affected by them. These responses are completely isolated from the GLLS procedure. This capability is sometimes useful to easily "turn off" an active system to observe its impact on the application results or on the consistency (chi-square) of the set of remaining experimental responses.

6.8.2 SOURCES OF RESPONSE UNCERTAINTY

Transport calculations of responses such as the neutron multiplication factor inherently have biases and uncertainties due to several factors that can be grouped into three classes:

(A) numerical approximations in the transport code;

(B) system modeling approximations; and

(C) input data uncertainties.

6.8.2.1 Class-A uncertainties (numerical)

Class-A uncertainties are sometimes referred to as "methods uncertainties." In Monte Carlo calculations these may be caused by imperfections in random number generation routines, approximations in techniques for scoring neutron multiplication (e.g., incomplete convergence of fission source distribution, neglect of correlations between generations, etc.), and biases from algorithms used to represent nuclear data and to sample probability distributions, as well as the basic statistical uncertainty that is fundamental to the Monte Carlo method. Deterministic methods have uncertainties from using finite space-energy-direction meshes, truncated (rather than infinite) expansions of functions, incomplete convergence of iterations, and especially self-shielding approximations for the multigroup cross sections. Computational benchmark studies often can establish a reasonable upper limit for these effects, which may be judged either as negligible or as requiring some conservative bias to be applied to the application calculations. Here it is assumed that class-A uncertainties in the calculated response can be made acceptably small (e.g., by running more histories or refining mesh sizes) or at least have been previously quantified and can be bounded by a margin applied to the computation. Hence class (A) uncertainties are considered as systematic "tolerance," and are not addressed in the present GLLS methodology used by TSURFER.

6.8.2.2 Class-B uncertainties (modeling/experimental)

Class-B uncertainties occur because the mathematical model used in the transport computations of an application or an experimental response does not correspond exactly to the "true" system. The response uncertainty caused by modeling effects may be associated with either (i) direct computational simplifications such as omitting or homogenizing some components in the calculation model or (ii) fundamental uncertainties in the material compositions, densities, and dimensions of the experiment. The former are systematic uncertainties similar in effect to Class-A numerical uncertainties and may be addressed in the same manner; that is, by bounding the magnitude of the uncertainty through the applied safety margins. However, the latter are true random uncertainties that in theory have probability distributions, and these may be addressed with the TSURFER code.

Even "clean" critical benchmark experiments have uncertainties in the nominal system parameters-such as fuel enrichment, impurities, densities, critical dimensions, and numerous other components-that may lead to discrepancies in the measured and calculated responses for the system. In TSURFER the impact of these uncertainties is designated as the "experimental uncertainty" in the response, since this uncertainty will be present even if no simplifications or approximations are made in the model used for the transport computation. The terminology is sometimes a source of confusion. For example the measured k_{eff} in a critical experiment usually is known to be unity with a very small uncertainty associated with the long, but finite, stable period. While there is little doubt about k_{eff} for a critical experiment, there may be considerable uncertainty in the system parameter values describing the benchmark configuration. This contribution to the modeling uncertainty could be justifiably considered either "experimental" (because system parameters such as material compositions and dimensions are specified by the experimentalists) or "computational" (because uncertainties in the system parameters affect the calculation model), but in TSURFER they are designated as experimental uncertainties. In any case the uncertainty in each system parameter must be propagated to an uncertainty in the measured response. For a k_{eff} response this may be done experimentally by physically varying the system parameter and measuring the reactivity effect or, more commonly, by performing auxiliary transport calculations to determine the eigenvalue variation. This is discussed in a somewhat more quantitative manner in Sect. 6.8.4.1.

The response uncertainty components associated with the respective modeling uncertainties in system parameters determine the overall experimental uncertainty. Many benchmark experiment descriptions in the *International Handbook of Evaluated Criticality Safety Benchmark Experiments* [TSURFER-Bri06] include information about uncertainties in the system parameters and their estimated impact on the multiplication factor. The standard deviations in k_{eff} due to uncertainties in various system parameters are assigned by the benchmark evaluators based on published or archived experiment descriptions, and sometimes on other considerations.

A complication in specifying experimental uncertainties is how to treat correlations among the experiments. Response correlations in two benchmark experiments may be caused by factors such as use of the same fuel pins and container tank, and common instrumentation (same detectors, hydrometers, etc.). For example, if two different experiments use the same fuel material, then it is not reasonable to conclude that the enrichment in one is too high while the other is too low, even if both differences fall within the specified standard deviation. Reference [TSURFER-WBP01] has shown that these correlations may not be negligible when applying the GLLS technique to a set of benchmark experiments. Only a limited amount of experiment correlation data has been published, but more is expected in future revisions to the *International Handbook of Evaluated Criticality Safety Benchmark Experiments*. TSURFER allows experimental uncertainties caused by uncertainties in system modeling parameters to be input for individual components and correlation coefficients can be specified for the shared system parameters of each response. This approach provides the capability for users to describe the actual sources of benchmark experiment correlations without having to know the overall correlation between two different experiments. See Sect. 6.8.4.1 and Sect. 6.8.4.2.

6.8.2.3 Class-C uncertainties (nuclear data)

In many applications, the major source of uncertainty in the calculated response is due to uncertainties in evaluated nuclear data such as microscopic cross sections, fission spectra, neutron yield (nu-bar), and scattering distributions that are contained in ENDF/B. These arise from uncertainties in experimental nuclear data measurements, as well as uncertainties in the evaluation process itself, which in general combine differential experimental information with nuclear physics theory to generate the basic data in compilations like ENDF/B. Class-C uncertainties are governed by probability distributions. The actual probabilities are unknown, but the evaluated data values are assumed to represent the mean of the distribution, and the evaluated variance represents a measure of the distribution width. Correlations as well as uncertainties in nuclear data

can have a significant impact on the overall uncertainty in the calculated response; thus, it is important to include covariances as well as variances in the TSURFER calculations. The uncertainties in fundamental nuclear data also impact resonance self-shielding of multigroup cross-section values, further contributing to the response uncertainty [TSURFER-WBP01]. In the SCALE S/U methodology the effects of implicit changes in self-shielded cross sections are included in the overall response *sensitivity coefficients*, rather than in the covariance data, so that the fundamental data uncertainties are isolated from problem-specific effects [TSURFER-LKH+08]

Covariance information is currently quite limited in all evaluated nuclear data compilations such as ENDF/B. A more complete library of multigroup uncertainties has been created for SCALE using data from a variety of sources, including ENDF/B-VI and VII, JENDL3.1, and approximate covariances based on uncertainties in measured integral data and nuclear model calculations [TSURFER-LKH+08, TSURFER-WR08]. A detailed description of the SCALE covariance libraries is found in the COVLIB chapter.

The GLLS methodology in TSURFER is mainly concerned with treating Class-C uncertainties due to nuclear data, along with Class-B experimental uncertainties.

6.8.3 ANALYSIS PROCEDURE

6.8.3.1 Functional relation to other SCALE modules

TSURFER is a functional module within the overall SCALE S/U methodology. Other modules in SCALE and outside SCALE perform complementary calculations and provide data files used by TSURFER, as described below.

- PUFF-IV: AMPX code that processes ENDF/B nuclear data covariances and generates multigroup covariance data; creates nuclear data uncertainty files for input to TSURFER.
- TSUNAMI-1D/2D/3D SCALE control sequence that computes sensitivity coefficients for k_{eff} or other responses in a 1D/2D/3D model of the experiment or application system; creates sensitivity files used by TSURFER.
- TSAR: SCALE functional module that computes sensitivity coefficients for eigenvalue-difference responses such as reactor reactivity parameters, using k_{eff} sensitivities from a TSUNAMI sequence; creates sensitivity files used by TSURFER.
- TSUNAMI-IP SCALE functional module that computes similarity and completeness indices for a set of responses with sensitivity coefficients. Prior to running TSURFER, it may be advantageous to perform scoping studies with TSUNAMI-IP to determine if the selected set of benchmark experiments provides adequate "coverage" for data uncertainties that have a significant impact on the application response.

6.8.3.2 Guidelines for TSURFER analysis

Both active and passive responses may be included in the TSURFER calculation. For example, in criticality safety validation procedures, responses of interest typically correspond to the system multiplication factor, k_{eff}. The desired sub-critical design configuration would be a passive application system, while the critical benchmarks used for validation are active experiment systems. TSURFER determines the application bias and uncertainty by propagating data variations obtained from GLLS analysis of the active systems to the calculated multiplication factor of the passive system. The bias represents the change of the application's original k_{eff} as a result of the consolidation of all the active critical benchmark experiments and the adjusted nuclear data parameters. An increase in k_{eff} computed for the applications system response indicates that the calculated value was initially too low (a negative bias), and a decrease that the application's multiplication factor was too high (a positive bias).

TSURFER also computes uncertainties in the initial and adjusted estimates for the system responses (e.g., multiplication factors). These response uncertainties include effects of experimental uncertainties (class-B) and nuclear data uncertainties (class-C) but not the impact of simplifications made to the experiment specifications and numerical approximations (class-A)-which should be included in the safety margin.

Several quantities can be examined to give confidence to the predicted results [TSURFER-BHCP99, TSURFER-BHP99]. The first is the completeness parameter, R, given in the output of the TSUNAMI-IP code. It has been suggested that values of R greater than about 0.7-0.8 for a set of active experiments indicate adequate cross-section coverage for an application response in the GLLS procedure; however, this is a preliminary conclusion that may change as more experience is gained [TSURFER-Gol04].

The *chi-square* (χ^2) statistic indicates the overall consistency of the suite of benchmarks and is key to proper interpretation of the TSURFER results. The value of χ^2 per degree of freedom represents the average discrepancy between the calculated and measured responses, expressed in units of the combined variance of the calculation plus experiment. Values of chi-square per degree of freedom ideally should be within about ±20% of unity, indicating that the calculations and measurements on average agree within about one standard deviation. Results in which this test is not strictly met may still be valid, but in general these should be viewed with skepticism unless the reasons for the test failure are understood. An excessively large χ^2 can lead to unreliable results in the GLLS adjustment. TSURFER provides the total χ^2 value, as well as estimated contributions from each experiment (see Sect. 6.8.4.2.1). Individual χ^2 values suggest which experiments may contain inconsistencies (i.e., the difference between the measured and calculated k_{eff} is larger than their combined uncertainties).

Several methods can be used to improve the initial value of chi-square. One approach is to reevaluate the measurement uncertainties and their correlations for identified discrepant experiments. If the experimental or data uncertainties are underestimated, the data adjustments will correspond to an excessive number of standard deviations, as reflected in high χ^2 values. Values of χ^2 that are too low suggest that the input uncertainty estimates may be too high, and again a reevaluation should be considered. Thus it is quite important to utilize *realistic* (not conservative) estimates for the uncertainties in nuclear data and experimental measurements.

Even when best estimates are used for all input uncertainties, it is not uncommon to encounter a few active responses that are inconsistent with the others, especially when dealing with a large number of benchmark experiments. In this case the best alternative to improve χ^2 is to remove the outliers, either by transforming those experiments into passive responses or by omitting them entirely from the GLLS adjustment. TSURFER provides a "chi-square filtering" procedure that automatically omits inconsistent experiments until a specified target value of chi-square is achieved. Several options are provided to select the experiments to be omitted, as discussed in Sect. 6.8.4.2.1. Omitted experiments should be examined to ensure that simple errors in the problem description are not present.

An internal consistency test such as described in [TSURFER-BHCP99] also may be useful. The consistency test is performed by changing one of the benchmark experiments that is similar (see Sect. 6.8.4.3) to the application response into a passive, pseudo-application response. The predicted bias for this passive response should be close to that of the original application; furthermore, in this case the bias prediction can be checked because this passive response actually has a measured experimental value.

6.8.3.3 Required data for TSURFER

Active and passive responses considered in the GLLS analysis should have sensitivity data provided for each nuclide-reaction pair that significantly impacts the response. The sensitivity coefficients are pre-calculated using other SCALE modules as described in Sect. 6.8.3.1 and are stored in individual files for each response included in the TSURFER analysis. The sensitivity data files must be in one of the SCALE sensitivity data formats described in Data File Formats. The locations of the sensitivity files are specified in the TSURFER input data. It is not required for all sensitivity files to have the same group structures; for example, the sensitivity coefficients for one response may have been computed using a 238-group cross-section library, while sensitivities for another response could have a 44-group structure. Whatever the group structure of the sensitivity data, it is mapped into the same group structure as the covariance file. At present the SCALE covariance files use the SCALE 56-group structure by default.

A file of nuclear data covariances also must be input to the TSURFER calculation. The covariance data file must be in COVERX format described in the COVERX format section. SCALE includes a comprehensive applications-oriented covariance library that includes evaluated covariances taken from ENDF/B-VII, ENDF/B-VI, and JENDL nuclear data files [TSURFER-WR08] described in the COVLIB chapter. Ideally, the covariance files should contain data for all nuclide-reaction pairs on the response sensitivity data files. However, cross-section covariance data are not available for all nuclide-reaction pairs. Nuclide-reaction pairs without available covariance data are omitted from the GLLS analysis, but it is assumed that either the cross-section covariance data values for these pairs are well known (i.e., small uncertainties) or that the sensitivity to these nuclide-reaction pairs is small. Where these assumptions hold, the cross sections for these nuclide-reaction pairs should not be adjusted and can be omitted from the GLLS analysis. For situations where these assumptions are judged to be invalid, the use of GLLS analysis is not appropriate. However, TSURFER provides several input options to define uncertainty values for nuclide-reaction pairs with missing covariance data to assess the impact of the additional covariance data on the GLLS analysis. These input options are discussed in more detail in Sect. 6.8.5.1 and Sect. 6.8.5.3.

6.8.4 TSURFER COMPUTATION METHODOLOGY

A recent detailed derivation of the GLLS formalism is given in [TSURFER-BHCP99]. The general formalism allows cross correlations between the initial integral experiment measurements and the original nuclear data, such as would be present if the calculations used a previously "adjusted" library of nuclear data. Since this is not normally done in SCALE, correlations between the benchmark experiment measurements and the cross-section data in the multigroup libraries are not considered in the TSURFER code; therefore, the GLLS equations presented here are somewhat simplified compared to the more general expressions in [TSURFER-Wil86].

At present, the SCALE cross-section-covariance data files characterize nuclear data uncertainties in terms of relative covariances. Therefore, response sensitivity data in TSURFER are defined in terms of relative changes in the nuclear data. An *absolute* response sensitivity is defined as an absolute change in response due to a relative change in the nuclear data, that is,

$$\tilde{S}_{\alpha}=\alpha\frac{\partial \mathrm{R}}{\partial \alpha} \tag{6.8.1}$$

In this equation, R represents the response, α represents the nuclear data, and the tilde will be used to represent absolute sensitivity and uncertainty data. Likewise, a *relative* response sensitivity is defined as a relative change in response due to a relative change in the nuclear data, that is,

$$\mathrm{S}_{\alpha}=\frac{\alpha}{\mathrm{R}}\frac{\partial \mathrm{R}}{\partial \alpha} \tag{6.8.2}$$

The initial development that follows is for *relative*, rather than *absolute*, response sensitivity and uncertainty parameters. It is then shown how to express the quantities in absolute form for reactivity analysis and mixed relative-absolute form for combined k_{eff} and reactivity analysis. A summary of the notation and definitions used in this section can be found in TSURFER Appendix A: Sensitivity/Uncertainty Notation.

The methodology consists of calculating values for a set of I integral responses (k_{eff}, reaction rates, etc.), some of which have been measured in selected benchmark experiments. Responses with no measured values are the selected "applications," described previously. The set of measured response values $\{m_i ; i=1,2,\ldots, I\}$ can be arranged into an I-dimension column vector designated as **m**. By convention the (unknown) experimental values corresponding to applications are represented by the corresponding calculated values. As discussed in Sect. 6.8.2.2, the measured integral responses have uncertainties—possibly correlated—due to uncertainties in the system parameter specifications. The I × I covariance matrix describing the relative experimental uncertainties is defined to be $\mathbf{C_{mm}}$.

The calculated integral values for each experiment and application are obtained by neutron transport calculations, producing a set of calculated responses $\{k_i ; i=1,2,\ldots, I\}$ arranged in a I-dimension vector **k**. The multigroup cross-section data for all nuclide-reaction pairs used in the transport calculations of all responses comprise a set $\{\alpha_n ; n=1,2,\ldots, M\}$, where M is the number of unique nuclide-reaction pairs multiplied by the number of energy groups. It is convenient to arrange these data into a M-dimensional column vector α, so that the dependence of the initial calculated responses upon the input nuclear data values can be indicated as $\mathbf{k} = \mathbf{k}(\alpha)$. The prior covariance matrix for the nuclear data is equal to the M × M matrix $\mathbf{C}_{\alpha\alpha}$, which contains relative variances along the diagonal and relative covariances in the off-diagonal positions. These data describe uncertainties in the *infinitely dilute* multigroup cross sections.

Nuclear data uncertainties cause uncertainties in the calculated response values. In general, these uncertainties are correlated because the same nuclear data library is used for all the transport calculations. The covariance matrix describing uncertainties in the calculated responses due to class-C uncertainties is designated as $\mathbf{C_{kk}}$. Using expressions for propagation of error (the so called sandwich rule), the following relationship is obtained for the relative uncertainty in the calculated responses:

$$\mathbf{C_{kk}} = \mathbf{S_{k\alpha}} \mathbf{C_{\alpha\alpha}} \mathbf{S^T_{k\alpha}} \tag{6.8.3}$$

where $\mathbf{S_{k\alpha}}$ is the relative sensitivity matrix, whose (i, n) element is equal to the relative sensitivity of the i_{th} response with respect to the n_{th} data value, that is, $\frac{1}{R_i}\frac{\partial R_i}{\partial \alpha_n}\alpha_n$. Sensitivity coefficients appearing in the sensitivity matrix are computed using first-order perturbation theory. A description of the equations used to compute sensitivity coefficients using first order perturbation theory can be found in [TSURFER-Wil86] or in the SAMS chapter. In the SCALE methodology, the sensitivity coefficients consist of an "explicit" component that accounts for the direct impact of the data on the neutron transport calculation, as well as an "implicit" component that accounts for its impact on other self-shielded multigroup data [TSURFER-WBP01]. For example, a variation in the hydrogen multigroup elastic cross section has an explicit effect on k_{eff} through its impact on neutron moderation and leakage in the transport solution and has an implicit effect on the self-shielded ^{238}U multigroup cross sections, which causes additional change in k_{eff}. Because self-shielding effects are addressed through the sensitivity coefficients, the nuclear data uncertainties in the covariance matrix correspond to the infinitely dilute values.

Each row i of the sensitivity matrix contains sensitivity coefficients for all nuclear data used in the transport calculation of response i. These data also can be arranged into an M-component sensitivity *vector* $\mathbf{S}_i$ for a particular response "i", which may be either an experiment or application. For example, the sensitivity vector $\mathbf{S}_i$ is an M dimensional vector whose n^{th} element is equal to the sensitivity coefficient of response "i" to data element α_n as specified previously.

It is often convenient to express covariance matrices in terms of standard deviations [represented as σ_{i} for variable *i*] and correlation coefficients [represented by $\rho_{i,j}$ for the variable pair (*i,j*)]. The correlation coefficient is related to the corresponding covariance value by the equation

$$\rho_{\mathrm{i,j}} = \frac{\mathrm{Cov(i,j)}}{\sigma_{\mathrm{i}}\sigma_{\mathrm{j}}} \tag{6.8.4}$$

Correlation coefficients, which have values between -1 and 1, indicate the degree of correlation between the pair of variables, where a value of 1.0 indicates full correlation, 0.0 no correlation, and -1.0 full anti-correlation. Using matrix notation, relative standard deviations are arranged in a diagonal matrix $\boldsymbol{\sigma}$ and the correlation coefficients in a square matrix $\mathbf{R}$ (symmetrical, but generally non-diagonal). The previously defined covariance matrices can be expressed as follows:

$$\mathbf{C_{mm}} = \sigma_{\mathbf{m}}\mathbf{R_{mm}}\sigma_{\mathbf{m}} \tag{6.8.5}$$

$$\mathbf{C}_{\boldsymbol{\alpha\alpha}} = \sigma_{\boldsymbol{\alpha}}\mathbf{R}_{\boldsymbol{\alpha\alpha}}\sigma_{\boldsymbol{\alpha}} \tag{6.8.6}$$

$$\mathbf{C_{kk}} = \sigma_{\mathbf{k}}\mathbf{R_{kk}}\sigma_{\mathbf{k}} \tag{6.8.7}$$

Eq. (6.6.3) and Eq. (6.8.7) can be substituted into Eq. (6.8.3) and rearranged to relate the nuclear data correlations to the correlations in the computed responses:

$$\mathbf{R_{kk}} = \left[\boldsymbol{\sigma}_{\mathbf{k}}^{-1}\ \mathbf{S}_{\mathbf{k}\boldsymbol{\alpha}}\boldsymbol{\sigma}_{\boldsymbol{\alpha}}\right]\mathbf{R}_{\boldsymbol{\alpha\alpha}}\left[\boldsymbol{\sigma}_{\mathbf{k}}^{-1}\ \mathbf{S}_{\mathbf{k}\boldsymbol{\alpha}}\sigma_{\boldsymbol{\alpha}}\right]^{\mathbf{T}}. \tag{6.8.8}$$

The bracketed term on the right side of the above equation is an I × M matrix whose elements equal the number of relative standard deviations ($\boldsymbol{\sigma}_{\mathbf{k}}$) that the response changes, due to a one relative standard deviation change in the nuclear data ($\boldsymbol{\sigma}_{\boldsymbol{\alpha}}$). Even if the nuclear data are not correlated—that is, $\mathbf{R}_{\boldsymbol{\alpha\alpha}}$ is an identity matrix—$\mathbf{R_{kk}}$ is generally not diagonal.

The expressions thus far describe *relative* response sensitivities and covariances (i.e., uncertainties). Similar expressions can also be derived for absolute quantities. In this report, absolute response sensitivities and covariances are denoted by a tilde, such as $\tilde{\mathbf{C}}_{\mathbf{mm}}$, $\tilde{\mathbf{C}}_{\mathbf{kk}}$, and $\tilde{\mathbf{S}}_{\mathbf{k}\boldsymbol{\alpha}}$, which are explicitly defined in Appendix A.

TSURFER allows for a mixed relative and absolute response sensitivities and covariances to be used in the analysis. In the TSURFER input (described in Sect. 6.8.5), each response is designated as an *absolute*-formatted response or a *relative*-formatted response using the input keywords *"absolute"* or *"relative"*. This flexibility allows for the simultaneous use of both relative-formatted k_{eff} sensitivity data (generated by TSUNAMI modules) and absolute-formatted eigenvalue-difference sensitivity data (generated by TSAR) in the same analysis. In this report, mixed relative-absolute response sensitivities and covariances are denoted by a caret, such as $\hat{\mathbf{C}}_{\mathbf{mm}}$, $\hat{\mathbf{C}}_{\mathbf{kk}}$, and $\hat{\mathbf{S}}_{\mathbf{k}\boldsymbol{\alpha}}$.

6.8.4.1 Representation of experimental uncertainty components

Experimental uncertainties (i.e., type-B uncertainties as described in Sect. 6.8.2.2) may be entered directly in the TSURFER input, or alternatively, it may be specified by defining individual "uncertainty components." The latter approach is useful in defining experimental correlations between measured responses. In this case, an index " ℓ " is introduced to identify the response uncertainty components associated with a particular system parameter, p_{ℓ}. For example, the measured k_{eff} uncertainty components for a particular critical experiment consisting of uranyl nitrate dissolved in water might correspond to the following eight p_{ℓ} contributors, as identified by the value of (ℓ): (1) isotopic composition; (2) fuel concentration in the solution; (3) solution density; (4) excess acid concentration in the solution; (5) fuel impurities; (6) dimension of the solution tank; (7) thickness of the solution tank; (8) composition of the tank [TSURFER-Bri06].

The relative standard deviation of a measured response m_i due to an uncertainty in the system parameter p_ℓ is designated as the uncertainty component $\sigma_{m,i}^{(\ell)}$. Assuming that uncertainties in system parameters are uncorrelated, the response uncertainty component is related to the uncertainty in system parameter p_ℓ by the expression

$$\sigma_{m,i}^{(\ell)} = \frac{1}{m_i}\left(\frac{\partial k_i}{\partial p} p\right)\sigma_p = S_{m_i p}\sigma_p, \tag{6.8.9}$$

where σ_{p_ℓ} is the relative standard deviation of system parameter p:$_\ell$ and $S_{m_i p_\ell}$ is the relative sensitivity coefficient relating p_ℓ to the measured response m_i. In principle, the system parameter values and uncertainties could be treated directly in the TSURFER calculation by providing the sensitivity coefficients $S_{m_i p_\ell}$, thus allowing the experiment parameters to be included in the GLLS adjustment. However, at the present time the response uncertainty components $\boldsymbol{\sigma}_{m,i}^{(\ell)}$ must be determined prior to the TSURFER calculation and are read into TSURFER. Values for the response uncertainty components sometimes can be found in the benchmark experiment specifications [TSURFER-Gol04], or auxiliary sensitivity analysis may be necessary. The relative experimental standard deviation of the i_{th} measured response is calculated from

$$\sigma_{m,i} = \sqrt{\sum_1 \left(\sigma_{m,i}^{(1)}\right)^2} \tag{6.8.10}$$

The (i,i) diagonal element of the relative covariance matrix corresponds to the relative experimental variance in response i, which is equal the square of $\sigma_{m,i}$ above. Note that similar expressions can be derived for uncertainty components using absolute sensitivities and uncertainties. For absolute-formatted responses, the uncertainty components on the TSURFER input must be entered in terms of absolute standard deviation. This is discussed in more detail in Sect. 6.8.5.2.

If a different response j is measured in a benchmark system that shares some or all of the same uncertainty components as response i, then the two experiment responses have correlated uncertainties. In such a case the (i, j) element of the relative covariance matrix $\mathbf{C_{mm}}$ is equal to

$$C_{mm}(i,j) = \sum_\ell \left(\sigma_{m,i}^{(\ell)}\sigma_{i,j}^{(\ell)}\sigma_{m,j}^{(\ell)}\right) \tag{6.8.11}$$

and the total correlation coefficient for response pair (i, j) is

$$R_{mm}(i,j) = \frac{C_{mm}(i,j)}{\sigma_{m,i}\sigma_{m,j}} = \frac{\sum\left(\sigma_{m,i}^{(\ell)}\rho_{i,j}^{(\ell)}\sigma_{m,j}^{(\ell)}\right)}{\sigma_{m,i}\sigma_{m,j}} \tag{6.8.12}$$

where $\rho_{i,j}^{(\ell)}$. is the correlation coefficient for responses i and j due uncertainty component ℓ.

TSURFER allows the user to input text-identifiers for the various experiment uncertainty components, along with the associated values for relative standard deviations, $\sigma_{m,i}^{(\ell)}$. Response correlation coefficients $\rho_{i,j}^{(\ell)}$ can be input for each type of uncertainty component, by response pair (i, j).

The previous discussion applies only to *experiment responses* for which measurements have been performed. In the case of an *application response* for which no experimental measurement is known, the uncertainty is set internally by TSURFER to the large value of 10^{10}, to approximate the "infinite" uncertainty in the unknown measurement, and correlations to other responses are set to zero. The large uncertainty for an application response has the effect of letting the response "float" in a passive manner; that is, the application response has a negligible effect on the adjustment of active responses, but the GLLS consolidation of the active responses with finite uncertainties can impact the adjusted value for the application.

6.8.4.2 Generalized linear least-squares equations

Discrepancies in the calculated and measured responses are defined by the I dimensional column vector

$$\mathbf{d} = \left\{ \mathrm{d}_i = \frac{\mathrm{k_i}(\alpha) - \mathrm{m}_i}{\mathrm{k_i}(\alpha)}, i = 1, \ldots, I \right\} \tag{6.8.13}$$

In TSURFER the components of **d** corresponding to application responses are set to zero because applications have no measured values. Using the standard formula for propagation of error and assuming no correlations between k and m, the relative uncertainty matrix for the discrepancy vector **d** can be expressed as the I by I matrix:

$$\mathbf{C}_{\mathrm{dd}} = \mathbf{C_{kk}} + \mathbf{F_{m/k}} \mathbf{C_{mm}} \mathbf{F_{m/k}} = \mathbf{S_{k\alpha}} \mathbf{C}_{\alpha\alpha} \mathbf{S}^{\mathbf{T}}_{\mathbf{k}\alpha} + \mathbf{F_{m/k}} \mathbf{C_{mm}} \mathbf{F_{m/k}} \tag{6.8.14}$$

where the expression in Eq. (6.8.3) was substituted for $\mathbf{C_{kk}}$, and $\mathbf{F_{m/k}}$ is an I × I diagonal matrix containing m/k factors, that is, $\frac{E}{C}$ factors (ratio of experimental to calculated response values). The inverse of the matrix $\mathbf{C_{dd}}$ appears in several expressions presented later in this section. In TSURFER the inversion is performed using routines from the LINPACK software package.

The goal of the GLLS method is to vary the nuclear data ($\alpha \rightarrow \alpha'$) and the measured integral responses ($\mathrm{m} \rightarrow \mathrm{m}'$), such that they are most consistent with their respective uncertainty matrices, $\mathbf{C}_{\alpha\alpha}$ and $\mathbf{C_{mm}}$. This is done by minimizing chi-square, expressed as

$$\begin{aligned} \chi^2 &= \left[\frac{\boldsymbol{\alpha}' - \boldsymbol{\alpha}}{\boldsymbol{\alpha}} \right]^{\mathrm{T}} \mathbf{C}^{-1}_{\alpha\alpha} \left[\frac{\boldsymbol{\alpha}' - \boldsymbol{\alpha}}{\boldsymbol{\alpha}} \right] + \left[\frac{\mathbf{m}' - \mathbf{m}}{\mathbf{m}} \right]^{\mathrm{T}} \mathbf{C}^{-1}_{\mathbf{mm}} \left[\frac{\mathbf{m}' - \mathbf{m}}{\mathbf{m}} \right] \\ &= [\boldsymbol{\Delta\alpha}]^{\mathrm{T}} \mathbf{C}^{-1}_{\alpha\alpha} [\boldsymbol{\Delta\alpha}] + [\boldsymbol{\Delta\mathbf{m}}]^{\mathrm{T}} \mathbf{C}^{-1}_{\mathbf{mm}} [\boldsymbol{\Delta\mathbf{m}}] \end{aligned} \tag{6.8.15}$$

where $\Delta\alpha_i = \frac{\alpha'_i - \alpha_i}{\alpha_i}$ and $\Delta \mathrm{m}_i = \frac{\mathrm{m}'_i - \mathrm{m}_i}{\mathrm{m}_i}$. Eq. (6.8.15) is rearranged to give

$$\chi^2 = \left[\boldsymbol{\sigma}^{-1}_{\boldsymbol{\alpha}} \boldsymbol{\Delta\alpha} \right]^{\mathbf{T}} \mathbf{R}^{-1}_{\alpha\alpha} \left[\boldsymbol{\sigma}^{-1}_{\boldsymbol{\alpha}} \boldsymbol{\Delta\alpha} \right] + \left[\boldsymbol{\sigma}^{-1}_{\mathbf{m}} \boldsymbol{\Delta\mathbf{m}} \right]^{\mathbf{T}} \mathbf{R}^{-1}_{\mathbf{mm}} \left[\boldsymbol{\sigma}^{-1}_{\mathbf{m}} \boldsymbol{\Delta\mathbf{m}} \right] \tag{6.8.16}$$

Eq. (6.8.16) expresses the variations in the nuclear data and measured responses in units of their respective standard deviations; that is, $\left[\boldsymbol{\sigma}^{-\mathbf{1}}_{\boldsymbol{\alpha}} \boldsymbol{\Delta\alpha} \right]$ and $\left[\boldsymbol{\sigma}^{-1}_{\mathbf{m}} \boldsymbol{\Delta\mathbf{m}} \right]$

Chi-square is a quadratic form indicating the squared magnitude of the combined data variations with respect to their uncertainties. This is easily seen for the simple case in which $\mathbf{R}_{\alpha\alpha}{}^{-1}$ and $\mathbf{R_{mm}}^{-1}$ in Eq. (6.8.16) are identity matrices, so that Eq. (6.8.16) reduces to just the diagonal contributions:

$$\chi^2 \rightarrow \sum_{\mathrm{n}=1}^{\mathrm{M}} \left(\frac{\alpha'_n - \alpha_n}{\sigma_{\alpha_n}} \right)^2 + \sum_{\mathrm{i}=1}^{\mathrm{I}} \left(\frac{\mathrm{m}'_\mathrm{i} - \mathrm{m}_\mathrm{i}}{\sigma_{\mathrm{m}_i}} \right)^2 \tag{6.8.17}$$

The first term on the on the right side of Eq. (6.8.17) is equal to the sum of the squares of the individual nuclear data variations expressed in units of their standard deviations while the second term represents a similar quantity for the measured integral responses. In the general case where correlations exist, the inverse matrices in Eq. (6.8.16) are not diagonal, and the value of chi-square must be evaluated using the indicated matrix multiplication.

Thus it can be seen that the GLLS method determines adjustments in the nuclear data and experimental measurements that (a) make the calculated and measured responses agree [i.e., $k' = k'(\alpha') = m'$ within the limitations of first-order sensitivity theory], and (b) minimize Eq. (6.8.15) so that the adjustments are most

consistent with the data uncertainties. Although many possible combinations of data variations may make $k' = m'$, there is a unique set that also minimizes χ^2.

Note: In TSURFER the term "chi-square" normally is meant to signify the minimum value of the quadratic form in Eq. (6.8.15). The significance of this minimum value is discussed in Sect. 6.8.4.2.1.

The following variations minimize Eq. (6.8.15), subject to the constraint $k'(\alpha') = m'$ [TSURFER-Wil86] and the linearity condition $[\boldsymbol{\Delta k}] = \mathbf{S_{k\alpha}}[\boldsymbol{\Delta\alpha}]$ where $\Delta k_i = \frac{k_i' - k_i}{k_i}$:

$$\boldsymbol{\Delta\alpha} = -\left[\mathbf{C_{\alpha\alpha}} \mathbf{S_{k\alpha}^T} \mathbf{C_{dd}^{-1}}\right] \mathbf{d} \tag{6.8.18}$$

$$\boldsymbol{\Delta m} = \left[\mathbf{C_{mm}} \mathbf{F_{m/k}} \mathbf{C_{dd}^{-1}}\right] \mathbf{d} \tag{6.8.19}$$

In the above equations the initial response discrepancy vector $\mathbf{d}$ is operated on by the transformation matrix in square brackets to obtain the desired variations in nuclear data and integral measurements; thus, it is the discrepancy components that drive the adjustments. If the linearity assumption is valid, then the changes in the calculated responses are found to be

$$\boldsymbol{\Delta k} = \mathbf{F_{m/k}} \boldsymbol{\Delta m} - \mathbf{d} = \mathbf{S_{k\alpha}} \boldsymbol{\Delta\alpha}. \tag{6.8.20}$$

Eq. (6.8.20) relates the adjustments in calculated responses, measured responses, and nuclear data.

As previously discussed, consolidation of the calculated and measured responses reduces the prior uncertainties for α', $\mathbf{m}$, and $\mathbf{k}$ because additional knowledge has been incorporated. This is indicated by their modified covariance matrices $\mathbf{C_{\alpha'\alpha'}}$, $\mathbf{C_{m'm'}}$, $\mathbf{C_{k'k'}}$, respectively, given by [TSURFER-Wil86]

$$\mathbf{C_{\alpha'\alpha'}} = \mathbf{C_{\alpha\alpha}} - \left[\mathbf{C_{\alpha\alpha}} \mathbf{S_{k\alpha}^T} \mathbf{C_{dd}^{-1}} \mathbf{S_{k\alpha}} \mathbf{C_{\alpha\alpha}}\right] \tag{6.8.21}$$

$$\mathbf{C_{m'm'}} = \mathbf{C_{mm}} - \left[\mathbf{C_{mm}} \mathbf{F_{m/k}} \mathbf{C_{dd}^{-1}} \mathbf{F_{m/k}} \mathbf{C_{mm}}\right] \tag{6.8.22}$$

$$\mathbf{C_{k'k'}} = \mathbf{C_{kk}} - \left[\mathbf{C_{kk}} \mathbf{C_{dd}^{-1}} \mathbf{C_{kk}}\right]. \tag{6.8.23}$$

If all the responses on the TSURFER input are relative formatted, then the adjusted data and response values edited by TSURFER are obtained from Eq. (6.8.18)-Eq. (6.8.20), while the square roots of diagonal elements in Eq. (6.8.21)-Eq. (6.8.23) correspond to the edited values for adjusted uncertainties in the nuclear data and in the experiment responses, respectively.

The adjustment formulas must be modified slightly to be consistent with the absolute-formatted responses. In the following expressions, absolute response covariance and response sensitivity data are denoted by a tilde [see Appendix A.]:

$$\tilde{\mathbf{d}} = \mathbf{k}(\alpha) - \mathbf{m} \tag{6.8.24}$$

$$\tilde{\mathbf{C}}_{\mathbf{dd}} = \tilde{\mathbf{C}}_{\mathbf{kk}} + \tilde{\mathbf{C}}_{\mathbf{mm}} = \tilde{\mathbf{S}}_{\mathbf{k}\alpha} \mathbf{C}_{\alpha\alpha} \tilde{\mathbf{S}}_{\mathbf{k}\alpha}^{\mathbf{T}} + \tilde{\mathbf{C}}_{\mathbf{mm}} \tag{6.8.25}$$

$$\Delta\tilde{\boldsymbol{\alpha}} = \boldsymbol{\alpha}' - \boldsymbol{\alpha} = -\left[\mathbf{C}_{\alpha\alpha} \tilde{\mathbf{S}}_{\mathbf{k}\alpha}^{\mathbf{T}} \tilde{\mathbf{C}}_{\mathbf{dd}}^{-\mathbf{1}}\right] \tilde{\mathbf{d}} \tag{6.8.26}$$

$$\Delta\tilde{\mathbf{m}} = \mathbf{m}' - \mathbf{m} = \left[\tilde{\mathbf{C}}_{\mathbf{mm}} \tilde{\mathbf{C}}_{\mathbf{dd}}^{-1}\right] \tilde{\mathbf{d}} \tag{6.8.27}$$

$$\Delta\tilde{\mathbf{k}} = \mathbf{k}' - \mathbf{k} = (\mathbf{m}' - \mathbf{m}) - \tilde{\mathbf{d}} = \mathbf{S}_{\mathbf{k}\alpha} (\boldsymbol{\alpha}' - \boldsymbol{\alpha}) \tag{6.8.28}$$

Relative covariances for the posterior values of the nuclear data and measured responses are given as

$$\mathbf{C}_{\alpha'\alpha'} = \mathbf{C}_{\alpha\alpha} - \left[\mathbf{C}_{\alpha\alpha}\tilde{\mathbf{S}}^{\mathbf{T}}_{\mathbf{k}\alpha}\right]\tilde{\mathbf{C}}^{-1}_{\mathbf{dd}}\left[\tilde{\mathbf{S}}_{\mathbf{k}\alpha}\mathbf{C}_{\alpha\alpha}\right] \tag{6.8.29}$$

$$\tilde{\mathbf{C}}_{\mathbf{m}'\mathbf{m}'} = \tilde{\mathbf{C}}_{\mathbf{mm}} - \left[\tilde{\mathbf{C}}_{\mathbf{mm}}\tilde{\mathbf{C}}^{-1}_{\mathbf{dd}}\tilde{\mathbf{C}}_{\mathbf{mm}}\right] \tag{6.8.30}$$

If all the responses on the TSURFER input are absolute formatted, the adjusted data and response values edited by TSURFER are obtained from Eq. (6.8.26)-Eq. (6.8.28), while the square roots of diagonal elements in Eq. (6.8.29)-Eq. (6.8.30) correspond to the edited values for adjusted uncertainties in the nuclear data and in the experiment responses, respectively.

The adjustment formulas again must be modified slightly given a set of mixed relative/absolute-formatted responses. In the following expressions, mixed response covariance and response sensitivity data are denoted by a caret (see Appendix A.), and $\hat{\mathbf{F}}_{\mathbf{m/k}}$ is an I × I diagonal matrix containing m/k factors for relative-formatted responses or a value of one for absolute-formatted responses:

$$\hat{\mathbf{d}} = \begin{cases} \frac{\mathbf{k}(\alpha)_i - \mathbf{m}_i}{\mathbf{k}(\alpha)_i} & relative \\ \mathbf{k}(\alpha)_i - \mathbf{m}_i & absolute \end{cases} \tag{6.8.31}$$

$$\Delta\hat{\mathbf{m}}_{\mathbf{i}} = \begin{cases} \frac{\mathbf{m}'_{\mathrm{i}} - \mathbf{m}_{\mathrm{i}}}{\mathbf{m}_{\mathrm{i}}} & relative \\ \mathbf{m}'_{\mathrm{i}} - \mathbf{m}_{\mathrm{i}} & absolute \end{cases} \tag{6.8.32}$$

$$\Delta\hat{\mathbf{k}}_{\mathrm{i}} = \begin{cases} \frac{\mathbf{k}'(\alpha')_i - \mathbf{k}(\alpha)_i}{\mathbf{k}(\alpha)_i} & relative \\ \mathbf{k}(\alpha)_i - \mathbf{k}(\alpha)_i & absolute \end{cases} \tag{6.8.33}$$

$$\hat{\mathbf{C}}^{-1}_{\mathbf{dd}} = \hat{\mathbf{C}}_{\mathbf{kk}} + \hat{\mathbf{F}}_{\mathbf{m/k}}\hat{\mathbf{C}}_{\mathbf{mm}}\hat{\mathbf{F}}_{\mathbf{m/k}} = \hat{\mathbf{S}}_{\mathbf{k}\alpha}\mathbf{C}_{\mathbf{dd}}\hat{\mathbf{S}}^{\mathbf{T}}_{\mathbf{k}\alpha} + \hat{\mathbf{F}}_{\mathbf{m/k}}\hat{\mathbf{C}}_{\mathbf{mm}}\hat{\mathbf{F}}_{\mathbf{m/k}} \tag{6.8.34}$$

$$\Delta\hat{\alpha} = -\left[\mathbf{C}_{\mathbf{dd}}\hat{\mathbf{S}}^{\mathbf{T}}_{\mathbf{k}\alpha}\hat{\mathbf{C}}^{-1}_{\mathbf{dd}}\right]\hat{\mathbf{d}} \tag{6.8.35}$$

$$\Delta\hat{\mathbf{m}} = \left[\hat{\mathbf{C}}_{\mathbf{mm}}\hat{\mathbf{F}}_{\mathbf{m/k}}\hat{\mathbf{C}}^{-1}_{\mathbf{dd}}\right]\hat{\mathbf{d}} \tag{6.8.36}$$

$$\Delta\mathbf{k} = \hat{\mathbf{S}}_{\mathbf{k}\alpha}\Delta\hat{\alpha} \tag{6.8.37}$$

Covariances for the posterior values of the nuclear data and measured responses are given as

$$\mathbf{C}_{\alpha'\alpha'} = \mathbf{C}_{\alpha\alpha} - \left[\mathbf{C}_{\alpha\alpha}\hat{\mathbf{S}}^{\mathbf{T}}_{\mathbf{k}\alpha}\right]\hat{\mathbf{C}}^{-1}_{\mathbf{dd}}\left[\hat{\mathbf{S}}_{\mathbf{k}\alpha}\mathbf{C}_{\alpha\alpha}\right] \tag{6.8.38}$$

$$\hat{\mathbf{C}}_{\mathbf{m}'\mathbf{m}'} = \hat{\mathbf{C}}_{\mathbf{mm}} - \left[\hat{\mathbf{C}}_{\mathbf{mm}}\hat{\mathbf{F}}_{\mathbf{m/k}}\hat{\mathbf{C}}^{-1}_{\mathbf{dd}}\hat{\mathbf{F}}_{\mathbf{m/k}}\hat{\mathbf{C}}_{\mathbf{mm}}\right] \tag{6.8.39}$$

If responses on the TSURFER input are both relative formatted and absolute formatted, the adjusted data and response values edited by TSURFER are obtained from Eqs. Eq. (6.8.35)-Eq. (6.8.37), while the square roots of diagonal elements in Eqs. Eq. (6.8.38)-Eq. (6.8.39) correspond to the edited values for adjusted uncertainties in the nuclear data and in the experiment responses, respectively.

Consistency relations and chi-square filtering

The variations for Δm and $\Delta\alpha$ defined by Eq. Eq. (6.8.18) and Eq. Eq. (6.8.19) are those that give the smallest value of the quadratic form χ^2. This minimum χ^2 value is found by substituting these equations into Eq. Eq. (6.8.15):

$$\chi^2_{\min} = \mathbf{d}^{\mathbf{T}}\mathbf{C}^{-1}_{\mathbf{dd}}\mathbf{d} = \mathbf{d}^{\mathbf{T}}\left[\mathbf{C}_{\mathbf{kk}} + \mathbf{F}_{\mathbf{m/k}}\mathbf{C}_{\mathbf{mm}}\mathbf{F}_{\mathbf{m/k}}\right]^{-1}\mathbf{d} \tag{6.8.40}$$

It is interesting to observe that Eq. Eq. (6.8.40) does not depend upon adjustments in nuclear data or integral experiments and physically expresses a measure of the initial discrepancies ($\mathbf{d}$) in all responses, compared to their combined calculation and experiment uncertainties ($\mathbf{C_{kk}} + \mathbf{F_{m/k}C_{mm}F_{m/k}}$). In fact, the parameter is identical to the chi-square statistic discussed in Sect. 6.8.3.2 that denotes consistency between the calculations and measurements. Equation Eq. (6.8.40) can be viewed as an inherent limit on the consistency of the GLLS adjustment procedure. If the initial calculated and measured responses are not consistent with their stated uncertainties, then adjustments in nuclear data and experiment values obtained by TSURFER cannot be consistent either.

TSURFER provides an option for "chi-square filtering" to ensure that a given set of benchmark experiments is consistent; that is, that the input responses have an acceptable $\chi^2_{\min}$ defined by Eq. (6.8.40). The code progressively removes individual experiments until the calculated $\chi^2_{\min}$ is less than the input target value "*target_chi"*. Each iteration removes one experiment estimated to have the greatest impact on chi-square per degree of freedom. The method used to assess individual contributions to $\chi^2_{\min}$ is specified by input parameter "*chi_sq_filter"*, which refers to the different approaches described below.

Independent Chi-Square Option (*chi_sq_filter=independent*).

The consistency of the i-th measured and calculated response values, disregarding any other integral response, is equal to the discrepancy in the measured and calculated value squared divided by the variance of the discrepancy of the i-th response:

$$\chi^2_{\mathbf{ind,i}} = \frac{(\mathbf{k_i} - \mathbf{m_i})^2}{\sigma^2_{\mathbf{ki}} + \sigma^2_{\mathbf{mi}}} \tag{6.8.41}$$

Equation Eq. (6.8.41) is strictly valid only when no correlations exist, but it may be a useful approximation to estimate the experiment having the greatest impact on chi-square per degree of freedom. Hence, this expression is called the "*independent chi-square*" approximation in TSURFER. This approximation executes fast since no matrix inversions are required.

Diagonal Chi-Square Option (*chi_sq_filter=diagonal*)

The "*diagonal chi-square*" approach uses diagonal values of the original inverse $\mathbf{C_{dd}}$ matrix to estimate the experiment having the greatest impact on chi-square per degree of freedom:

$$\chi^2_{\mathbf{dia,i}} \equiv (\mathbf{k_i} - \mathbf{m_i})^2 \, \mathbf{C^{-1}_{dd}}(\mathbf{i},\mathbf{i}) \tag{6.8.42}$$

In this method the correlations in all responses are taken into account to some extent. The original $\mathbf{C^{-1}_{dd}}$. is used in each iteration; therefore, the diagonal chi-square method requires only a single matrix inversion.

Iterative-Diagonal Chi-Square Option (*chi_sq_filter=iter_diag*).

This approach is identical to the diagonal chi-square method, except that an updated value of is computed each iteration to re-evaluate the total chi-square from Eq. Eq. (6.8.40). Thus one matrix inversion is performed per iteration.

Delta Chi-Square Option (*chi_sq_filter=delta_chi*).

The most rigorous method to determine the impact of an individual response on the overall consistency is called the "*delta chi-square*" method in TSURFER. This method [TSURFER-YWMW80] calculates the change in chi-square whenever a particular response is omitted for the analysis; that is, omitting the i*th* response results in

$$\Delta\chi^2_{\mathrm{i}} = \left[\mathbf{d^T C^{-1}_{dd} d}\right] - \left[\mathbf{d}^{\mathrm{T}}_{\neq \mathrm{i}} \left(\mathbf{C}^{\neq \mathrm{i}}_{\mathbf{dd}}\right)^{-1} \mathbf{d}_{\neq \mathrm{i}}\right] \tag{6.8.43}$$

where $\mathbf{d}_{\neq i}$ and $\mathbf{C}_{\mathbf{dd}}^{\neq \mathrm{i}}$ are, respectively, the discrepancy vector and discrepancy covariance with response i omitted. While Eq. Eq. (6.8.43) is the most rigorous method, it also requires the most computation effort. A matrix inversion must be performed for every omitted response, in each iteration. For SCALE 6.3, the runtime of this method was reduced by using the matrix inversion lemma to compute the inverse of each submatrix, according to the method of [TSURFER-JRCMPR16].

It has been observed that independent chi-square and diagonal chi-square options execute fast but often eliminate more experiments than necessary to obtain the target chi-square value. The diagonal chi-square option is somewhat faster than the iterative-diagonal chi-square option but also sometimes omits more than the minimum number of experiments. The delta chi-square option is currently default in TSURFER.

Expressions for computational bias

The computational "bias" is defined here as the observed difference between a calculated and measured response. In conventional validation studies the expected bias in an application response (for which there is no measurement, by definition) often is estimated as the sample mean of the biases for a set of benchmark experiments and the uncertainty in the application bias is estimated by the sample standard deviation of the experimental biases.

The GLLS technique provides another method to compute the bias of an application response. The application response bias β_a is defined as the expected deviation of the original calculated response $\mathrm{k_a}$ from the best estimate of the measured response, which is unknown but has some probability distribution. Note that if the application response actually *did* have a prior measured value $\mathrm{m_a}$, then the best estimate for the experiment value would be the final adjusted value $\mathrm{m_a}$' obtained from the GLLS procedure. For this reason the notation $\mathrm{m_a}$' is used here to represent the (unknown) best estimate for the application's projected measured response, so that

$$\beta_a = E\left[k_a - m'_a\right] \tag{6.8.44}$$

where E is the expectation operator. The application's projected experiment value can be expressed as $m'_a = k_a\left(\alpha'\right) - \delta m_a$, where δm_a represents the difference between the best computed response obtained with the adjusted data α' and the expected value of the experimental measurement. Therefore Eq. Eq. (6.8.44) can be expressed

$$\beta_a = E\left[k_a - k_a\left(\alpha'\right) + \delta m_a\right] = k_a - k_a\left(\alpha'\right) + E\left[\delta m_a\right] \tag{6.8.45}$$

Recall that all *experiment* responses are sure to have $\delta m_i = 0$, because the GLLS procedure forces k'=m' within the approximation of first-order theory. However, $\delta m_a\,(= k'_a - m'_a)$ for the application is not guaranteed to be zero, since there is no known measured value. Nevertheless the application response calculated using the best cross sections α' should approach the desired (unknown) experiment value if a "sufficient" number of experiments similar to the application of interest are considered [TSURFER-BHCP99] so that under these conditions $E\left[\delta m_a\right] \rightarrow 0$ for the application as well. More details concerning the suitable degree of similarity and the sufficient number of experiments necessary for convergence of the GLLS methodology are discussed in other publications [TSURFER-BHCP99, TSURFER-BHP99, TSURFER-MWB81, TSURFER-PC88]. TSURFER also provides an automated procedure to examine the convergence of the bias, which is described in Sect. 6.8.4.4.

Assuming an adequate benchmark data base such that $E\left[\delta m_a\right] \rightarrow 0$, Eq. Eq. (6.8.45) simplifies to

$$\beta_a = k_a - k'_a\left(\alpha'\right) \sim -\left(k_a\right)\mathbf{S}_a^{\mathbf{T}}\Delta\boldsymbol{\alpha} \tag{6.8.46}$$

or, stated in absolute terms,

$$\beta_a \sim -\mathbf{S_a^T}\Delta\boldsymbol{\alpha}. \tag{6.8.47}$$

In the above equations $\mathbf{S_a}$ is the column vector of relative sensitivities for the application response. A negative bias indicates that the original computed value was too low; therefore, the adjusted application result will be higher than the original ($k'_a > k_a$). Similarly, a positive bias means that the original response was calculated too high, and therefore $k'_a < k_a$.

6.8.4.3 Expressions for response similarity parameters

TSURFER estimates the similarity in a pair of responses using one of three internally computed similarity coefficients-respectively designated as E, G, and C-specified by the input parameter *"sim_type"*. These are essentially equivalent to the corresponding similarity coefficients described in [TSURFER-BRH+04], although there are slight differences in the definitions of E and G. Similarity coefficients are defined so that a value of zero indicates no similarity between the systems, and unity is maximum similarity. It is also theoretically possible, but unusual, to have a negative similarity in the range [-1,0], indicating systems that are "anti-correlated" in some sense—in which case they are treated as completely dissimilar. Input parameter *"sim_min"* specifies the minimum similarity coefficient (compared to a specified reference application) of systems to be included in the GLLS procedure. TSURFER also optionally edits the I by I similarity matrix whose elements are the similarity coefficients for every response-pair combination (including both experimental and application responses).

The three types of similarity coefficients used in TSURFER are described below. In these expressions, $\mathbf{S_i}$ is defined as the sensitivity *vector* (not matrix) for a particular response "i" which may be an experiment or application. The magnitude of the sensitivity vector corresponds to the L2 norm: $|\mathbf{S_i}| = \sqrt{\mathbf{S_i^T S_i}}$.

The* E *similarity parameter (*sim_type=E*)

The E-similarity coefficient relating two responses i and j is defined analogously to the cosine of the angle between two direction vectors:

$$\mathrm{E_{i,j}} \equiv \frac{\mathbf{S_i^T S_j}}{|\mathbf{S_i}|\,|\mathbf{S_j}|} \tag{6.8.48}$$

A value of E=1.0 corresponds to the case when **Si** and **Sj** are "parallel", such as would occur when the two sensitivity vectors are proportional. A value of E = 0.0 corresponds to the case when **Si** and **Sj** are "perpendicular", such as occurs when the two sensitivity vectors have no common components (i.e., for every non-zero component in one, the corresponding component is zero in the other). Thus, E indicates the "relative direction" of the two sensitivity vectors in an N-dimensional vector space, with the assumption that the larger the parallel component, the greater the similarity. In theory, E could also take on the negative values in the interval [-1,0] if the two responses are anti-parallel. In addition, the E coefficient is the same for absolute-formatted sensitivities (i.e., $\tilde{\mathbf{S}}_\mathbf{i}$ and $\tilde{\mathbf{S}}_j$) or mixed relative-absolute sensitivities (e.g., $\tilde{\mathbf{S}}_\mathbf{i}$ and $\mathbf{S}_j$).

The G similarity parameter (sim_type=G)

The G-similarity coefficient for responses i and j is defined as,

$$G_{ij} \equiv 1 - \frac{\left|\mathbf{S_i} - \mathbf{S_j}\right|^2}{|\mathbf{S_i}|^2 + \left|\mathbf{S_j}\right|^2} = \frac{\mathbf{S_i^T S_j}}{|\mathbf{S}|^2}, \tag{6.8.49}$$

where $\overline{|\mathbf{S}|^2} \equiv \frac{|\mathbf{S_i}|^2 + |\mathbf{S_j}|^2}{2}$.

As seen in the last term, the G parameter is similar to the E parameter, except the denominators are different. The effect of the different normalization is that G will be unity only if S_i and S_j are *identical*, while E indicates maximum similarity if they are *proportional*. It is important to note that the expression for the G parameter in the TSUNAMI-IP manual is different from Eq. Eq. (6.8.49). In both the TSURFER and TSUNAMI-IP formulations of G, the calculated parameter depends on the sensitivity format. It is recommended that Eq. Eq. (6.8.49) be used with relative-formatted sensitivities to calculate G for k_{eff} responses.

The* C *similarity parameter (*sim_type=C*)

The C similarity coefficient represents the correlation in two calculated responses due to the shared uncertainty from common nuclear data. While E and G similarity coefficients only depend on the sensitivity vectors of two responses, the C parameter also involves cross-section covariance data. The C-similarity parameter for responses i and j is the value of the correlation coefficient (ρ_{ij}) in position (i, j) of the R_{kk} correlation matrix; thus,

$$C_{ij} \equiv \rho_{ij} = R_{kk}(i, j) = \frac{\mathbf{S_i^T} C_{\alpha\alpha} \mathbf{S_j}}{\boldsymbol{\sigma_i \sigma_j}}. \tag{6.8.50}$$

The C coefficient has the usual interpretation of a correlation coefficient: 1.0 implies that the two responses are completely correlated by their nuclear data; 0.0 means no correlation; and -1.0 means full anti-correlation. The C coefficient is the same for absolute-formatted sensitivities (i.e., $\tilde{\mathbf{S}}_\mathbf{i}$ and $\tilde{\mathbf{S}}_j$) or mixed relative-absolute sensitivities (e.g., $\tilde{\mathbf{S}}_\mathbf{i}$ and $\mathbf{S}_j$).

6.8.4.4 Convergence of reference application response

It is sometimes useful to consider how the GLLS procedure "converges" the estimated bias in an application response, as the number and similarity of integral experiment responses included in the analysis is increased [TSURFER-Wil86]. In TSURFER, the bias-convergence can be edited for any one of the application responses, called the "reference application," which is defined by the value of "*ref_app*" in the TSURFER input. Inserting the keyword *"calc_cumul_effect"* on the TSURFER input activates the option to edit the cumulative impact of increasing the number of benchmark experiments in the GLLS calculation. In this case, the range of similarity coefficients [0.0→1.0] is subdivided in bins of constant width set by the TSURFER input parameter *"bin_width,"* and the experiment responses are sorted into the bins according their similarity to the reference application response. Any experiments with negative similarity coefficients are included in the first bin. Each bin of benchmark experiments is successively added to the GLLS calculation, going from low to high response similarity, until the whole suite of benchmarks is included. Ideally, the calculated reference application bias (β_a) should converge and stabilize at some value as the number and similarity of the experiment responses increases. Under these conditions the value $E[\delta m_a]$ in Eq. Eq. (6.8.45) is approximately zero.

6.8.5 TSURFER INPUT DESCRIPTION

The user input for TSURFER is described in this section. The input consists of an optional title on a single line followed by one required and four optional blocks of data which are identified in Table 6.8.1 and individually described in subsequent subsections. These data blocks must begin with **READ KEYNAME**and end with **END KEYNAME**, where **KEYNAME** is the name of an individual data block. The *PARAMETER* data block, if requested, should be entered first after the optional title. The *HTML, COVARIANCE,* and *RESPONSE* data blocks may follow in any order. If the *CORR* data block is necessary to specify experiment correlations, it should be the last block of data on the input. All keyword inputs are internally translated to lowercase with the exception of sensitivity data filenames and their file paths.

Table 6.8.1: Table keynames and descriptions for TSURFER input data blocks.

Keyname	**Description**	**Required/Optional**
PARAMETER	Parameters that specify the covariance data file, chi-square filtering options, similarity filtering options, output edit options, and approximate cross-section covariance data options can be entered in this section.	Optional
RESPONSE *EXPERIMENTS*[a] *APPLICATIONS*[a]	File paths to sensitivity data files representing experiments or applications are input in this section. Measured response values and measured response uncertainties are also input in this section.	Required
COVARIANCE	User-input standard deviation for nuclide-reaction pairs for which cross-section-covariance data are not available can be entered in this section.	Optional
HTML	Parameters to customize the HTML-formatted output can be entered in this section.	Optional
CORR	Correlations between measured responses and measured response uncertainty components can be entered in this section.	Optional
[a] The TSUNAMI-IP block keynames *EXPERIMENTS* and *APPLICATIONS* are also allowed. By default, sensitivity data files listed in *RESPONSE* or *EXPERIMENTS* data blocks are designated experiment responses and files listed in the *APPLICATIONS* data block are designated application responses. The response designation can be easily changed by the *use* keyword in the response definition record described in Sect. 6.8.5.2.		

6.8.5.1 Parameter block

The *PARAMETER* data block is used to specify various keyword options used to control the execution of the code. These options include the name of the cross-section covariance data file, output edits, default covariance data, and chi-square or similarity filtering options. The parameter block must begin with *READ PARAMETER* and end with *END PARAMETER*. The data input to the parameter data block consist of numerous keywords that are shown, along with their default values and descriptions, in

Table 6.8.2. A keyword that ends with "=" must be followed by numeric data or a character string. Keywords that do not end with "=" are Boolean flags that are used to turn on certain features of the code, such as the computation of certain data or certain output edits. If the keyword is present for a Boolean entry, the value is set to true. Otherwise, the value is set to false. All *PARAMETER* block keywords are optional.

Table 6.8.2: Input data for the Parameter block of TSURFER.

Keyword	**Default value**	**Description**
absolute or *abs*	False	Use absolute sensitivities and uncertainties for all applications and experiments in the analysis unless specifically overridden by experiment or application input.
adj_cov_cut	0.000001	Cutoff value for including an adjusted cross-section-covariance matrix in the post adjustment analysis and data file. If a nuclide-reaction to nuclide-reaction covariance contains no values exceeding adj_cov_cut,the matrix is excluded from further analysis. Note that adj_cov_cut represents a variance, not a standard deviation.
adjcut	0.00001	Cutoff value for the cross-section adjustment edit. If the maximum (absolute value) multigroup cross-section adjustment for a given nuclide-reaction pair is less than *adjcut*, then the nuclide-reaction pair is not included in the cross-section adjustment edit.
bin_widtha	0.01	Size of the similarity bins for the cumulative iteration edits.
cov_fix	False	Replace zero and large (standard deviation >1000%) values on diagonal of cross-section-covariance data with user-input values and default values.
coverx=	56group-cov7.1	Name of cross-section covariance data file to use in analysis. See the COVLIB chapter of SCALE documentation for detailed description of the available covariance library.
calc_cumul_effect[a]	False	Perform cumulative iteration edit.

continues on next page

Table 6.8.2 – continued from previous page

chi_sq_filter [b]	delta_chi	Method used for chi-square filtering. Allowed values are *independent*, *diagonal*, *iter_diag*, and *delta_chi*.
def_min=	0.001	Minimum sensitivity criteria to adjust nuclear data. The minimum sensitivity criteria is only applied to nuclide-reaction pairs with **missing** covariance data and if *use_dcov* or *use_icov* is entered.
large_cov=	10.0	Cutoff fractional standard deviation value for *cov_fix*. Cross-section-covariance data with uncertainties larger than *large_cov* are replaced with user-input or default values. Default =10, which is 1000% uncertainty.
nohtml	False	If *nohtml* is present, HTML-formatted output is not generated.
print=	regular	Level of ouput edits discussed below. Options are *minimum* and *regular*.
print_adjustments	False	Option to print cross-section adjustment edit.
print_adj_corr	False	Option to print the adjusted response correlation matrix.
print_init_corr	False	Option to print the initial response correlation matrix.
print_sim_matrix	False	Option to print the initial response similarity matrix.
ref_app= [a]	First Application on Input	If application systems are included, *ref_app* is the index to the reference application response. Additional output edits are given for the reference application described in Sample Problem Input and Output Description.
relative or *rel*	True	Use relative sensitivities and uncertainties for all applications and experiments in the analysis. This is the default and keyword *relative* is not required.
return_adj_cov	False	Option to create a COVERX-formatted covariance data file of the adjusted cross-section-covariance matrix. If *return_adj_cov* is present, the adjusted covariance data file is returned to the working directory with the file name *job_name.adj.cov* where *job_name* is the name of the input file.

continues on next page

Table 6.8.2 – continued from previous page

return_work_cov	False	If *return_work_cov* is present, the working covariance library is copied to the return directory with the file name *job_name.wrk.cov* where *job_name* is the name of the input file. If *return_work_cov* is not present, the working covariance library remains in the temporary working directory with the file name *job_name.wrk*.
sim_min= [c]	-1	Minimum similarity coefficient of experimental responses with the reference application response to be included in the adjustment.
sim_type= [c]	None	Criteria to calculate initial response similarity matrix. Allowed values are *none, E, C,* and *G.*
target_chi= [b]	1.2	Target chi-square per degree of freedom for consistency acceptance. If *target_chi=0.0*, chi-square filtering is not performed.
udcov= (optional)	0.05	User-defined default value of standard deviation in cross-section data to use for all groups for nuclide-reaction pairs for which cross-section-covariance data are not available on the input covariance library.
udcov_corr= (optional)	1.0	User-defined default correlation value to use for nuclide-reaction pairs for which cross-section-covariance data are not available on the input covariance library.
udcov_corr_type= (optional)	zone	User-defined default correlation in cross-section data to use for nuclide-reaction pairs for which cross-section-covariance data are not available on the input SCALE covariance library. Allowed values are *long*, *zone*, and *short.*
udcov_therm= (optional)	0.0	User-defined default value of standard deviation in cross-section data to use for thermal data for nuclide-reaction pairs for which cross-section-covariance data are not available on the input covariance library.
udcov_inter= (optional)	0.0	User-defined default value of standard deviation in cross-section data to use for intermediate data for nuclide-reaction pairs for which cross-section-covaria nce data are not available on the input covariance library.

continues on next page

Table 6.8.2 – continued from previous page

udcov_fast= (optional)	0.0	User-defined default value of standard deviation in cross-section data to use for fast data for nuclide-reaction pairs for which cross-section-covariance data are not available on the input covariance library.
uncert_long	False	Prints extended table of uncertainty in response due to covariance data.
use_dcov	False	Use default cross-section-covariance data for nuclide-reaction pairs not included on the input covariance data file.
use_diff_groups=	true	Permit sensitivity data files to have different energy group structures. This parameter is now always true and does not need to be set.
usename	False	Use the name of the sensitivity data file as the default response identifier in the TSURFER output.
use_icov	False	Use user-defined cross-section-covariance data input in the *COVARIANCE* input data block in place of the default values for user-input nuclide-reaction pairs that are not on the input covariance data file.
[a] See Sect. 6.8.4.4 for additional information on bias convergence analysis. [b] See Sect. 6.8.4.2.1 for additional inforomation on chi-square filtering methods. [c] See Sect. 6.8.4.3 for additional information on similarity coefficients.		

The PARAMETER block keyword *print* controls the general level of the TSURFER output print. The minimum print level *"print=minimum"* summarizes the input values for experimental responses and uncertainties, edits chi-square values, and prints GLLS results for the application responses. The regular print option *"print=regular"* additionally shows GLLS results computed for all adjusted experimental responses.

The *PARAMETER* block keywords-*use_dcov, udcov, udcov_therm, udcov_inter, udcov_fast, udcov_corr,* and *udcov_corr_type*-are used to specify the default covariance data for nuclide-reaction pairs that do not have covariance data available on the SCALE covariance data file. The Boolean flag keyword *use_dcov* activates the use of default covariance data for nuclide-reaction pairs with missing covariance data. The *udcov* keyword specifies a default relative standard deviation for all energy groups. The keywords *udcov_therm, udcov_inter,* and *udcov_fast* can be used to specify the default relative standard deviation for the thermal energy groups, intermediate energy groups, and fast energy groups, respectively. If either *udcov_therm, udcov_inter,* or *udcov_fast* are omitted from the input, the default uncertainty applied for their respective energy groups is the *udcov* value. The keyword *udcov_corr* specifies the correlation coefficient for the default covariance data, and *udcov_corr_type* specifies the correlation type. The correlation type options are (a) *long* - apply correlation coefficient in all energy groups, (b) *short* - apply correlation coefficient in adjacent groups, and (c) *zone* - apply correlation within fast, intermediate, and thermal groups, but no correlation is applied between different group ranges.

For additional user control over the approximate cross-section covariance data, the *COVARIANCE* data block can be used to input uncertainty values for particular nuclide-reaction pairs. To utilize the covariance data generated by user-input in the *COVARIANCE* data block, the keyword *use_icov* must be entered in the *PARAMETER* data block. Approximate covariance data specified in the *COVARIANCE* data block are

referred to as user-input data. The input for the COVARIANCE data block is described in more detail in Sect. 6.8.5.3.

When *use_dcov* and/or *use_icov* and *cov_fix* are specified in the *PARAMETER* data block, and a reaction has zero or large (standard deviation > 1000%) values on the diagonal of the covariance matrix, these values are replaced with the square of the user-input or default standard deviation value, and the corresponding off-diagonal terms are substituted according to the user-input or default correlation values. Warning messages are printed to identify which values were replaced and which standard deviation value was used in the replacement. The maximum relative standard deviation in which to apply the covariance correction can be specified by the user with the *large_cov* keyword.

The *def_min* keyword is used to determine if the default or user-input covariance data is applied for nuclide-reaction pairs with missing covariance data. For each nuclide-reaction pair with missing covariance data, TSURFER calculates the maximum, absolute-value, groupwise response sensitivity over all active (i.e., experiment) and passive (i.e., application) responses on the input. If the maximum sensitivity value for a given nuclide-reaction pair is greater than *def_min*, the default or user-input covariance data is applied and the cross-section data for the nuclide-reaction pair is adjusted in the analysis. If the *relative* keyword is entered in the *PARAMETER* data block, the value of *def_min* is interpreted as a relative-formatted sensitivity. Likewise, if the *absolute* keyword is entered in the *PARAMETER* data block, the value of *def_min* is interpreted as an absolute-formatted sensitivity. If both *relative* and *absolute* are entered, the last keyword in the *PARAMETER* data block sets the format for both *def_min* and the response sensitivity data files. If both *relative* and *absolute* are omitted, the default format for *def_min* is relative. The minimum sensitivity criterion is slightly different if both relative-formatted k_{eff} responses and absolute-formatted eigenvalue-difference (reactivity) responses are included in the analysis. In this case, the minimum sensitivity criteria can be entered for each response in the *RESPONSE* block described in the next section.

During the GLLS analysis, TSURFER computes a new covariance data file that contains cross-section-covariance data only for the nuclide-reaction pairs that are listed in the response sensitivity data files. The new covariance data file, referred to as the working covariance data file, is written in COVERX format like the input SCALE covariance data file. The working covariance data file contains any default or user-input cross-section-covariance data for nuclide-reaction pairs that were not in the input SCALE covariance data file as well as any corrected cross-section-covariance data if the *cov_fix* keyword is entered on the input. The working covariance data file can be read by the data plotting tool in Fulcrum to visualize the cross section covariance data used in the analysis.

6.8.5.2 RESPONSE block

In the *RESPONSE* data block, sensitivity data files are designated as either application responses or experiment responses. The *RESPONSE* data block is also used to specify experimental response values, experimental response uncertainties, and uncertainties of experimental response components. The TSUNAMI-IP block keynames *EXPERIMENTS* and *APPLICATIONS* are also allowed. Each data block must begin with *READ KEYNAME* and end with *END KEYNAME* where *KEYNAME* can be *APPLICATIONS, EXPERIMENTS,* or *RESPONSE*.

By default, sensitivity data files listed in *RESPONSE* or *EXPERIMENTS* data blocks are designated as experiment responses, while files listed in the *APPLICATIONS* data block are designated as application responses. Multiple *RESPONSE*, *EXPERIMENTS*, and *APPLICATIONS* data blocks are allowed, and they can be entered in any order. However, the order of the sensitivity data files in the TSURFER input is important when defining experiment correlations. Two recommended input methods are (a) define all experiment and application responses in a single *RESPONSE* data block using the *use* keyword and specify the role of each

response in the analysis or (b) define all experiment responses in a single *EXPERIMENTS* block, and define all application responses in a single *APPLICATIONS* block.

Inside each data block, sensitivity data files are listed using response definition records. A response definition record is a single line of input that contains the sensitivity data filename, two required keywords and eight optional keywords shown in parentheses. The sensitivity data filename and keywords can be entered in any order, with the following format:

filename (use=R) (name=N) (type=T) ev=E uv=U (cv=C) (nu=P) (omit) (abs) (rel) (msen=M)

where

filename = sensitivity data filename. The filename can include the file path.

R = adjustment role. Allowed values are *appl*, *expt*, and *omit*. The default value is *expt* in the RESPONSE or EXPERIMENT block and *appl* in the APPLICATION block.

N = 20-character maximum alphanumeric response identifier in TSURFER output.

T = 8-character maximum alphanumeric identifier for the response type (e.g., "keff", "gpt", or "rho"). The response-type identifier is used in various output edits along with the response name identifier.

E = experimental value of the response.

U = uncertainty value of the response.

C = calculated value of the response.

P = number of uncertainty components to characterize the experiment uncertainty for this response.

omit - Optional keyword used to omit the response from the analysis. This can also be done by the *use=omit* keyword specification.

abs - Optional keyword that specifies absolute sensitivities, absolute experiment uncertainties, and absolute components of uncertainty that are used for this response. The keyword *absolute* is also valid.

rel - Optional keyword that specifies relative sensitivities, relative experiment uncertainties, and relative components of uncertainty that are used for this response. The keyword *relative* is also valid.

M = minimum sensitivity criteria for this response. This value will replace the def_min value in the PARAMETER block to determine if nuclide-reaction pairs with missing covariance data are included in the adjustment.

Case-sensitive filenames and file paths are allowed for sensitivity data filename. However, **spaces are not allowed in the filenames or file paths.** The sensitivity data filename is limited to 80 characters, and the total length of the response definition must not exceed 255 characters. The *use* keyword specifies the role of the response in the GLLS analysis. "*use=expt"* designates the corresponding sensitivity data file as an experiment response. Likewise, "*use=appl"* designates the corresponding data file as an application response. In addition, the user can omit the sensitivity data file from the analysis by entering either '*use=omit"* or simply *omit* on the response definition record. If the *use* keyword is not included, the role of the response is determined by the data block name; that is, "*use=appl"* is implied for the *APPLICATIONS* block and "*use=expt"* is implied for the *EXPERIMENTS* and *RESPONSE* blocks.

By default, TSURFER identifies responses in the output according to the title on the sensitivity data files. For files that have the same titles, or have long or non-descriptive titles, the *usename* keyword in the *PARAMETER* data block can be used to identify the response by their sensitivity data filename. Although filenames are unique, they can also be non-descriptive. For this reason, the *name* keyword on the response definition record can be used to create a new identifier for the response in the TSURFER output. Similarly, the *type* keyword can be used to identify the response type in the output. The default response type is *"keff"* for k_{eff} responses and *"rho"* for eigenvalue-difference responses. It may be useful to include a sequence number in the response name, in order to more easily associate the response number to the input response data. For example, the response names for the first three responses entered could be *name=1_GODIVA, name=2_JEZEBEL,* and *name=3_ZPR4*. In the *CORR* data block and in the printed output, responses are identified by their sequence number (i.e., the order read in), so it is convenient to show this number in the response Name, especially when dealing with a large number of responses.

The measured value of the response (*ev*=) and the measured uncertainty *(uv*=) are required for experiment responses. For application or omitted responses, the *ev* and *uv* keywords are permitted but are not required. The calculated response value is read from the sensitivity data file, but can be overridden by the *cv* keyword. The *nu*= keyword defines the number of uncertainty components that characterize the experiment response uncertainty. If the experiment response uncertainty is given in terms of uncertainty components, the *uv*= keyword specification is optional. An uncertainty component definition record follows the response definition record if the *nu*= keyword specification is given. The uncertainty component definition record has the following format:

ucmp1 val1 ucmp2 val2 . . . . . ucmpP valP,

where

uncmp1 = 4-character alphanumeric identifier for the 1st uncertainty component,

val1 = experiment uncertainty for component *uncmp1,*

Uncmp2 = 4-character alphanumeric identifier for the 2nd uncertainty component,

val2 = experiment uncertainty for component *uncmp2,*

uncmpP = 4-character alphanumeric identifier for the Pth uncertainty component, and

valP = experiment uncertainty for component *uncmpP.*

The uncertainty component definition record contains *nu=P* pairs of alphanumeric identifiers and numeric values. The measured uncertainty value is determined by Eq. Eq. (6.8.10).

The keywords *abs* and *rel* are used to determine the format of sensitivity and uncertainty data on the response definition record and the uncertainty component definition record. For a k_{eff} response, the following four input definitions are equivalent:

```
1)    name=exp_001 ev=1.001 uv=0.005000 rel C:\sensitivity\k_critical_a.sdf

2)    name=exp_001 ev=1.001 uv=0.005005 abs C:\sensitivity\k_critical_a.sdf

3)    name=exp_001 ev=1.001 nu=2        rel C:\sensitivity\k_critical_a.sdf
       enri 0.003000 sden 0.004000

4)    name=exp_001 ev=1.001 nu=2        abs C:\sensitivity\k_critical_a.sdf
       enri 0.003003 sden 0.004004
```

In the example above, the measured k_{eff} is 1.001 ± 0.5% or 1.001 ± 0.005005. (Although most critical experiments have measured k_{eff}= 1, this contrived example reveals the difference between the *absolute* format and the *response* format.) The sensitivity data filename is given as *C:sensitivityk_critical_a.sdf*, and the experiment response is referred to as *exp_001* in the TSURFER output. In 1), the *relative* format is used to specify the relative standard deviation of the measured response as 0.005. In 2), the *absolute* format is used to specify the absolute standard deviation of the measured response as 0.005005. Because the TSUNAMI-generated sensitivity data file is in relative format, TSURFER internally renormalizes the relative sensitivities to absolute sensitivities. In 3), the *relative* format is used to specify the relative standard deviation of k_{eff} due to two components (*enri* and *sden*) as 0.003 and 0.004, respectively. Using Eq. Eq. (6.8.10), the relative standard deviation of k_{eff} is computed to be 0.005. In 4), the *absolute* format is used to specify the absolute standard deviation of k_{eff} due to two components (*enri* and *sden*) as 0.003003 and 0.004004, respectively. The absolute standard deviation of k_{eff} is computed to be 0.005005. Like 2), the sensitivity data file is internally converted to contain absolute sensitivities.

For a second example, the following input definitions are equivalent for an eigenvalue-difference, or reactivity, response:

```
1)    C:\sensitivity\reactivity.sdf ev=15.0000  uv=3.0 abs

2)    C:\sensitivity\reactivity.sdf ev=0.00015  uv=0.2 rel
```

In this example, the measured reactivity is 15 pcm (percent-mille) ± 3 pcm or 0.00015 ± 20%. TSAR creates reactivity sensitivity files in either (a) *absolute* format where the calculated reactivity response and sensitivities are in pcm units or (b) *relative* format with relative sensitivities and the calculated reactivity response are not in pcm units. The TSURFER response definition records are designed to be consistent with the TSAR formats. In 1), the *absolute* format is used to specify the absolute standard deviation of the measured response as 3 pcm. In 2), the *relative* format is used to specify the measured reactivity response as 0.00015 with a relative standard deviation of 0.20 (or 20%). Because TSAR-generated reactivity sensitivity data files may be in absolute format or relative format, TSURFER internally renormalizes the reactivity sensitivity data file to the user-requested format. On occasion, it is desired to adjust a set of nuclear data with zero-valued reactivity responses (i.e., *ev=0.0*). For this case, the *absolute* format should be used because the relative standard deviation of the measured response approaches infinity.

If the *abs* or *rel* keywords are not included on the response definition record, the default format is determined by the *abs* or *rel* keywords in the PARAMETER data block. If more than one formatting keyword is entered in either the PARAMETER data block or response definition record, the last keyword entered sets the format. As an example, the following inputs are equivalent:

1)

```
read parameter
  relative
end parameter
read response
  C:\sensitivity\k_critical_a.sdf ev=1.0 uv=0.005 rel
  C:\sensitivity\reactivity.sdf   ev=0.0 uv=3.0   abs
end response
```

2)

```
read parameter
  relative
end parameter
```

(continues on next page)

(continued from previous page)

```
read response
  C:\sensitivity\k_critical_a.sdf ev=1.0 uv=0.005
  C:\sensitivity\reactivity.sdf   ev=0.0 uv=3.0   abs
end response
```

3)

```
read parameter
  absolute
end parameter
read response
  C:\sensitivity\k_critical_a.sdf ev=1.0 uv=0.005 rel
  C:\sensitivity\reactivity.sdf   ev=0.0 uv=3.0
end response
```

4)

```
read response
  C:\sensitivity\k_critical_a.sdf ev=1.0 uv=0.005
  C:\sensitivity\reactivity.sdf   ev=0.0 uv=3.0   abs
end response
```

In this example, two experiment responses are given. The first response is a relative-formatted k_{eff} response. The second response is an absolute-formatted reactivity response. In 1), the format is determined by the formatting keyword on the response definition record. In 2), the relative-format is set as the default format by the *PARAMETER* block and the absolute format for the reactivity response is specified on its response definition record. In 3), the absolute-format is set as the default format by the *PARAMETER* block and the relative format for the k_{eff} is set by its response definition record. Case 4) is the same as case 2) where the default relative format is applied if no *PARAMETER* block is included.

The final optional keyword for the response definition record is *msen=M*. This record sets the minimum sensitivity criteria for nuclide-reaction pairs with missing covariance data. The keyword is useful when dealing with mixed formatted responses. For example, the following input contains three relative formatted k_{eff} responses and two absolute-formatted reactivity responses.

```
1)
read parameter
  use_dcov
  udcov=0.05
  def_min=0.00001
  relative
end parameter
read response
  C:\sensitivity\godiva.sdf       ev=1.0 uv=0.005
  C:\sensitivity\zpr.sdf          ev=1.0 uv=0.005
  C:\sensitivity\jezebel.sdf      ev=1.0 uv=0.005
  C:\sensitivity\void_react_1.sdf ev=0.0 uv=3.0   abs msen=0.1
  C:\sensitivity\void_react_2.sdf ev=0.0 uv=3.0   abs msen=0.1
end response
```

In this example, the *PARAMETER* block keywords initialize all the responses that follow as relative-formatted responses and the minimum sensitivity criteria for applying default covariance data is 0.00001 or 0.001%. This criteria is used for the three k_{eff} responses. In the response definition records for the two reactivity responses, the absolute-format is specified and the minimum sensitivity criteria is 0.1 pcm. Therefore, default covariance data is used for a nuclide-reaction pair with missing cross-section covariance data if at least one k_{eff} sensitivity for one of the three k_{eff} responses is greater than 0.001% or at least one reactivity sensitivity

for one of the two reactivity responses is greater than 0.1 pcm. Similar to the example above, this example has the following equivalent input:

```
2)
read parameter
  use_dcov
  udcov=0.05
  def_min=0.1
  absolute
end parameter
read response
  C:\sensitivity\godiva.sdf       ev=1.0 uv=0.005 rel msen=0.00001
  C:\sensitivity\zpr.sdf          ev=1.0 uv=0.005 rel msen=0.00001
  C:\sensitivity\jezebel.sdf      ev=1.0 uv=0.005 rel msen=0.00001
  C:\sensitivity\void_react_1.sdf ev=0.0 uv=3.0
  C:\sensitivity\void_react_2.sdf ev=0.0 uv=3.0
end response
```

6.8.5.3 COVARIANCE block

The *COVARIANCE* data block allows the user to specify a covariance matrix for specific nuclide-reaction pairs for which covariance data are not present on the input SCALE covariance library or that have zero or large values on the diagonal. The *COVARIANCE* data block must begin with *READ COVARIANCE* and end with *END COVARIANCE*. The available *COVARIANCE* data block keywords and their default values are given in Table 6.8.3.

Table 6.8.3: Input data for the Covariance block of TSURFER.

Input parameter	**Requirement**	**Default value**	**Allowed values**	**Description**
Nuclide	Required	none	Nuclide name or ZA number	Nuclide for which covariance data are to be entered
Reaction	Required	none	Reaction name or ZA number	Reaction for which covariance data are to be entered
all=	Optional	0.0	any number	Fractional standard deviation value to be applied to all groups
fast=	Optional	0.0	any number	Fractional standard deviation value to be applied to fast groups
therm=	Optional	0.0	any number	Fractional standard deviation value to be applied to thermal groups
inter=	Optional	0.0	any number	Fractional standard deviation value to be applied to intermediate groups
corr=	Optional	1.0	any number from -1.0 to 1.0	Correlation between groups

continues on next page

Table 6.8.3 – continued from previous page

Input parameter	Requirement	Default value	Allowed values	Description
corr_type=	Optional	*zone*	*long, short, zone*	Type of correlation applied from group-to-group covariance values *long* - correlation is applied between all groups *short* - correlation is applied only between adjacent groups *zone* - correlation is applied within fast, intermediate, and thermal groups, but no correlation is applied between zones
end	Required			Denotes end of input for current nuclide/reaction (must not start in column 1)

Any MT number or reaction name will be treated as a valid input, but only those present on the response sensitivity data files will produce useful information. The available reaction sensitivity types are shown in table *Reaction Sensitivity Types Computed by SAMS* in the TSUNAMI-IP manual. An energy-covariance matrix is created for the specified nuclide-reaction pair with the square of the entered standard deviation for the diagonal terms for all groups using the *all=* value. Groups in the fast, intermediate, and thermal energies are then set to the square of the standard deviation value entered for *fast=*, *inter=*, and *therm=*, respectively. The off-diagonal terms of the energy matrix are generated according to the input for *corr=*, and *corr_type=*, with default settings of *1.0* and *zone.* Data entered in this block do not override data present on the covariance data file. The SCALE 5.1 input format is supported where data are entered in triplets with the nuclide name or ZA identifier (e.g., u-235 or 92235), then the reaction MT name or number (e.g., 18 or fission), and then a standard deviation value. In this case, the *end* keyword must not be entered. These data are only used if *use_icov* is specified in the *PARAMETER* data block. When both *use_icov* and *cov_fix* are specified in the *PARAMETER* data block, and a reaction has zero or large (standard deviation > 1000%) values on the diagonal of the covariance matrix, these values are replaced with the square of the user input standard deviation value, and the corresponding off-diagonal terms are substituted according to the values of *corr* and *corr_type*.

6.8.5.4 HTML block

The optional *HTML* data block is used to customize HTML-formatted output. The *HTML* data block must begin with *READ HTML* and end with *END HTML.* The data input in the *HTML* data block consist of several keywords that are shown, along with their default values and descriptions, in Table 6.8.4.

A keyword that ends with "=" must be followed by text data. For color entries, any valid html color name can be entered or the hexadecimal representation can be used if preceded by a # sign. For example, to change the background color of the html output to white, *bg_clr=white* and *bg_clr=#ffffff* have the same effect, because *ffffff* is the hexadecimal representation of white. An extensive list of available colors for customized output is shown in HTML colors. Please note that not all features are supported by all browsers.

Table 6.8.4: Input data for HTML block of TSURFER

Keyword	Default value	Description
bg_clr=	*papayawhip*	Background color.
h1_clr=	*maroon*	Color used for major headings.
h2_clr=	*navy*	Color used for sub-headings.
txt_clr=	*black*	Color for plain text.
lnk_clr=	*navy*	Color for hyperlinks.
lnk_dec=	*none*	Decoration for hyperlinks. (none, underline, overline, line-through, blink).
vlnk_clr	*navy*	Color for visited hyperlinks.
ud_clr=	*blue*	Color for values in tables that use default covariance data.
ui_clr=	*red*	Color for values in tables that use user-input covariance data.
udfix_clr=	*royalblue*	Color for values in tables that use default corrected covariance data.
uifix_clr=	*green*	Color for values in tables that use user-input corrected covariance data.

6.8.5.5 CORR block

The CORR block specifies correlation coefficients between different experiment responses. When present, this block must be the last data block in the input file. The correlation block must begin with *READ CORR* and end with *END PARAMETER*. Correlation coefficients for experimental response uncertainties may be entered either as the total correlation coefficient for a pair of responses; or for a particular uncertainty-component shared by two responses. Values for correlation coefficients are input in the form:

corr_typ (i,j)=ρ ..... {repeat for I=1,N } end

where:

`corr_typ` = 4-character alphanumeric identifier for the response uncertainty component previously defined in the READ RESPONSES block (i.e., *ucmp1*, *umcp2*, etc.). `corr_typ` may also equal *totl* indicating that the total correlation is entered. The `corr_typ` identifier may be omitted and the total correlation is assumed.

N = number of responses in TSURFER input.

ρ = the correlation coefficient at the specified position in the correlation matrix for each uncertainty component.

i,j = the row and column index to the correlation matrix for each uncertainty component. Correlation coefficients can be entered the following five ways:

1) Element-by-element - (i,j)= ρ
2) By row - (i,j1:j2)= ρ
3) By column - (i1:j2,j)= ρ
4) By block - (i1:i2,j1:j2)= ρ. This option can be used to set a large block of the correlation matrix to one number. All diagonal elements in the block are reset to 1.0.
5) By shorthand block - (i1:i2)= ρ. This is identical to (i1:i2,i1:i2)= ρ. All diagonal elements in the block are reset to 1.0.

TSURFER initializes each correlation matrix as an N by N identity matrix. Therefore, all uncorrelated elements (i.e., values equal to 0) do not have to be entered. The correlation matrix can be specified using multiple lines of input with each line having a maximum of 255 characters. As each correlation coefficient is

processed, the symmetric element of the correlation matrix is assigned to the same value. Therefore only the upper or lower triangular portion of each correlation matrix must be specified. For example, given the following *RESPONSE* block:

```
read response
  name=1_k  C:\sensitivity\k_critical_a.sdf ev=1.0 uv=0.005
  name=2_k  C:\sensitivity\k_critical_b.sdf ev=1.0 uv=0.005
  name=3_k  C:\sensitivity\k_critical_c.sdf ev=1.0 uv=0.005
  name=4_k  C:\sensitivity\k_critical_d.sdf ev=1.0 uv=0.005
end response
```

then the following forms of the CORR block are equivalent in specifying the 4 x 4 total correlation matrix as:

$$\begin{bmatrix} 1 & .2 & .3 & .2 \\ .2 & 1 & .2 & .2 \\ .3 & .2 & 1 & .1 \\ .2 & .2 & .1 & 1 \end{bmatrix} \tag{6.8.51}$$

1) Specify the upper triangular portion of the matrix element by element:

```
read corr
   totl (1,2)=.2 (1,3)=.3 (1,4)=.2 (2,3)=.2 (2,4)=.2 (3,4)=.1 end
end corr
```

2) Specify the lower triangular portion of the matrix element by element:

```
read corr
   totl (2,1)=.2 (3,1)=.3 (4,1)=.2 (3,2)=.2 (4,2)=.2 (4,3)=.1 end
end corr
```

3) Use the colon character to specify multiple elements at one time in the upper triangular portion of the matrix:

```
read corr
   totl (1,2)=.2 (1,3)=.3 (1,4)=.2 (2,3:4)=.2 (3,4)=.1 end
end corr
```

Values entered for the total correlation matrix will override any component correlations entered. Correlation coefficients may be specified in the *CORR* data block for responses that share one or more of the same uncertainty components. The value of *corr_typ* must correspond to one of the 4-character alphanumeric identifiers given to an uncertainty component. Only those uncertainty components that appear in more than one response description should be entered, since these are the only ones with correlations. An END keyword is required to terminate the data of an individual uncertainty component, and the input is repeated for each type of correlated uncertainty component.

Note: The experiment covariance matrix should be positive definite to ensure a physical result for all possible sensitivities. If the input correlation values do not satisfy this constraint, a warning message is printed. Use of several fully correlated uncertainties can lead to an over-constrained system, which may result in a non-positive-definite covariance matrix. In order to help avoid this problem, correlation values usually should be limited to a maximum of 0.95, suggesting that a small random component is always present.

As an example of correlation matrices for uncertainty components, consider the following input:

```
read response
  name=1_k  C:\sensitivity\k_critical_a.sdf  ev=1.0  nu=2
     enri=0.003 soln=0.004
  name=2_k  C:\sensitivity\k_critical_b.sdf  ev=1.0  nu=2
     enri=0.0005 soln=0.0012
  name=3_k  C:\sensitivity\k_application.sdf use=app
end response
read corr
   enri (1,2)=0.5 end
   soln (1,2)=0.8 end
end corr
```

In this example, two uncertainty components are used, identified as *enri* and *soln*. Using the propagation of error formula Eq. Eq. (6.8.10) , the relative standard deviation of the experiment responses *1_k* and *2_k* are determined as $\sqrt{(0.003^2 + 0.004^2)} = 0.005$ and $\sqrt{(0.0005^2 + 0.0012^2)} = 0.0013$, respectively. The correlation matrix *enri* and *soln* are given as

$$\begin{bmatrix} 1 & .5 \\ .5 & 1 \end{bmatrix} \tag{6.8.52}$$

and

$$\begin{bmatrix} 1 & .8 \\ .8 & 1 \end{bmatrix} \tag{6.8.53}$$

Using Eq. Eq. (6.8.11), the relative covariance between response *1_k* and *2_k* is calculated as: $0.003 * 0.5 * 0.0005$ (*enri* component) + $0.0005 * 0.8^*0.0012$ (*soln* component) = 1.23E-6.

6.8.6 SAMPLE PROBLEM INPUT AND OUTPUT DESCRIPTION

6.8.6.1 Input and text output

An example TSURFER input is given in Example 6.8.1 and the text output is shown in Example 6.8.2-Example 6.8.14. In this sample problem, 40 k_{eff} responses are specified in the *RESPONSE* block, 37 experiments and 3 applications. All calculation options are turned on including the use of default and user-input covariance data, similarity filtering to the reference application, chi-square filtering for consistency, and bias convergence analysis. Each section of the text output is described in order below. Some of the figures of the text output have been truncated from their original length. The examples of output are for illustrative purposes and only demonstrate the format of the TSURFER results.

1. Echo of Input (Example 6.8.2) - The TSURFER input data are printed for the *PARAMETER, HTML*, and *COVARIANCE* data blocks. Both user-specified and default values for the various keywords are edited.
2. Covariance Warnings (Example 6.8.3) - If the PARAMETER block keywords *use_dcov* and/or *use_icov* and/or *cov_fix* are entered, covariance warnings are listed that specify the nuclide-reaction pairs for which approximate covariance data is applied.
3. Listing of Input Responses (Example 6.8.4) - Various information is listed for each response. This includes the response index, name, title, adjustment role (e.g., *expt*), type, calculated response value, measured response value, and similarity coefficient to the reference application. The similarity coefficient column is only edited if a reference application is listed on the input.
4. Experiment Uncertainties (Example 6.8.5) - The experiment standard deviations, as well as any input uncertainty components, are edited for each measured response. When uncertainty components are given, the total standard deviation is computed from Eq. .

5. Chi-square summary (Example 6.8.6) - Different chi-squared values are edited based on the GLLS analysis. This includes the initial value of chi-squared, the target value of chi-squared based on the *target_chi* keyword, and the final value of chi-squared. The independent and diagonal chi-squares are also edited.

6. Correlation Matrices (Example 6.8.7-Example 6.8.9) - Correlation matrices are printed after the chi-squared edit in the following order: (1) response similarity matrix if *print_sim_matrix* is entered in the input, (2) the prior calculated response correlation matrix and prior measured response correlation matrix if *print_init*_corr is entered in the input, and (3) the adjusted response correlation matrix if *print_adj_corr* is entered in the input. The value of the keyword **sim_type** designates the type of similarity coefficient appearing in the similarity matrix. See Sect. 6.6.4.3 for description of the types of similarity coefficients. The response correlation matrices are defined in Appendix A.

7. Cumulative Convergence Edit (Example 6.8.10) - The cumulative convergence edit follows the printout of the requested correlation matrices. TSURFER only performs the cumulative convergence calculation if the keyword *calc_cumul_effect* is entered in the input. Four columns of data are printed that specify the cumulative range number, the maximum similarity coefficient allowed for each adjustment, the number of experiments with similarity coefficients within the specified range, and the computed application bias for each range, shown as o/v(A-C)/C, where A represents the adjusted k_{eff} value and C represents the original calculated k_{eff} value.

8. Summary of Adjustments (Example 6.8.11) - The adjustment summary table is an 11-column table that summarizes the prior and posterior values of each response. The 11 columns include the response adjustment role (i.e., *expt, appl,* or *omit*), the name and type identifiers, the prior and posterior uncertainties of each response, the independent and diagonal chi-squared values, and the change in the response between the prior and posterior values.

9. Summary of Adjusted Responses (Example 6.8.12) - Following the adjustment summary table, the adjusted values of each response are listed in tabular format. The adjusted uncertainty values of the response are also included.

10. Application and Bias Summary (Example 6.8.13) - The application and bias summary table follows the adjusted response table. This edit is only printed if applications are specified on the TSURFER input. For each application, the following values are tabulated: the name and type of the response, the prior and posterior values of the application response, the prior and posterior values of the application uncertainty, and the application bias as determined by Eq. . If the application is a relative-formatted response, the fractional bias is also included in the table. Following this table, a second table is printed that lists the contribution to the reference application bias for each nuclide-reaction pair used in the analysis. The nuclide-reaction pairs are listed in descending order based on the fraction of bias L1-norm, defined as

$$f_x = \frac{\sum_g \left| S_{x,g} \Delta\alpha_{x,g} \right|}{\sum_{x'} \sum_g \left| S_{x',g} \Delta\alpha_{x',g} \right|} \tag{6.8.54}$$

11. Multigroup Cross-Section Adjustment Table (Example 6.8.14) - The Multigroup cross-section adjustment tables are printed if the *print_adjustments* keyword is included in the TSURFER input. For each nuclide-reaction pair, a table is printed that includes the relative adjustment of each multigroup cross-section, and the prior and posterior values of the cross-section uncertainty. If an application is included in the TSURFER input, the bias contribution and fraction of bias L1-norm are also edited. The order of the nuclide-reaction pairs is determined by the fraction of bias L1-norm.

Example 6.8.1: TSURFER sample input.

++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++

                         I N P U T  D A T A

 PARAMETER         VALUE       DESCRIPTION

 absolute          false       Print uncertainty values and penalty
                               assessments in absolute format.  This is
                               the default format. Relative format can be
                               specified using the "rel" keyword in the
                               APPLICATIONS, EXPERIMENTS, or RESPONSE
                               input blocks.

 adjcut             1.0000E-05 Cutoff value for the cross-section
                               adjustment edits. If the maximum
                               group-wise relative adjustment for a given
                               cross-section is less than adjcut, then it
                               is omitted from the cross-section
                               adjustment table.
 adj_cov_cut        1.0000E-06 Cutoff value for including an adjusted
                               cross-section-covariance matrix in the
                               post adjustment analysis and data file.
                               If a nuclide-reaction to nuclide-reaction
                               covariance contains no values exceeding
                               adj_cov_cut,the matrix is excluded from
                               further analysis.  Note that adj_cov_cut
                               represents a variance, not a standard
                               deviation.
```

(continued from previous page)

```
bin_width=          1.000E-02  Size of similarity bins for cumulative
                               iteration edits.

cov_fix             true       Replace zero and large values on diagonal
                               of  cross-section covariance data with
                               user input values and dcov value.

cov_unit=           33         Logical unit for cross-section covariance
                               data.

calc_cumul_effect true         Perform cumulative iteration edit.

chi_sq_filter=      delta_chi  Method used for chi^2 filter analysis.
                               Possible values are:

                               independent - use independent chi^2
                                             filtering method.

                               diagonal    - use diagonal    chi^2
                                             filtering method.

                               iter_diag   - use iterative diagonal
                                             chi^2 filtering method.

                               delta_chi   - use iterative delta-chi
                                             chi^2 filtering method.

large_cov=          10.0000    Cutoff fractional standard deviation
                               value for cov_fix.

nohtml              false      Flag to cause HTML output to not be
                               produced.

print=              regular    Level of output edits for this analysis
                               (minimum or regular).

print_sim_matrix    false      Option to print similarity matrix.

print_adjustments   true       Option to print 1-D cross-section
                               adjustments.

print_init_corr     true       Option to print initial response
                               correlation matrix.

print_adj_corr      true       Option to adjusted response correlation
                               matrix.

ref_app=            40         Index to reference application response.

relative            true       Print uncertainty values and penalty
                               assessments in relative format.  This is
                               the default format. Absolute format can be
```

(continued from previous page)

```
                              specified using the "abs" keyword in the
                              APPLICATIONS, EXPERIMENTS, or RESPONSE
                              input blocks.

return_work_cov   true        Option to copy the working covariance
                              data file back to the return directory.

return_adj_cov    true        Option to copy the adjusted covariance
                              data file back to the return directory. If
                              return_adj_cov is false, the adjusted
                              covariance data file is not created.

sen_unit=         41          Logical unit for sensitivity data files.

sim_type=         C           Criteria used to calculate sim matrix.

                              Possible values are:

                              E - Calculate the similarity matrix
                                 using Esum correlation coefficients.

                              G - Calculate the similarity matrix
                                 using Gm  correlation coefficients.

                              C - Calculate the similarity matrix
                                 using Ck  correlation coefficients.

target_chi=        3.000E+00  Target chi-square per degree of freedom
                              for consistency acceptance.

udcov=             0.0500     User-defined default value of standard
                              deviation in cross-section data to use for
                              nuclide-reaction pairs for which
                              covariance data are not available on the
                              selected data file.

udcov_corr=        1.0000     User-defined default correlation value to
                              use for nuclide-reaction pairs for which
                              covariance data are not available on the
                              selected data file.

udcov_corr_type=  zone        User-defined default correlation in
                              cross-section data to use for
                              nuclide-reaction pairs for which
                              covariance data are not available on the
                              selected data file.  (long, zone, short)

udcov_fast=        0.0000     User-defined default value of standard
                              deviation in cross-section data to use for
                              fast data for nuclide-reaction pairs for
                              which covariance data are not available on
                              the selected data file.

udcov_inter=       0.0000     User-defined default value of standard
                              deviation in cross-section data to use for
```

(continues on next page)

(continued from previous page)

```
                              intermediate data for nuclide-reaction
                              pairs for which covariance data are not
                              available on the selected data file.

udcov_therm=       0.0000     User-defined default value of standard
                              deviation in cross-section data to use for
                              thermal data for nuclide-reaction pairs
                              for which covariance data are not
                              available on the selected data file.

uncert_long       false       Prints extended table of uncertainty in
                              response due to covariance data.

use_dcov          true        Use user-defined default covariance data,
                              udcov, for nuclide reaction pairs not
                              included on the covariance data file.

use_diff_groups   true        Allow sensitivity data files to have
                              different energy group structures.

usename           false       Use the name of the sensitivity data file
                              in place of its title in all output.

use_icov          true        Use user-defined data input in COVARIANCE
                              input data block in place of udcov value
                              for user input nuclide-reaction pairs that
                              are not on the covariance data file.

 Total   -3.625E+00 ---------- ----------  9.994E-01    1.221E-01     3.141E-01

 NOTE: The contribution to the application bias is tabulated in units of % dk/k.
       The contribution to the application bias is normalized to the calculated response value.
 NOTE: The fraction of the bias L1-norm is equal to the absolute value of the bias contribution
       divided by the sum of the absolute value of all groupwise bias contributions.

6.8.6.2 HTML Output

The input file for the TSURFER sample problem is named tsurfer.inp. In this case, the HTML-formatted output is stored in a file called tsurfer.html and additional resources are stored in directories called tsurfer.htmd and applet_resources. This section contains example TSURFER HTML-formatted output only for demonstration of the interface. When tsurfer.html is opened in a web browser, the information shown in Fig. 6.8.1 is displayed. The title of the input file is displayed between the two SCALE logos. Because this SCALE input file only executed TSURFER, only a single-output listing is available. The text "1. TSURFER" is a hyperlink to view the output from TSURFER. Clicking on the "1. TSURFER" hyperlink will bring up the information shown in Fig. 6.8.2. Clicking on the SCALE logos will link the user to the SCALE website, if external internet access is available.

Fig. 6.8.1: Initial screen from TSURFER HTML output.

The initial page of output from TSURFER is shown in Fig. 6.8.2. Program verification information is shown in the table under the TSURFER logo. This table includes information about the code that was executed and the date and time it was run. The menu on the left side of the screen contains hyperlinks to specific portions of the code output. Echoes of the input data are available in the Input Data section. Any errors or warning messages are available in the Messages sections. Results from the code execution are shown in the results section.

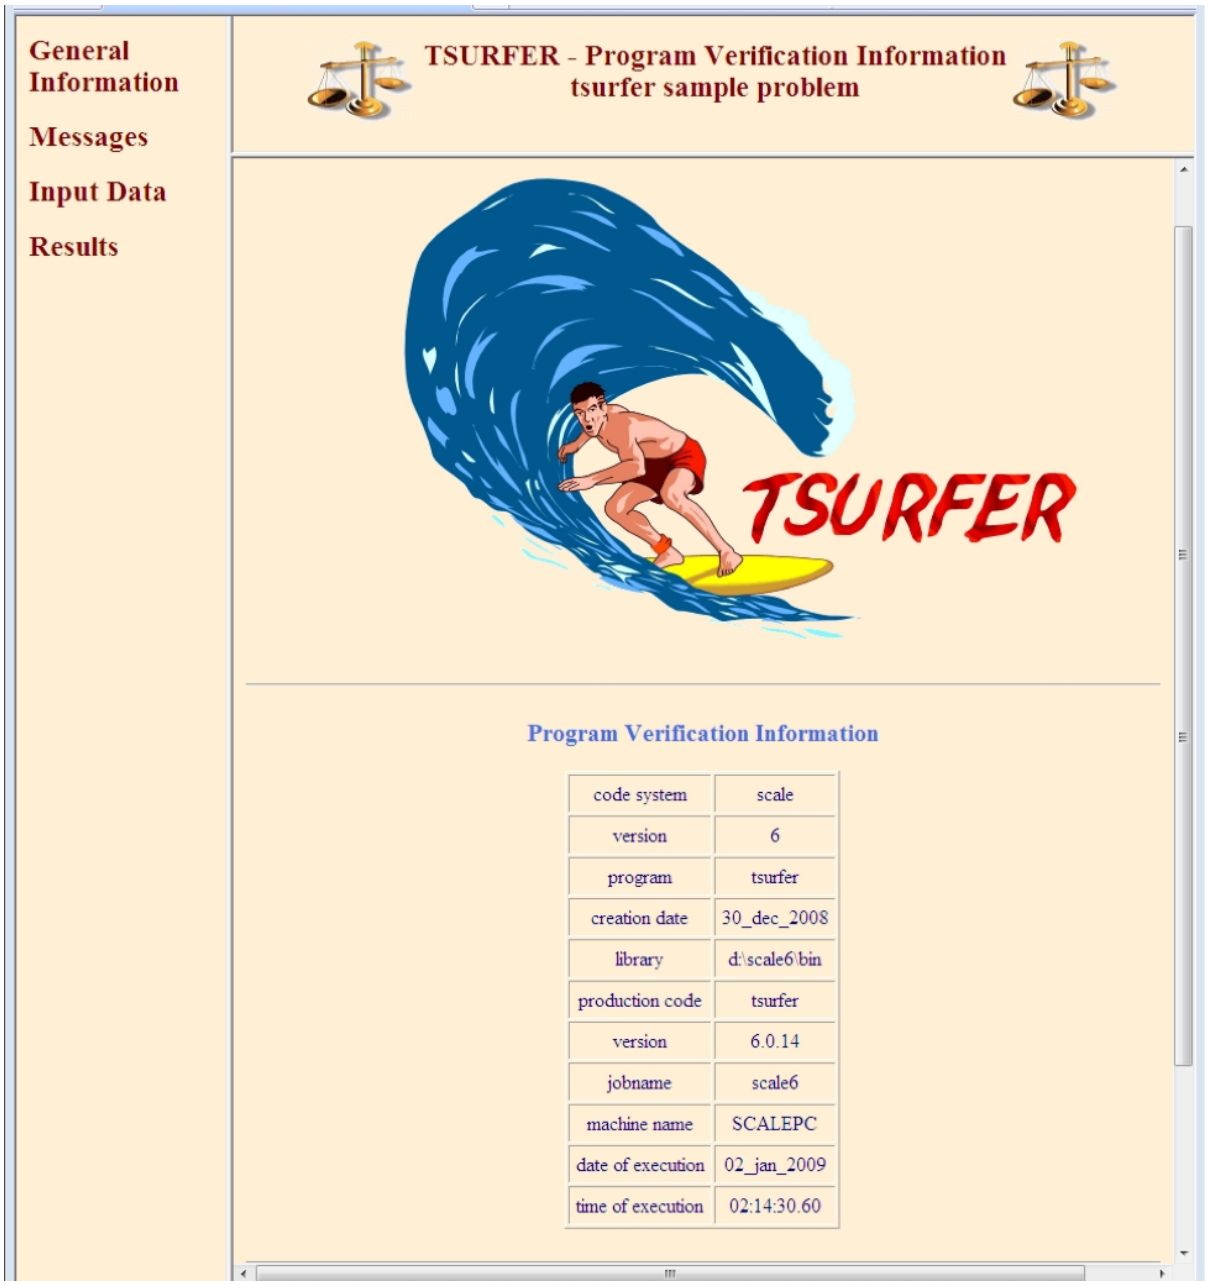

Fig. 6.8.2: Program verification screen from TSURFER HTML output.

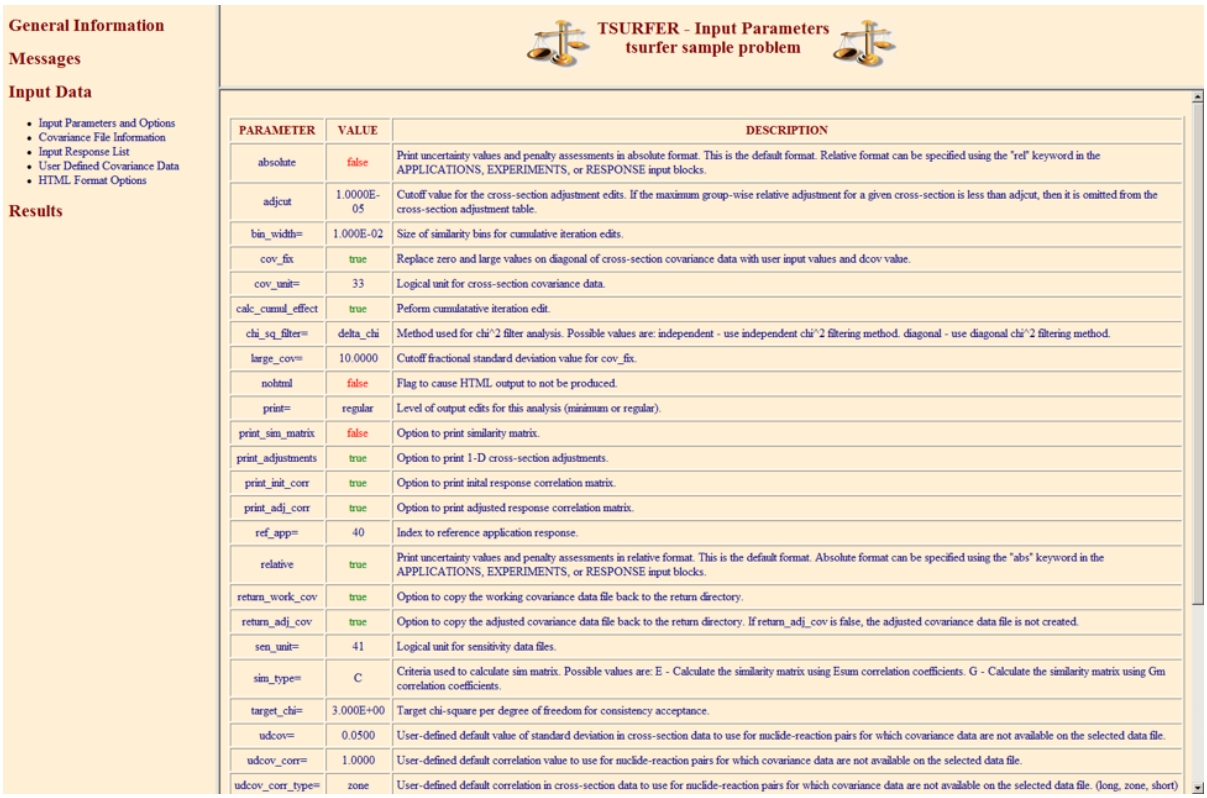
Selecting Input Parameters will reveal the menu of available input data. Selecting Input Parameters causes the table shown in Fig. 6.8.3 to be displayed. Other input data can also be displayed by selecting the desired data from the menu.



PARAMETER	VALUE	DESCRIPTION
absolute	false	Print uncertainty values and penalty assessments in absolute format. This is the default format. Relative format can be specified using the "rel" keyword in the APPLICATIONS, EXPERIMENTS, or RESPONSE input blocks.
adjcut	1.0000E-05	Cutoff value for the cross-section adjustment edits. If the maximum group-wise relative adjustment for a given cross-section is less than adjcut, then it is omitted from the cross-section adjustment table.
bin_width=	1.000E-02	Size of similarity bins for cumulative iteration edits.
cov_fix	true	Replace zero and large values on diagonal of cross-section covariance data with user input values and dcov value.
cov_unit=	33	Logical unit for cross-section covariance data.
calc_cumul_effect	true	Peform cumulatative iteration edit.
chi_sq_filter=	delta_chi	Method used for chi^2 filter analysis. Possible values are: independent - use independent chi^2 filtering method. diagonal - use diagonal chi^2 filtering method.
large_cov=	10.0000	Cutoff fractional standard deviation value for cov_fix.
nohtml	false	Flag to cause HTML output to not be produced.
print=	regular	Level of output edits for this analysis (minimum or regular).
print_sim_matrix	false	Option to print similarity matrix.
print_adjustments	true	Option to print 1-D cross-section adjustments.
print_init_corr	true	Option to print inital response correlation matrix.
print_adj_corr	true	Option to print adjusted response correlation matrix.
ref_app=	40	Index to reference application response.
relative	true	Print uncertainty values and penalty assessments in relative format. This is the default format. Absolute format can be specified using the "abs" keyword in the APPLICATIONS, EXPERIMENTS, or RESPONSE input blocks.
return_work_cov	true	Option to copy the working covariance data file back to the return directory.
return_adj_cov	true	Option to copy the adjusted covariance data file back to the return directory. If return_adj_cov is false, the adjusted covariance data file is not created.
sen_unit=	41	Logical unit for sensitivity data files.
sim_type=	C	Criteria used to calculate sim matrix. Possible values are: E - Calculate the similarity matrix using Esum correlation coefficients. G - Calculate the similarity matrix using Gm correlation coefficients.
target_chi=	3.000E+00	Target chi-square per degree of freedom for consistency acceptance.
udcov=	0.0500	User-defined default value of standard deviation in cross-section data to use for nuclide-reaction pairs for which covariance data are not available on the selected data file.
udcov_corr=	1.0000	User-defined default correlation value to use for nuclide-reaction pairs for which covariance data are not available on the selected data file.
udcov_corr_type=	zone	User-defined default correlation in cross-section data to use for nuclide-reaction pairs for which covariance data are not available on the selected data file. (long, zone, short)

Fig. 6.8.3: Input parameters from TSURFER HTML output.

Selecting Messages will reveal a menu of available messages. Selecting Warning Messages from the Messages section of the menu causes the information shown in Fig. 6.8.4 to appear. The Warning Messages edit contains all warning messages that were generated during the execution of the code. If errors were encountered in the code execution, an Error Messages item would have also been available in the menu under Messages.

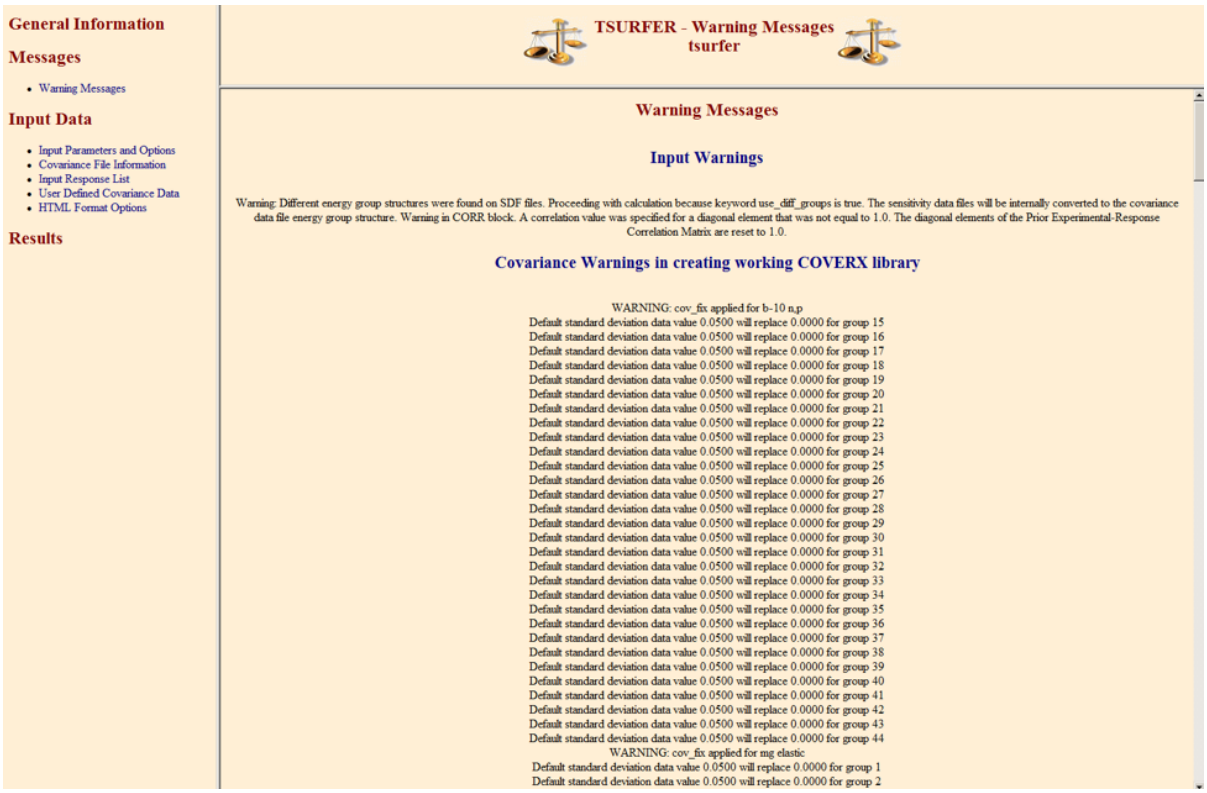


Fig. 6.8.4: Warning messages from TSURFER HTML output.

Selecting Results causes a menu of available results to be revealed. From this menu, selecting Cross-Section Adjustments causes a menu on the right to be revealed. From this menu, nuclide-reaction pairs can be selected to visualize their cross-section adjustments in tabular format. The U-235 nubar adjustments are shown in Fig. 6.8.5.

Fig. 6.8.5: Cross-section adjustments from TSURFER HTML output.

Various plots can also be viewed in the TSURFER HTML output. Selecting “Plots” in the Results menu brings up a submenu of various TSURFER plots. The correlation matrices may be viewed by selecting “Correlation Matrices” in the Plots submenu. A Java applet version of Javapeño will appear in the browser window with the correlation matrices preloaded. Data can be added to the plot by double-clicking on the list of available data on the right side of Javapeño. The plot shown in Fig. 6.8.6 was produced with this procedure.

6.8.7 APPENDICES

6.8.7.1 TSURFER Appendix A: Sensitivity/Uncertainty Notation

In the following expressions, the notation E[X] represents the expected value of random variable X, which is equal to the integral of X weighted by its probability density function over the range of allowable values.

Basic variables

I =

number of integral response (experiment and applications) used in GLLS analysis

M =

number of nuclear data parameters used in transport calculations (i.e., number of unique nuclide-reaction pairs multiplied by the number of energy groups)

$\boldsymbol{\alpha}$ =

M dimensional vector of prior nuclear data parameters, where component-i = α_i

A =

M by M diagonal matrix of prior nuclear data parameters, where diagonal element **A**(i,i) = α_i

m =

I dimensional vector of prior measured responses, where component-i = m_i

M =

I by I diagonal matrix of prior measured responses, where diagonal element **M**(i,i) = m_i

$\mathbf{k}(\boldsymbol{\alpha})$ =

I dimensional vector of prior calculated responses obtained with nuclear data $\boldsymbol{\alpha}$, where component I = k_i

K =

I by I diagonal matrix of prior calculated responses, where diagonal element **K**(i,i) = k_i

$\mathbf{F_{m/k}}$ =

I by I diagonal matrix of "E/C" values =

$$\mathbf{MK}^{-1} = \mathbf{K^{-1}M} \tag{6.8.55}$$

where diagonal element

$$F_{m/k}(i,i) = \frac{m_i}{k_i} \tag{6.8.56}$$

$\hat{\mathbf{F}}_{\mathbf{m/k}}$ =

I by I diagonal matrix, where diagonal element

$$F_{m/k}\,(i,i) = \frac{m_i}{k_i} \tag{6.8.57}$$

for a relative-formatted response and $F_{m/k}(i,i) = 1$

$\boldsymbol{\alpha}'$ =

M dimensional vector of adjusted nuclear data parameters produced by GLLS procedure

m' =

I dimensional vector of adjusted measured responses produced by GLLS procedure

$\mathbf{k}'(\boldsymbol{\alpha}')$ =

I dimensional vector of adjusted calculated responses obtained with modified nuclear data $\boldsymbol{\alpha}'$

Note: $\mathbf{k}'(\boldsymbol{\alpha}') = \mathbf{m}'$, due to GLLS adjustment procedure.

$\tilde{\mathbf{d}}$ =

original absolute discrepancy vector = $\mathbf{k} - \mathbf{m}$, where component-i= $k_i - m_i$

d =

original relative discrepancy vector = $\mathbf{K}^{-1}(\mathbf{k} - \mathbf{m})$, where component-i = $(k_i - m_i)\,/k_i$

$\hat{\mathbf{d}}$

original mixed absolute-relative discrepancy vector, where component-i = $(k_i - m_i)/k_i$ for a relative-formatted response and $(k_i - m_i)$ for an absolute-formatted response

$[\Delta\boldsymbol{\alpha}]$ =

M dimensional vector of relative variations in nuclear data = $\mathbf{A}^{-1}(\boldsymbol{\alpha}' - \boldsymbol{\alpha})$ where component-i = $\frac{\alpha_i' - \alpha_i}{\alpha_i}$

$[\Delta\mathbf{m}]$ =

I dimensional vector of relative variations in measured responses = $\mathbf{M}^{-1}(\mathbf{m}' - \mathbf{m})$ where component-i = $\frac{m_i' - m_i}{m_i} \rightarrow \frac{k_i' - m_i}{m_i}$

$[\Delta\mathbf{m}]$ =

I dimensional vector of absolute variations in measured responses = $\mathbf{m}' - \mathbf{m}$ where component-i $m_i' - m_i \rightarrow k_i' - m_i$

$[\Delta\hat{\mathbf{m}}]$ =

I dimensional vector of mixed absolute-relative variations in measured responses, where component-i = $\frac{m_i' - m_i}{m_i}$ for a relative-formatted response and $m_i' - m_i$ for an absolute-formatted response

$[\Delta\mathbf{k}]$ =

I dimensional vector of relative variations in calculated responses = $\mathbf{K}^{-1}(\mathbf{k}' - \mathbf{k})$ where component-i = $\frac{k_i' - k_i}{k_i}$

$[\Delta\mathbf{k}]$ =

I dimensional vector of absolute variations in calculated responses = $\mathbf{k}' - \mathbf{k}$, where component-i = $k_i' - k_i$

$[\Delta\hat{\mathbf{k}}]$ =

I dimensional vector of mixed absolute-relative variations in calculated responses, where component-i = $k_i' - k_i$ for an absolute formatted response

Sensitivity Relations

$\widetilde{\mathbf{S}}_{\mathbf{k}\boldsymbol{\alpha}}$ =

I by M absolute sensitivity matrix; where element $\widetilde{\mathbf{S}}_{\mathbf{k}\boldsymbol{\alpha}}(i, n) = \alpha_n \frac{\partial k_i}{\partial \alpha_n}$

$\mathbf{S}_{\mathbf{k}\boldsymbol{\alpha}}$ =

I by M relative sensitivity matrix = $\mathbf{K}^{-1}\mathbf{S}_{\mathbf{k}\boldsymbol{\alpha}}$, where element $\mathbf{S}_{k\alpha}(i, n) = \frac{\alpha_n}{k_i}\frac{\partial k_i}{\partial \alpha_n}$.

$\hat{\mathbf{S}}_{\mathbf{k}\boldsymbol{\alpha}}$ =

I by M mixed absolute-relative sensitivity matrix, where element $\hat{\mathbf{S}}_{\mathbf{k}\boldsymbol{\alpha}}(i, n) = \frac{\alpha_n}{k_i}\frac{\partial k_i}{\partial \alpha_n}$ if response-i is relative-formatted and $\hat{\mathbf{S}}_{\mathbf{k}\boldsymbol{\alpha}}(i, n) = \alpha_n \frac{\partial \mathbf{k}_i}{\partial \alpha_n}$ if response-i is absolute-formatted

$$\begin{aligned} [\Delta\mathbf{k}] &= \quad \mathbf{S}_{\mathbf{k}\boldsymbol{\alpha}}[\Delta\boldsymbol{\alpha}] \\ [\Delta\mathbf{k}] &= \mathbf{S}_{\mathbf{k}\boldsymbol{\alpha}}[\Delta\boldsymbol{\alpha}] \\ [\Delta\hat{\mathbf{k}}] &= \hat{\mathbf{S}}_{\mathbf{k}\boldsymbol{\alpha}}[\Delta\boldsymbol{\alpha}] \end{aligned} \tag{6.8.58}$$

Absolute covariances

$\tilde{\mathbf{C}}_{\mathbf{mm}}$ =

I by I covariance matrix for prior measured experiment responses where element $\tilde{\mathbf{C}}_{\mathbf{mm}}(\mathrm{i,j}) = E\left(\delta m_i\, \delta m_j\right)$

$\tilde{\mathbf{C}}_{\mathbf{kk}}$ =

I by I covariance matrix for prior calculated responses, where element $\tilde{\mathbf{C}}_{\mathbf{kk}}(\mathrm{i,j}) = E\left(\delta k_i\, \delta k_j\right)$

$\tilde{\mathbf{C}}_{\mathbf{dd}}$ =

I by I covariance matrix for the discrepancies (k-m), where element $\tilde{\mathbf{C}}_{\mathbf{dd}}(\mathrm{i,j}) = E\left(\delta d_i\, \delta d_j\right) = \mathrm{E}\left(\delta\left(\mathrm{k_i} - \mathrm{m_i}\right)\delta\left(\mathrm{k_j} - \mathrm{m_j}\right)\right)$

$\tilde{\mathbf{C}}_{\mathbf{k'k'}}$ =

I by I covariance matrix for adjusted responses, where element $\tilde{\mathbf{C}}_{\mathbf{k'k'}}(\mathrm{i,j}) = E\left(\delta k'_i\, \delta k'_j\right)$

$\boldsymbol{\sigma}_{\mathbf{m}}$ =

I by I diagonal matrix containing standard deviations in prior measured responses, where diagonal element $\widetilde{\sigma}_{\mathrm{m}}\,(\mathrm{ii}) = \sqrt{\widetilde{\mathrm{C}}_{\mathrm{mm}}(\mathrm{i,i})}$

$\boldsymbol{\sigma}_{\mathbf{k}}$ =

I by I diagonal matrix containing standard deviations in prior calculated responses, where diagonal element $\widetilde{\sigma}_{\mathrm{k}}(\mathrm{i,i}) = \sqrt{\widetilde{\mathrm{C}}_{\mathrm{kk}}(\mathrm{i,i})}$

$\boldsymbol{\sigma}_{\mathbf{k'}}$

Relative covariances

$C_{\mathbf{mm}}$ =

I by I relative covariance matrix for prior measured responses, $= \mathbf{M}^{-1}\left[\tilde{\mathbf{C}}_{\mathbf{mm}}\right]\mathbf{M}^{-1}$ $C_{mm}(i,j) = \frac{\mathrm{C_{mm}(i,j)}}{\mathrm{m_i m_j}}$

$C_{\alpha\alpha}$ =

M by M relative covariance matrix for prior nuclear data, where element $\widetilde{C}_{\alpha\alpha}(i,j) = \frac{\mathrm{E}\left(\delta\alpha_\mathrm{i}\delta\alpha_\mathrm{j}\right)}{\alpha_\mathrm{i}\alpha_\mathrm{j}}$

$C_{\mathbf{kk}}$ =

I by I relative covariance matrix for prior calculated responses $= \mathbf{K}^{-1}\,[\mathbf{C}_{\mathrm{kk}}]\,\mathbf{K}^{-1}$ where element $C_{kk}(i,j) = \frac{\mathrm{C_{kk}(i,j)}}{\mathrm{k_i k_j}}$

$C_{\mathbf{dd}}$

I by I relative covariance matrix for response discrepancies; $= \mathbf{K}^{-1}\,[\mathbf{C}_{\mathbf{dd}}]\,\mathbf{K}^{-1}$, where element $C_{dd}(i,j) = \frac{\mathrm{C_{dd}(i,j)}}{\mathrm{k_i k_j}}$

$\boldsymbol{\sigma}_{\mathbf{m}}$ =

I by I diagonal matrix containing relative standard deviations in measured responses, where diagonal element $\sigma_{\mathrm{m}}\,(\mathrm{i,i}) = \sqrt{\mathrm{C_{mm}(i,i)}}$

$\boldsymbol{\sigma}_{\mathbf{k}}$ =

I by I diagonal matrix containing relative standard deviations in calculated responses, where diagonal element $\sigma_{k'}(i,i) = \sqrt{C_{k'k'}(i,i)}$

$\boldsymbol{\sigma_\alpha}$ =

M by M diagonal matrix containing standard deviations in nuclear data, where diagonal element $\boldsymbol{\sigma_\alpha}(i,i) = \sqrt{C_{\alpha\alpha}(i,i)}$

Mixed absolute-relative covariances

If response-i and response-j are both absolute formatted, then

$$\begin{aligned} \hat{C}_{kk}(i,j) &= C_{kk}(i,j) \\ \hat{C}_{mm}(i,j) &= C_{mm}(i,j) \\ \hat{C}_{dd}(i,j) &= C_{dd}(i,j) \\ \hat{C}_{k'k'}(i,j) &= C_{k'k'}(i,j) \end{aligned} \tag{6.8.59}$$

Likewise, if both response-i and response-j are relative-formatted, then

$$\begin{aligned} \hat{C}_{kk}(i,j) = C_{kk}(i,j) &= \frac{C_{kk}(i,j)}{k_i k_j} \\ \hat{C}_{mm}(i,j) = C_{mm}(i,j) &= \frac{C_{mm}(i,j)}{m_i m_j} \\ \hat{C}_{dd}(i,j) = C_{dd}(i,j) &= \frac{C_{dd}(i,j)}{d_i d_j} \\ \hat{C}_{k'k'}(i,j) = C_{kk'}(i,j) &= \frac{C_{kk'}(i,j)}{k'_i k'_j} \end{aligned} \tag{6.8.60}$$

If response-i is absolute-formatted and response-j is relative-formatted, then

$$\begin{aligned} \hat{C}_{kk}(i,j) &= \frac{C_{kk}(i,j)}{k_j} \\ \hat{C}_{mm}(i,j) &= \frac{C_{mm}(i,j)}{m_j} \\ \hat{C}_{dd}(i,j) = \frac{C_{dd}(i,j)}{d_j} \hat{C}_{k'k'}(i,j) &= \frac{C_{k'k'}(i,j)}{k'_j} \end{aligned} \tag{6.8.61}$$

Similar expressions can be derived if response-i is relative-formatted, and response-j is absolute-formatted. The I by I diagonal matrices of standard deviation values are the following:

$$\hat{\sigma}_k(i,i) = \begin{cases} \sigma_k(i,i) & \text{absolute-formatted} \\ \sigma_k(i,i) & \text{relative-formatted} \end{cases} \tag{6.8.62}$$

$$\hat{\sigma}_m(i,i) = \begin{cases} \sigma_m(i,i) & \text{absolute-formatted} \\ \sigma_m(i,i) & \text{relative-formatted} \end{cases} \tag{6.8.63}$$

$$\hat{\sigma}_d(i,i) = \begin{cases} \sigma_d(i,i) & \text{absolute-formatted} \\ \sigma_d(i,i) & \text{relative-formatted} \end{cases} \tag{6.8.64}$$

$$\hat{\sigma}_{k'}(i,i) = \begin{cases} \sigma_{k'}(i,i) & \text{absolute-formatted} \\ \sigma_{k'}(i,i) & \text{relative-formatted} \end{cases} \tag{6.8.65}$$

Correlation matrices

$\mathbf{R_{kk}}$ =

I by I correlation matrix for prior calculated responses, where element $R_{kk}(i,j) = \frac{C_{kk}(i,j)}{\sigma_k(i,i)\sigma_k(j,j)} = \frac{C_{kk}(i,j)}{\sigma_k(i,i)\sigma_k(j,j)} = \frac{\hat{C}_{kk}(i,j)}{\hat{\sigma}_k(i,i)\hat{\sigma}_k(j,j)}$

$\mathbf{R_{mm}}$ =

I by I correlation matrix for prior measured responses, where element $R_{mm}(i,j)$ $\frac{C_{mm}(i,j)}{\sigma_m(i,i)\sigma_m(j,j)}$ = $\frac{C_{mm}(i,j)}{\sigma_m(i,i)\sigma_m(j,j)} = \frac{\hat{C}_{mm}(i,j)}{\hat{\sigma}_m(i,i)\hat{\sigma}_m(j,j)}$

$\mathbf{R_{\alpha\alpha}}$ =

M by M correlation matrix for prior nuclear data, where element $R_{\alpha\alpha}(i,j) = \frac{C_{\alpha\alpha}(i,j)}{\sigma_\alpha(i,i)\sigma_\alpha(j,j)}$

$\mathbf{R_{k'k'}}$ =

I by I correlation matrix for adjusted responses, where element $R_{k'k'}$ (i, j) = $\frac{C_{k'k'}(i,j)}{\sigma_{k'}(i,i)\sigma_{k'}(j,j)}$ = $\frac{C_{k'k'}(i,j)}{\sigma_{k'}(i,i)\sigma_{k'}(j,j)} = \frac{\hat{C}_{k'k'}(i,j)}{\hat{\sigma}_{k'}(i,i)\hat{\sigma}_{k'}(j,j)}$

7. MATERIAL SPECIFICATION AND CROSS SECTION PROCESSING

Introductiom by M. L. Williams and B. T. Rearden

XSProc (Cross Section Processing) provides material input and multigroup (MG) cross section preparation for most SCALE sequences. XSProc allows users to specify problem materials using easily remembered and easily recognizable keywords associated with mixtures, elements, nuclides, and fissile solutions provided in the SCALE **Standard Composition Library**. For MG calculations, XSProc provides cross section temperature correction and resonance self-shielding as well as energy group collapse and spatial homogenization for systems that can be represented in *celldata* input as infinite media, finite 1D/2D systems, or repeating structures of 1D/2D systems, such as uniform arrays of fuel units. Improved resonance self-shielding treatment for nonuniform lattices can be achieved through the use of the **MCDancoff** (Monte Carlo Dancoff) code that generates Dancoff factors for generalized 3D geometries for subsequent use in XSProc. Cross sections are generated on a microscopic and/or macroscopic basis as needed. Although XSProc is most often used as part of an integrated sequence, it can be run without subsequent calculations to generate problem-dependent MG data for use in other tools.

This chapter provides detailed descriptions of the methods and modules used for self-shielding. Self-shielding calculations are effectively a problem-specific extension of the processing procedures used to create the SCALE cross section libraries. SCALE includes continuous energy (CE) and several MG (MG) cross section libraries described in the chapter on SCALE Cross Section Libraries. The AMPX nuclear data processing system [MAT-WWCD15] was used to convert evaluated data from ENDF/B into CE cross sections, which were then averaged into problem-independent MG data at a reference temperature of 300K, weighted with a generic energy spectrum (see the SCALE Cross Section Libraries chapter). After being transformed in probability distributions by AMPX, the CE data require no further modifications for application to a specific problem except for possible interpolation to the required temperatures. However, in MG calculations, reaction rates depend strongly on the problem-specific energy distribution of the flux, which implies that the problem-independent MG data on the library should be modified into problem-dependent values representative of the actual flux spectrum rather than the library generic spectrum. The neutron energy spectrum is especially sensitive to the concentrations and heterogeneous arrangement of resonance absorbers, which may dramatically reduce the flux at the resonance peaks of a nuclide, thus reducing its own reaction rate–a phenomenon known as self-shielding. In general, the higher the concentration of a resonance nuclide and the more the interaction between heterogeneous lumps (e.g. fuel pins), the greater the degree of self-shielding for the nuclide.

Reference [MAT-Wil11] gives a general description of the SCALE self-shielding methods. The individual computational modules perform distinct functions within the overall all self-shielding methodology of XSProc. More theoretical details about individual computational modules are given in Sect. 7.2 through Sect. 7.9. XSProc provides capabilities for two different types of self-shielding methods, which are summarized below.

Bondarenko Method

The Bondarenko approach [MAT-IB64] uses MG cross sections pre-computed over a range of self-shielding conditions, varying from negligibly (infinitely dilute) to highly self-shielded. Based on the following approximations [MAT-StammlerA83] it can be shown that the degree of self-shielding in both homogeneous and heterogeneous systems depends only on a single parameter called the background cross section, "sigma0," and on the Doppler broadening temperature:

(a) neglect of resonance interference effects,

(b) intermediate resonance approximation, and

(c) equivalence theory.

During the SCALE MG library processing with AMPX, self-shielded cross sections are computed using a CE flux calculated at several background cross section values and temperatures. These are used to calculate ratios of the shielded to unshielded cross sections, called "Bondarenko factors" (a.k.a. shielding factors or f-factors). As described in the SCALE Cross Section Libraries chapter, Bondarenko factors are tabulated on the SCALE libraries as a function of sigma0 values and Doppler temperatures for all energy groups of each nuclide.

Bondarenko factors are multiplicative correction factors that convert the generic unshielded data into problem-dependent self-shielded values. The BONAMI computational module performs self-shielding calculations with the Bondarenko method by using the input concentrations and unit cell geometry to calculate a sigma0 value for each nuclide and then interpolating the appropriate MG shielding factors from the tabulated library values.

CENTRM/PMC Method

Self-shielding calculations with BONAMI are fast and are always performed for all SCALE MG sequences. However, due to the approximations (a)–(c) listed in the previous section, a more rigorous method is also provided which can replace the BONAMI results over a specified energy range, usually encompassing the resolved resonance ranges of important absorber nuclides. This approach is designated as the CENTRM/PMC method, named after the two main computational modules, although several additional modules are also used. CENTRM/PMC eliminates the main approximations of the BONAMI approach by performing detailed neutron transport calculations with a combination of MG and CE cross sections for the actual problem-dependent compositions and unit cell descriptions [MAT-WA95]. This provides a problem-dependent pointwise (PW) flux spectrum for averaging MG cross sections, which reflects resonance cross-interference effects, an accurate slowing down treatment, and geometry-specific transport calculations using several available options. Shielded MG cross sections processed with CENTRM/PMC are usually more accurate than BONAMI, so it is the default for most SCALE MG sequences. However, depending on the selected transport option, CENTRM/PMC may run considerably longer than BONAMI alone.

The CENTRM/PMC methodology first executes BONAMI, which provides shielded cross sections outside the specified range of the PW flux calculation. Then the computational module CRAWDAD reads CE cross section files and bound thermal scatter kernels and interpolates the data to the desired temperatures for CENTRM. Using a combination of shielded MG data from BONAMI and CE data from CRAWDAD, CENTRM calculates PW flux spectra by solving the deterministic neutron transport equation for all unit cells described in the input. CENTRM calculations cover the energy interval 10^{-5} eV to 2×10^{7} eV spanned by the SCALE MG libraries. This energy range is subdivided into three sections: (a) upper MG range: E>*demax*, (b) PW range: *demin*<E<*demax*, and (c) lower MG range: E<*demin*, where *demin* and *demax* are the boundaries of the PW range, which can be defined by user input. The default values are *demin*=10^{-3} eV and *demax*=2×10^{4}. The values encompass the resolved resonance ranges of essentially all actinide and fission product nuclides. MG transport calculations are performed in the upper and lower ranges, which are coupled to the PW transport calculation by the scattering sources.

Several methods are available for the CENTRM transport solutions within each energy range, and the default methods can be changed through parameters in the XSProc input. The discrete S_n method is default for homogeneous media and for arbitrary one dimensional (1D) slab, spherical, and cylindrical geometries with general boundary conditions. A unit cell model is used for self-shielding arrays of spherical or cylindrical fuel regions. For the common case of a square-pitch lattice with cylindrical fuel pins, the default transport solver is the 2D method of characteristics (MoC). The CENTRM MoC solution exactly models the outer

rectangular cell surface using a reflected boundary condition. CENTRM also has an option for discrete S_n calculations using a 1D Wigner-Seitz cell with a white outer boundary condition. The 1D cell model is always used for spherical fuel arrays (e.g., pebbles), and can also be selected as a faster alternative than MoC for cylindrical fuel lattices. Finally, a two-region collision probability method can be used for any type of array. The two-region solver executes very fast but is usually more approximate than the MoC and S_n methods.

After CENTRM computes the average PW flux for each material zone, PMC uses the spectra to process the CE cross sections into problem-specific MG values for each material zone. A typical energy grid for the flux solution consists of 50,000–90,000 points, providing good resolution of the spectral fine-structure caused by resonance self-shielding. PMC has several options for processing the MG data, such as correcting for resonance absorption effects on the elastic removal. Shielded cross sections from PMC may also be used to perform an optional MG eigenvalue calculation with the XSDRNPM S_n module for cell-averaging and/or group collapsing of the MG values.

A variation of the standard CENTRM/PMC method is used to perform self-shielding for doubly heterogeneous cells in which cylindrical or spherical fuel elements, composed of small spherical fuel particles dispersed in a moderator material, are distributed in an array configuration. Self-shielding of this type of system requires multiple CENTRM/PMC passes, effectively representing the two levels of heterogeneity [MAT-GW05]. First-level CENTRM calculations are performed for each type of fuel particle using a spherical unit cell to represent the array of multi-layered fuel particles distributed in the moderator matrix. Space-dependent CE fluxes from these calculations are used in the CHOPS module to compute CE disadvantage factors (fuel-average flux divided by cell-average flux) for generating cell-averaged, CE cross sections representative of the homogenized fuel compact. The spatially averaged CE cross sections are used in a second-level CENTRM transport calculation corresponding to a 1D unit cell model for the array of fuel elements, with homogenized number densities for the fuel compact. The CE flux spectrum from this calculation is used in PMC to process the final MG, problem-dependent cross sections. This entire procedure is transparent to the user and has been automated in XSProc. Reference 2 provides more details about the SCALE treatment for doubly heterogeneous fuel.

Treatment of Non-Uniform Lattice Effects

For self-shielding of lattice configurations, both the BONAMI and CENTRM/PMC approaches assume that the fuel is arranged in an infinite, uniform array of identical cells. For most pins in an actual lattice, the uniform-array approximation is satisfactory; however, self-shielding of some cells may be affected by boundary effects along the edge of the array or by the presence of water holes or control rods. These effects can be treated by incorporating a nonuniform Dancoff factor into the self-shielding calculations for the affected cells. The SCALE module MCDancoff performs a simplified one-group Monte Carlo calculation to compute Dancoff factors for arbitrary absorber mixtures within a complex (nonuniform) 3D array. The input for MCDancoff is described in Sect. 7.8. This module must be run as a standalone executable prior to the self-shielding calculations for a given sequence, and the computed Dancoff factors must be entered as XSProc input. The input Dancoff factor is used directly in defining the background cross section for BONAMI calculations. In the CENTRM/PMC methodology, the input Dancoff factor is used in CENTRM to calculate a Dancoff-equivalent unit cell, which defines a uniform lattice pitch that produces the same Dancoff value as the nonuniform lattice. The CENTRM transport calculation then proceeds as usual using 2D MoC or 1D S_n for the unit cell.

7.1 XSPROC: THE MATERIAL AND CROSS SECTION PROCESSING MODULE FOR SCALE

M. L. Williams, L. M. Petrie, R. A. Lefebvre, K. T. Clarno, J. P. Lefebvre, U. Merturyek, D. Wiarda, and B. T. Rearden

ABSTRACT

The material and cross section processing module of SCALE (XSProc) was improved for the 6.2 release to prepare data for continuous-energy and multigroup calculations. XSProc expands material input from Standard Composition Library definitions into atom number densities and, for multigroup calculations, performs cross section resonance self-shielding, energy group collapse, and spatial homogenization. XSProc implements capabilities for problem-dependent temperature interpolation, calculation of Dancoff factors, resonance self-shielding using Bondarenko factors with full-range intermediate resonance treatment, as well as use of continuous energy resonance self-shielding in the resolved resonance region. The SCALE 6.3 XSProc maintains the same architecture with SCALE 6.2 which integrated and enhanced the capabilities previously implemented independently in BONAMI, CENTRM, PMC, WORKER, ICE, and XSDRNPM, along with some additional capabilities that were provided by MIPLIB and SCALELIB. The SCALE 6.3 XSProc development focuses on improving accuracy, applicability and stability for any advanced reactor analysis including Light Water Reactors (LWR), Pebble and Prismatic High Temperature Gas-cooled Reactors (HTGR), Molten Salt Reactors (MSR), Sodium- and Lead-cooled Fast Reactors (SFR and LFR) without any limitation.

ACKNOWLEDGMENTS

Development and maintenance of XSProc and related codes and methods have been sponsored by the US Nuclear Regulatory Commission (NRC) and the US Department of Energy (DOE).

VERSION INFORMATION

XSProc has evolved from the concept of a Material Information Processor library (MIPLIB) that used alphanumeric material specifications, which was initially proposed and developed by R. M. Westfall. J. R. Knight and J. A. Bucholz expanded and refined MIPLIB in early SCALE releases.

SCALE 6.1 (2011) and 6.2 (2016): M. L. Williams and L. M. Petrie led development and improvement for XSProc and contributors include, R. A. Lefebvre, K. T. Clarno, J. P. Lefebvre, U. Merturyek, D. Wiarda, B. T. Rearden, S. Goluoglu, D. F. Hollenbach, N. F. Landers, J. A. Bucholz, C. F. Weber, and C. M. Hopper. With the SCALE modernization initiative beginning in SCALE 6.2, MIPLIB is no longer part of the XSProc analysis, but the original concepts and input formatting were preserved in the new implementation.

SCALE 6.3 (2021): K. S. Kim led responsibility and contributors include A. M. Holcomb, D. Wiarda, R. Bostelmann, M. A. Jessee, and W. A. Wieselquist. The SCALE 6.3 XSProc has been focused on improving accuracy, applicability and stability for advanced reactor analysis including high temperature gas cooled reactors and fast spectrum reactors.

7.1.1 INTRODUCTION

Self-shielding of multigroup cross sections is required in SCALE sequences for criticality safety, reactor physics, radiation shielding, and sensitivity analysis. In all previous versions of SCALE, resonance self-shielding calculations were done by executing a series of stand-alone executable codes, each dedicated to a specific aspect of the self-shielding operations. Each sequence had its own unique internal coding to launch the executable codes. Multigroup (MG) and continuous-energy (CE) cross sections and other data were passed between the individual executable codes by external I/O, which could require a substantial amount of clock time. In the modern version of SCALE, all self-shielding operations are consolidated into a single

driver module named XSProc, and the stand-alone executable codes have been transformed into callable "computational modules" [XSProc-RLL+15]. The functions of XSProc are to (a) read input data, (b) generate in-memory data structures (objects) containing problem-definition information (compositions, cell geometries, computation options), as well as self-shielding information (MG and CE cross sections and fluxes), and (c) execute appropriate computational modules for the requested self-shielding option. Calculated results produced by one module may be stored in the internal data objects and passed to other modules through application program interfaces (APIs). At the completion of XSProc the self-shielded MG cross sections on the data objects can be passed along to transport solvers for continued execution of the control sequence or can be written to an external AMPX library file.

In the future, XSProc will be extended to parallel computations in which self-shielding calculations are done simultaneously for multiple types of unit cells. At the present time, however, XSProc is limited to serial computations; but even in serial mode it typically requires less time than older versions of SCALE to process shielded cross sections, and significant speedups have been observed for heavily I/O bound problems. Integrating the self-shielding capabilities into a single module has a number of additional benefits as well, including maintainability, extensibility, and the ability to easily replace an entire computational module with a future implementation containing new features. Additionally, the size of the problem-dependent MG library generated by XSProc may be greatly reduced compared to previous versions of SCALE because macroscopic cross sections are stored rather than a general-purpose library of microscopic data.

7.1.2 TECHNIQUES

XSProc integrates and enhances the capabilities previously implemented independently in BONAMI, CENTRM, PMC, WORKER, ICE, and XSDRNPM, as well as other capabilities formerly provided by MIPLIB and SCALELIB. It provides capabilities for problem-dependent temperature interpolation of both CE and MG nuclear data, calculation of Dancoff factors, and resonance self-shielding of MG cross sections using several available options. XSProc produces shielded microscopic data for each nuclide or macroscopic data for each material. Additionally, a flux-weighting spectrum can be applied to collapse cross sections to a coarser group structure and/or to integrate over volumes for homogenized cross sections. The flux-weighting spectrum can be input by the user or calculated using one-dimensional (1-D) coupled neutron/gamma transport model. These operations are performed by the sequences CSAS-MG, CSAS1, CSASI, and T-XSEC described in Sect. 7.1.3.2.

7.1.2.1 Overview of XSProc procedures

XSProc reads the COMPOSITION and CELL DATA blocks of the SCALE input, which are described in the following sections. After reading the user input data, XSProc loads the specified MG library to be self-shielded and, depending on the selected self-shielding method, additional CE data files for nuclides appearing in the problem specification. Finally XSProc performs MG self-shielding calculations for all compositions by calling APIs to computational modules such as BONAMI (**BON**darenko **AM**PX **I**nterpolator), CRAWDAD (**C**ode to **R**ead **A**nd **W**rite **DA**ta for **D**iscretized solution), CENTRM (**C**ontinuous **EN**ergy **TR**ansport **M**odule), PMC (**P**roduce **M**ultigroup **C**ross sections), CHOPS (**C**ompute **HO**mogenized **P**ointwise **S**tuff), CAJUN (**C**E **AJ**AX **UN**iter), WAX (**W**orking **AJAX**), XSDRNPM (**X**-**S**ection **D**evelopment for **R**eactor **N**ucleonics with **P**etrie **M**odifications), and/or MIXMACRO to provide a problem-dependent cross section library. Many computational modules have been modernized compared to earlier executable codes distributed in previous versions of SCALE.

Like earlier versions of SCALE, XSProc provides several options for self-shielding an input MG library [XSProc-Wil11]. The first, based on the Bondarenko method [XSProc-IB64], uses the computational module BONAMI. BONAMI is always used to compute self-shielded cross sections for all energy groups. If *parm=bonami* is specified, the shielded cross sections provided by BONAMI are the final values output from

XSProc. However the Bondarenko method has several limitations, especially in the resolved resonance range. Therefore XSProc provides another self-shielding method, with several computation options, which often produces more accurate MG data in the resolved resonance and thermal energy ranges. If *parm=centrm* or *parm=2region* is specified on the sequence line, XSProc calls APIs for the modules CRAWDAD, CENTRM, and PMC to compute CE flux spectra for processing problem-specific, self-shielded cross sections "on the fly [XSProc-WA95]. CENTRM performs MG transport calculations in the fast and lower energy ranges, coupled to pointwise (PW) transport calculations that use CE cross sections in the resonance range. PMC uses the PW flux spectra from CENTRM to compute MG values, which replace the previous values obtained from BONAMI over the specified range of the CE calculation. The original BONAMI shielded cross sections are retained for all other groups.

The CENTRM/PMC approach is the default for criticality and lattice physics calculations, while the BONAMI-only method is default for radiation shielding calculations. The end results of an XSProc calculation are self-shielded macroscopic and/or microscopic MG cross sections stored in memory for subsequent transport calculations; or alternatively a shielded MG AMPX library can be written to an external file and saved for future use.

7.1.2.2 Standard composition material processing

A primary function of the XSProc module is to expand user input in the COMPOSITION block into nuclear number densities (nuclei/b-cm) for every nuclide in each defined mixture. Mixtures can be specified through the direct use of materials presented in the Standard Composition Library, which includes individual nuclides, elements with natural abundances, numerous compounds, alloys and mixtures found in engineering practice, as well several variations of fissile solutions. Additionally, users may define their own materials as atom percent or weight percent combinations. Nuclear masses and theoretical densities are provided in the Standard Composition Library, and methods are available to determine equilibrium states for fissile solutions. Input options for composition data are described in Sect. 7.1.3.3 with several examples provided in Appendix A.

7.1.2.3 Unit cells for MG resonance self-shielding

XSProc utilizes a unit cell description to provide information for resonance self-shielding calculations of the input mixtures. As many unit cells as needed to describe the problem may be specified; however, each mixture (other than 0 for a void mixture) can appear only in one unit cell in the CELLDATA block. If a nuclide appears in more than one mixture, multiple sets of self-shielded cross sections are calculated for the nuclide-one for each mixture in each unit cell. Four types of cells are available for self-shielding calculations: **INFHOMMEDIUM**, **LATTICECELL**, **MULTIREGION**, and **DOUBLEHET**. The default calculation type is CENTRM/PMC for CSAS, TRITON, and TSUNAMI sequences and BONAMI for MAVRIC. All materials not specified in a unit cell are treated as infinite homogeneous media and shielded with BONAMI only, unless the mixture contains a fissionable nuclide, in which case an infinite medium CENTRM/PMC model is used. Note that previous versions of SCALE used infinite medium CENTRM/PMC calculations for all unassigned mixtures. The default type of self-shielding calculation can be overridden, as described in Sect. 7.1.3.2. The following is a brief description of the types of unit cells that can be input in CELLDATA and the computation procedures used.

INFHOMMEDIUM (infinite homogeneous medium) Treatment

The **INFHOMMEDIUM** treatment is best suited for large masses of materials where the size of each material is large compared with the average mean-free path of the material or where the fraction of the material that is a mean-free path from the surface of the material is very small. When **INFHOMMEDIUM** cell is specified, the material in the unit cell is treated as an infinite homogeneous lump. Systems composed of small fuel lumps or resonance nuclides sandwiched between moderating regions should not be treated as infinite homogeneous media. In these cases a MULTIREGION or LATTICECELL geometry should be used.

LATTICECELL Treatment

The **LATTICECELL** model is appropriate for arrays of resonance absorber mixtures-with or without clad-arranged in a square or a triangular pitch configuration within a moderator. Annular fuel (e.g., with an internal moderator in the center) can also be addressed. Input data for the **LATTICECELL** treatment are described in Sect. 7.1.3.5. Self-shielded cross sections are generated for each material zone in a unit cell of the lattice. If a nuclide appears in more than one zone, self-shielded cross sections are produced for each zone where the nuclide is present. Limitations of the **LATTICECELL** treatment are listed below.

1. The cell description is limited to unit cells for arrays of spherical, plate (slab), or cylindrical fuel bodies. In the case of cylindrical pins in a square-pitch lattice, the default (*parm=centrm*) self-shielding calculation uses the CENTRM method of characteristics (MoC) option to represent the 2D rectangular unit cell with reflected boundary conditions. By default, self-shielding for all other arrays uses a CENTRM 1D S_N calculation for the unit cell (spherical and cylindrical geometries use Wigner-Seitz cells). If *parm=bonami* is specified, heterogeneous self-shielding effects are treated by equivalence theory [XSProc-Wil11] The computation option *parm=2region*, described in Sect. 7.1.3.1, can also be used for self-shielding lattice cells.

2. Only predefined choices of cell configurations are available. The available options are described in detail in Sect. 7.1.3.5.

3. The basic treatment for **LATTICECELL** assumes an infinite, uniform array of unit cells. This assumption is a good approximation for interior fuel regions within a large, uniform array. The approximation becomes less rigorous for fuel regions on the periphery of the array or adjacent to a nonuniformity (e.g., control rod, water hole, etc.) in the lattice. For some cases it may be desirable to address this issue by specifying a different lattice cell for this type of fuel pin and using a modified procedure to define an effective unit cell, as described below.

**** LATTICECELL treatment for nonuniform arrays*.

Nonuniform lattice effects may be treated in CENTRM calculation by specifying the keyword **DAN2PITCH=***dancoff* in the optional CENTRM DATA (see Sect. 7.1.3.9). In this approach, the SCALE standalone code MCDancoff must be run prior to the self-shielding calculation in order to compute Dancoff factors for the fuel regions of interest in the nonuniform lattice configuration. MCDancoff performs a simplified one-group Monte Carlo calculation to compute Dancoff factors for complex geometries (see Sect. 7.8). The Dancoff value for the fuel region of interest is assigned to the DAN2PITCH keyword in the input for the corresponding cell. Using an iterative procedure, CENTRM computes the pitch of a uniform lattice that has the same Dancoff value as the nonuniform lattice.

MULTIREGION Treatment

The **MULTIREGION** treatment is appropriate for 1-D geometric regions where the geometry effects may be important, but the limited number of zones and boundary conditions in the **LATTICECELL** treatment are not applicable. The **MULTIREGION** unit cell allows more flexibility in the placement of the mixtures but requires all regions of the cell to have the same geometric shape (i.e., slab, cylinder, sphere, buckled slab, or buckled cylinder). Lattice arrangements can be approximated by specifying a non-vacuum boundary condition on the outer boundary. See Sect. 7.1.3.6 for more details. Limitations of the **MULTIREGION** cell treatment are listed below.

1. A **MULTIREGION** cell is limited to a 1-D approximation of the system being represented. An exact 1D model can be defined for the following multizone geometries with vacuum boundary conditions: spheres, infinitely long cylinders, and slabs; and for an infinite array of slabs with reflected or periodic boundaries.
2. The shape of the outer boundary of the **MULTIREGION** cell is the same as the shape of the inner regions. Cells with curved outer surfaces cannot be stacked physically to create arrays; however, arrays can be approximated by a Wigner-Sietz cell with a white outer boundary condition, where the outer radius is defined to preserve the area of the true rectangular or hexagonal unit cell.
3. Boundary conditions available in a **MULTIREGION** problem include vacuum (eliminated at the boundary), reflected (reflected about the normal to the surface at the point of impact), periodic (a particle exiting the surface effectively enters an identical cell having the same orientation and continues traveling in the same direction), and white (isotropic return about the point of impact). Reflected and periodic boundary conditions on a slab can represent real physical situations but are not valid on a curved outer surface. A single, non-interacting cell has a vacuum outer boundary condition. If the cell outer boundary condition is not a vacuum boundary, the unit cell approximates some type of array.
4. When using the CENTRM/PMC self-shielding method, the MULTIREGION cell model must include fissionable material. This can be accomplished by adding a trace amount of a fissionable material to one or more mixtures, or by modeling a region of homogenized fuel and water, or by adding a thin (e.g., 1e-6 cm-thick) layer containing at least a trace of a fissionable nuclide on the periphery of the problem.

DOUBLEHET Treatment

DOUBLEHET cells use a specialized CENTRM/PMC calculational approach to treat resonance self-shielding in "doubly heterogeneous" systems. The fuel for these systems typically consists of small, heterogeneous, spherical fuel particles (grains) embedded in a moderator matrix to form the fuel compact. The fuel-grain/matrix compact constitutes the first level of heterogeneity. Cylindrical(rod). spherical (pebble), or slab fuel elements composed of the compact material are arranged in a moderating medium to form a regular or irregular lattice, producing the second level of heterogeneity. The fuel elements are also referred to as "macro cells." Advanced reactor fuel designs that use TRISO (tri-material, isotopic) or fully ceramic microencapsulated (FCM) fuel require the **DOUBLEHET** treatment to account for both levels of heterogeneities in the self-shielding calculations. Simply ignoring the double-heterogeneity by volume-weighting the fuel grains and matrix material into a homogenized compact mixture can result in a large reactivity bias.

In the **DOUBLEHET** cell input, keywords and the geometry description for grains are similar to those of the **MULTIREGION** treatment, while keywords and the geometry for the fuel element (macro-cell) are similar to those of the **LATTICECELL** treatment. The following rules apply to the **DOUBLEHET** cell treatment and must be followed. Violation of any rules may cause a fatal error.

1. As many grain types as needed may be specified for each unique fuel element. Note that grain type is different from the number of grains of a certain type. For example, a fuel element that contains both UO_2 and PuO_2 grains has two grain types. The same fuel element may contain 10000 UO_2 grains and 5000 PuO_2 grains. In this case, the number of grains of type UO_2 is 10000, and the number of grains of type PuO_2 is 5000.

2. As many fuel elements as needed may be specified, each requiring its own **DOUBLEHET** cell. This may be the case for systems with many fuel elements at different fuel enrichments, burnable poisons, etc. Each fuel element may have one or more grain types.

3. Since the grains are homogenized into a new mixture to be used in the fuel element (macro-cell) cell calculation, a unique fuel mixture number must be entered. XSProc creates a new material with the new mixture number designated by the keyword f*uelmix*=, containing all the nuclides that are homogenized. The user must assign the new mixture number in the transport solver geometry (e.g., KENO) input unless a cell-weighted mixture is created.

4. The type of lattice or array configuration for the fuel-element may be spheres on a triangular pitch (**SPHTRIANGP**), spheres on a square pitch (**SPHSQUAREP**), annular spheres on a triangular pitch (**ASPHTRIANGP)**, annular spheres on a square pitch (**ASPHSQUAREP)**, cylindrical rods on a triangular pitch (**TRIANGPITCH**), cylindrical rods on a square pitch (**SQUAREPITCH**),annular cylinderical rods on a triangular pitch (**ATRIANGPITCH)**, annular cylindrical rods on a square pitch (**ASQUAREPITCH)**, a symmetric slab (**SYMMSLABCELL)**, or an asymmetric slab (**ASYMSLABCELL)**.

5. If there is only one grain type for a fuel element, the user must enter either the pitch, the aggregate number of particles in the element, or the volume fraction for the grains. The code needs the pitch and will directly use it if entered. If pitch is not given, then the volume fraction (if given) is used to calculate the pitch. If neither the pitch nor the volume fraction is given, then the number of particles is used to calculate the pitch and the volume fraction. The user should only enter one of these items.

   If the fuel matrix contains more than one grain type, all types are homogenized into a single mixture for the compact. As for the one grain type case, the pitch is needed for the spherical cell calculations. However, the pitch by itself is not sufficient to perform the homogenization. Since each grain's volume is known (grain dimensions must always be entered), entering the number of particles for each grain type essentially provides the total volume of each grain type and therefore enables the calculation of the volume fraction and the pitch. Likewise, entering the volume fraction for each grain type essentially provides the total volume of each grain type and therefore enables the calculation of the number of particles and the pitch. Therefore, one of these two quantities must be entered for multiple grain types. In these cases, since pitch is not given, the available matrix material is distributed around the grains of each grain type proportional to the grain volume and is used to calculate the corresponding pitch. Over-specification is allowed as long as the values are not inconsistent to greater than 0.01%.

6. For cylindrical rods and for slabs, fuel height must also be specified. For slabs the slab width must also be specified.

7. The CENTRM calculation option must be S_n.

7.1.2.4 Cell weighting of MG cross sections

Cell-weighted self-shielded cross sections are created when **CELLMIX**= is specified in a **LATTICECELL** or **MULTIREGION** cell input. In this case, after finishing the self-shielding calculations for all mixtures in the cell, XSProc calls the computational module XSDRNPM, which solves the 1-D MG transport equation to obtain k_∞ and space-dependent MG fluxes for the cell. The resultant fluxes are used to compute MG flux disadvantage factors for processing cell-weighted cross sections of all nuclides in the cell. When the cell-weighted cross sections are used with *homogenized* number densities of the cell nuclides, the reaction rates of the homogenized mixture preserve the spatially averaged reactions rates of the heterogeneous configuration. The user must input a new mixture ID to identify the homogenized mixture associated with the cell-weighted cross sections. **This homogenized mixture should not be used in the heterogeneous geometry data for other transport codes such as KENO, NEWT, etc.** Instead, the cell-homogenized mixture that is created should be used at the location of the original cell. Also, cell weighted homogenized cross sections should not be used in MG sensitivity data calculations performed using the TSUNAMI sequences.

7.1.3 XSPROC INPUT DATA GUIDE

XSProc input data are entered in free form, allowing alphanumeric data, floating-point data, and integer data to be entered in an unstructured manner. Up to 252 characters per line are allowed. Data can usually start or end in any column. Each data entry must be followed by one or more blanks to terminate the data entry. For numeric data, either a comma or a blank can be used to terminate each data entry. Integers may be entered for floating values. For example, 10 will be interpreted as 10.0 if a floating point value is required. Imbedded blanks are not allowed within a data entry unless an E precedes a single blank as in an unsigned exponent in a floating-point number. For example, 1.0E 4 would be correctly interpreted as 1.0×10^4. A number with a negative exponent must include an "E". For example 1.0-4 cannot be used for 1.0E-4.

The word "END" is a special data item. An END may have a name or label associated with it. The name or label associated with an END is separated from the END by a single blank and is a maximum of 12 characters long. *At least two blanks or a new line MUST follow every labeled and unlabeled END. WARNING: It is the user's responsibility to ensure compliance with this restriction. Failure to observe this restriction can result in the use of incorrect or incomplete data without the benefit of warning or error messages.*

Multiple entries of the same data value can be achieved by specifying the number of times the data value is to be entered, followed by either R, *, or $, followed by the data value to be repeated. Imbedded blanks are not allowed between the number of repeats and the repeat flag. For example, 5R12, 5*12, 5$12, or 5R 12, etc., will enter five successive 12's in the input data. Multiple zeros can be specified as nZ where n is the number of zeroes to be entered.

7.1.3.1 XSProc data checking and resonance processing options

To check the XSProc input data, run CSAS-MG and specify PARM=CHECK or PARM=CHK after the sequence specification as shown below.

```
=CSAS-MG PARM=CHK
```

In this case the actual XSProc cross section processing calculations are not performed. The input data are checked, the problem description is printed, appropriate error and warning messages are printed, and a table of additional data is printed.

Resonance processing will automatically be performed by the default method for the sequence selected. The default methods are CENTRM/PMC for CSAS, TRITON, and TSUNAMI sequences and BONAMI for the MAVRIC sequences. Alternatively, a resonance processing procedure may be chosen by entering

PARM=*option*, where *option* CENTRM selects the recommended CENTRM/PMC transport method for each cell type, *option* 2REGION selects the CENTRM/PMC two-region calculation, and *option* BONAMI applies full range Bondarenko factors to all energy groups without utilizing CENTRM/PMC. For example, to run CSAS1X sequence using only BONAMI for self-shielding, rather than the default CENTRM/PMC method, enter the computational sequence specification shown below.

```
=CSAS1X PARM=BONAMI
```

Multiple PARM options are specified by enclosing parameters in parenthesis, such as

```
=CSAS1X PARM=(CHK, BONAMI)
```

XSProc resonance self-shielding options are summarized below.

PARM=BONAMI.

This is the fastest MG processing method. It performs resonance self-shielding for all energy groups using the Bondarenko method. BONAMI computes the appropriate background cross section of a given unit cell and then interpolates the corresponding shielding factor from Bondarenko factors on the MG library. Dancoff factors needed to evaluate the background cross section for lattices are computed internally, but these can be overridden by input values in the MORE DATA block. More details on this method are given in the BONAMI section of the manual.

PARM=CENTRM.

This executes the CENTRM/PMC modules to process shielded MG cross sections using CE flux spectra calculated with the recommended type of CE transport solver for the designated type of cell. The CENTRM-recommended CE transport solvers are (a) infinite homogeneous medium calculation for INFHOMMEDIUM cells; (b) 2D MoC transport calculation for a LATTICECELL consisting of cylindrical fuel pins in a square lattice; and (c) 1-D discrete S_n transport for all other LATTICECELLs and for all MULTIREGION cells. The recommended type of transport solver can be overridden for individual cells, as well as for selected energy ranges, by using the CENTRM DATA block described in Sect. 7.1.3.9.

PARM=2REGION.

The CENTRM two-region (2R) option computes the PW flux using a simplified collision probability method for an absorber (e.g., fuel) region surrounded by an external moderator region which has an asymptotic energy spectrum. To account for the heterogeneous effects of a lattice, a correction known as the Dancoff factor is applied to the escape probabilities in the 2R calculation (see the CENTRM chapter of the SCALE manual). These Dancoff factors are calculated internally by XSProc for a uniform array of mixtures in slab, spherical, or cylindrical geometries. These mixture-dependent Dancoff factors can be modified by user input using the DAN parameters contained in the MORE DATA block, as defined in Sect. 7.1.3.8.

Note on CENTRM/PMC self-shielding options:

The energy range of the CENTRM flux calculation is subdivided into three sections: fast, PW, and low energy. PMC only computes self-shielded cross sections for groups within the PW range defined by parameters *demax* and *demin*, which, respectively, define the upper and lower energies of the CENTRM PW flux calculation. Problem-dependent cross sections for groups in the fast and low energy ranges are obtained with the more approximate BONAMI method. Default values for parameters *demax* and *demin* are defined appropriately for self-shielding of important resonance materials in thermal reactor systems. The PW self-shielding range can be extended or decreased for individual cells by modifying these parameters using CENTRM DATA.

7.1.3.2 XSProc input data

The types of input data required for XSProc are given in Table 7.1.1, and individual entries are explained in the text following the table. The title, cross section library name (either CE or MG), and standard composition specification data (**READ COMP** input block) are required for all sequences that use XSProc. The name of the cross section library is used to determine if the transport solver is executed using CE or MG data (e.g., CE or MG KENO calculations). The unit cell descriptions (**READ CELL** input block) are only used for MG self-shielding calculations. If the specified sequence executes in CE mode, the cell data input can be omitted, or it will be skipped if present. If the cell data information is omitted for MG calculations, all mixtures are self-shielded using the infinite medium approximation.

There are seven standard SCALE sequences that run just XSProc, and produce a MG cross section library or libraries.

=XSPROC produces three libraries with an optional fourth library.

- **sysin.microLib** is a self-shielded library of the individual nuclides in the problem for use in a later transport calculation,
- **sysin.macroLib** is a self-shielded library of the mixture cross sections in the problem for use in a later transport calculation,
- **sysin.smallMicroLib** is a self-shielded library of specific reaction rate cross sections and the elastic and total inelastic scattering transfer matrices for later use in calculating reaction rates and sensitivity values, and
- **sysin.xsdrnWeightedLib** is an optional library produced if the input specifies having **XSDRN** do a weighting calculation. This can be a cell weighted and/or a group collapse calculation. The library can be either individual nuclides or mixtures, depending on input.

=CSAS-MG produces an **ft04f001** library that is equivalent to the **sysin.microLib**. With appropriate input it can also produce an **ft03f001** which is equivalent to **sysin.xsdrnWeightedLib** above.

=CSASI or **=CSASIX** produce an **ft04f001** library that is equivalent to **sysin.microLib**, and an **ft02f001** library that is equivalent to **sysin.macroLib**. CSASIX will run an **XSDRN** on the first cell without any MOREDATA input. With appropriate input they both can produce an **ft03f001** that is the equivalent of **sysin.xsdrnWeightedLib**.

=CSAS1 or **=CSAS1X** produce an **ft04f001** library that is the equivalent of **sysin.microLib**. Both sequences will run an **XSDRN** on the first cell. With appropriate input, they both can produce an **ft03f001** that is the equivalent of **sysin.xsdrnWeightLib**.

=T-XSEC produces an **ft04f001** library that is equivalent to **sysin.macroLib**. and an **ft44f001** library that is equivalent to sysin.microLib.

The reactions (MT numbers) written to each library are listed in the `SequenceNeutronMT.txt` file located in the etc directory installed with SCALE.

Table 7.1.1: Outline of XSProc input data

Data Position	Type of Data	Data Entry	Comments
1	Title	Enter title	Limit to 80 characters
2	Cross section library name		The currently available libraries are listed in the table *Standard SCALE cross-section libraries* of the XSLib chapter.
3	Standard composition specification data	Enter the appropriate data	Begin this data block with **READ COMP** and terminate with **END COMP**. See Section **7.1.3.2**
4	Unit cell(s) description for MG calculations only		Begin this data block with **READ CELL (or CELLDATA)**
	a. Type of self shielding calculation	**INFHOMMEDIUM** **LATTICECELL** **MULTIREGION** **DOUBLEHET**	These are the available options. See the explanation in Section Error! Reference source not found..
	b. Unit cell geometry specification	Enter the appropriate data	See Section **7.1.3.4** for **INFHOMMEDIUM**. See Section **7.1.3.5** for **LATTICECELL**. See Section **7.1.3.6** for **MULTIREGION**. See Section **7.1.3.7** for **DOUBLEHET.**
	c. Optional **MORE** parameter data	Enter the desired data	Begin this data block with **MORE DATA** (or **MOREDATA**) and terminate with **END MORE** (or END **MOREDATA**). Use only if MORE parameter data are to be entered; otherwise, omit these data entirely. See Section **7.1.3.8**
	d. Optional **CENTRM** parameter data	Enter the desired data	Begin this data block with **CENTRM DATA** (or **CENTRMDATA**) and terminate with **END CENTRM** (or END **CENTRMDATA**). Use only if CENTRM parameter data are to be entered; otherwise, omit these data entirely.
	e. End of unit cell data		Terminate with **END CELL (or END CELLDATA)**

Repeat positions 4a–4d as needed to specify all unit cells. Position 4 data are applicable to the MG calculations only.

1. TITLE. An 80-character maximum title is required. The title is the first 80 characters of the XSPROC data.
2. CROSS SECTION LIBRARY NAME. This item specifies the cross section library that is to be used in the calculation. See Table *Standard SCALE cross-section libraries* in the XSLIB chapter of the SCALE manual for a discussion of the available libraries.
3. The keywords **READ COMP** followed by the standard compositions specifications. These data are used to define mixtures used in the problem. See Sect. 7.1.3.3 and Table 7.1.2 for a description of the standard composition specification data. These data are required for every problem. After all mixtures have been entered, the keywords **END COMP** must be entered.
4. The keywords **READ CELLDATA** followed by the input describing each unit cell as defined below. After all unit cells are described, the keywords **END CELLDATA** terminate this input block.

a. TYPE OF CALCULATION. The options are **INFHOMMEDIUM**, **LATTICECELL**, **MULTIREGION**, **DOUBLEHET**, or nothing. A description of these cell types and the associated computational methods are provided in Sect. 7.1.2.3. If all input mixtures are to be treated as infinite homogeneous media, the **CELLDATA** block can be omitted. In this case the self-shielding calculations will not account for any geometrical effects, so users should be careful in applying this approach. Similarly, mixtures not explicitly assigned to a cell are treated as infinite homogeneous media in the manner discussed in Sect. 7.1.2.3.

b. CELL GEOMETRY SPECIFICATION. See Sect. 7.1.3.4 and Table 7.1.7 for an explanation of the optional unit cell data associated with an **INFHOMMEDIUM** problem. See Sect. 7.1.3.5 for an explanation of the data associated with **LATTICECELL** problems. Sect. 7.1.3.6 explains the data required for a **MULTIREGION** problem. Sect. 7.1.3.7 explains the required data for a **DOUBLEHET** problem. The **DOUBLEHET** input may be thought of as a combination of **MULTIREGION** input for the fuel grains and **LATTICECELL** input for the fuel element.

c. OPTIONAL MORE PARAMETER DATA. This option allows certain defaulted parameters to be re-specified by the user. This block begins with **MORE DATA** and is used by XSDRN. These data apply only to the unit cell immediately preceding them. Data placed prior to all unit cell data apply to all materials not listed in any unit cell and are treated as infinite homogeneous media. Omit these data unless they are needed. This block ends with **END MORE**. See Sect. 7.1.3.8.

d. OPTIONAL CENTRM PARAMETER DATA. This optional data block begins with **CENTRM DATA** and ends with **END CENTRM**. These data allow the user to override default data for CENTRM and PMC. These data apply only to the unit cell immediately preceding them. Data placed prior to all unit cell data apply to all materials not listed in any unit cell and are treated as infinite homogeneous media.

7.1.3.3 Standard composition specification data

Mixtures utilized in the problem are defined using standard composition specification data. The standard composition input begins with the keywords **READ COMP**, followed by standard composition specifications for all mixtures in the problem. When all mixtures have been described, enter the words **END COMP** to signal the completion of this block of data. XSProc computes macroscopic cross sections for all mixtures defined in the **COMP** block.

The required input for the standard composition specification data varies, depending on the type of standard composition material. However, every standard composition specification must include the following:

1. a standard composition material name.

2. a mixture number (MX) that contains this material, and
3. a terminator for the standard composition specification data (enter the word END).

The types of standard compositions in SCALE are (a) basic mixtures, (b) fissile solutions, (c) chemical compounds, and (d) alloys. The four general options for inputting these types of data are shown in Table 7.1.2. For some cases, more than one option could possibly be used to specify the mixture. The user may select whichever options are most convenient to define a particular mixture, and these may be entered in any order.

Table 7.1.2: Outline of standard composition specification options (Mixtures can be defined using one or more of these options in any order).

Input data name	Comments
READ COMP	Enter once for a problem. Enter the words **READ COMP** prior to entering any standard composition data.
sc	This option is used for defining basic mixtures. Enter one of the alphanumeric identifiers, symbols, or names from Standard Composition Library tables *Isotopes in standard composition library*, *Isotopes and their natural abundances*, *Elements and special nuclide symbols*, *Compounds*, or *Alloys and mixtures* in place of SC. This indicates the isotope, nuclide, compound, or alloy that will make up this standard composition. See **Table 6.1.3.3.0.2** for additional required and optional data for each standard composition.
SOLUTION	This option is used to specify a fissile solution mixture. See **Table 6.1.3.3.0.3** for additional required and optional data for each solution. End the data with an **END**.
ATOM	This option creates a chemical compound mixture composed of the specified nuclide in the compound. Each nuclide is entered followed by the relative number of atoms of the nuclide in the compound. All compounds must begin with the four letters **ATOM** followed by up to eight additional alphanumeric characters. See **Table 6.1.3.3.0.4** for additional required and optional data for each compound.
WTPT	This option creates a mixture/alloy composed of the specified nuclides in the mixture/alloy. Each nuclide is entered followed by the weight percent of the nuclide in the mixture/alloy. All mixture/alloys must begin with the four letters **WTPT** followed by up to eight additional alphanumeric characters. See **Table 6.1.3.3.0.5** for additional required and optional data for each arbitrary physical mixture or alloy.
END COMP	Enter once for a problem. Enter the exact words **END COMP** when all the standard composition components have been described. At least two blanks or a new line must follow the words **END COMP** prior to continuing data entry.

Names of the standard composition materials (the alphanumeric identifiers) appearing in the **COMP** block input must be selected from the tables of elements, compounds, solutions, and alloys given in the SCALE manual section describing the Standard Composition Library. An error message will be printed if the user enters an invalid standard composition material name or if any isotopes in the compound do not exist in the specified library

Input data to define each of the standard composition types in Table 7.1.2 are summarized in Table 7.1.3 through Table 7.1.6. Optional input is indicated by curly brackets { }. *Since some of the input is not keyword based, the order of entries is important in the standard composition specification*. The temperature specification is used for Doppler broadening and/or determination of the proper thermal scattering data. Input material densities are not modified for temperature effects. Additional description of the standard composition input for each type of material is given following all the tables. As in the tables, input parameters enclosed by

curly brackets { } indicate that these are optional.

Table 7.1.3 – continued from previous page

Table 7.1.3: Standard composition specification for basic mixtures.

Entry no.	Data name	Data type	Entry requirement	Comment
1	**sc**	Standard composition name	Always	Enter one of the alphanumeric identifiers, symbols, or names from Tables *Isotopes in standard composition library*, *Isotopes and their natural abundances*, *Elements and special nuclide symbols*, *Compounds*, or *Alloys and mixtures* in the STDCMP chapter in place of **sc**. This indicates the isotope, nuclide, compound, or alloy that will make up this standard composition. This entry is required.
2	*mx*	Mixture ID number	Always	Skip at least one blank after SC prior to entering the mixture number. This must be an integer greater than zero. This entry is required.
3	**DEN**=*roth*	Density	Optional	If the density of a basic standard composition (*roth*) is to be entered, add **DEN** = *roth*, where *roth* is the density in g/cm^3, following the mixture ID number with at least one space between *mx* and the keyword **DEN**.
4	{**VF**=}*vf*	Density multiplier	See comment	Default value is 1. Enter the density multiplier (density fraction, volume fraction, or a combination). **VF** = 0 indicates that syntax 2 is to be used and that the next number entered will be ADEN. In this case entries 7-8 are omitted.
5	*aden*	Number density	**VF** = 0	Atom density of the nuclide in atoms / barn-cm. This can only be entered for elements and isotopes. See chapter STDCMP tables *Isotopes in standard composition library*, *Isotopes and their natural abundances*, and *Elements and special nuclide symbols*.
6	*temp*	Temperature (K)	See comment	Default value is 300 K. This entry may be omitted if the default temperature is acceptable and *iza* / *wpt* data are not entered.
7	*iza*	Isotope's ZA number	**VF** ≠ 0	Enter for each isotope in a multiple isotope nuclide. Omit if **VF** = 0 or the default values are acceptable. Entries 7 and 8 are entered in pairs until each isotope in the nuclide is defined. See STDCMP chapter tables *Elements and special nuclide symbols*, *Compounds*, and *Alloys and mixtures* for isotope IDs contained in nuclides, compounds, and alloys.
8	*wtp*	weight percent of isotope	**VF** ≠ 0	Enter the weight percent of the isotope in the nuclide. Omit if **VF** = 0 or the default values are acceptable. For each multiple isotope nuclide, the weight percents of the isotopes must sum to 100. Entries 7 and 8 are entered in pairs until each isotope in the nuclide is defined.
9	**END**	Terminate the standard composition	Always	This terminates the data for a standard composition. Enter the keyword **END** to terminate standard composition. A tag, up to 12 characters long, may follow the keyword **END** preceded by a single blank. At least two blanks or an end of line must separate this entry from the next entry.

Table 7.1.3 – continued from previous page

continues on next page

Table 7.1.4 – continued from previous page

Table 7.1.4: Standard composition specification for solutions.

Entry no.	Data name	Data type	Entry requirement	Comment
1	**SOLUTION**	keyword	Always	Identifies a new fissile solution. See the Standard Composition Library documentation.
2	{**MIX**=} *mx*	mixture number	Always	If the mixture number is not keyworded, it must immediately follow the SOLUTION keyword.
*3a	**RHO[***name***]**= *rho*	metal density	Optional	The density of the metal in *name* in grams/liter
*3b	**MOLAR[***name***]**= *molar*	molarity	Optional	moles of *name* per liter of solution
*3c	**MASSFRAC[***name***]**= *massfrac*	relative density	Optional	grams of metal in *name*/gram of solution
*3d	**MOLEFRAC[***name***]**= *molefrac*	fractional molarity	Optional	moles of *name* per mole of solution
*3e	**MOLALITY[***name***]**= *molality*	molality	Optional	moles of *name* per kilogram of water
4	**DENSITY**= *density*	solution density	Optional	density of the solution in grams/milliliter
5	**TEMPERATURE**= *temperature*	temperature	Optional	temperature of the solution in Kelvin
6	**VOL_FRAC**= *vf*	density multiplier	Optional	an overall, after the fact multiplier of the solution density
7	**END SOLUTION**	keyword	Always	ends the solution input

* Nuclides that occur in an item 3 will, by default, have naturally occurring isotopics. If this is not appropriate, the desired isotope and weight percent of each isotope making up the nuclide can be input in pairs following the value associated with the specified item 3.

Table 7.1.5 – continued from previous page

Table 7.1.5: Standard composition specification for chemical compounds.

Entry no.	Data name	Data type	Entry requirement	Comment
1	**ATOM**	Arbitrary compound name	Always	Enter the four characters ATOM followed by up to 12 additional alphanumeric characters in place of ATOM. As many compounds as required may be entered, but each must have a unique name. This entry is required.
2	*mx*	Mixture ID number	Always	Skip at least one blank after the compound name prior to entering the mixture number. This must be an integer greater than zero. This entry is required.
3	*roth*	Density	Always	This is the mixture density in g/cm^3.
4	*nel*	Number of *ncza* entries	Always	This is the number of elements or nuclides that make up the compound.
5	*ncza*	Nuclide ID number	Always	Repeat entries 6 and 7 for each element in the arbitrary compound before entering *temp*. Enter the ID number from the far right column of tables *Isotopes in Standard composition library* or *Isotopes and their natural abundances*. (Premixed standard compositions cannot be used in a chemical compound definition.)
6	*atpm*	Atoms per molecule	Always	Enter the number of atoms of this element per molecule of compound following each *ncza*. Repeat entries 6 and 7 for each element in the arbitrary compound before entering *temp*.
7	*vf*	Density multiplier	Always	Enter the density multiplier (density fraction, volume fraction, or a combination). A value of 1 means the material density is *roth*.
8	*temp*	Temperature (K)	See comment	Default value is 300 K. This entry may be omitted if the default temperature is acceptable and *iza* / *wpt* data are not entered.
9	*iza*	Isotope's ZA number	Optional	Enter for each isotope in a multiple isotope nuclide. Entries 9 and 10 are entered in pairs until each isotope in the nuclide is defined. See table *Isotopes and their natural abundances* for multiple isotope nuclide IDs and table *Elements and special nuclide symbols* in the Standard Composition Library for a list of isotopes in a multiple isotope nuclide.
10	*wtp*	weight percent of isotope	Optional	Enter the weight percent of the isotope in the nuclide. For each nuclide the weight percents must sum to 100. Entries 9 and 10 are entered in pairs until each isotope in the nuclide is defined.
11	**END**	Terminate the standard composition	Always	This terminates the data for an compound. Enter the keyword **END** to terminate compound. A tag, up to 12 characters long, may follow the keyword **END** preceded by a single blank. At least two blanks or a new line must separate this entry from the next entry.

Table 7.1.6 – continued from previous page

Table 7.1.6: Input specification for user-specified mixture/alloy data.

Entry no.	Data name	Data type	Entry requirement	Comment
1	**WTPT**	Mixture/alloy name	Always	Enter the four characters **WTPT** followed by up to 12 additional alphanumeric characters in place of WTPT. As many physical mixtures or alloys as required may be entered but each must have a unique name. This entry is required.
2	*mx*	Mixture ID number	Always	Skip at least one blank after the alloy name prior to entering the mixture number. This must be an integer greater than zero. This entry is required.
3	*roth*	Density	Always	This is the mixture density in g/cm^3.
4	*nel*	Number of *ncza* entries	Always	This is the number of elements or nuclides that make up the mixture/alloy.
5	*ncza*	Nuclide or element ID number	Always	Repeat the sequences 6 and 7 for each element in the mixture/alloy before entering *temp*. Enter the ID number from the far right column of table *Isotopes in Standard composition library* or *Isotopes and their natural abundances* in the Standard Composition Library section. (Premixed standard compositions cannot be used in an arbitrary mixture/alloy definition.)
6	*wpct*	Weight percent of nuclide or element	Always	Enter the weight percent of this element in the mixture/alloy following each *ncza*. Weight percents must sum to 100. Repeat the sequence 6 and 7 for each element in the mixture before entering *temp*.
7	*vf*	Density multiplier	Always	Enter the density multiplier (density fraction, volume fraction, or a combination). A value of 1 means the material density is *roth*.
8	*temp*	Temperature (K)	See comment	Default value is 300 K. This entry may be omitted if the default temperature is acceptable and *iza* / *wpt* data is not entered.
9	*iza*	Isotope's ZA number	Optional	Enter for each isotope in a multiple isotope nuclide. Entries 9 and 10 are entered in pairs until each isotope in the nuclide is defined. See the Standard Composition Library tables *Isotopes and their natural abundances* in for multiple isotope nuclide IDs and *Elements and special nuclide symbols* for a list of isotopes in a multiple isotope nuclide.
10	*wtp*	Weight percent of isotope	Optional	Enter the weight percent of the isotope in the nuclide. For each nuclide the weight percents must sum to 100 for each isotope in a multiple isotope nuclide. Entries 9 and 10 are entered in pairs until each isotope in the nuclide is defined.
11	**END**	Terminate the standard composition	Always	This terminates the data for an arbitrary mixture. Enter the keyword **END** to terminate arbitrary mixture/alloy. Repeat entries 1 through 11 until all the mixtures have been defined. A tag, up to 12 characters long, may follow the keyword **END** preceded by a single blank. At least two blanks or a new line must separate this entry from the next entry.

continues on next page

STANDARD COMPOSITION INPUT FOR BASIC MIXTURES (see Table 7.1.3).

Two input syntaxes are available for standard composition specifications of basic mixtures in the **COMP** block. The first uses information (e.g., densities, atomic weights, physical constants, etc.) contained in the Standard Composition Library, along with user specified input, to automatically compute the number densities for mixture components. In the second option, the user computes the nuclide number densities, and inputs these directly for each component of the mixture. XSProc recognizes syntax 2 if the third entry of the composition specification is zero, as shown below. It is allowable to use syntax 1 for some standard composition specifications and syntax 2 for others. The two syntaxes to define basic mixtures with the standard composition specifications are shown below.

syntax 1: Standard Composition Library data used to compute number densities.

sc *mx* **DEN**=*roth* {**VF**=}*vf temp* iza_1 wtp_1 ... iza_N wtp_N **END**

syntax 2: User input number densities

sc *mx* 0 *aden temp* **END**

The definitions for these input parameters are given below.

A1. **sc**

STANDARD COMPOSITION MATERIAL NAME. This corresponds to one of the material names given in the Standard Composition Library for isotopes, elements, thermal moderators and activity materials, chemical compounds, and alloys/mixtures. Some types of these materials require entering certain data such as the volume fraction or theoretical density and other engineering-type data. For standard compositions containing more than one isotope of an element (such as UO_2), the user is free to specify the weight percent for each isotope, such that they total 100%. See the Basic standard composition specifications section for examples of basic standard compositions.

A2. *mx*

MIXTURE ID NUMBER. An arbitrary mixture number is required on every standard composition specification for both syntaxes. It defines the mixture that contains the material defined by the standard composition specification data. The mixture numbers are utilized in the CELLDATA block Cell Block for INFHOMMEDIUM, LATTICECELL, MULTIREGION, or DOUBLEHET problems and the geometry data.

A3. **DEN**=*roth*

MIXTURE DENSITY. The keyword **DEN** is assigned a value of *roth,* where *roth* is the specified density of the mixture component in g/cm^3. It should always be entered for materials that contain enriched multi-isotopic nuclides. The effective density of the material component is equal to the product of *roth* and *vf.* An example of this is demonstrated in Appendix A.

A4. {**VF**=}*vf*

VOLUME FRACTION. The keyword **VF** is assigned a value of *vf.* It is also allowable to omit the keyword **VF=** and just enter the value *vf* . The default value of the volume fraction is 1.0. The volume fraction can be interpreted as

a. the volume fraction of this standard composition component in the mixture,

b. the density of the standard composition component in this application divided by the theoretical or default density given in the Standard Composition Library, or

c. the product of (a) and (b).

Appendix A discusses the interaction between *roth* and *vf*. For example, assume a homogenized mixture representing the water moderator and Zircaloy cladding around a fuel pin is to be described. If the volume of the clad is 5.32 cc and the volume of the water moderator is 44.68 cc, the mixture can be described using H_2O with a volume fraction of 0.8936 [i.e., 44.68/(44.68+5.32)] and ZIRCALOY with a volume fraction of 0.1064 [i.e., 5.32/(44.68+5.32)].

A5. *aden*

NUMBER DENSITY (not used for syntax 1, but required for 2). The number density is entered ONLY if 3rd entry on the standard composition specification is entered as zero. The number density is entered in units of atoms per barn-cm.

A6. *temp*

TEMPERATURE. The default value of the temperature is 300 K. The temperature can be omitted if entries A7 and A8 are also omitted.

A7. *iza*

ISOTOPE ZA NUMBER. Enter a value for each isotope in the standard composition component, entry 1. Do not enter a value if the volume fraction, **VF**, is zero (A4 above).

The ZA number of the isotope is entered if the user wishes to specify the isotopic distribution. This is done by entering *iza* and *wtp* for each isotope until all the desired isotopes have been described. In most cases the "ZA" ID number is (A+1000*Z), where A is the atomic mass or weight of the isotope, and Z is the atomic number. For example, the ZA number for ^{235}U is 92235.

Entries A7 and A8 can be skipped if the default values listed in Table 7.1.2 are acceptable.

A8. *wtp*

WEIGHT PERCENT OF THE ISOTOPE. If entry A7 is entered, a value must also be entered for A8. The weight percent of the isotope is the percent of this isotope in the element. The weight percent of all specified isotopes of the element must sum to 100 (± 0.01).

A9. **END**

The word **END** is entered to terminate the input data for a standard composition component. This **END** can have a label associated with it that can be as long as 12 characters. The label is optional, and if entered must be preceded from the **END** by a single blank. At least two blanks or a new line must separate this item from the next data entry.

STANDARD COMPOSITION INPUT FOR FISSILE SOLUTIONS (see Table 7.1.4).

Syntax:

```
SOLUTION {MIX=}mx RHO[fuelsalt]=fd (iza_i  wtp_i) MOLAR[acid]=aml
     MASSFRAC[name]=mfrac  MOLEFRAC[name] =molfrac
     MOLALITY[name]=molal  DENSITY=roth
     TEMPERATURE=temp VOL_FRAC=vf
END SOLUTION
```

where

mx is the mixture number,

fuelsalt is the Standard Composition Library component name of one of the fissile compounds

fd is the fuel density in grams of uranium or plutonium per liter of solution

acid is one of the Standard Composition Library acid compounds (e.g., HNO3 or HFACID)

name is one of the Standard Composition Library solution components

aml is the acid molarity of the *acid* component (moles of *acid/* liter of solution)

mfrac is the mass fraction of *name* in the solution (grams of metal in *name*/gram solution)

molfrac is the mole fraction of *name* in the solution (moles of *name*/mole solution)

molal is the mass fraction of *name* in the solution (moles of *name*/kg water)

roth is the density of the solution,

vf is the density multiplier (ratio of actual to theoretical density of the solution),

temp is the temperature in Kelvin,

iza is the isotope ID number from table *Available fissile solution components*, and

wtp is the weight percent of the isotope in the material.

Below are the input data for fissile solutions.

1. **SOLUTION**

   Keyword starting a solution specification. Solutions require the specification of the mixture and at least one component. Current possible components are given in the Standard Composition Library table, *Available fissile solution components*. Only the mixture number and one component are required. Appendix A contains examples of the input data for solutions.

2. *mx*

   MIXTURE ID NUMBER. A mixture number is required on every standard composition specification. It defines the mixture that contains the material defined by the standard composition specification data. The mixture numbers are utilized in the Unit Cell Specification for INFHOMMEDIUM, LATTICECELL, or MULTIREGION.

3. **RHO**[*fuelsalt*]=*fd*
MOLAR[*acid*]=*aml*
MASSFRAC[*name*]=*mfrac*
MOLEFRAC[*name*]=*molfrac*
MOLALITY[*name*]=*molal*

KEYWORD PARAMETERS TO DEFINE CONCENTRATIONS OF SOLUTION COMPONENTS. Each keyword specifies the unit, the component name from the Standard Composition Library and the component value, as shown Table 7.1.4. Up to three components can be specified for a solution if one is an acid. After the value, the isotopic enrichments of the nuclides can be given as pairs of isotope IDs and weight percent. **NOTE: the square brackets [ ] containing the component name are required.**

4. **DENSITY=***roth*

   Keyword specifying the overall solution density as grams per cubic centimeter or as a "?", meaning it is to be solved for. Solving for the density is the default behavior, but the density can be given, and a component value can be solved for instead.

5. **TEMPERATURE=***temp*

   Keyword defining temperature of the solution. The default value is 300 K.

6. **VOLFRAC=***vf*

   Keyword defining volume fraction - the default volume fraction is 1.0. This value must be greater than 0.0. The volume fraction can be interpreted as: a. the volume fraction of this solution specification in the mixture, b. the density of the solution in this application divided by the calculated density of the solution, or c. the product of (a) and (b).

7. **END SOLUTION**

STANDARD COMPOSITION INPUT FOR CHEMICAL COMPOUNDS (see Table 7.1.5)

Syntax:

ATOMnn *mx roth nel* $ncza_1$ $atpm_1$ … $ncza_{\text{nel}}$ $atpm_{\text{nel}}$ {*vf* {*temp* {iza_1 wtp_1 …} } } **END**

Below are the data for user-defined chemical compounds.

C1. **ATOMnn**

COMPOUND NAME. User-specified compounds (also defined as "arbitrary" in older versions of SCALE) require the user to provide all the information normally found in the Standard Composition Library. This option allows specifying a compound not available in the Standard Composition Library by utilizing nuclides and elements available in the library. An user-specified compound name must start with the four characters "**ATOM**." A maximum of twelve characters is allowed for the compound name, and imbedded blanks are not allowed.

C2. *mx*

MIXTURE ID NUMBER. A mixture number is required on every standard composition specification. It defines the mixture that contains the material defined by the compound specification data. The mixture numbers are utilized in the Unit Cell Specification for **INFHOMMEDIUM**, **LATTICECELL**, or **MULTIREGION** problems and the KENO V.a or KENO-VI geometry data.

C3. *roth*

MIXTURE DENSITY. The density of the arbitrary material is entered in units of g/cm^3. *roth* and *vf* interact to produce the density of the mixture used in the problem. Note that this is a required entry and does not use "**DEN**=" keyword.

C4. *nel*

NUMBER OF ELEMENTS IN THE MATERIAL. Enter the number of components from the Standard Composition Library that are to be used to define this material.

C5. *ncza*

ID NUMBER. This is the "ZA" ID number for the element or isotope. Usually, *ncza*=A+1000*Z, where A is the atomic mass or weight of the nuclide, and Z is the atomic number.

C6. *atpm*

ATOMIC or ELEMENT ABUNDANCE. Enter the number of atoms of this element per molecule of compound. Repeat the sequence *ncza* and *atpm* (C5 and C6) for every element in the compound before going to entry C7.

C7. *vf*

VOLUME FRACTION. The default value of the volume fraction is 1.0. This value must be greater than 0.0. The volume fraction can be interpreted as

a. the volume fraction of this compound in the mixture,

b. the density of the compound in this application divided by the input density of the compound, or

c. the product of (a) and (b).

C8. *temp*

TEMPERATURE. The default value of the temperature is 300 K. The temperature can be omitted if entries C9 and C10 are also omitted.

C9. *iza*

ISOTOPE ZA NUMBER. Enter a value for each isotope in the element in the compound. The ZA number of the isotope is entered if the user wishes to specify the isotopic distribution. This is done by entering *iza* and *wtp* for each isotope until all the desired isotopes have been described. In most cases the "ZA" ID number is (A+1000*Z), where A is the atomic mass or weight of the isotope, and Z is the atomic number.

Entries C9 and C10 can be skipped if the default values listed in Table 7.1.2 of Sect. 7.1 are acceptable.

C10. *wtp* WEIGHT PERCENT OF THE ISOTOPE. If entry C9 is entered, a value must also be entered for C10. The weight percent of the isotope is the percent of this isotope in the element. The weight percents of all specified isotopes of the element must sum to 100 (± 0.01).

Repeat the sequence *iza wtp* until the sum of the *wtp*s sum to 100. The sequence *iza wtp* is repeated until all of the desired isotopes have been specified.

C11. **END**

The word **END** is entered to terminate the input data for compound. This **END** can have a label associated with it that can be as long as 12 characters. The label is optional, and if entered must be preceded from the **END** by a single blank. At least two blanks or a new line must separate item C11 from the next data entry.

STANDARD COMPOSITION INPUT FOR MIXTURES AND ALLOYS (see Table 7.1.6)

Syntax:

WTPTnn *mx roth nel* $ncza_1$ $wpct_1$ ... $ncza_{\text{nel}}$ $wpct_{\text{nel}}$ {*vf* {*temp* {iza_1 wtp_1 ... } }} **END**

Below are the input data for arbitrary (i.e., user-defined) physical mixture or alloy.

D1. **WTPTnn**

ARBITRARY MIXTURE/ALLOY NAME. The arbitrary user-specified mixture/alloy option allows specifying a mixture or an alloy not available in the Standard Composition Library by utilizing the nuclides and elements available in the library. An arbitrary mixture/alloy name must start with the four characters "**WTPT**." A maximum of 12 characters is allowed for the arbitrary mixture/alloy name. Imbedded blanks are not allowed in an arbitrary mixture/alloy name. Appendix A contains input data for arbitrary mixture/alloys.

D2. *mx*

MIXTURE ID NUMBER. A mixture number is required on every standard composition specification. It defines the mixture that contains the material defined by the arbitrary compound specification data. The mixture numbers are utilized in the Unit Cell Specification for **INFHOMMEDIUM**, **LATTICECELL**, **MULTIREGION**, or **DOUBLEHET** problems and the KENO V.a or KENO-VI geometry data.

D3. *roth*

MIXTURE DENSITY. The density of the arbitrary material is entered in units of g/cm^3. *roth* and *vf* interact to produce the density of the mixture used in the problem. Note that this is a required entry and does not use "**DEN**=" keyword.

D4. *nel*

NUMBER OF ELEMENTS IN THE MATERIAL. Enter the number of components from the Standard Composition Library that are to be used to define this arbitrary material.

D5. *ncza*

ID NUMBER. This is the "ZA" ID number for the element or isotope. Usually, *ncza*=A+1000*Z, where A is the atomic mass or weight of the nuclide, and Z is the atomic number.

D6. *wpct*

ATOMIC or ELEMENT ABUNDANCE. Enter the weight percent of this element in the arbitrary alloy. The sum of all the weight percents for each specified element in the arbitrary alloy MUST be 100.0. Repeat the sequence *ncza* and *wpct* (D5 and D6) for every element in the arbitrary mixture/alloy before going to entry D7.

D7. *vf*

VOLUME FRACTION. The default value of the volume fraction is 1.0. This value must be greater than 0.0. The volume fraction can be interpreted as:

a. the volume fraction of this mixture or alloy in the mixture,

b. the density of the mixture or alloy in this application divided by the input density (*roth*) of the mixture or alloy, or

c. the product of (a) and (b).

D8. *temp*

TEMPERATURE. The default value of the temperature is 300 K. The temperature can be omitted if entries D9 and D10 are also omitted.

D9. *iza*

ISOTOPE ZA NUMBER. Enter a value for each isotope in the element in the arbitrary alloy. The ZA number of the isotope is entered if the user wishes to specify the isotopic distribution. This is done by entering *iza* and *wtp* for each isotope until all the desired isotopes have been described. In most cases the "ZA" ID number is (A+1000*Z), where A is the atomic mass or weight of the isotope, and Z is the atomic number.

Entries D9 and D10 can be skipped if the default values listed in Table 7.1.2 are acceptable.

D10. *wtp*

WEIGHT PERCENT OF THE ISOTOPE. If entry D9 is entered, a value must also be entered for D10. The weight percent of the isotope is the percent of this isotope in the element. Weight percents of all specified isotopes of the element must sum to 100 (±0.01).

D11. **END**

The word **END** is entered to terminate the input data for an arbitrary compound. This **END** can have a label associated with it that can be as long as 12 characters. The label is optional and if entered must be preceded from the **END** by a single blank. At least two blanks or a new line must separate this item from the next data entry.

7.1.3.4 Unit cell specification for infinite homogeneous problems

This section describes the unit cell data that can be entered for an **INFHOMMEDIUM** problem. Additional information is available in Appendix B.

Syntax:

INFHOMMEDIUM *mx* {**CELLMIX**{=}*mix*} **END**

The data required to specify the unit cell for an **INFHOMMEDIUM** unit cell are given in Table 7.1.7. The individual entries are explained in the following text.

1. **celltype**

   INFHOMMEDIUM. The keyword **INFHOMMEDIUM** is entered to indicate this unit cell contains one mixture with no geometry corrections. This data must be entered. The keyword may be truncated to any number of characters as long as the characters present are identical from the beginning of the keyword (i.e., INF is acceptable). All mixtures not in a defined unit cell are by default processed as infhommedium.

2. *mx*

   MIXTURE NUMBER. The mixture number defines the mixture to be used in the cell. This data must be entered. Be sure the mixture number entered is defined in the standard composition data.

3. **CELLMIX**=*mix*

CELL-WEIGHTED MIXTURE NUMBER. (the = sign can be replaced by a space if desired). Enter ONLY if a cell-weighted mixture is to be generated. Enter a unique mixture number to be used by XSDRN to create the cell-weighted mixture (Sect. 7.1.2.4). For **INFHOMMEDIUM** cells, cross sections for the cell mixture are equal to the shielded values of the original mixture.

4. **END**

   The word **END** is entered to terminate the **INFHOMMEDIUM** data. An optional label can be associated with this **END**. The label can be as many as 12 characters long and is separated from the **END** by a single blank. At least two blanks must follow this entry.

Table 7.1.7: Unit cell specifications for INFHOMMEDIUM problems.

Entry no.	Input data	Data type	Comments
1	**INFHOMMEDIUM**	Keyword	Keyword to begin infhommedium unit cell. Enter the keyword INFHOMMEDIUM. This word may be truncated to any number of letters as long as they exactly replicate the beginning part of the keyword (e.g., INF is acceptable).
2	*mx*	Cell mixture number	Specifies the mixture number to be used in the cell.
3	**CELLMIX**= *mix*	Keyword + new mixture number	Enter the keyword **CELLMIX**= followed immediately by a unique positive integer (*mix*). The integer will be a new mixture number that has the neutronic properties of the self-shielded unit cell.[a]
4	**END**		Terminate **INFHOMMEDIUM** data

7.1.3.5 Unit cell specification for LATTICECELL problems

This section describes the unit cell input data for a **LATTICECELL** problem. The **LATTICECELL** description is especially suited to self-shield arrays of repeated cells such as a fuel assembly lattice. The unit cell specification plays a major role in providing accurate problem-dependent cross sections using the computational procedures described in Sect. 7.1.2.3. Unit cells are limited to (a) infinitely long cylindrical rods in a square or triangular lattice, (b) spheres in a cubic or triangular lattice, (c) a symmetric array of slabs, or (d) an asymmetric array of slabs. Both "regular" and "annular" fuel geometries can be used in **LATTICECELL** problems. "Regular" cells allow a concentric spherical, cylindrical, or symmetric slab configuration, where the central region is fuel, surrounded by an optional gap, an optional clad, and an external moderator. "Annular" cells also allow concentric spherical, cylindrical, or asymmetric slab configurations, but the central region corresponds to an inner moderator region which is surrounded by a fuel region having an optional gap and optional clad on each side of the fuel. An inner gap may be specified inside the fuel region, and an outer gap may be specified outside the fuel region. Similarly an inner clad may be specified inside the fuel region, and an outer clad may be specified outside the fuel region. For both regular and annular fuel cells, the outer boundary of the unit cell is determined from the square or triangular pitch of the array.

Regular cells are **SQUAREPITCH**, **TRIANGPITCH**, **SPHSQUAREP**, **SPHTRIANGP**, and **SYMMSLABCELL**.

Annular cells are **ASQUAREPITCH** (or **ASQP**), **ATRIANGPITCH** (or **ATRP**), **ASPHSQUAREP** (or **ASSP**), **ASPHTRIANGP** (or **ASTP**), and **ASYMSLABCELL**

Syntax:

celltype ctp PITCH (or **HPITCH**) *pitch mm* **FUELD (or FUELR**) *fuel mf*

GAPD (or GAPR) *gap mg* **CLADD (or CLADR**) *clad mc*

IMODD (or IMODR) *imod mim* **IGAPD** (**or IGAPR**) *igap mig*

ICLADD (or **ICLADR**) *iclad mic* {**CELLMIX**=*mix*} **END**

The unit cell geometry data required to specify a LATTICECELL problem are given in Table 7.1.8. The individual entries are explained in the text below.

1. **celltype**

   LATTICECELL. The keyword **LATTICECELL** is entered to indicate this unit cell contains mixtures that are positioned in a regular array. This data must be entered. The keyword may be truncated to any number of characters as long as the characters present are identical from the beginning of the keyword (e.g., **LAT** is acceptable). This unit cell is normally used for regular arrays of materials such as fuel pins in an assembly.

2. **ctp**

   TYPE OF LATTICE. This defines the type of lattice or array configuration. Any one of the following alphanumeric descriptions may be used. Note that the alphanumeric description must be separated from subsequent data entries by one or more blanks. Fig. 7.1.1 Mixture and position data are entered using keywords. Mixture number 0 may be entered for void and may be used multiple times in each and all unit cells. For regular cells, the minimum requirement is that a fuel region and a moderator region are specified and no other inner components are specified. For annular cells, the minimum requirement is the fuel and outer moderator and inner moderator regions are specified. Regular and annular cell configurations are specified as shown below.

   Regular Cells

   SQUAREPITCH is used for an array of cylinders arranged in a square lattice, as shown in Fig. 7.1.1. The clad and/or gap can be omitted.

   TRIANGPITCH is used for an array of cylinders arranged in a triangular-pitch lattice as shown in Fig. 7.1.2. The clad and/or gap can be omitted.

   SPHSQUAREP is used for an array of spheres arranged in a square-pitch lattice. A cross section view through a cell is represented by Fig. 7.1.1. The clad and/or gap can be omitted.

   SPHTRIANGP is used for an array of spheres arranged in a triangular-pitch (dodecahedral) lattice. A cross section view through a cell is represented by Fig. 7.1.2. The clad and/or gap can be omitted.

   SYMMSLABCELL is used for an infinite array of symmetric slab cells, as shown in Fig. 7.1.3. The clad and/or gap can be omitted.

   Annular Cells

   ASQUAREPITCH or **ASQP** is used for annular cylindrical rods in a square-pitch lattice as shown in Fig. 7.1.4. The inner and outer clad and gap are independently entered so they must be different materials and dimensions. Note that each mixture in the problem can be used only once and in only one zone of a cell.

   ATRIANGPITCH or **ATRP** is used for annular cylindrical rods in a triangular-pitch lattice as shown in Fig. 7.1.5. The inner and outer clad and gap are independently entered, so they must be different materials and dimensions.

   ASPHSQUAREP or **ASSP** is used for spherical shells in a square-pitch lattice as shown in Fig. 7.1.4. The inner and outer clad and gap are independently entered, so they must be different materials and dimensions.

   ASPHTRIANGP or **ASTP** is used for spherical shells in a triangular-pitch (dodecahedral) lattice as shown in Fig. 7.1.5. The inner and outer clad and gap are independently entered, so they must be different materials and dimensions.

ASYMSLABCELL is used for a periodic, but asymmetric, array of slabs as shown in Fig. 7.1.6. The inner and outer clad and gap are independently entered, so they may be different materials and dimensions.

3. **PITCH** or **HPITCH**

   ARRAY PITCH. This is the center-to-center spacing or half-spacing between the fuel lumps (rods, pellets, or slabs), *pitch*, in cm followed by the outer moderator material number, mm, as shown in Fig. 7.1.1 through Fig. 7.1.6.

4. **FUELD** or **FUELR**

   OUTSIDE DIMENSION OF FUEL. This is the outside diameter or radius of the fuel, fuel, in cm followed by the fuel mixture number, *mf*, as shown in Fig. 7.1.1 through Fig. 7.1.6.

5. **GAPD** or **GAPR**

   OUTSIDE DIMENSION OF OUTER GAP. Enter only if outer gap is present. This is the outside diameter or radius of the outer gap, *gap*, in cm followed by the gap mixture number, mg, as shown in Fig. 7.1.1 through Fig. 7.1.6.

6. **CLADD** or **CLADR**

   OUTSIDE DIMENSION OF OUTER CLAD. Enter ONLY if a clad is present. This is the outside diameter or radius of the outer clad, *clad*, in cm followed by the clad mixture number, mc, as shown in Fig. 7.1.1 through Fig. 7.1.6.

7. **IMODD** or **IMODR**

   DIMENSION OF INNER MODERATOR. Enter ONLY if an annular cell is specified. This is the outside diameter or radius of the inner moderator, *imod*, in cm followed by the inner moderator mixture number, *mim*, as shown in Fig. 7.1.4 through Fig. 7.1.6.

8. **IGAPD** or **IGAPR**

   OUTSIDE DIMENSION OF INNER GAP. Enter ONLY if an annular cell is specified and inner gap is present. This is the outside diame*ter or radius of the inner gap, *igap*, in cm followed by the inner gap mixture number, *mig*, as shown in Fig. 7.1.4 through Fig. 7.1.6.

9. **ICLADD** or **ICLADR**

   OUTSIDE DIMENSION OF INNER CLAD. Enter ONLY if an annular cell is specified and inner clad is present. This is the outside diameter or radius of the inner clad, *iclad*, in cm followed by the inner clad mixture number, *mic*, as shown in Fig. 7.1.4 through Fig. 7.1.6.

10. {**CELLMIX=}mix**

    CELL-WEIGHTED MIXTURE NUMBER. [the = sign can be replaced by a space if desired). Enter ONLY if a cell-weighted mixture is to be generated. Enter a unique mixture number to be used by XSDRN to create the cell-weighted mixture (Sect. 7.1.2.4).

11. **END**

    The word **END** is entered to terminate the **LATTICECELL** data. An optional label can be associated with this **END**. The label can be as many as 12 characters long and is separated from the **END** by a single blank. At least two blanks must follow this entry. Must not start in column 1.

Table 7.1.8 – continued from previous page

Table 7.1.8: Unit cell specification for LATTICECELL problems

Entry no.	Input keyword		Comments		
1	**LATTICECELL**		Keyword to begin LATTICECELL unit cell. Enter the keyword **LATTICECELL**. This word may be truncated to any number of letters as long as they exactly replicate the beginning part of the keyword (e.g., **LAT** is acceptable).		
2			One of the following keywords is specified. This keyword determines the type of lattice or array configuration and which subsequent data need to be specified.		
	SQUAREPITCH		Used for cylindrical rods in a square pitch.		
	ASQUAREPITCH		Used for annular cylindrical rods in a square pitch.		
	ASQP		Used for annular cylindrical rods in a square pitch.		
	TRIANGPITCH		Used for cylindrical rods in a triangular pitch.		
	ATRIANGPITCH		Used for annular cylindrical rods in a triangular pitch.		
	ATRP		Used for annular cylindrical rods in a triangular pitch.		
	SPHSQUAREP		Used for spherical pellets in a cubic lattice.		
	ASPHSQUAREP		Used for annular spherical pellets in a cubic lattice.		
	ASSP		Used for annular spherical pellets in a cubic lattice.		
	SPHTRIANGP		Used for spherical pellets in a bi-centered or face-centered hexagonal close-packed lattice.		
	ASPHTRIANGP or **ASTP**		Used for annular spherical pellets in a bi-centered or face-centered hexagonal close-packed lattice.		
	SYMMSLABCELL		Used for a symmetric array of slabs.		
	ASYMSLABCELL		Used for a periodic but asymmetric array of slabs.		
Enter the following keywords and subordinate data as required to specify the unit cell. Each dimension can be entered as a diameter or radius using the appropriate keyword. The following keywords may be entered in any order.					
3	**PITCH**	**HPITCH**	Cell pitch or half-pitch (cm) + moderator mixture	Always	The pitch is the center-to-center spacing (cm) between fuel lumps. For asymmetric slab cell, **PITCH** is the center-to-center distance between inner moderators (cm).
4	**FUELD**	**FUELR**	Outside diameter or radius of fuel (cm) + fuel mixture	Always	Outside diameter (radius) of fuel (cm) or the thickness (half-thickness) of the fuel in a slab. For asymmetric slab cells, **FUELR** is measured from the centerline of the inner moderator.
5	**GAPD**	**GAPR**	Outside diameter or radius of outer gap (cm) + gap mixture	Outer gap Present	OMIT IF NO GAP between the fuel and clad outer clad. A mixture number of zero is often used. For asymmetric slab cells, **GAPR** is measured from the centerline of the inner moderator.
6	**CLADD**	**CLADR**	Outside diameter or radius of outer clad (cm) + clad mixture	Outer clad Present	OMIT IF NO CLAD between fuel and outer moderator. For asymmetric slab cells, **CLADR** is measured from the centerline of the inner moderator.
7	**IMODD**	**IMODR**	Outside diameter or radius of inner moderator (cm) + moderator mixture	Annular cell	Dimension of inner moderator mixture inside the fuel. For a slab, this is the moderator on the other side of the slab. Enter for annular cells only.
8	**IGAPD**	**IGAPR**	Outside diameter or radius of inner gap (cm) + gap mixture	Annular cell + Inner Gap Present	OMIT IF NO GAP between the inner clad and fuel. For an asymmetric slab, **IGAPR** is the distance from the center of the inner moderator to the outside of the inner gap (cm).
9	**ICLADD**	**ICLADR**	Outside diameter or radius of inner clad (cm) + clad mixture	Annular cell + Inner Clad Present	OMIT IF NO CLAD between fuel and inner moderator. For an asymmetric slab, **ICLADR** is the distance from the center of the inner moderator to the outside of the inner clad (cm).
10	**CELLMIX**		Unique mixture number	Cell-weighted mixture	Used if a cell-weighted mixture is specified. Calls XSDRN to produce a cell-weighted mixture (Section **7.1.2.4**).
11	**END**		Terminate **LATTICECELL** data	Always	Terminate the **LATTICECELL** input data by entering the word **END**. Do not start in column 1. At least two blanks or a new line must follow **END**.

7.1.3.6 Unit cell specification for MULTIREGION cells

A **MULTIREGION** cell can be used to define a 1-D geometric arrangement that is more general than allowed by a **LATTICECELL**. It can also be used for large geometric regions where the geometry effects for the cross sections are small. For CENTRM/PMC self-shielding, lattice effects can be approximated by applying reflected, periodic, or white external boundary conditions to a MULTIREGION cell. HOWEVER, MULTIREGION CELLS SHOULD NOT BE USED FOR BONAMI-ONLY SELF-SHIELDING OF AN ARRAY UNIT CELL. In this case a LATTICECELL should always be used for BONAMI self-shielding in order to incorporate the proper Dancoff effects.

The data required for a MULTIREGION cell are given in Table 7.1.9 and explained in the following text.

1. **celltype**

   MULTIREGION. The keyword **MULTIREGION** is used to represent arbitrary 1-D geometries, with no restrictions the on number or placement of mixtures in the cell. The keyword may be truncated to any number of characters as long as the characters presented are identical from the beginning of the keyword (i.e., M is acceptable).

2. **cs**

   TYPE OF GEOMETRY. The type of geometry must always be specified for a **MULTIREGION** cell. The available geometry options are listed below.

   SLAB. This is used to describe a slab geometry.

   CYLINDRICAL. This is used to describe cylindrical geometry.

   SPHERICAL. This is used to describe spherical geometry.

BUCKLEDSLAB. This is used for slab geometry with a buckling correction for the two transverse directions. Inactive in SCALE 6.2 and later.

BUCKLEDCYL. This is used for cylindrical geometry with a buckling correction in the axial direction. Inactive in SCALE 6.2 and later.

3. **RIGHT_BDY**

RIGHT BOUNDARY CONDITION. This is defaulted to **VACUUM**. The available options and their qualifications are listed below.

VACUUM. This imposes a vacuum at the boundary of the system.

REFLECTED. This imposes mirror image reflection at the boundary. Do not use for **CYLINDRICAL** or **SPHERICAL**.

PERIODIC. This imposes periodic reflection at the boundary. Do not use for **CYLINDRICAL** or **SPHERICAL**.

WHITE. This imposes isotropic return at the boundary.

4. **LEFT_BDY**

LEFT BOUNDARY CONDITION. This is defaulted to **REFLECTED**. The available options and their qualifications are listed below.

VACUUM. This imposes a vacuum at the boundary of the system.

REFLECTED. This imposes mirror image reflection at the boundary. For **CYLINDRICAL** or **SPHERICAL**, this is the only valid boundary condition because the left boundary corresponds to the centerline of the cylinder or the center of the sphere.

PERIODIC. This imposes periodic reflection at the boundary.

WHITE. This imposes isotropic return at the boundary.

5. **ORIGIN**

LOCATION OF LEFT BOUNDARY ON THE ORIGIN. The default value of **ORIGIN** is 0.0. This is the only value allowed for **CYLINDRICAL** or **SPHERICAL** geometry. For **SLAB**s, enter the location of the left boundary on the X-axis perpendicular to the slab (in cm).

6. **DY**

BUCKLING HEIGHT. This is the buckling height in cm. It corresponds to one of the transverse dimensions of an actual 3-D slab assembly or the length of a finite cylinder. Inactive in SCALE 6.2 and later.

7. **DZ**

BUCKLING DEPTH. This is the buckling width in cm. It corresponds to the second transverse dimension of an actual 3-D slab assembly. Inactive in SCALE 6.2 and later.

8. **CELLMIX**

CELL-WEIGHTED MIXTURE NUMBER. Enter ONLY if a cell-weighted mixture is required. Enter a unique mixture number used to create a cell-weighted homogeneous mixture (Sect. 7.1.2.4).

9. **END**

   The word **END** is entered to terminate these data before entering the zone description data. It must not be entered in columns 1 through 3, and at least two blanks must separate it from the zone description. A label can be associated with this **END**. The label can be a maximum of 12 characters and is separated from the **END** by a single blank. At least two blanks must follow this entry.

   The zone description data are entered at this point. Entries 10 and 11 are entered for each zone, and the sequence is repeated until all the desired zones have been described. To terminate the data, enter the words END ZONE. Zone dimensions must be in increasing order.

10. **mxz**

    MIXTURE NUMBER IN THE ZONE. Enter the mixture number of the material that is present in the zone. Enter a zero for a void. Repeat the sequence of entries 10 and 11 for each zone. Mixtures other than zero must not be used more than once in a cell and may be used in no more than one cell.

11. **rz**

    OUTSIDE RADIUS OF THE ZONE. Enter the outside dimension of the zone in cm.

    In **SLAB** geometry, **rz** is the location of the zone's right boundary on the X-axis. Repeat the sequence of entries 10 and 11 for each zone.

12. **END ZONE**

    Is used to terminate the **MULTIREGION** zone data. Enter the words **END ZONE** when all the zones have been described. Note that **ZONE** is a label associated with this **END**. This label can be as long as 12 characters, but the first four characters must be **ZONE**. At least two blanks must follow this entry.

Table 7.1.9 – continued from previous page

Table 7.1.9: Unit cell specification for MULTIREGION problems.

Entry no.	Input keyword	Data following keyword	Entry requirement	Comments
1	**MULTIREGION**		Always	Keyword to begin multiregion unit cell. Enter the keyword **MULTIREGION**. This word may be truncated to any number of letters as long as they exactly replicate the beginning part of the keyword (e.g., **M** is acceptable).
2			Always	One of the following keywords is specified. This keyword determines the type of unit cell geometry.
	SLAB			Used for slab geometry.
	CYLINDRICAL			Used for cylindrical geometry.
	SPHERICAL			Used for spherical geometry.
	BUCKLEDSLAB			Used for slab geometry with a buckling correction for the two transverse directions.
	BUCKLEDCYL			Used for cylindrical geometry with a buckling correction in the axial direction.
3	**RIGHT_BDY**	**VACUUM** **REFLECTED** **PERIODIC** **WHITE**	Optional for all geometries	Default is **VACUUM**. Describes the right/outer boundary condition. This provides a non-return condition at the boundary. **REFLECTED** or **PERIODIC** not allowed for cylindrical or spherical.
4	**LEFT_BDY**	**VACUUM** **REFLECTED** **PERIODIC** **WHITE**	Optional for slab type geometries	Default is **REFLECTED**. Describes the left/inner boundary condition. Do not change for cylindrical or spherical. **VACUUM** provides a non-return condition at the boundary. **WHITE** provides isotropic return at the boundary.
5	**ORIGIN**	Left boundary location (cm)	Optional for slab type geometries	Default is 0.0. Should not be changed for cylindrical or spherical geometry.
6	**DY**	Buckling height (cm)		OMIT FOR **SLAB**, **CYLINDRICAL**, and **SPHERICAL**. This corresponds to one of the transverse dimensions of an actual 3-D slab assembly or to the length of a finite cylinder.
7	**DZ**	Bucking depth (cm)		OMIT UNLESS **BUCKLEDSLAB** IS SPECIFIED. This is the buckling depth corresponding to the second transverse dimension of a 3-D slab assembly.

(continued)

Entry no.	Input keyword	Data following keyword	Entry requirement	Comments
8	**CELLMIX**	Unique mixture no.	Cell-weighted mixture required	Used if a cell-weighted mixture is specified. Enter a unique mixture number in the problem (See **Cell weighting of MG cross sections**).
9	**END**		Always	Enter the word **END**. Do not start in column 1. At least two blanks or a new line must separate **END** from the next entry.
10		Zone mixture number	Always	Enter mixture number in zone. Repeat 10 and 11 until all zones are specified.
11		Zone outside radius (cm)	Always	Enter outside radius of zone. Repeat 10 and 11 until all zones are specified.
12	**END ZONE**		Always	Terminates MULTIREGION data. At least two blanks must follow.

Table 7.1.9 – continued from previous page

7.1.3.7 Unit cell specification for doubly heterogeneous (DOUBLEHET) cells

The data required for a **DOUBLEHET** cell are given in Table 7.1.10 and explained in the following text.

Details about the computation procedures for **DOUBLEHET** cells can be found in Sect. 7.1.2.3.

"Grain" refers to a spherical fuel particle surrounded by one or more coating zones and does not include the matrix material the grains are in. "Grain type" refers to a grain that has specified dimensions and mixtures such as a 0.025-cm-radius UO_2 fuel kernel with a 0.01-cm-thick carbon coating. Another grain type could be a 0.012-cm-radius PuO_2 fuel kernel with a 0.01-cm-thick carbon coating. The user must first define all grain types in a fuel element. Next, all fuel element–related data must be entered.

Since all grains and the matrix material are homogenized into a single uniform mixture for the fuel element, there are restrictions on how each grain type must be defined so that the volume fraction of each grain type within the homogenized fuel mixture can be determined. Related entries are **PITCH**, **NUMPAR** (number of particles), and **VF** (volume fraction). If there is only one grain type for a fuel element, the code needs the pitch and will directly use the input value if entered. If **PITCH** is not given, then the **VF** (if given) is used to calculate the pitch. If neither **PITCH** nor **VF** is given, then **NUMPAR** is used to calculate the pitch and the volume fraction. The user should only enter one of these items.

If more than one grain type is present, additional information is needed since all grain types are homogenized into a single mixture. Similar to the one grain type case, the pitch is needed to perform the CENTRM spherical cell calculations. However, the pitch by itself is not sufficient to perform the homogenization. Therefore, the user needs to input **VF** or **NUMPAR** for each grain type. Since each grain's volume is known (grain dimensions must always be entered), entering **NUMPAR** or **VF** for each grain type essentially provides the total volume of each grain type and therefore enables the calculation of the other unknowns (**VF** or **NUMPAR**, and **PITCH**). In this case, since pitch is not given, the available matrix material is distributed around the grains of each grain type proportional to the grain volume to calculate the corresponding pitch.

Syntax:

DOUBLEHET *fuelmix* **END**

GF(**D**|**R**)=*fuel mg* (**COAT**(**D**|**R**)=*coat mc*)|(**COATT**=*coat mc*) {**H**}**PITCH**=*mod* **MATRIX**=*mm* **NUMPAR**=*npar* **VF**=*vf* **END GRAIN**

mct ctp FUEL(**D**|**R**)=*mfuel* {**FUELH**=*hfuel*} {**FUELW**=wfuel} {**GAP**(**D**|**R**)=*mgap mmg*} {**CLAD**(**D**|**R**)=*mclad mmc*} {**H**}**PITCH**=*mpitch mmm* {**CELLMIX**=*mcmx*} **END**

1. **celltype**

   DOUBLEHET. The keyword DOUBLEHET is used to represent a doubly heterogeneous problem such as fuel units that are composed of grains of fuel.

2. *fuelmix*

   HOMOGENIZED MIXTURE NUMBER. Enter a unique mixture number to be used for the homogenized grains and matrix material.

3. **END**

   The word **END** is entered to terminate these data before entering the grain and fuel element description data. It must not be entered in columns 1 through 3, and at least two blanks must separate it from the zone description. A label can be associated with this **END**. The label can be a maximum of 12 characters and is separated from the **END** by a single blank. At least two blanks must follow this entry.

The grain description data are entered at this point. Entries 5 through 12 are entered for each grain, and the sequence is repeated until all the grains have been described. To terminate the data, enter the words **END GRAIN**. Data may be entered in any order.

4. **PITCH** or **HPITCH**

   EQUIVALENT CELL DIMENSION. This is the equivalent spherical diameter (or radius), in cm, of the "average" unit cell for this grain, as shown in Fig. 7.1.7. Physically, the volume of the average unit cell is equal to the volume of the fuel element divided by the total number of all grain types.

5. **GFD** or **GFR**

   OUTSIDE DIMENSION OF FUEL. This is the outside diameter or radius of the fuel zone in a grain, *fuel*, in cm followed by the fuel mixture number, *mg*, as shown in Fig. 7.1.7.

6. **COATD** or **COATR**

   OUTSIDE DIMENSION OF COATING. This is the outside diameter or radius of a coating zone, *coat*, in cm followed by the coating mixture number, *mc*, as shown in Fig. 7.1.7. As many coating-mixture pairs as desired may be entered. If the coating dimensions are entered using COATD or COATR, then the COATT keyword should not be used.

7. **COATT**

   THICKNESS OF COATING. This is the thickness of a coating zone, *coat*, in cm followed by the coating mixture number, *mc*, as shown in :numref`fig7-1-7`. As many coating-mixture pairs as desired may be entered. If the coating dimensions are entered using COATT, then the COATD or COATR keyword should not be used.

8. **MATRIX**

   MIXTURE NUMBER OF THE MATRIX MATERIAL. This is the mixture number, *mm*, of the matrix material that encloses the grains.

9. **NUMPAR**

   NUMBER OF PARTICLES. This is the number of grains, *npar*, of this type in each fuel element.

10. **VF**

    VOLUME FRACTION. This is the volume fraction, *vf*, of grains of this type in each fuel element's fuel zone. A fuel element's fuel zone is entered using the entry number 16-**FUELD** (or **FUELR**).

11. **END GRAIN**

    This is used to terminate the grain zone data for this grain type. At least two blanks must follow this entry.

REPEAT ENTRIES 4-11 FOR EACH GRAIN TYPE IN A FUEL ELEMENT.

12. **mct**

    TYPE OF FUEL ELEMENT (macro cell type). One of the keywords **PEBBLE** or **ROD** or SLAB is entered to indicate the type of the fuel element, i.e., the second layer of heterogeneity. This data must be entered. The keyword may NOT be truncated. **PEBBLE** is used for spherical fuel elements; **ROD** is used for cylindrical fuel elements; and SLAB for plate fuel elements.

13. **ctp**

TYPE OF LATTICE. This defines the type of lattice or array configuration. Any one of the following alphanumeric descriptions may be used. Note that the alphanumeric description must be separated from subsequent data entries by one or more blanks. Fig. 7.1.1 Mixture and position data are entered using keywords. Mixture number 0 may be entered for void and may be used multiple times in each and all unit cells. For regular cells, the minimum requirement is that a fuel region and a moderator region are specified and no inner components are specified. For annular cells, the minimum requirement is the fuel and outer moderator and inner moderator regions are specified. Regular and annular cell configurations are specified as shown below.

Regular Cells

SQUAREPITCH is used for an array of cylinders arranged in a square lattice, as shown in Fig. 7.1.1. The clad and/or gap can be omitted.

TRIANGPITCH is used for an array of cylinders arranged in a triangular-pitch lattice as shown in Fig. 7.1.2. The clad and/or gap can be omitted.

SPHSQUAREP is used for an array of spheres arranged in a square-pitch lattice. A cross section view through a cell is represented by Fig. 7.1.1. The clad and/or gap can be omitted.

SPHTRIANGP is used for an array of spheres arranged in a triangular-pitch (dodecahedral) lattice. A cross section view through a cell is represented by Fig. 7.1.2. The clad and/or gap can be omitted.

SYMMSLABCELL is used for an infinite array of symmetric slab cells, as shown in Fig. 7.1.3. The clad and/or gap can be omitted.

Annular Cells

ASQUAREPITCH or **ASQP** is used for annular cylindrical rods in a square-pitch lattice as shown in Fig. 7.1.4. The inner and outer clad and gap are independently entered so they may be different materials and dimensions.

ATRIANGPITCH or **ATRP** is used for annular cylindrical rods in a triangular-pitch lattice as shown in Fig. 7.1.5. The inner and outer clad and gap are independently entered, so they may be different materials and dimensions.

ASPHSQUAREP or **ASSP** is used for spherical shells in a square-pitch lattice as shown in Fig. 7.1.4. The inner and outer clad and gap are independently entered, so they may be different materials and dimensions.

ASPHTRIANGP or **ASTP** is used for spherical shells in a triangular-pitch (dodecahedral) lattice as shown in Fig. 7.1.5. The inner and outer clad and gap are independently entered, so they may be different materials and dimensions.

ASYMSLABCELL is used for a periodic, but asymmetric, array of slabs as shown in Fig. 7.1.6. The inner and outer clad and gap are independently entered, so they may be different materials and dimensions.

14. **PITCH** or **HPITCH**

ARRAY PITCH. This is the center-to-center spacing or half-spacing between the fuel lumps (pebbles or rods or slabs), *mpitch*, in cm followed by the outer moderator material number, *mmm*, as shown in Fig. 7.1.1 and Fig. 7.1.2.

15. **FUELD** or **FUELR**

    OUTSIDE DIMENSION OF FUEL. This is the outside dimension (diameter or radius for sphere/cylinder or x-thickness for slab) of the fuel region, *mfuel*, in cm, as shown in Fig. 7.1.1 and Fig. 7.1.2.

16. **FUELH**

    HEIGHT OF FUEL ROD OR SLAB. This is the height (z-dimension) of the fuel plate, *hfuel*, in cm. (only used to compute volume of fuel plate).

17. **FUELW**

    WIDTH OF FUEL ROD or slab. This is the width/depth (y-dimension) of the fuel plate, *wfuel*, in cm. (only used to compute volume of fuel plate).

18. **GAPD** or **GAPR**

    OUTSIDE DIMENSION OF GAP. Enter only if outer gap is present. This is the outside diameter or radius of the outer gap, *mgap*, in cm followed by the gap mixture number, *mmg*, as shown in Fig. 7.1.1 and Fig. 7.1.2.

19. **CLADD** or **CLADR**

    OUTSIDE DIMENSION OF CLAD. Enter ONLY if a clad is present. This is the outside diameter or radius of the outer clad, *mclad*, in cm followed by the clad mixture number, *mmc*, as shown in Fig. 7.1.1 and Fig. 7.1.2.

20. **CELLMIX**

    CELL-WEIGHTED MIXTURE NUMBER. Enter ONLY if cell-weighted mixture, *mcmx*, is to be created.

21. **IMODD** or **IMODR**

    DIMENSION OF INNER MODERATOR. Enter ONLY if an annular cell is specified. This is the outside diameter or radius of the inner moderator, *imod*, in cm followed by the inner moderator mixture number, *mim*, as shown in Fig. 7.1.4 through Fig. 7.1.6.

22. **IGAPD** or **IGAPR**

    OUTSIDE DIMENSION OF INNER GAP. Enter ONLY if an annular cell is specified and inner gap is present. This is the outside diameter or radius of the inner gap, *igap*, in cm followed by the inner gap mixture number, *mig*, as shown in Fig. 7.1.4 through Fig. 7.1.6.

23. **ICLADD** or **ICLADR**

    OUTSIDE DIMENSION OF INNER CLAD. Enter ONLY if an annular cell is specified and inner clad is present. This is the outside diameter or radius of the inner clad, *iclad*, in cm followed by the inner clad mixture number, *mic*, as shown in Fig. 7.1.4 through Fig. 7.1.6.

24. **END**

    The word **END** is entered to terminate the **DOUBLEHET** data. An optional label can be associated with this **END**. The label can be as many as 12 characters long and is separated from the **END** by a single blank. At least two blanks must follow this entry.

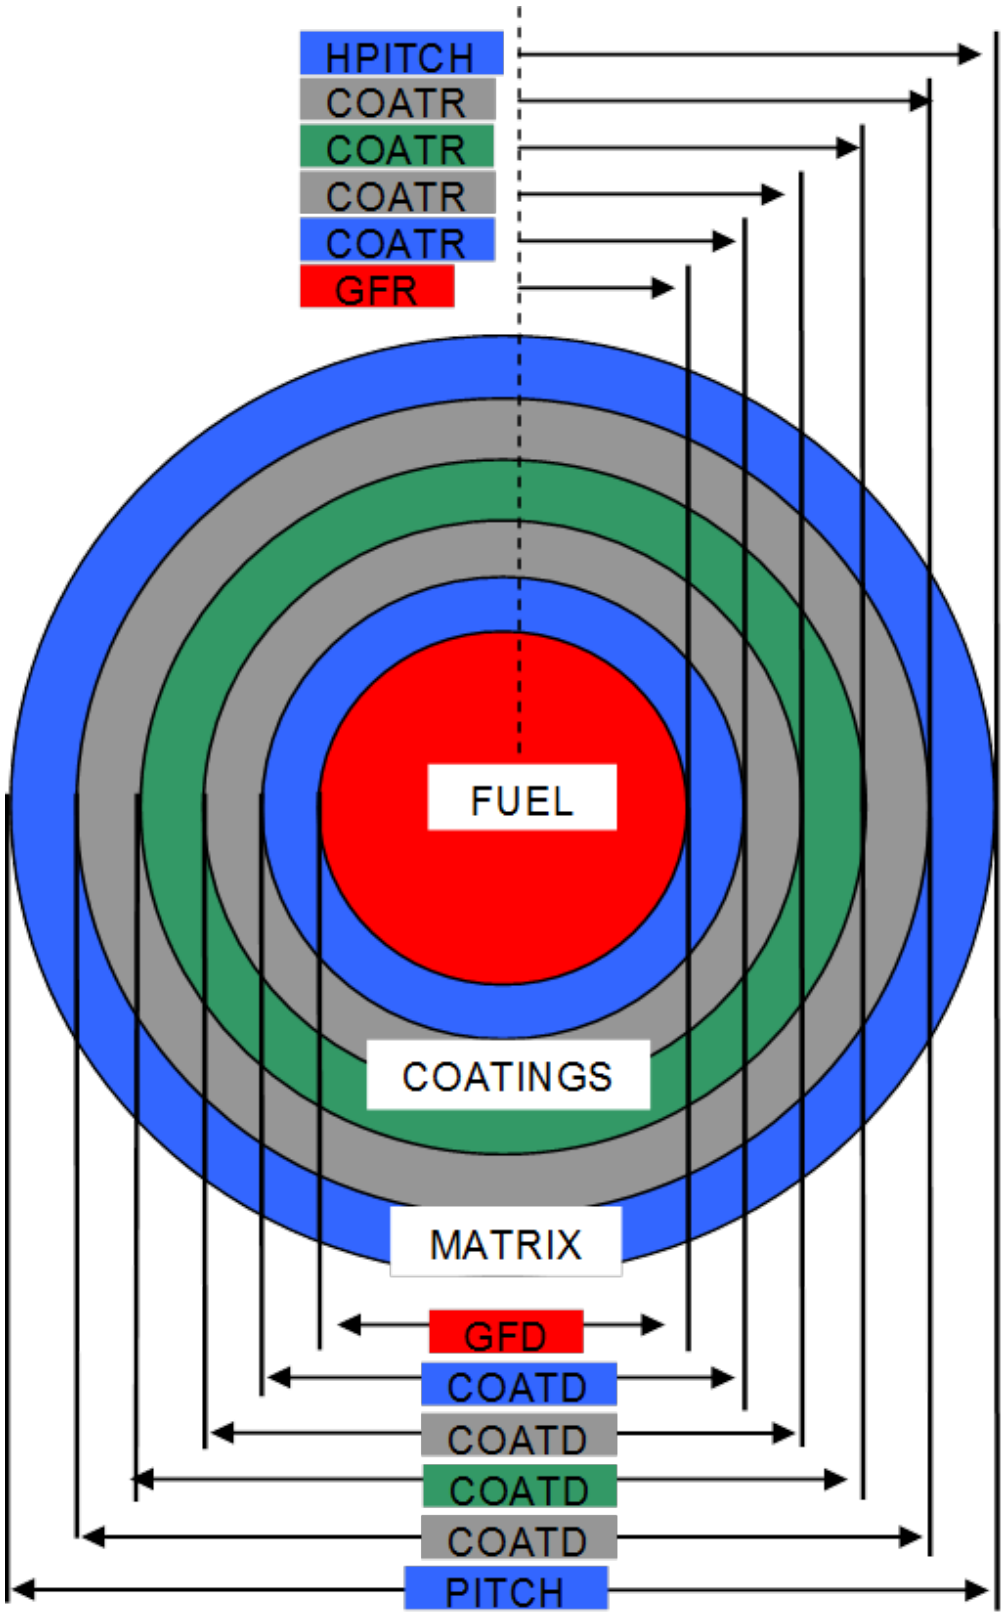

Fig. 7.1.7: Arrangement of materials in a grain (first level cell) in a DOUBLEHET unit cell.

GEOMETRY (region)

Format: READ GEOM enter geometry region data here END GEOM

See sections on Geometry, Geometry data, Multiple entries in geometry data, and Alternative Sample problem mockups.

GEOMETRY REGION DATA consist of SIMPLE GEOMETRY REGION DATA and EXTENDED GEOMETRY REGION DATA.

ENTER GEOMETRY DATA IN THE FOLLOWING FORM:

OPTIONAL GLOBAL SPECIFICATION

UNIT n

OPTIONAL GEOMETRY COMMENT

GEOMETRY REGION DATA and/or EXTENDED GEOMETRY REGION DATA

****

ENTER SIMPLE REGION DATA IN THE FOLLOWING FORM:

GLOBAL Enter only to specify this unit as the global unit.

UNIT n

COM=delim comment delim This optional comment can be up to 132 characters long. It must begin and end with a delimiter (i.e. “ , ‘ , * , ^ , or !)

fgeom mix no. bias ID dimensions optional origin data (ORIGIN coordinates) optional chord data (CHORD distance) optional center data (CENTER type X-offset Y-offset Z-offset)

Enter as many geometry description specifications as necessary to describe the unit and as many units as necessary to describe the system.

SIMPLE GEOMETRY REGION INPUT DATA REQUIREMENTS

TYPE OF DATA	TYPE 1 DATA	TYPE 2 DATA	TYPE 3 DATA	TYPE 4 DATA	TYPE 5 DATA	TYPE 6 DATA
fgeom	SPHERE	XCYLINDER	YCYLINDER	CYLINDER	CUBE	CUBOID
	HEMISPHERE	XHEMICYL+Y	YHEMICYL+X	ZCYLINDER		
	HEMISPHE+X	XHEMICYL–Y	YHEMICYL–X	ZHEMICYL+X		
	HEMISPHE–X	XHEMICYL+Z	YHEMICYL+Z	ZHEMICYL–X		
	HEMISPHE+Y	XHEMICYL–Z	YHEMICYL–Z	ZHEMICYL+Y		
	HEMISPHE–Y			ZHEMICYL–Y		
	HEMISPHE+Z					
	HEMISPHE–Z					
dimensions	R (radius)	R +X –X	R +Y –Y	R +Z –Z	+X –X	+X –X +Y –Y +Z –Z
optional origin coordinates*	Enter the X Y Z coordinates of origin	Enter the Y Z coordinates of centerline	Enter the X Z coordinates of centerline	Enter the X Y coordinates of centerline	omit	omit
optional chord data**	Enter the dist. to plane	Enter the dist. to plane	Enter the dist. to plane	Enter the dist. to plane	omit	omit
optional center data***	Center type	X-offset	X-offset	Z-offset	omit	omit

*Enter ORIG or ORIGIN for *fgeom*.

**Enter CHORD for *fgeom*.

***Center data are only applicable when flux moments (PNM>0) or angular fluxes (NQD>0) are requested with the coordinate transform (TFM) set to YES.

NOTE: Chord data are not applicable for SPHERE, XCYLINDER, YCYLINDER, CYLINDER, ZCYLINDER, CUBE, or CUBOID.
Origin data are not applicable for a CUBE or CUBOID.

Table 7.1.11: Unit cell specification for DOUBLEHET problems (continued).

GEOMETRY (region) (continued)

ENTER GEOMETRY DATA IN THE FOLLOWING FORM:

fgeom ref. ID bias ID thickness per region origin coordinates nreg

EXTENDED GEOMETRY REGION INPUT DATA REQUIREMENTS

TYPE OF DATA	TYPE 1 DATA	TYPE 2 DATA	TYPE 3 DATA
fgeom	ARRAY	HOLE	REPLICATE REFLECTOR
ref. ID	array no.	emplaced unit number	mixture number in generated regions
bias ID	omit for ARRAY	omit	first bias ID
thickness / region	omit	omit	variable[a]
origin coordinates	Enter the X Y Z coordinates of the most negative point of the array	Enter the X Y Z coordinates of the origin	omit
nreg	omit	omit	number of regions to be generated

[a]The number of dimensions to be entered is the same as the region preceding the replicate or reflector specification because the g enerated regions have that shape. The value of the dimensions is the thickness of each generated region of material on that surface and must therefore be a positive value.

Table 7.1.12: Unit cell specification for DOUBLEHET problems (continued).

(continued)

14	**PITCH** or **HPITCH**	Macro cell array pitch + moderator mixture	Always	ARRAY PITCH. This is the center-to-center spacing or half-spacing between the fuel lumps (pebbles or rods) in cm followed by the outer moderator material number, as shown in Figure 1 and Figure 2.
15	**FUELD** or **FUELR**	Macro cell fuel diameter or radius	Always	OUTSIDE DIMENSION OF FUEL. This is the outside diameter or radius of the fuel in cm, as shown in Figure 1 and Figure 2.
16	**FUELH**	Macro cell fuel height	Optional	HEIGHT OF FUEL ROD OR SLAB. This is the height of the fuel in cm.
17	**FUELW**	Macro cell fuel width	Optional	WIDTH OF FUEL SLAB. This is the width of the fuel in a plate element, in cm.
18	**GAPD** or **GAPR**	Macro cell gap diameter or radius + gap mixture	Optional	OUTSIDE DIMENSION OF GAP. Enter only if outer gap is present. This is the outside diameter or radius of the outer gap in cm followed by the gap mixture number, as shown in Figure 1 and Figure 2.
19	**CLADD** or **CLADR**	Macro cell clad diameter or radius + clad mixture	Optional	OUTSIDE DIMENSION OF CLAD. Enter ONLY if a clad is present. This is the outside diameter or radius of the outer clad in cm followed by the clad mixture number, as shown in Figure 1 and Figure 2.
20	**IMODD or IMODR**	Macro cell inner moderator diameter or radius + moderator mixture	Optional	OUTSIDE DIMENSION OF INNER MODERATOR . Enter ONLY for annular cells or asymmetric slab cells
21	**IGAPD or IGAPR**	Macro cell inner gap diameter or radius + gap mixture	Optional	OUTSIDE DIMENSION OF INNER GAP Enter ONLY if Annular cell + Inner Gap Present
22	**ICLADD or ICLADR**	Macro cell inner clad diameter or radius + clad mixture	Optional	OUTSIDE DIMENSION OF INNER CLAD. Enter ONLY if Annular cell + Inner Clad Present
23	**CELLMIX**	Cell-weighted mixture number	Optional	CELL-WEIGHTED MIXTURE NUMBER. Enter ONLY if cell-weighted macro-cell mixture is to be created (**Cell weighting of MG cross sections**).
24	**END**		Always	The word **END** is entered to terminate the **DOUBLEHET** data. An optional label can be associated with this **END**. The label can be as many as 12 characters long and is separated from the **END** by a single blank. At least two blanks must follow this entry.

continues on next page

7.1.3.8 Optional MORE DATA parameter data

MORE DATA is an optional sub-block of the **READ CELL** block. **MORE DATA** parameters allow certain default options in BONAMI and XSDRNPM to be modified for individual cell calculations. Each **MORE DATA** sub-block applies only to the unit cell immediately preceding it. However a **MORE DATA** sub-block placed prior to all unit cell definitions applies to all mixtures not assigned to a unit cell, which are treated as infinite homogeneous media. If the default parameters are acceptable, this section of input data should be omitted in its entirety. Non-default values for one or more of the parameters can be specified by entering the words **MORE DATA** followed by the desired keyword parameters and their associated values. One or more of the parameters can be entered in any order. Default values are used for parameters that are not entered. Each parameter is entered by spelling its name, followed immediately by an equal sign and the value to be entered. There should not be a blank between the parameter name and the equal sign. Each parameter specification must be separated from the rest by at least one blank. For example, if an XSDRNPM calculation is performed for particular unit cell (e.g., *cellmix*= is specified),

MORE DATA ISN=16 **EPS**=0.00008 **END MORE**

would result in using an S16 angular quadrature set and tightening the convergence criteria to 0.00008 in the XSDRNPM calculation.

A description of each entry is given. (Also see sections on BONAMI and XSDRNPM input description.)

1. **MORE DATA** These words, followed by one or more blanks, are entered ONLY if optional parameter data are to be entered. Entries 2 through 42 can be entered in any order.
2. **NSENSX** This is the XSDRNPM sensitivity output file for TSUNAMI sequences.
3. **CROSSEDT** BONAMI CROSS SECTION EDIT. Cross section print option for BONAMI 0/1 –no/yes (default is 0).
4. **FFACTEDT** BONDARENKO FACTOR EDIT. Bondarenko factor (f-factor) print option 0/1 –no/yes (default is 0).
5. **ISSOPT** BONAMI BACKGROUND XSEC OPTIONS. BONAMI background cross section selection option if > 1000 potential; otherwise, total cross section is used (default is –1).
6. **IROPT** BONAMI IR/NR CALCULATION OPTION. BONAMI uses intermediate resonance (IR) if iropt=1 and narrow resonance (NR) approximation for iropt=0 (default is 0).
7. **BELLOPT** BELL FACTOR OPTION. Optional user-defined bell factor calculation option (default is -1).
8. **BELLFACT** BELL FACTOR. Optional user-defined bell factor for BONAMI (default is 0.0).
9. **ESCXSOPT** ESCAPE CROSS SECTION CALC OPTION. Escape cross section calculation for IR calculations. 0/1 =consistent/inconsis tent (default is 0).
10. **BONAMIEPS** BONAMI CONVERGENCE CRITERIA. BONAMI Bondarenko iteration convergence criteria (default is 0.001).
11. **LBARIN** INPUT MEAN CORD LENGTH. Mean cord length for each zone (default is 0.00).
12. **ADJTHERM** ADJUST 1D THERMAL CROSS SECTIONS TO MATCH SUM OF 2D CROSS SECTIONS. Flag determining whether 1-D cross sections are scaled to match the 2-D cross sections or the 2-D cross sections are scaled to match the 1-D cross sections.

13. **EXSIG** ESCAPE CROSS SECTION. External escape cross section for BONAMI (default is 0.00).

14. **IEVT** XSDRNPM CALCULATION TYPE. The type of calculation to be performed- fixed source, eigenvalue, alpha, zone width search, outer radius search, buckling search, direct buckling search (default is 1).

15. **ICLC** THEORY OPTION. Number of outer iterations to use an alternative theory (diffusion, infinite medium, or B_N) before using discrete ordinates. Negative values indicate alternative theory (default is 0).

16. **IPVT** PARAMETRIC EIGENVALUE SEARCH. 0 – none; 1 – search for eigenvalue equal PV; 2 – alpha search (default is 0).

17. **IPP** WEIGHTED CROSS SECTION PRINT. 2 -> No print; -1 -> 1-D edit; 0-N – edit through PN cross section arrays (default is 2).

18. **IFLU** GENERALIZED ADJOINT CALCULATION. 0 is a standard calculation; 1 is a generalized adjoint calculation (default is 0).

19. **IFSN** FISSION SOURCE SUPPRESSION. Non-zero suppresses the fission source in a fixed source calculation (default is 0).

20. **IQM** VOLUMETRIC FIXED SOURCES. The number of volumetric sources in a fixed source problem (default is 0).

21. **IPM** BOUNDARY FIXED SOURCES. The number of boundary sources in a fixed source problem (default is 0).

22. **XNF** SOURCE NORMALIZATION FACTOR. The value used to normalize the problem source (default is 1.0).

23. **VSC** VOID STREAMING CORRECTION. The height of a void streaming path in a cylinder or slab in centimeters (default is 0.0).

24. **EV** EIGENVALUE GUESS. Starting eigenvalue guess for a search calculation (default is 0.0).

25. **EQL** INITIAL SEARCH CONVERGENCE. Initial eigenvalue search convergence (default is 0.0001).

26. **XNPM** DAMPING FACTOR. Damping factor used in search calculations (default is 0.75).

27. **ISN** ORDER OF ANGULAR QUADRATURE FOR XSDRNPM. Quadrature sets are geometry-dependent quantities that are defaulted to order 8 by the XSProc for **LATTICECELL** and cylindrical **MULTIREGION**. The default is 32 for **MULTIREGION** slabs and spheres. See the automatic quadrature generator and Appendix B for a more detailed explanation.

28. **SZF** SPATIAL MESH SIZE FACTOR FOR XSDRNPM. The size of the mesh intervals can be adjusted by entering a value for **SZF**, which is a multiplier of the mesh size. The default value is 1.0. A value between zero and 1.0 yields a finer mesh; a value greater than 1.0 yields a coarser mesh. If **SZF** $\leq$ 0, the user specifies the number of mesh intervals in each zone immediately following the **MORE DATA** block. If **SZF** = 0, the interval spacing is automatically generated, while if **SZF** < 0 the intervals are equally spaced intervals in each zone.

29. **IIM** MAXIMUM NUMBER OF INNER ITERATIONS FOR XSDRNPM. This is the maximum number of inner iterations to be used in the XSDRNPM calculation. The default value is 20. See Appendix B for a more detailed explanation.

30. **ICM** MAXIMUM NUMBER OF OUTER ITERATIONS FOR XSDRNPM. This is the maximum number of outer iterations to be used in the XSDRNPM calculation. The default value is 25. If the calculation reaches the outer iteration limit, a larger value should be used. See Appendix B for a more detailed explanation.

31. **EPS** OVERALL CONVERGENCE CRITERIA FOR XSDRNPM. This is used by XSDRNPM after each outer iteration to determine if the problem has converged. The default value of **EPS** is 0.00001. A value less than 0.00001 tightens the convergence criteria; a larger value loosens the convergence criteria.

32. **PTC** POINTWISE CONVERGENCE CRITERIA FOR XSDRNPM. This is the point flux convergence criteria used by XSDRNPM to determine if convergence has been achieved after an inner iteration. The default value for PTC is 0.000001. A smaller value tightens convergence; a larger value loosens it.

33. **BKL** BUCKLING FACTOR FOR XSDRNPM. A buckling factor should be used ONLY for a **MULTIREGION BUCKLEDSLAB** or **BUCKLEDCYL** problem. Because cylinders are assumed to be infinitely long and slabs are assumed to be infinite in both transverse directions, the analytic sequence may tend to overestimate the total flux for a finite system. A buckling correction can be used to approximate the leakage from the system in the transverse direction(s). The extrapolation distance factor, **BKL**, is defaulted to 1.420892.

34. **IUS** UPSCATTER SCALING FLAG for XSDRNPM. This option allows the use of upscatter scaling to accelerate the solution or force convergence. The default value is zero, in which case upscatter scaling is not used. **IUS**=1 facilitates upscatter scaling. Guidelines are not available to indicate when upscatter scaling is needed. Some problems will not converge with it, and some will not converge without it. See Appendix B for a more detailed explanation.

35. **DAN**(mm) DANCOFF FACTOR for the specified mixtures used in BONAMI and in the CENTRM 2REGION option. This value overrides the internally computed Dancoff factor used in the resonance correction for the specified mixture *mm*. The Dancoff data are entered in the form **DAN**(mm) = Dancoff factor. Note that the parentheses must be entered as part of the data, and the mixture number, mm, must be enclosed in the parentheses. See Appendix B for additional details. (Note: this is not to be confused with the DAN2PITCH parameter in CENTRMDATA)

36. **BAL** BALANCE TABLE PRINT FLAG for XSDRNPM. This allows control of the balance table print from **XSDRNPM**. The default value is **FINE**. **BAL**=**NONE** suppresses the balance table print. **BAL**=**ALL** prints all of the balance tables. **BAL**=**FINE** prints only the fine-group balance tables. See Appendix B for additional details.

37. **DY** FIRST TRANSVERSE DIMENSION for XSDRNPM. This is the first transverse dimension, in cm, used in a buckling correction to calculate the leakage normal to the principal calculation direction (the height of a slab or cylinder). It should only be entered if XSDRNPM is to create cell-weighted cross sections and/or calculate the eigenvalue of a cylinder or slab system of finite height for a **LATTICECELL** problem. **DY**= is defaulted to an infinite height, or is set to **DY** for a buckled **MULTIREGION** cell description. A value entered here overrides any buckling height value entered in the **MULTIREGION** data.

38. **DZ** SECOND TRANSVERSE DIMENSION for XSDRNPM. This is the second transverse dimension, in cm, used for a buckling correction for a slab of finite width. It should only be entered if XSDRNPM is to create cell-weighted cross sections and/or calculate the eigenvalue of a **LATTICECELL** slab of finite width. **DZ**= is defaulted to an infinite width, or is set to **DZ** for a buckled **MULTIREGION** slab cell of finite width. A value entered here overrides any buckling depth value entered in the **MULTIREGION** data.

39. **COF** DIFFUSION COEFFICIENT FOR TRANSVERSE LEAKAGE CORRECTIONS IN XSDRNPM. The default value is 3. The available options are as follows.

    COF=0 sets a transport-corrected cross section for each zone

    COF=1 use a spatially averaged diffusion coefficient for each zone

    COF=2 use a diffusion coefficient for all zones that is one-third of the diffusion coefficient determined from the spatially averaged transport cross section for all zones

    COF=3 use a flux and volume weighting across all zones

    See Appendix B or XSDRNPM Input/Output Assignments in the XSDRNPM chapter, 3$ array, variable **IPN** for more details.

40. **NT3** UNIT WHERE XSDRNPM WRITES THE WEIGHTED LIBRARY. If XSDRN does a weighting calculation, this is the unit number it uses to write the weighted library on (default is 3).

41. **NT4** UNIT WHERE XSDRNPM WRITES THE ANGULAR FLUXES. XSDRN writes the angular fluxes on this unit if it is non-zero (default is 16).

42. **ADJ** Adjoint mode flag for XSDRNPM. Set to 1 to cause XSDRNPM to solve the adjoint problem (default is 0).

43. **NTA** UNIT WHERE XSDRNPM WRITES THE ACTIVITIES. XSDRN writes the calculated activities on this unit if it is non-zero (default is 75).

44. **NBU** UNIT WHERE XSDRNPM WRITES BALANCE TABLES. If the balance tables file is to be saved, enter the unit number where it is to be written (default is 76).

45. **NTC** UNIT WHERE XSDRNPM WRITES THE DERIVED DATA. XSDRN writes the derived input data on this unit if it is non-zero (default is 73).

46. **NTD** UNIT WHERE XSDRNPM WRITES THE DATA FOR A SENSITIVITY ANALYSIS. XSDRN writes the data for a sensitivity analysis on this unit if it is non-zero (default is 0).

47. **FRD** UNIT WHERE XSDRNPM READS INPUT FLUX GUESS. If greater than 0, a flux guess will be read from this unit.

48. **FWR** UNIT WHERE XSDRNPM WRITES OUPUT FLUX. If greater than 0, the space-dependent multigroup scalar flux is written in binary format to this unit.

49. **WGT** CROSS SECTION WEIGHTING FLAG for XSDRNPM. The default is 0, not to perform cross section weighting. To turn on cross section weighting, a positive value should be entered. A value of 1 will weight the cross sections by nuclide; 2 will weight by mixture.

50. **ZMD**(iz) ZONE WIDTH MODIFIERs for an XSDRNPM search problem. This allows entering a zone width modifier for zone iz in the XSDRNPM problem description. The zone width data are entered in the following form:

    ZMD(iz)=modifier

    Note that the parentheses must be entered as part of the keyword. The zone number iz, to which the modifier is applied, must be enclosed in the parentheses. The modifier is entered after the equal sign. See the "Dimension Search Calculations" description in the XSDRNPM chapter for more information.

51. **INT**(iz) NUMBER OF MESH INTERVALS FOR ZONE IZ in XSDRNPM. The default is 0, which causes the number to be calculated. The data are entered in the following form:

    INT(iz)=number

Note that the parentheses must be entered as part of the keyword. The zone number iz, for which the number of intervals is specified, must be enclosed in the parentheses. The number of intervals is entered after the equal sign.

52. **KEF** DESIRED VALUE OF k_{EFF} for an XSDRNPM zone width search. The default value is 1.0. If it is desired to search for some other value, such as 0.9, then input it here.

53. **KFM** The first eigenvalue modifier used in an XSDRNPM search. This value is used to make the first change in the XSDRNPM search. The default value is -0.1. A user may sometimes need to change this to make the search converge.

54. **ID1** SCALAR FLUX PRINT CONTROL. The default value is -1, which suppresses printing the scalar fluxes in XSDRNPM. See the XSDRNPM Input/Output Assignments section in the XSDRNPM chapter, 2$ array, variable **ID1** for allowed values and corresponding actions.

55. **ISCT** ORDER OF SCATTERING for XSDRMPM. The default is 5 for all libraries.

56. **ICON** TYPE OF WEIGHTING (see Cross-Section Weighting section in the XSDRNPM chapter).

    INNERCELL - followed by integer N (zones in the cell). Cell weighting is performed over the N innermost regions in the problem. Nuclides outside these regions are not weighted.

    CELL - cell weighting

    ZONE - zone weighting

    REGION - region weighting

57. **IGMF** NUMBER OF GROUPS IN COLLAPSED LIBRARY. Enter number of groups after equal sign, followed by group lower energy boundaries (eV) in descending order.

58. **ITP** COLLAPSED OUTPUT FORMAT. The default is 0.

    0-19 - cross sections are written only in the AMPX weighted library formats on logical 3. A weighted library is always written when IFG=1.

    The various values of ITP (modulo 10) are used to select the different transport cross section weighting options mentioned earlier. The options are as follows:

    ITP = 0, 10, ... $\sqrt{(\psi_1^g + (DG\psi))^2}$

    ITP = 1 ,11, ... absolute value of current

    ITP = 2, 12, ... $DB^2\psi_g$ + outside leakage

    ITP = 3, 13, ... $\frac{\psi}{\Sigma_t^g}$

    ITP = 4, 14, ... $DB\psi_g$

    ITP = Other values are reserved for future development and should not be used.

59. **GAMMA_MT_LIST** LIST OF GAMMA 1D REACTIONS ASSOCIATED WITH INPUT. A list of 1-D gamma reactions to be included on a condensed library for later use gamma_mt_list= numberEntries mt1 mt2 ... mt_numberEntries.

60. **NEUTRON_MT_LIST** LIST OF NEUTRON 1D REACTIONS ASSOCIATED WITH INPUT. A list of 1-D neutron reactions to be included on a condensed library for later use neutron_mt_list= numberEntries mt1 mt2 ... mt_numberEntries.

61. **NEUTRON_2D_LIST** LIST OF NEUTRON 2D ARRAYS FOR THE MICRO LIBRARY. This list flags the finalizer to place 2-D arrays (currently MT 2, 4, 16) on the micro library for use in SAMS.
62. **ACTIVITY** Enter:

    IAZ (number of activities)

    IAI (calculate activities by zone or interval)

        0 – zone

        1 – interval

    LACFX (unit number to which activities are written)

    LAZ (IAZ sets of numbers consisting of the nuclide and process numbers for each activity)
63. **BAND** NUMBER OF REBALANCE BANDS for XSDRNPM (default is 1).
64. **IPRT** CROSS SECTION PRINT CONTROL. The default value is -2, which suppresses printing the cross sections in XSDRNPM. See XSDRNPM chapter, 2$ array, variable IPRT for allowed value, and corresponding actions.
65. **GRAIN_K** Flag to control execution of XSDRNPM after each grain calculation for a **DOUBLEHET** cell.
66. **SOURCE**(iz) ZONE SOURCE for an XSDRNPM fixed source problem. This allows entering a source spectrum for zone iz in the XSDRNPM problem description. The source spectrum data are entered in the following form:

    SOURCE(iz)= numEntries spectrum_grp_1 . . . spectrum_grp_numEntries

    Note that the parentheses must be entered as part of the keyword. The zone number, iz, to which the spectrum is applied, must be enclosed by the parentheses. The numEntries follows the equal sign and must be less than or equal to the number of energy groups for the problem. It is followed by numEntries numbers defining the spectrum for the first numEntries groups for zone iz. Groups not defined are set to zero. The spectrum applies uniformly to zone iz. A different spectrum may be entered for different zones.
67. **END MORE** Terminate the optional parameter data.

7.1.3.9 Optional CENTRM DATA parameter data

The CENTRM DATA block defines input parameter values for the CENTRM, PMC and CRAWDAD modules. XSProc defines default values for these parameters which are adequate for most applications. If all default values are acceptable, this section of input data can be omitted. The CENTRM DATA block applies only to the unit cell immediately preceding it. CENTRM DATA placed prior to all unit cell data applies to all materials not listed in any unit cell. Parameter values are assigned by entering the words **CENTRM DATA** followed by the desired keyword parameters and their associated values. One or more parameters can be entered in any order. There should not be a blank between the parameter name and the equal sign. Each parameter specification must be separated from the rest by at least one blank. For example,

CENTRM DATA ISN=16 **PTC**=0.0008 **N1D**=1 **END CENTRM DATA**

A description of CENTRM DATA parameters is given below.

1. **CENTRM DATA** These words, followed by one or more blanks, are entered ONLY if optional parameter data are to be entered. They must precede all other optional parameter data. Entries 2 through 42 can be entered in any order.

2. **ISN** ORDER OF SN ANGULAR QUADRATURE FOR CENTRM. SN Quadrature sets are geometry-dependent quantities. Default value for **ISN** is 6 (only used for **NFST** and **NTHR**=0; and **NPXS**=1).

3. **ISCT** LEGENDRE POLYNOMIAL P_N ORDER OF SCATTERING. These are used to determine the number of moments calculated for the scattering cross sections. Default value is 0 for 2-D MoC option and 1 for 1-D S_n, which have been found adequate for nearly all cases.

4. **IIM** MAXIMUM NUMBER OF INNER ITERATIONS. This is the maximum number of inner iterations for Sn transport calculations in CENTRM. Default value is 10.

5. **IUP** MAXIMUM NUMBER OF OUTER ITERATIONS IN THERMAL RANGE. This is the maximum number of outer iterations used to converge PW flux changes caused by upscattering in the thermal range. Default value is 3. More iterations (~ 15) may be required for higher accuracy in some cases.

6. **NFST** FAST RANGE MULTIGROUP CALCULATION OPTION, E > **DEMAX**. This determines what type of calculation is done above **DEMAX**. The options are (0) S:sub:*N*, (1) diffusion theory, (2) homogenized infinite medium, (3) zonewise infinite medium, or (6) 2D MoC lattice cell [NOTE: NFST=4,5 are deprecated]. Default value is 0 (S_N).

7. **NTHR** THERMAL RANGE MULTIGROUP CALCULATION OPTION, E < **DEMIN**. This determines what type of calculation is done below **DEMIN**. The options include (0) S:sub:*N*, (1) diffusion, (2) homogenized infinite medium, (3) zonewise infinite medium, or (6) 2-D MoC lattice cell [NOTE: NTHR=4,5 are deprecated]. Default value is 0 (S_N).

8. **NPXS** POINTWISE RANGE MULTIGROUP CALCULATION OPTION, **DEMIN** < E < **DEMAX**. This determines what type of calculation is done between **DEMIN** and **DEMAX**. The options include (0) MG calculation, (1) 1-D S_N, (2) collision probability, (3) homogenized infinite medium, (4) zonewise infinite medium, (5) two-region, or (6) 2-D MoC lattice cell. Default value is 1 (S_N), except for square-pitch LATTICECELL where the default is 6 (2D MoC).

9. **ISVAR** LINEARIZATION OPTION. This determines if the MG source and/or the cross sections are linearized in CENTRM calculations. Options for linearizing are (0) neither, (1) source, (2) cross section, or (3) both. Default value is 3.

10. **ISCTI** LEGENDRE POLYNOMIAL P_N ORDER OF SCATTERING IN THE INELASTIC RANGE. These are used to determine the number of moments calculated for the inelastic scattering cross sections. Default value is 0, isotropic.

11. **NMF6** INELASTIC FLAG. This determines if inelastic data are used. The options are to include (-1) no inelastic data, (0) discrete inelastic data, and (1) discrete inelastic and continuum. Default value is -1. Use of **NMF6**=1 is not recommended due to long running times.

12. **IPRT** MIXTURE CROSS-SECTION OUTPUT OPTION. This determines the output of cross section. The options include (-3) none, (-2) output macro PW cross sections to file "_centrm.pw.macroxs", (-1) 1-D MG cross sections, (N) P_0 to P_N MG 2-D matrices. Default value is -3, none.

13. **ID1** FLUX EDIT OPTION. This option determines the output of flux energy spectra. The options are (-1) none, (0) print MG fluxes, (1) also print MG flux moments, (2) save CE fluxes on output file, "_centrm.pw_flux". Default value is -1.

14. **KERNEL** BOUND KERNELS. This indicates use of CENTRM PW thermal kernel data [S(α,:math:*beta*)] for bound nuclides if **KERNEL**=1. If **KERNEL**=0, all thermal kernels are treated as free gas; Default is 1, use bound scattering kernels if available.

15. **IPBT** PRINT GROUP SUMMARY TABLES. Group summary tables for each zone are printed in CENTRM if greater than 0. Default is 0. Balance ratios are not computed in thermal groups or for MoC option.

16. **IPN** GROUP DIFFUSION COEFFICENT. Used for DB^2 loss term. See XSDRNPM chapter for more information. Default is 2.

17. **IXPRT** PRINT OPTION FOR CENTRM. This value is >0 if more information is printed to output. Default value is 0, minimum output.

18. **MLIM** MASS VALUE RESTRICTION ON ORDER OF SCATTERING. Nuclides with mass ratios greater than **MLIM** are limited to a **NLIM** order of scattering. Default value is 100.

19. **NLIM** ORDER OF SCATTERING RESTRICTION. This is the limiting order of scattering for all nuclides with mass ratios greater than **MLIM**. Default value is 0.

20. **EPS** INTEGRAL CONVERGENCE CRITERIA. This is used by CENTRM after each outer iteration to determine if the problem has converged. Default value is 0.001. A value less than 0.0001 tightens the convergence criteria; a larger value loosens the convergence criteria.

21. **PTC** POINTWISE CONVERGENCE CRITERIA. This is the point flux convergence criteria used by CENTRM to determine if convergence has been achieved after an inner iteration. Default value is 0.0001. A smaller value tightens convergence; a larger value loosens it.

22. **B2** MATERIAL BUCKLING FACTOR (cm^{-2}). This is used with a buckled system. If a buckled system is specified for a unit cell, the code will use this value. Default value is 0.0.

23. **DEMIN** LOWEST ENERGY OF POINTWISE FLUX CALCULATION. This value is the lowest energy (eV) for which CENTRM calculates PW fluxes. Default is 0.001 eV.

24. **DEMAX** HIGHEST ENERGY OF POINTWISE FLUX CALCULATION. This value is the highest energy (eV) for which CENTRM calculates PW fluxes. Default is 20,000.0 eV, which encompasses the resolved resonance range of all actinides. It is recommended that DEMAX be <500 keV.

25. **TOLE** CENTRM PW THINNING TOLERANCE. This is the tolerance used to thin the PW material cross sections after they are mixed. Default value is 0.001.

26. **FLET** FRACTIONAL LETHARGY CONSTRAINT. This is the maximum lethargy difference between points in the flux solution energy mesh. Smaller values increase the number of energy points. Default value is 0.1.

27. **DAN2PITCH** CENTRM DANCOFF FACTOR SEARCH. Fuel Dancoff factor to search for a Dancoff-equivalent pitch used in the CENTRM cell calculation. Only applicable in LATTICECELL and DOUBLEHET cases with fuel in center region, with SN or MoC transport solvers. Default is 0, which indicates no pitch modification. NOTE! This option should not be used to enter Dancoff factors for the CENTRM *2REGION* transport option-use EDAN(m) array in **MOREDATA** for these values.

28. **MRANGE** PMC GROUP CROSS-SECTION PROCESSING RANGE. This option determines the range over which the group cross sections will be processed. The options are (0) compute new group cross section over the PW range, (1) over the resolved resonance range of each nuclide, or (2) over the PW flux range (**DEMAX** to **DEMIN**). Default value is 2.

29. **N2D** PMC ELASTIC MATRIX PROCESSING FLAG. This option determines how MG P_N elastic scattering matrices are obtained. Options are (-2) perform operations in both (-1) and (2); (-1) compute P0 self-scatter, then renormalize matrix to shielded 1-D elastic values; (0) normalize original scatter

matrix to shielded 1-D elastic values; (1) compute new P_N moments of elastic matrix using scalar flux and S-wave kinematics for both thermal and epithermal energy ranges; or (2) use flux-moments to compute "consistent PN" correction for diagonal elements of elastic P_N components. Default value is -1. For unit cell calculations in reactor lattices, option -2 may improve results. NOTE: option 0 is always used in thermal range except for option 1.

30. **IXTR3** PMC P_N ORDER FLAG. This option determines the maximum order of Legendre moments to be retained on output MG library. The default is 5; i.e., retain scattering moments up to P_5 if available on the input MG library. If (-1) is entered, all elastic moments on the MG library are included.

31. **NPRT** PMC PRINT FLAG. This option determines what is printed to output. The options include (-1) minimum output, (0) standard output, (1) print 1-D cross sections, (2) print both 1-D and 2-D cross sections. Default value is -1, minimum output.

32. **NWT** PMC MULTIGROUP SPATIAL-WEIGHTING FLAG. This option determines if the MG data are (0) zone-weighted or (1) cell-weighted. Default value is 0.

33. **MTT** PMC MT PROCESSING FLAG. This option determines if reaction MTs are processed individually or treat dependencies explicitly. If **MTT**=0 all MTs are processed independently; if **MTT**=1, all MTs are processed except 1, 27, and 101. These are then computed as follows: MT101 = sum MT102 - 114, MT27 = MT18 + MT101, MT1 = MT2 + MT4 + MT16 + MT17 + MT27. Default value is 1.

34. **N1D** PMC WEIGHTING FUNCTION FLAG. This is used to determine if (0) flux weighting or (1) current weighting is used to collapse the cross sections. Default value is 0, flux weighting.

35. **PMC_DILUTE** PMC DILUTE BACKGROUND CROSS SECTION. The background cross section σ_0 value above which nuclide cross sections are not processed in PMC but the BONAMI cross sections are used instead. No resonance shielding corrections are performed for materials with background cross sections greater than *pmc_dilute*. Higher values of *pmc_dilute* result in more nuclides being processed. The default value is 1.0E10.

36. **MTOUT** PW REACTION TYPES. Reactions included by CRAWDAD on PW library for MG processing in PMC: (0) all; (1) output only MTs 1, 2, 4, 102, 18, 452, 455, 456 (and 107 for ^{10}B or ^{7}Li); (2) all from option (1) and all inelastic MTs and 16. Default is **MTOUT**=1 for **NMF6**=-1 and **MTOUT**=2 for **NMF6**>-1.

37. **IBR** CENTRM RIGHT BOUNDARY TYPE. Type of boundary condition on right boundary of unit cell for CENTRM **LATTICECELL** calculations. See allowable IBR values in CENTRM. Default is white (**IBR** = 3) for 1D SN; 2D MoC transport option always uses reflected.

38. **IBL** CENTRM LEFT BOUNDARY TYPE. Same as **IBR**, but for left boundary. Default is reflected (**IBL** = 1).

39. **ALUMP** MASS LUMPING FRACTION. A value in range [0.0, 1.0] indicates fractional mass lumping criterion for CENTRM. Value of 0 indicates no lumping applied. For example, **ALUMP**=0.3 means that materials are combined into one or more lumps such that their masses are within +/-30% of the effective lump mass, while preserving the slowing-down power. This approximation reduces execution time. Default value is 0.2.

40. **PMC_OMIT** PMC NUCLIDES SKIPPED. PMC normally processes problem-dependent (e.g., self-shielded) MG cross sections for all materials. If **PMC_OMIT**=1, processing is only performed for materials contained in fuel mixtures. Default value is 0 (all materials processed).

41. **PXSMEM** CENTRM PW DATA STORAGE. Option to store PW data in memory or in external file during centrm execution. If **PXSMEM**=1, PW cross section data are stored by group in external scratch file during CENTRM calculation; if **PXSMEM**=0 (default value), all PW cross sections are kept in memory.
42. **MOCMESH** CENTRM MOC MESH OPTION. Pre-defined space mesh intervals for CENTRM MoC calculation: 0=>coarse mesh (1 interval per zone); 1=>regular mesh (4 intervals in fuel, 2 in moderator, 1 in others); 2=> fine mesh (8 in fuel, 4 in moderator, 1 in others). Default=0.
43. **MOCRAY** CENTRM MOC RAY SPACING. Distance between characteristic rays in CENTRM MoC calculation. Default=0.02.
44. **MOCPOL** CENTRM NUMBER OF MOC POLAR ANGLES. Allowable values are 2, 3, 4. Default=3 (only used for **NPXS**=6).
45. **MOCAZI** CENTRM NUMBER OF MOC AZIMUTHAL ANGLES. Allowable values are 2–16. Default=8 (only used for **NPXS**=6).
46. **MOCZONE_INT** CENTRM MOC MESH BY ZONE. User-defined mesh intervals by zone; e.g., moczone_int(1)=5 defines five intervals for zone 1; zero value means not used. This overrides the predefined meshs described by **MOCMESH**
47. **ISRC** CENTRM SOURCE TYPE. CENTRM can use a fission-spectrum source (isrc=1), an input source spectrum (isrc=0), or a combination(isrc=3) for transport. Default=1.
48. **XNF** CENTRM SOURCE NORMALIZATION. The integrated source (fission-spectrum and/or fixed source spectrum) is normalized to this value. Default=1.0.
49. **ITERP** CRAWDAD TEMPERATURE INTERPOLATION METHOD. Method to use for CE cross section interpolation 0=>combination of square-root(T) and finite-difference; 1=>only square-root(T); 2=> only finite-difference. Default is 0.
50. **END CENTRM** The word **END** is entered to terminate the optional parameter data. A label can be associated with this **END**. The label can be as long as 12 characters but must be preceded by a single blank. If this **END** is entered without a label, it must not begin in column 1. At least two blanks must follow this entry.

7.1.4 APPENDICES

7.1.4.1 XSProc: Standard Composition Examples

Standard composition fundamentals

The standard composition specification data are used to define mixtures using standardized engineering data entered in a free-form format. The XSProc uses the standard composition specification data and information from the Standard Composition Library to provide number densities for each nuclide of every defined mixture according to Eq. (7.1.1).

$$NO = \frac{RHO \times AVN \times C}{AWT}, \tag{7.1.1}$$

where

NO is the number density of the nuclide in atoms/b-cm,

RHO is the actual density of the nuclide in g/cm^3,

AVN is Avogadro's number, $6.02214199 \times 10^{23}$, in atoms/mol,

C is a constant, 10^{-24} cm^2/b,

AWT is the atomic or molecular weight of the nuclide in g/mol.

The actual density, RHO, is defined by

$$RHO = ROTH \times VF \times WGTF, \tag{7.1.2}$$

where

RHO is the actual density of the standard composition in g/cm^3,

ROTH is either the specified density of the standard composition or the theoretical density of the standard composition in g/cm^3,

VF is a density multiplier compatible with ROTH as defined by Eq. Eq. (7.1.3),

WGTF is the weight fraction of the nuclide in the standard composition. This value is automatically obtained by the code from the Standard Composition Library. WGTF is 1.0 for a single nuclide standard composition.

$$VF = DFRAC \times VFRAC, \tag{7.1.3}$$

where

VF is the density multiplier,

DFRAC is the density fraction,

VFRAC is the volume fraction.

To illustrate the interaction between ROTH and VF, consider an Inconel having a density of 8.5 g/cm^3. It is 7.0% by weight iron, 15.5% chromium, and 77.5% nickel. The Inconel occupies a volume of 4 cm^3.

Method 1:

To describe the iron, enter 8.5 for ROTH and 0.07 for VF.

To describe the chromium, enter 8.5 for ROTH and 0.155 for VF.

To describe the nickel, enter 8.5 for ROTH and 0.775 for VF.

Method 2:

Do not enter the density, and by default the theoretical density of each component will be used for ROTH. DFRAC will be the ratio of the specified density to the theoretical density. The specified density of each component is the density of the Inconel × the weight fraction of that component.

Thus, the density of the iron is $8.5 \times 0.07 = 0.595$ g/cm^3

chromium is $8.5 \times 0.155 = 1.318$ g/cm^3

nickel is $8.5 \times 0.775 = 6.588$ g/cm^3.

To calculate DFRAC, the theoretical density of each material must be obtained from the table *Elements and special nuclide symbols* in the STDCMP chapter. These values are

7.86 g/cm^3 for iron

8.90 g/cm^3 for nickel

7.20 g/cm^3 for chromium

The DFRAC entered for the iron is 0.595/7.86 = 0.0757

for the nickel is 1.318/8.90 = 0.1481

for the chromium is 6.588/7.20 = 0.9163.

Since there are no volumetric corrections, VFRAC is 1.0 and the values of DFRAC are entered for VF.

Method 3:

Assume the Inconel, which occupies 4 cm^3, is to be spread over a volume of 5 cm^3. Then the volume fraction, VFRAC, is 4 cm^3/5 cm^3 = 0.8 and can be combined with the density fraction, DFRAC, to obtain the density multiplier, VF.

To describe the iron, enter 8.5 for ROTH and 0.07 × 0.8 = 0.056 for VF

To describe the chromium, enter 8.5 for ROTH and 0.155 × 0.8 = 0.124 for VF

To describe the nickel, enter 8.5 for ROTH and 0.775 × 0.8 = 0.620 for VF.

Alternatively, the volume fraction can be applied to the density before it is entered. Then the ROTH can be entered as 8.5 g/cm^3 × 0.8 = 6.8 g/cm^3, and DFRAC is entered for the density multiplier, VF.

To describe the iron, enter 6.8 for ROTH and 0.07 for VF

for chromium, enter 6.8 for ROTH and 0.155 for VF

for nickel, enter 6.8 for ROTH and 0.775 for VF.

Method 4:

Assume the Inconel, which occupies 4 cm^3, is to be spread over a volume of 5 cm^3. Then the volume fraction, VFRAC, is 4 cm^3/5 cm^3 = 0.8. Do not enter the density, and by default the theoretical density of each component will be used for ROTH.

VF is then entered as the product of VFRAC and DFRAC according to Eq. . The specified density of each component is the density of the Inconel × the weight fraction of that component.

Thus, the density of the iron is 8.5 × 0.07 = 0.595 g/cm^3

Chromium is 8.5 × 0.155 = 1.318 g/cm^3

Nickel is 8.5 × 0.775 = 6.588 g/cm^3.

To calculate DFRAC, the theoretical density of each material must be obtained from Table 7.2.3. These values are

7.86 g/cm^3 for iron 8.90 g/cm^3 for nickel 7.20 g/cm^3 for chromium.

Then DFRAC for the iron is 0.595/7.86 = 0.0756

for nickel is 1.318/8.90 = 0.1481

for chromium is 6.588/7.20 = 0.9150.

Then VF is DFRAC × VFRAC

VF for the iron is 0.0757 × 0.8 = 0.0606

for nickel is 0.1481 × 0.8 = 0.1185

for chromium is 0.9150 × .8 = 0.7320.

Basic standard composition specifications

EXAMPLE 1. Material name is given. Create a mixture 3 that is Plexiglas.

Since no other information is given, the information on the Standard Composition Library can be assumed to be adequate. Therefore, the only data to be entered are the standard composition name and the mixture number

```
PLEXIGLAS  3  END
```

EXAMPLE 2. Material name and density (g/cm^3) are given.

Create a mixture 3 that is Plexiglas at a density of 1.15 g/cm^3. Since no other data are specified, the defaults from the Standard Composition Library will be used. Therefore, the only data to be entered are the standard composition name, the mixture number, and the density.

```
PLEXIGLAS  3  DEN=1.15  END
```

EXAMPLE 3. Material name and number density (atoms/b-cm) are given. Create a mixture 2 that is aluminum having a number density of 0.060244.

```
AL  2  0  .060244  END
```

EXAMPLE 4. Material name, density (g/cm^3) and isotopic abundance are given.

Create a mixture 1 that is uranium metal at 18.76 g/cm^3 whose isotopic composition is 93.2 wt % ^{235}U, 5.6 wt % ^{238}U, and 1.0 wt % ^{234}U, and 0.2 wt % ^{236}U. This example uses the DEN= keyword to enter the density and define the standard composition. Example 5 demonstrates another method of defining the standard composition.

```
URANIUM   1  DEN=18.76 1 300  92235  93.2  92238  5.6  92234  1.0  92236  0.2  END
```

EXAMPLE 5. Material name, density (g/cm^3) and isotopic abundance are given.

Create a mixture 7 defining B_4C with a density of 2.45 g/cm^3. The boron is 40 wt % ^{10}B and 60 wt % ^{11}B. This example utilizes the **DEN**= keyword. Example 6 illustrates an alternative description.

```
B4C 7  DEN=2.45  1.0 300  5010  40.0  5011  60.0  END
```

EXAMPLE 6. Material name, density (g/cm^3) and isotopic abundance are given.

Create a mixture 7 defining B_4C with a density of 2.45 g/cm^3. The boron is 40 wt % ^{10}B and 60 wt % ^{11}B. This example incorporates the known density into the density multiplier, *vf*, rather than using the **DEN**= keyword. The default density for B_4C given in the COMPOUNDS table in the SCL section 7.2 is equal to 2.52 g/cm^3.

```
B4C  7  0.9722 300  5010  40.0  5011  60.0  END
```

Note: In the above examples, the actual density is input for materials containing enriched multi-isotope nuclides (uranium in Examples 4 and 5 and boron in Examples 6 and 7). The default density should never be used for enriched materials, especially low atomic mass neutron absorbers such as boron and lithium. The default density is a fixed value for nominal conditions and naturally occurring distributions of isotopes. Use of the default density for enriched materials will likely result in incorrect number densities

---

User-defined (arbitrary) chemical compound specifications

The user-defined compound option allows the user to specify materials that are not found in the Standard Composition Library and can be specified by the number of atoms of each element or isotope that are contained in the molecule. To define a user-defined compound, the first four characters of the standard composition component name must be **ATOM**. The remaining characters of the standard composition component name are chosen by the user. The maximum length of the standard composition name is 16 characters. All the information that would normally be found in the Standard Composition Library must be entered in the user-defined compound specification. Sect. 7.1.3.3 contains data input details for arbitrary compounds.

EXAMPLE 1. Density and chemical equation are given.

Create a mixture 3 that is a hydraulic fluid, C_2H_6SiO, with a density of 0.97 g/cm^3. The input data for this user-defined compound are given below:

```
ATOM     3  0.97  4 6000 2 1001 6 14000 1 8000 1 END
```

EXAMPLE 2. Density and chemical equation are given. Create a mixture 7, TBP, also known as phosphoric acid tributyl ester or tributylphosphate, $(C_4H_9O)_3PO$, having a density of 0.973 g/cm^3.

```
ATOMtbp          7  0.973  4 1001 27 6000 12 8016 4 15031 1 end
```

User-defined (arbitrary) mixture/alloy specifications

The user-defined compound or alloy option allows the user to specify materials that are not found in the Standard Composition Library and are defined by specifying the weight percent of each element or isotope contained in the material. To define a user-defined weight percent mixture, the first four characters of the standard composition component name must be *wtpt*. The remaining characters of the standard composition component name are chosen by the user. The maximum length of the standard composition name is 16 characters. All the information that would normally be found in the Standard Composition Library must be entered in the arbitrary mixture/alloy specification. Sect. 7.1.3.3 contains data input details for user-defined compounds.

EXAMPLE 1. Density and weight percents are given.

Create a mixture 5 that defines a borated aluminum that is 2.5 wt % natural boron. The density of the borated aluminum is 2.65 g/cm^3.

```
SOLUTION MIX=2 RHO[UO2(NO3)2]=415 92235 92.6 92238 5.9 92234 1 92236
0.5 MASSFRAC[HNO3]=6.339-6 TEMPERATURE=293 END SOLUTION
```

EXAMPLE 2. Density, weight percents, and isotopic abundance are given.

Create a mixture 5 that defines a borated aluminum that is 2.5 wt % boron. The boron is 90 wt % ^{10}B and 10 wt % ^{11}B. The density of the borated aluminum is 2.65 g/cm^3. The minimum generic input specification for this arbitrary material is

```
WTPTBAL  5  2.65  2  5000 2.5  13027 97.5  1  293  5010 90.  5011 10. END
```

Fissile solution specifications

Solutions of fissile materials are available in the XSProc. A list of the available solution salts and acids is given in the table *Available fissile solution components* in Sect. 7.2.3. When the XSProc processes a solution, it breaks the solution into its component parts (basic standard composition specifications) and uses the solution density to calculate the volume fractions.

EXAMPLE 1. Fuel density, excess acid and isotopic abundance are given.

> Create a mixture 2 that is a highly enriched uranyl nitrate solution with 415 g/L and 0.39 mg of excess nitrate per gram of solution. The uranium isotopic content is 92.6 wt % ^{235}U, 5.9 wt % ^{238}U, 1.0 wt % ^{234}U, and 0.5 wt % ^{236}U. The temperature is 293 Kelvin.

```
SOLUTION MIX=2 RHO[UO2(NO3)2]=415 92235 92.6 92238 5.9 92234 1 92236
0.5 MASSFRAC[HNO3]=6.339-6 TEMPERATURE=293 END SOLUTION
```

where

> The molecular weight of NO_3 is 62.0049 g/mole, of H is 1.0078 g/mole, so the grams of excess H per gram of solution is 1.0078 / 62.0049 × (0.39 mg/g) × (1 g/1000 mg) = 6.339 × 10^{-6}.

Combinations of standard composition materials to define a mixture

Frequently more than one standard composition is required to define a mixture. This section contains such examples.

EXAMPLE 1. Boral from B_4C and Aluminum.

> Create a mixture 6 that is Boral, 15 wt % B_4C and 85 wt % Al, having a density of 2.64 g/cm^3. Natural boron is used in the B_4C. Note that Example 2 demonstrates the use of the keyword **DEN=** to enter the density of the mixture and avoid having to look up the theoretical density from the table *Isotopes in standard composition library,* in the section 7.2.2, and calculate the density multiplier (VF)

```
B4C  6  0.1571  END
 AL  6  0.8305  END
```

EXAMPLE 2. Boral from B_4C and Aluminum.

> This is the same problem as Example 1 using a different method of specifying the input data. Create a mixture 6 that is Boral, 15 wt % B_4C and 85 wt % Al, having a density of 2.64 g/cm^3. Natural boron is used in the B_4C.

```
B4C  6  DEN=2.64  0.15  END
 AL  6  DEN=2.64  0.85  END
```

EXAMPLE 3. Boral from Boron, Carbon, and Aluminum.

> If neither Boral nor B_4C were available in the Standard Composition Library, Boral could be described as follows:
>
> Create a mixture 2 that is Boral composed of 35 wt % B_4C and 65 wt % aluminum with an overall density of 2.64 g/cm^3. The boron is natural boron.

vf is the density multiplier. (The density multiplier is the ratio of actual to theoretical density.) From the Standard Composition Library chapter, table *Isotopes in standard composition library*, the theoretical density of aluminum is 2.702 g/cm^3; boron is 2.37 g/cm^3; and carbon is 2.1 g/cm^3. The density multiplier, *vf*, for Al is (0.65)(2.64)/2.702 = 0.63509. The isotopic abundances in natural boron are known to have some variability. Here it is assumed that natural boron is 18.4309 wt % ^{10}B at 10.0129 amu and 81.5691 wt % ^{11}B at 11.0096 amu. C is 12.000 amu.

Convert the weight percents to atom percents for the natural boron where w denotes weight fraction, a denotes atom fraction, and M denotes atomic mass:

$$w_{B10} = 0.184309 \equiv \frac{a_{B10}M_{B10}}{a_{B10}M_{B10} + a_{B11}M_{B11}} = \frac{a_{B10}(10.0129)}{a_{B10}(10.0129) + (1 - a_{B10}))(11.0093)} \tag{7.1.4}$$

Solving for a_{B10} gives:

$$[a_{B10}=0.184309 = \frac{(0.184309)\ (11.0093)}{(0.184309)\ (11.0093)\text{-}(0.184309)\ (10.0129)\text{+}(10.0129)} = 19.900 \tag{7.1.5}$$

Therefore the atom percent of ^{11}B is, aB_{11} = 80.1 a%.

Similarly, the mass of the B_4C molecule is

$$[(0.199 \times 4 \times 10.0129) + (0.801 \times 4 \times 11.0093) + (12.000)] = 55.24407 \text{ amu.}$$

The mass of the boron is (55.24407 - 12.000) = 43.24407 amu.

The *vf* of boron would be $\left(\frac{43.24407}{55.24407}\right)\left(\frac{(0.35)(2.64)}{2.37}\right) = 0.30519$

The *vf* of C would be

$$\left(\frac{12.0000}{55.24407}\right)\left(\frac{(0.35)(2.64)}{2.1}\right) = 0.09558 \tag{7.1.6}$$

$$\left(\frac{12.000}{55.25045}\right)\left[\frac{(0.35)(2.64)}{2.30}\right] = 0.08725 \tag{7.1.7}$$

The standard composition input data for the Boral follows:

```
AL     2       0.63509 END
BORON  2       0.30519 END
C      2       0.09558 END
```

EXAMPLE 4. Boral from ^{10}B, ^{11}B, Carbon, and Aluminum.

Create a mixture 2 that is Boral composed of 35 wt % B_4C and 65 wt % aluminum. The Boral density is 2.64 g/cm^3. The boron is natural boron.

vf is the density multiplier. Use 0.63581 for AL and 0.08725 for C as explained in Example 3 above. From the Standard Composition Library chapter, *Isotopes in standard composition library* table, the theoretical density of ^{10}B is 1.00 g/cm^3 and ^{11}B is 1.00 g/cm^3. As computed in Example 3, the mass of the B_4C molecule is 55.25045 amu, and the boron is 19.764 atom % ^{10}B and 80.236 atom % ^{11}B. The mass of ^{10}B is 10.0129 amu and the ^{11}B is 11.0096. Thus, the *vf* of ^{10}B is

$$\left(\frac{(4)(0.199)(10.0129)}{55.24407}\right)\left(\frac{(0.35)(2.64)}{1.0}\right) = 0.13331\ . \tag{7.1.8}$$

The *vf* of ^{11}B is

$$\left(\frac{(4)(0.801)(11.0093)}{55.24407}\right)\left(\frac{(0.35)(2.64)}{1.0}\right) = 0.58998\ . \tag{7.1.9}$$

The standard composition input data for the Boral are given as

```
AL     2        0.63509 END
B-10   2        0.13331 END
B-11   2        0.58998 END
C      2        0.09558 END
```

EXAMPLE 5. Specify all of the number densities in a mixture.

Create a mixture 1 that is vermiculite, defined as

hydrogen at a number density of 6.8614-4 atoms/b-cm

oxygen at a number density of 2.0566-3 atoms/b-cm

magnesium at a number density of 3.5780-4 atoms/b-cm

aluminum at a number density of 1.9816-4 atoms/b-cm

silicon at a number density of 4.4580-4 atoms/b-cm

potassium at a number density of 1.0207-4 atoms/b-cm

iron at a number density of 7.7416-5 atoms/b-cm

In this example we use the 2nd syntax option described in Sect. 7.1.3.3, in which the 3rd entry must be 0. The standard composition input data for the vermiculite are given below:

```
H    1          0        6.8614-4         END
O    1          0        2.0566-3         END
MG   1          0        3.5780-4         END
AL   1          0        1.9816-4         END
SI   1          0        4.4580-4         END
K    1          0        1.0207-4         END
FE   1          0        7.7416-5         END
```

Combinations of user-defined compound and user-defined mixture/alloy to define a mixture

Mixtures can usually be created using only basic standard composition specifications. Occasionally, it is convenient to create two or more user-defined materials for a given mixture. This procedure is demonstrated in the following example.

EXAMPLE 1. Specify Boral using a user-defined compound and user-defined mixture/alloy.

Create a mixture 6 that is Boral, 15 wt % B_4C and 85 wt % Al, having a density of 2.64 g/cm^3. Natural boron is used in the B_4C. Boral can be described in several ways. For demonstration purposes, it will be described as a combination of a user-defined compound and user-defined mixture/alloy. This is not necessary, because both B_4C and Al are available as standard compositions. A method of describing the Boral without using user-defined compounds or user-defined mixtures/alloys is given in Examples 1 and 2 of Sect. 7.1.4.1.6. The minimum generic input specifications for this user-defined compound and alloy are

```
ATOM-B4C   6       2.64    2       5000            4       6012    1       0.15    END
WTPT-AL    6       2.64    1       13027           100.0           0.85    END
```

Combinations of solutions to define a mixture

This section demonstrates the use of more than one solution definition to describe a single mixture. The assumptions used in processing the cross sections are likely to be inadequate for solutions of mixed oxides of uranium and plutonium. Therefore, this section is given purely for demonstration purposes.

EXAMPLE 1. Solution of uranyl nitrate and plutonium nitrate.

Note that the assumptions used in processing the cross sections are likely to only be adequate for CENTRM/PMC calculations of mixed-oxide solutions. This example is given purely for demonstration purposes. Create a mixture 1 consisting of a mixture of plutonium nitrate solution and uranyl nitrate solution. The specific gravity of the mixed solution is 1.4828. The solution contains 325.89 g (U + Pu)/L soln. The acid molarity of the solution is 0.53. In this solution 77.22 wt % of the U+Pu is uranium. The isotopic abundance of the uranium is 0.008% ^{234}U, 0.7% ^{235}U, 0.052% ^{236}U, and 99.24% ^{238}U. The isotopic abundance of the plutonium is 0.028% ^{238}Pu, 91.114% ^{239}Pu, 8.34% ^{240}Pu, 0.426% ^{241}Pu, and 0.092% ^{242}Pu. Note that a single quote in the first column indicates a comment line in SCALE input.

```
'   Uranium density of 77.22% of 325.89 g/L
SOLUTION  MIX=1  RHO[UO2(NO3)2]=251.65  92234 .008 92235 .700 92236 .052
                                        92238 99.240
'   Plutonium density if 22.78% of 325.89 g/L
                 RHO[PU(NO3)4]=74.24  94238 .028 94239 91.114 94240 8.34
                                      94241 .426 94242 .092
'   Acid molarity is 0.53 M
                 MOLAR[HNO3]=0.53
'   Specifying the density over specifies the problem, which means the solution may
'   not be in thermodynamic equilibrium.  The specification below adds about 0.3%
'   extra hydrogen to the problem
                 DENSITY=1.4828
END SOLUTION
```

Combinations of basic and user-defined standard compositions to define a mixture

EXAMPLE 1. Burnable poison from B_4C and Al_2O_3.

Create a mixture 6 that is a burnable poison with a density of 3.7 g/cm^3 and composed of Al_2O_3 and B_4C. The material is 1.395 wt % B_4C. The boron is natural boron. This material can be easily specified using a combination of user-defined material to describe the Al_2O_3 and a simple standard composition to define the B_4C. The minimum generic input specification for this user-defined material and the standard composition are

The density multiplier of the B_4C is the density of the material times the weight percent, divided by the theoretical density of B_4C [$(3.7 \times 0.01395)/2.52$] or 0.02048; the density multiplier of the Al_2O_3 is 1.0 - 0.01395 or 0.98605 (the theoretical density of B_4C was obtained from *Isotopes in standard composition library* table in the STDCMP chapter).

The input data for the burnable poison are given below:

```
ATOM-AL2O3  6  3.70  2  13027  2  8016  3  0.98605  END
B4C  6  2.048-2  END
```

The B_4C input can be specified using the **DEN**= parameter as shown below:

```
ATOM-AL2O3  6  3.70  2  13027  2  8016  3  0.98605  END
B4C  6  DEN=3.7  0.01395  END
```

The fraction of B_4C in the mixture is ((3.7 × 0.01395)/2.52) = 0.02048. The fraction of Al_2O_3 in the mixture is 1.0 - 0.02048 = 0.979518. The density of the Al_2O_3 can be calculated as shown below.

$$F_{Al_2O_3} * Density_{Al_2O_3} + 0.020482 * 2.52 = 3.7 = Density \ \ of \ \ the \ \ mixture$$

$$Density_{Al_2O_3} = \frac{3.7 - 0.020482 * 2.52}{0.979518} = 3.72467$$

Input data using the density of Al_2O_3 are given below:

```
ATOM-AL2O3  6  3.72467  2  13027  2  8016  3  END
B4C  6  2.048-2  END
```

EXAMPLE 2. Borated water from H_3BO_3 and water.

Create a mixture 2 that is borated water at 4350 parts per million (ppm) by weight, resulting from the addition of boric acid, H_3BO_3 to water. The density of the borated water is 1.0078 g/cm^3 (see "Specific Gravity of Boric Acid Solutions," Handbook of Chemistry, 1162, Compiled and Edited by Norbert A. Lange, Ph.D, 1956.). The solution temperature is 15ºC and the boron is natural boron.

An easy way to describe this mixture is to use a combination of a user-defined compound to describe the boric acid, and a basic composition to describe the water.

STEP 1. INPUT DATA TO DESCRIBE THE USER-DEFINED COMPOUNDThe generic input data for the boric acid are given below. The actual input data are derived in steps 2 through 5.

```
ATOMH3BO3  2  0.025066  3  5000  1  1001  3  8016  3  1.0  288.15  END
```

STEP 2. AUXILIARY CALCULATIONS FOR THE USER-DEFINED COMPOUND INPUT DATA

In calculating the molecular weights, use the atomic weights from SCALE, which are available in the table *Isotopes in standard composition library* in Sect. 7.2.2 of the SCALE manual. The atomic weights used in SCALE may differ from some periodic tables. The SCALE atomic weights used in this problem are listed below:

H (1001) 1.0078

O (8016) 15.9949

^{10}B 10.0129

^{11}B 11.0093

The natural boron abundance, in weight percent, is defined to be:

^{10}B 18.4309

^{11}B 81.5691

The molecular weight of natural boron is given by

DEN nat B/AWT nat B = DEN ^{10}B/AWT ^{10}B + DEN ^{11}B/AWT ^{11}B

DEN ^{10}B = WTF ^{10}B × DEN nat B

DEN ^{11}B = WTF ^{11}B × DEN nat B

where:

DEN is density in g/cm^3,

AWT is the atomic weight in g/mol,

WTF is the weight fraction of the isotope.

Substituting,

DEN nat B/AWT nat B = DEN nat B × ((WTF ^{10}B/AWT ^{10}B) + (WTF ^{11}B/AWT ^{11}B))

Solving for AWT nat B yields:

AWT nat B = 1/((WTF ^{10}B/AWT ^{10}B) + (WTF ^{11}B/AWT ^{11}B))

The atomic weight of natural boron is thus

1.0/((0.184309 g ^{10}B/g nat B/10.0129 g ^{10}B/mol ^{10}B) + (0.815691 g ^{11}B/g nat B/11.0093 g /mol ^{11}B)) = 10.81103 g nat B/mol nat B

The molecular weight of the boric acid, H_3BO_3 is given by:

(3 × 1.0078) + 10.81103 + (3 × 15.9949) = 61.8191

Calculate the grams of boric acid in a gram of solution:

Boric acid, H_3BO_3 is 61.8222 g/mol

Natural boron is 10.81261 g/mol

(4350 × 10^{-6} g B/g soln) × (1 mol/10.81261 g B) × (61.8191 g boric acid/mol) =

0.024874 g boric acid/g soln (2.4874 wt %)

Interpolating from the referenced page from Lange's Handbook of Chemistry, the specific gravity of the boric acid solution at 2.4872 weight percent is 1.0087. This value is based on water at 15°. Therefore, the density of the boric acid solution is 1.0087 × 0.99913 g/cm^3 = 1.0078 g soln/cm^3.

Calculate ROTH, the theoretical density of the boric acid.

1.0078 g soln/cm^3 × 0.024874 g boric acid/g soln = 0.025068 g boric acid/cm^3

STEP 3. DESCRIBE THE BASIC STANDARD COMPOSITION INPUT DATA

```
H2O     2  0.984507  288.15  END
```

where the volume fraction =0.984506 (see step 4 auxiliary calculations below)

STEP 4. AUXILIARY CALCULATIONS FOR THE BASIC STANDARD COMPOSITION INPUT DATA

Calculate the volume fraction of the water in the solution, assuming 0.9982 is the theoretical density of water from Table 7.2.4. Each gram of solution contains 0.024872 g of boric acid, so there is 0.975128 g of water in each gram of solution. The volume fraction of water is then given by:

(1.0078 g soln/cm^3 × 0.975128 g water/g soln)/0.9982 g water/cm^3 = 0.984506

STEP 5. CREATE THE MIXTURE FOR BORATED WATER

```
ATOMH3BO3  2  0.025068  3  5000  1  1001  3  8016  3  1.0  288.15  END
H2O                  2  0.984506  288.15  END
```

Combinations of basic and solution standard compositions to define a mixture

The solution specification is the easiest way of specifying the solutions listed in the *Available fissile solution components* table in Sect. 7.2.3. A combination of solution and basic standard compositions can be used to describe a mixture that contains more than just a solution as demonstrated in the following example.

EXAMPLE 1. Uranyl nitrate solution containing gadolinium.

> Create a 4.306% enriched uranyl nitrate solution containing 0.184 g gadolinium per liter. The uranium in the nitrate is 95.65% ^{238}U, 0.022% ^{236}U, 4.306% ^{235}U, and 0.022% ^{234}U. The uranium concentration is 195.8 g U/L and the specific gravity of the uranyl nitrate is 1.254. There is no excess acid in the solution. The presence of the gadolinium is assumed to produce no significant change in the solution density. The solution is defined to be mixture 3.

```
SOLUTION  MIX=3
  RHO[UO2(NO3)2]=195.8 92238 95.65 92236 0.022 92235 4.306 92234 0.022
  VOL_FRAC=0.99985
  DENSITY=1.254
END SOLUTION
GD  3  0.000184  293  END
```

Combinations of user-defined compound and solution to define a mixture

The solution specification is the easiest way of specifying the solutions listed in the *Available fissile solution components* table in Sect. 7.2.3 of the SCALE manual. A solution specification and user-defined compound specification can be used to describe a mixture that contains more than just a solution as demonstrated in the following example.

EXAMPLE 1. Uranyl nitrate solution with gadolinium nitrate.

> Create a 4.306% enriched uranyl nitrate solution containing gadolinium in the form of $Gd(NO_3)_3$. The uranium in the nitrate is 95.65% ^{238}U, 0.022% ^{236}U, 4.306% ^{235}U, and 0.022% ^{234}U. The uranium concentration is 195.8 g U/L and the density of the uranyl nitrate is 1.254. There is no excess acid in the solution. The concentration of the gadolinium is 0.184 g/L. The volume fraction of the mixture that is uranyl nitrate (0.99985 = 1.254/ (1.254 + 0.000184)). The solution is defined to be mixture 3.

```
SOLUTION  MIX=3
  RHO[UO2(NO3)2]=195.8 92238 95.65 92236 0.022 92235 4.306 92234 0.022
  VOL_FRAC=0.99985
  DENSITY=1.254
END SOLUTION
```

The density of the gadolinium is given as 0.184 g/L. To describe the user-defined compound, the density of the $Gd(NO_3)_3$ is needed. The atomic weights from the Standard Composition Library are:

> Gd 157.25
>
> N 14.0067
>
> O 15.999

Therefore, the density of the $Gd(NO_3)_3$ = 0.000184 g Gd/cm^3 × (157.25 + 3(14.0067 + 3(15.999))/157.25) = 0.0004017 g/cm^3.

The input data for this user-defined compound are given below:

```
ATOMGD(NO3)3  3  .0004017  3  64000  1  7014  3  8016  9  1.0  300  END
```

The complete input data for the mixture of uranyl nitrate and gadolinium nitrate are given as:

```
SOLUTION  MIX=3
  RHO[UO2(NO3)2]=195.8 92238 95.65 92236 0.022 92235 4.306 92234 0.022
  VOL_FRAC=0.99985
  DENSITY=1.254
END SOLUTION
ATOMGD(NO3)3  3  .0004017  3  64000  1  7014  3  8016  9  1.0  300  END
```

Note: Since the default temperature (300 K) is to be used, it can be omitted from the user-defined compound standard composition. The temperature must be entered if the standard composition contains a multiple-isotope nuclide whose isotopic abundance is to be specified.

7.1.4.2 XSProc Standard Composition Examples

Infinite homogeneous medium unit cell data

EXAMPLE 1. A single mixture 1.

> Consider a single cylindrical configuration of mixture 1, composed of 10% enriched UO_2 having a radius of 35 cm and a height of 20 cm. This fuel region is sufficient large to model as an infinite medium. Mixture 100 may be used in subsequent multigroup neutron transport calculations.

```
INFHOMMEDIUM  1  CELLMIX=10  END
```

XSDRNPM will calculate the eigenvalue of an infinite mass of 10% enriched UO_2.

LATTICECELL unit cell data

Examples of "regular" **LATTICECELL** unit cells are given in Examples 1–5, and examples of "annular" **LATTICECELL** unit cells are given in Examples 6–10 below.

EXAMPLE 1. SQUAREPITCH (infinitely long cylindrical pins in a square-pitched array).

> Consider a large array of UO_2 fuel pins having a fuel O.D. of 0.79 cm, a 0.015-cm gap, and a 0.06-cm-thick aluminum clad. The array is a square-pitched array with a center-to-center spacing of 1.60 cm and is completely flooded with water. In the standard composition data, UO_2 is defined to be mixture 1, the aluminum clad is defined to be mixture 2, and the water moderator is defined to be mixture 3.

```
LATTICECELL  SQUAREPITCH PITCH=1.60 3 FUELD=0.79 1 CLADD=0.94 2 GAPD=0.82 0 END
```

EXAMPLE 1a. SQUAREPITCH (infinitely long cylindrical pins with multiple fuel zones in a square-pitched array).

Consider a large array of UO2 fuel pins having a fuel radius of 0.79 cm with three equi-volume fuel zones with different compositions, a 0.015-cm gap, and a 0.06-cm-thick aluminum clad. The array is a square-pitched array with a center-to-center spacing of 1.60 cm and is completely flooded with water. In the standard composition data, UO2 zones are defined to be mixtures 1 through 3, the aluminum clad is defined to be mixture 4, and the water moderator is defined to be mixture 5.

```
LATTICECELL  SQUAREPITCH      PITCH=1.60 5
                           FUELR=0.228053 1
                           FUELR=0.322516 2
                           FUELR=0.395000 3
                           CLADR=0.47 4
                           GAPR=0.41 0 END
```

EXAMPLE 2. TRIANGPITCH (infinitely long cylinders in a triangular-pitched array).

Consider an array of UO_2 pins with a diameter of 0.635 m. The outside diameter of the clad is 0.78 cm. There is no gap between the fuel and clad. The array is a triangular-pitched array with a center-to-center spacing of 5.0 cm and is flooded with water. In the standard composition data, the UO_2 is defined to be mixture 1, the aluminum is defined to be mixture 2, and the water moderator is defined to be mixture 3.

```
LATTICECELL  TRIANGPITCH PITCH=5.0  3  FUELD=.635  1  CLAD=.78  2  END
```

EXAMPLE 3. SPHSQUAREP (spheres in a square-pitched array).

Consider a large array of U_3O_8 spheres having a fuel O.D. of 18.6 cm, with an aluminum clad that is 0.18 cm thick. The array is a triangular-pitched array with a center-to-center spacing of 19.0 cm and is unmoderated. In the standard composition data, the aluminum is defined to be mixture 1 and the U_3O_8 is defined to be mixture 2. There is no moderator material, so 0 will be used to represent a void. Also, have XSDRNPM make a cell weighted material 20 from this unit cell.

```
LATTICECELL SPHSQUAREP PITCH=19.0 0 FUELD=18.6 2 CLADD=18.96 1 CELLMIX=20 END
```

EXAMPLE 4. SPHTRIANGP (spheres in a triangular-pitched array).

Consider a large array of U_3O_8 spheres having a fuel O.D. of 18.6 cm, with an aluminum clad that is 0.18 cm thick. The array is a triangular-pitched array with a center-to-center spacing of 19.0 cm and is flooded with water. In the standard composition data, the aluminum is defined to be mixture 1, the U_3O_8 is defined to be mixture 2, and the water moderator is defined to be mixture 3.

```
LATTICECELL  SPHTRIANGP  PITCH=19.0  3  FUELD=18.6  2 CLADD=18.96  1  END
```

EXAMPLE 5. SYMMSLABCELL (slabs repeated in a symmetric fashion).

Consider a system of alternating slabs of U_3O_8 and low-density water. Each U_3O_8 region is 1.27 cm thick, and each water region is 15.0 cm thick. In the standard composition data, the U_3O_8 is defined to be mixture 1, and the low-density water is defined to be mixture 2.

```
LATTICECELL  SYMMSLABCELL PITCH=16.27  2 FUELD=1.27  1  END
```

EXAMPLE 5a. SYMMSLABCELL (slabs repeated in a symmetric fashion).

Consider a system of alternating slabs of U_3O_8 and low-density water. Each U_3O_8 region is 1.27 cm thick, and each water region is 15.0 cm thick. The U_3O_8 regions have a 0.01-cm gap and 0.24-cm-thick aluminum clad on each face. In the standard composition data, the U_3O_8 is defined to be mixture 1, the aluminum is defined to be mixture 2, and the low-density water is defined to be mixture 3. Also, have XSDRNPM make a cell-weighted material 100 from this unit cell.

```
LATTICECELL  SYMMSLABCELL  PITCH=16.77  3  FUELD=1.27  1
CLADD=1.77  2  GAPD=1.29  0  CELLMIX=100  END
```

EXAMPLE 6. ASQUAREPITCH (infinitely long annular cylindrical rods in a square-pitched array).

Consider an array of uranium metal pipes having an inside diameter of 5.0 cm and an outer diameter of 6.75 cm. A gap of 0.025 cm and a clad of 0.25 cm exist on both the inner and outer surfaces of the fuel. The fuel rods are arranged in a square-pitched array. The center-to-center spacing is 8.0 cm. The array is completely flooded with water. In the standard composition data, the uranium metal is defined to be mixture 1, the outer clad is mixture 2, the inner clad is mixture 7, the inner moderator is Plexiglas and is mixture 3, the gap is a void, and the external moderator is water, defined to be mixture 4.

```
LATTICECELL  ASQUAREPITCH  PITCH=8.0  4  FUELD=6.75  1  GAPD=6.8  0
CLADD=7.3  2  IMODD=4.45  3  ICLADD=4.95 7  IGAPD=5.0  0  END
```

EXAMPLE 6a. ASQUAREPITCH (infinitely long annular cylindrical rods in a square-pitched array).

Consider an array of uranium metal pipes having an inside diameter of 5.0 cm and an outer diameter of 6.75 cm arranged in a square-pitched array. The center-to-center spacing is 8.0 cm. The array is completely flooded with water. In the standard composition data, the uranium metal is defined to be mixture 1, the water moderator is defined to be mixture 2, and the inside water moderator is defined as mixture 3.

```
LATTICECELL  ASQUAREPITCH  PITCH=8.0  2  FUELD=6.75  1  IMODD=5.0  3  END
```

Note: This problem defines two water mixtures. If mixture 2 were entered twice, i.e., for both the inner and outer moderator, an error message would be printed and the calculation terminated.

EXAMPLE 7. ATRIANGPITCH (infinitely long annular cylindrical rods in a triangular-pitched array).

Consider an array of uranium metal pipes having an inside diameter of 8.0 cm and a wall thickness of 0.75 cm arranged in a square-pitched array. The center-to-center spacing is 9.75 cm. The array is completely flooded with water. A Plexiglas rod fills the center of the uranium pipe. In the standard compositions data, the uranium metal is defined to be mixture 1, the Plexiglas is defined to be mixture 2, and the external water moderator is mixture 3.

```
LATTICECELL  ATRIANGPITCH  PITCH=9.75  3  FUELD=9.5  1  IMODD=8.0  2  END
```

EXAMPLE 8. ASPHSQUAREP (spherical annuli in a square-pitched array).

Consider a large array of hollow U_3O_8 spheres having a fuel I.D. of 8.0 cm and O.D. of 18.6 cm. The centers of the spheres are empty. The external moderator is water. The spheres are stacked in a square-pitched array with a center-to-center spacing of 19.0 cm. In the standard composition data, the U_3O_8 is defined to be mixture 1, and the water is defined to be mixture 2. The centers of the spheres are defined to be void, mixture 0.

```
LATTICECELL  ASPHSQUAREP  HPITCH=9.5  2  FUELR=9.3  1  IMODR=4.0  0  END
```

EXAMPLE 9. ASPHTRIANGP (spheres in a triangular-pitched array).

Consider a large array of hollow U_3O_8 spheres having a fuel I.D. of 8.0 cm and a fuel O.D. of 18.6 cm. A 0.18-cm-thick aluminum clad exists outside the fuel. The interior of each sphere is void. The array is a triangular-pitched array with a center-to-center spacing of 19.0 cm and is flooded with water. In the standard composition data, the aluminum is defined to be mixture 1, the U_3O_8 is defined to be mixture 2, and the water moderator is defined to be mixture 3. The void in the center of each sphere is entered as mixture 0.

```
LATTICECELL ASPHTRIANGP HPITCH=9.5  3 FUELR=9.3  2 IMODR=4.0  0 CLADR=9.48  1 END
```

EXAMPLE 10. ASYMSLABCELL (repeated slabs having different moderator conditions on the left and right boundaries).

Consider an array of U_3O_8 slabs with an inner moderator region composed of full-density water with a half thickness of 8.0 cm, and a low-density water outer moderator with a 16 cm half thickness of 16 cm half thickness. Each U_3O_8 slab is 10.54 cm thick. In the standard composition data, the U_3O_8 is defined to be mixture 1, the full density water is defined to be mixture 2, and the low-density water is mixture 3. Also, have XSDRNPM create a cell weighted mixture 100 from this unit cell.

```
LATTICECELL ASYMSLABCELL CELLMIX=100 IMODR=8.0 2 FUELR=18.54 1  HPITCH=34.54 3 END
```

EXAMPLE 10a. ASYMSLABCELL (repeated slabs having different moderator conditions on the left and right boundaries).

Consider an array of U_3O_8 fuel plates with an inner moderator region of full-density water with a half-thickness of 8.0 cm, and with a 16 cm thick low-density outer moderator. Each fuel plate includes a 10.54 cm thick U_3O_8 slab with a 0.01 cm gap and 0.24-cm-thick aluminum clad on each face. In the standard composition data, the U_3O_8 is defined to be mixture 1, the full density water is defined to be mixture 2, and the low-density water is mixture 3, the inner aluminum is mixture 4, the outer aluminum clad is mixture 5, and both gaps are voids.

```
LATTICECELL ASYMSLABCELL IMODR=8.0 2 ICLADR=8.24 5 IGAPR=8.25 0 FUELR=18.79 1
GAPR 18.80 0 CLADR 19.04 4 HPITCH=27.04 3 END
```

MULTIREGION unit cell data

Examples of **MULTIREGION** unit cells follow:

EXAMPLE 1. SLAB.

Consider a 5-cm-thick slab of fuel (mixture 1) with 0.5 cm of aluminum (mixture 3) and 15 cm of water (mixture 2) on each face. The unit cell data for this problem could be entered as follows:

```
MULTIREGION  SLAB  LEFT_BDY=REFLECTED  RIGHT_BDY=VACUUM  ORIGIN=0  END
1  2.5  3  3.0  2  18.0  END ZONE
```

EXAMPLE 2. CYLINDRICAL.

Consider a large array of fuel pins. Each pin is UO_2 (mixture 1) with a radius of 0.465 cm, a 0.009-cm gap (mixture 0), and a Zircaloy clad (mixture 9) 0.062 cm thick, centered in a water (mixture 8) region surrounded by a flooded support structure represented by homogenized water and Zircaloy (mixture 10). The outer radius of the water-Zircaloy region is 0.844 cm and it is 0.037 cm thick. This problem cannot be described as a **LATTICECELL** problem because the **LATTICECELL** configuration is limited to fuel-gap-clad-cell boundary and this problem is fuel-gap-clad-moderator-outer region. When **MULTIREGION** is used, lattice effects are accounted for by specifying a **WHITE**, **PERIODIC**, or **REFLECTED** right boundary condition, as long as the CENTRM/PMC self-shielding method is used. **MULTIREGION** cells should not be used for arrays if BONAMI-only method is specified

```
MULTIREGION  CYLINDRICAL RIGHT_BDY=WHITE  END
1  0.465  0  0.474  9  0.536  8  0.807  10  0.844  END ZONE
```

EXAMPLE 3. SPHERICAL.

Describe a bare sphere of uranium metal 8.72 cm in radius. The uranium metal is defined to be mixture 1. Also, have XSDRNPM create a cell weighted mixture 100 and calculate and eigenvalue. The unit cell data for this problem could be entered as follows:

```
MULTIREGION  SPHERICAL  CELLMIX=100  END   1  8.72    END ZONE
```

EXAMPLE 4. BUCKLEDSLAB.

Consider a plate of fuel 4 cm thick, reflected by 3 cm of water on both faces. The plate is 32 cm tall and 16 cm deep. The fuel is mixture 1 and the water is mixture 2. Also, have XSDRNPM create a cell weighted mixture 100 and calculate and eigenvalue.

```
MULTIREGION  BUCKLEDSLAB  CELLMIX=100  LEFT_BDY=REFLECTED  RIGHT_BDY=VACUUM
DY=32 DZ=16.0  END  1  2.0  2  5.0  END ZONE
```

EXAMPLE 5. BUCKLEDCYL.

Consider a solution of uranyl nitrate contained in a cylindrical stainless-steel container reflected by 33 cm of water. The inside dimensions of the steel container are 7.62 cm in radius and 130.0 cm tall. The steel is 0.15 cm thick. The uranyl nitrate is defined to be mixture 1, the steel is defined to be mixture 2, and the water is defined to be mixture 3.

```
MULTIREGION  BUCKLEDCYL  DY=130  END
1  7.62  2  7.77  3  40.77  END ZONE
```

DOUBLEHET unit cell data

Unit cell data are always required for **DOUBLEHET** calculations. As many unit cells as needed may be defined in the problem. If **CELLMIX**=*mx* is entered after the fuel element (macro cell) description, XSProc calls XSDRNPM to calculate the eigenvalue of the cell and to create a homogenized cell-weighted cross section having the characteristics of the doubly-heterogeneous cell configuration.

EXAMPLE 1: A doubly-heterogeneous spherical fuel element with 15,000 UO_2 particles in a graphite matrix.

Grain fuel radius is 0.025 cm. Grain contains one coating layer that is 0.009-cm-thick. Pebbles are in a triangular pitch on a 6.4-cm-pitch. Fuel pebble fuel zone is 2.5-cm in radius and contains a 0.5-cm-thick graphite clad that contains small amounts of ^{10}B. Pebbles are surrounded by ^{4}He. Assume the composition block is below:

```
' UO2 FUEL KERNEL
U-235  1 0 1.92585E-3 293.6 END
O      1 0 4.64272E-2 293.6 END
' FIRST COATING
C      2 0 5.26449E-2 293.6 END
' GRAPHITE MATRIX
C      6 0 8.77414E-2 293.6 END
' CARBON PEBBLE OUTER COATING
C      7 0 8.77414E-2 293.6 END
B-10   7 0 9.64977E-9 293.6 END
HE-4   8 0 2.65156E-5 293.6 END
```

The cell data for the **DOUBLEHET** cell follows:

```
DOUBLEHET FUELMIX=10 END
 GFR=0.025  1 COATT=0.009 2 MATRIX=6 NUMPAR=15000 END GRAIN
PEBBLE SPHTRIANGP RIGHT_BDY=WHITE HPITCH=3.2 8 FUELR=2.5 CLADR=3.0 7  END
```

In this case we designated the homogenized mixture as mixture 10. If we have a KENO V.a or KENO-VI input section, we would use mixture 10 in that section. Note that the keyword "**FUELR**=" is followed by the fuel dimension only, i.e., no mixture number. That is because the fuel mixture number is specified with "**FUELMIX**=" and therefore need not be repeated.

EXAMPLE 2: Same as Example 1, except volume fraction of the grain type is known and is 0.037732.

```
DOUBLEHET  RIGHT_BDY=WHITE FUELMIX=10 END
 GFR=0.025  1 COATT=0.009 2 MATRIX=6 VF=0.037732 END GRAIN
PEBBLE SPHTRIANGP RIGHT_BDY=WHITE HPITCH=3.2 8 FUELR=2.5 CLADR=3.0 7  END
```

EXAMPLE 3: Same as Example 1, except halfpitch of the grain type is known and is 0.10137 cm.

```
DOUBLEHET FUELMIX=10 END

```

EXAMPLE 4: A doubly-heterogeneous spherical fuel element with 10,000 UO2 particles and 5,000 PuO2 particles in a graphite matrix.

> Grain fuel radii for UO_2 and PuO_2 particles are 0.025 cm and 0.012 cm, respectively. UO_2 grains contain one coating layer that is 0.009 cm-thick. PuO_2 grains contain one coating layer that is 0.0095 cm-thick. Pebbles are in a triangular pitch on a 6.4-cm-pitch. Fuel pebble fuel zone is 2.5-cm in radius and contains a 0.5-cm-thick graphite clad that contains small amounts of ^{10}B. Pebbles are surrounded by ^{4}He. Assume the composition block is given below:

```
' UO2 FUEL KERNEL
U-235  1 0 1.92585E-3 293.6 END
O      1 0 4.64272E-2 293.6 END
' FIRST COATING
C      2 0 5.26449E-2 293.6 END
' GRAPHITE MATRIX
C      6 0 8.77414E-2 293.6 END
' CARBON PEBBLE OUTER COATING
C      7 0 8.77414E-2 293.6 END
B-10   7 0 9.64977E-9 293.6 END
HE-4   8 0 2.65156E-5 293.6 END
' PUO2 FUEL KERNEL
PU-239  11 0 1.24470E-02 293.6 END
O       11 0 4.60983E-02 293.6 END
' FIRST COATING
```

(continues on next page)

(continued from previous page)

```
C       12 0 5.26449E-2 293.6 END
' GRAPHITE MATRIX
C       16 0 8.77414E-2 293.6 END
```

The cell data for the **DOUBLEHET** cell follows:

```
DOUBLEHET FUELMIX=10 END
 GFR=0.025  1 COATT=0.009 2 MATRIX=6 NUMPAR=10000 END GRAIN
 GFR=0.012 11 COATT=0.0095 12 MATRIX=16 NUMPAR=5000 END GRAIN
PEBBLE SPHTRIANGP RIGHT_BDY=WHITE HPITCH=3.2 8 FUELR=2.5 CLADR=3.0 7 END
```

Since number of particles is entered, the total volume fraction and the pitch can be calculated by the code.

EXAMPLE 5: Same as Example 4 above except the volume fractions of UO_2 and PuO_2 grains are 0.02511 and 0.00318, respectively.

```
DOUBLEHET  RIGHT_BDY=WHITE FUELMIX=10 END
 GFR=0.025  1 COATT=0.009 2 MATRIX=6 VF=0.02511 END GRAIN
 GFR=0.012 11 COATT=0.0095 12 MATRIX=16 VF=0.00318 END GRAIN
PEBBLE SPHTRIANGP RIGHT_BDY=WHITE HPITCH=3.2 8 FUELR=2.5 CLADR=3.0 7 END
```

EXAMPLE 6: Same as Example 4 above except pitch is also known.

UO_2 grains have a pitch of 0.25 cm. PuO_2 grains have a pitch of 0.20 cm.

```
DOUBLEHET FUELMIX=10 END
 GFR=0.025  1 COATT=0.009 2
 MATRIX=6 NUMPAR=10000 PITCH=0.25 END GRAIN
 GFR=0.012  11 COATT=0.0095 12
 MATRIX=16 NUMPAR=5000 PITCH=0.20 END GRAIN
PEBBLE SPHTRIANGP RIGHT_BDY=WHITE HPITCH=3.2 8 FUELR=2.5 CLADR=3.0 7 END
```

Since number of particles is sufficient to perform the homogenization, it is used. However, instead of calculating the pitch for the 1-D cell calculation for each grain type, the user input pitch is used. Hence, the calculated k_{eff} of Example 6 will be different from those of Examples 4 and 5.

EXAMPLE 7: Same as Example 6 except the doubly-heterogeneous cell will be cell-weighted.

The final cell-weighted mixture number is 17.

```
DOUBLEHET FUELMIX=10 END
 GFR=0.025  1 COATT=0.009 2
 NUMPAR=10000 PITCH=0.25 MATRIX=6 END GRAIN
 GFR=0.012  11 COATT=0.0095 12
 NUMPAR=5000 PITCH=0.20 MATRIX=16 END GRAIN
PEBBLE SPHTRIANGP RIGHT_BDY=WHITE HPITCH=3.2 8 FUELR=2.5 CLADR=3.0 7 CELLMIX=17 END
```

EXAMPLE 8: A doubly-heterogeneous spherical fuel element with 15,000 UO_2 particles in a graphite matrix.

Grain fuel radius is 0.012 cm. Grain contains four coating layers that are 0.0095, 0.004, 0.0035, and 0.004-cm-thick. Pebbles are in a square pitch on a 6.0 cm-pitch. Fuel pebble fuel zone is 2.5-cm in radius and contains a 0.5-cm-thick graphite clad that contains small amounts of ^{10}B. Pebbles are surrounded by ^{4}He. Assume the composition block is given below:

```
' UO2 FUEL KERNEL
U-235  1 0 1.92585E-3 293.6 END
O       1 0 4.64272E-2 293.6 END
' FIRST COATING
```

(continues on next page)

(continued from previous page)

```
C       2 0 5.26449E-2 293.6 END
' INNER PYRO CARBON
C       3 0 9.52621E-2 293.6 END
' SILICON CARBIDE
C       4 0 4.77240E-2 293.6 END
SI      4 0 4.77240E-2 293.6 END
' OUTER PYRO CARBON
C       5 0 9.52621E-2 293.6 END
' GRAPHITE MATRIX
GRAPHITE 6 0 8.77414E-2 293.6 END
' CARBON PEBBLE OUTER COATING
C       7 0 8.77414E-2 293.6 END
B-10    7 0 9.64977E-9 293.6 END
HE-4    8 0 2.65156E-5 293.6 END
```

The cell data for the **DOUBLEHET** cell follows:

```
DOUBLEHET FUELMIX=10 END
 GFR=0.012  1 COATT=0.0095 2 COATT=0.004 3 COATT=0.0035 4 COATT=0.004 5 MATRIX=6 NUMPAR=15000 VF=0.0245 END␣
↪GRAIN
PEBBLE SPHSQUAREP RIGHT_BDY=WHITE HPITCH=3.0 8 FUELR=2.5 CLADR=3.0 7 END
```

Note that the grains are overspecified and the numbers are inconsistent. A **VF** value of 0.0245 results in a total number of particles of 10652.32 which is considerably less than 15,000. In this case, the code will issue a warning to this effect and will use **VF** value in the calculations (i.e., ignore **NUMPAR**=15000 entry).

EXAMPLE 9: Similar to Example 8 except radii for grain regions are entered.

```
DOUBLEHET FUELMIX=10 END
 GFR=0.012  1 COATR=0.0215 2 COATR=0.0255 3 COATR=0.029 4 COATR=0.033 5 MATRIX=6 NUMPAR=15000 VF=0.0245 END␣
↪GRAIN
PEBBLE SPHSQUAREP RIGHT_BDY=WHITE HPITCH=3.0 8 FUELR=2.5 CLADR=3.0 7 END
```

EXAMPLE 10: A doubly-heterogeneous spherical fuel element with two UO_2 grain types.

> First grain type has a fuel radius of 0.025 cm. Second grain type fuel radius is 0.004 cm. First grain type has one coating that is 0.009-cm-thick. Second grain type has two coatings each 0.004-cm-thick. Each grain type has a volume fraction of 0.45. Pebbles are in a triangular pitch on a 7.0-cm-pitch. Fuel pebble fuel zone is 2.5-cm in radius and contains a 0.5-cm-thick graphite clad that contains small amounts of ^{10}B and ^{11}B. Pebbles are surrounded by ^{4}He. Assume the composition block is given below:

```
' FUEL KERNEL

```

EXAMPLE 12: This is the same as Example 11 except the fuel elements (cylindrical rods) have 0.05 cm-thick iron cladding.

The cell data for the **DOUBLEHET** cell follows:

```
DOUBLEHET FUELMIX=10 END
 GFR=0.025  1 COATR=0.034 2  MATRIX=6 VF=0.45 END GRAIN
ROD TRIANGP RIGHT_BDY=WHITE HPITCH=3.5 7 FUELR=2.5
  CLADD=5.1 8 FUELH=10 END
```

Optional parameter data

The optional parameter data provide a means of providing additional information or alternative data to the cross-section processing codes. There are two types of optional parameter data. The first type of data is used by XSDRNPM and BONAMI for cross-section processing and cell-weighting cross sections. This type of data is initiated using the keywords **MORE DATA** and ends with the keywords **END MORE**. This input is described in Sect. 7.1.3.8. The second type of optional parameter data is used by CENTRM and PMC for cross-section processing. This type of data is initiated using the keywords **CENTRM DATA** and ends with the keywords **END CENTRM**. This input is described in Sect. 7.1.3.9. It is possible to input both types of data for a unit cell. The optional parameter data specified apply only to the unit cell that immediately precedes it.

MORE DATA examples

Consider a problem in which it is desirable to increase the number of inner iterations in XSDRNPM to 30 and to tighten the overall convergence criteria to a value of 0.000075. This could be accomplished by entering the data as follows:

```
MORE DATA   IIM=30  EPS=0.000075  END
```

The order of the data entry is not important, and it can be continued across several lines. However, a keyword and its value cannot be separated across lines. The terminator for the optional parameter data, END, must not begin in column 1 unless you assign a name to it. An alternative method of entering the above data is given below.

```
MORE DATA
  IIM=30  EPS=0.000075
END MORE
```

or,

```
MORE DATA  IIM=30  EPS=0.000075  END MORE DATA
```

CENTRM DATA examples

Consider a problem in which it is desirable to increase the upper energy of the CENTRM CE transport calculation from the default of 20000 eV to a value 50000 eV, and to extend the default lower energy from 0.001 eV to 0.0001. This is accomplished by entering the data as follows:

```
CENTRM DATA  DEMAX=50000  DEMIN=0.0001 END CENTRM
```

As with the **MORE DATA** block, an alternative method of entering the above data is given below.

```
CENTRMDATA
  DEMAX=50000  DEMIN=0.0001
END CENTRMDATA
```

CENTRM and PMC computation options can also be controlled with **CENTRM DATA.** A complete description of the CENTRM/PMC computational methods and options can be found the corresponding sections of the SCALE manual. The following example specifies that:

(a) discrete-level inelastic scattering will be used in CENTRM and processed in PMC [nmf6];

(b) the CENTRM 1D discrete S_N transport solver will be used in the upper MG energy range [nfst] and the CE energy range [npxs], while the infinitie medium model will be used for the thermal energy range [nthr];

(c) a P3 scattering order [isct] will be used in the transport calculations;

(d) PMC will perform "consistent PN" corrections on Legendre moments of the 2D elastic matrices [n2d]; (e) additional output information will be provided by CENTRM [ixprt] and by PMC [nprt].

```
CENTRM DATA  NMF6=0 NFST=0 NTHR=2 ISCT=3
       N2D=-2 IXPRT=1  NPRT=1    END CENTRM DATA
```

7.1.4.3 Examples of Complete XSProc Input Data

Infinite homogeneous medium input data

Examples of XSProc input data for infinite homogeneous media problems are given below. In these cases the cross section library name "fine_n" indicates that the latest recommended fine-group SCALE library will used in the calculations.

EXAMPLE 1. Default cell definition.

> Consider a cylindrical billet of 20 wt % enriched UO_2, having a density of 10.85 g/cm^3 that is 26 cm in diameter and 26 cm tall.

The average mean-free path in the uranium dioxide is on the order of 2.5 cm. Because only a small fraction of the billet is within a mean-free path of the surface, the material can be treated as an infinite homogeneous medium; therefore the CELL DATA block can be omitted. The XSProc data follows:

```
20%  ENRICHED  UO2  BILLET
fine_n
READ COMP
UO2  1  0.99  293  92235  20  92238  80  END
END  COMP
```

The volume fraction used for the UO_2, 0.99, is calculated by dividing the actual density by the theoretical density obtained from the *Isotopes in standard composition library* table in the STDCMP chapter, (10.85/10.96). Since the enrichment was specified as 20%, it is assumed that the remainder is ^{238}U.

An alternative input data description follows:

```
20% ENRICHED UO2 BILLET
fine_n
READ COMP
UO2 1 DEN=10.85  1  293  92235  20  92238  80  END
END COMP
```

EXAMPLE 2. Specify the cell definition.

> Consider a 5-liter Plexiglas bottle with an inner radius of 9.525 cm and inner height of 17.78 cm that is filled with highly enriched uranyl nitrate solution at 415 g/L and 0.39 mg of excess nitrate per gram of solution. The uranium isotopic content of the nitrate solution is 92.6 wt % ^{235}U, 5.9 wt % ^{238}U, 1.0 wt % ^{234}U, and 0.5 wt % ^{236}U. Solution density will be calculated from the given data.

The size of the nitrate solution is on the order of 16 to 20 cm in diameter and height. The average mean-free path in the nitrate solution is on the order of 0.5 cm. Therefore, infinite homogeneous medium is an appropriate choice for this problem. By default BONAMI is used for self-shielding the infinite medium of Plexiglas, while CENTRM is used to shield the infinite medium fissile solution.

```
SET UP 5 LITER URANYL NITRATE SOLUTION IN A PLEXIGLAS CONTAINER
fine_n
READ COMP
PLEXIGLAS   1  END
SOLUTION   MIX=2   RHO[UO2(NO3)2]=415
           92235   92.6   92238   5.9   92236   0.5
END SOLUTION
END  COMP
READ CELLDATA
INFHOMMEDIUM  2  END
END CELLDATA
```

LATTICECELL input data

Examples of XSProc input data for **LATTICECELL** problems are given below.

EXAMPLE 1. SQUAREPITCH ARRAY.

> Consider an infinite planar array (infinite in X and Y and one layer in Z) of 20 wt % enriched U metal rods with a 1-cm pitch. Each fuel rod is bare uranium metal, 0.75 cm OD × 30.0 cm long. The rods are submerged in water.

Because the diameter of the fuel rod, 0.75 cm, is only slightly larger than the average mean-free path in the uranium metal, approximately 0.5, and because the configuration is a regular array, **LATTICECELL** is the appropriate choice for proper cross-section processing. The *parm* field is not provided, so the default CENTRM/PMC self-shielding method is used. XSProc data follows:

```
INFINITE  PLANAR  ARRAY  OF  20%  U  METAL  RODS
fine_n
READ COMP
URANIUM  1  1  293  92235  20  92238  80  END
H2O      2  END
END  COMP
READ CELLDATA
LATTICECELL  SQUAREPITCH   PITCH=1.0  2  FUELD=0.75  1  END
END CELLDATA
```

Since the MORE DATA and CENTRM DATA blocks were omitted, default options will be used in the self-shielding calculations. The default CENTRM/PMC computation options for a square pitch lattice cell are the method-of-characteristics (MoC) method with P0 scatter in CENTRM calculations.

EXAMPLE 2. SQUAREPITCH PWR LATTICE.

> Consider an infinite, uniform planar array (infinite in X and Y and one layer in Z) of PWR-like fuel pins of 2.35% enriched UO_2 clad with zirconium. The density of the UO_2 is 9.21 g/cm^3. The fuel in each pin is 0.823 cm in diameter, the clad is 0.9627 cm in diameter, and the length of each pin is 366 cm. The fuel pins are separated by 0.3124 cm of water in the horizontal plane.

LATTICECELL is the appropriate choice for cross-section processing. Assume that all defaults are appropriate; thus the CENTRM/PMC methodology is used, and the MORE DATA and CELL DATA blocks are not entered. The input cross section library named "broad_n" indicates that the recommended broad group SCALE library will be used. In this case CENTRM uses the 2D MoC transport solver. The XSProc data follows:

```
PWR-LIKE FUEL BUNDLE; uniform infinite array model.
broad_n
READ COMP
UO2   1  .84  293.  92235  2.35  92238  97.65  END
ZR    2  1  END
H2O   3  1  END
END  COMP
READ CELLDATA
LATTICECELL  SQUAREPITCH  PITCH=1.2751  3  FUELD=0.823  1  CLADD=0.9627  2  END
END CELLDATA
```

EXAMPLE 3. SQUAREPITCH PWR LATTICE, with non-uniform Dancoff.

This example is a single PWR assembly of fuel pins of the type described above, contained in a water pool. The interior pins in the assembly can be self-shielded using the same uniform, infinite lattice model in previous example. However self-shielding of the outer boundary-edge pins will be modified to account for being adjacent to a water reflector, rather than surrounded on all sides by similar pins. This requires that the MCDancoff module be executed previously to obtain non-uniform Dancoff factors for the edge pins. The average edge-pin value of 0.61 is used to represent Dancoff factors of all boundary pins. The default CENTRM MoC transport solver is used for both cells, but the original pitch of 1.2751 cm for the second cell (i.e., boundary pin) is modified to a new pitch corresponding to a Dancoff value of 0.61.

```
PWR-LIKE FUEL BUNDLE, with boundary-pin corrections
broad_n

H2O   6  1  END
END  COMP
READ CELLDATA
LATTICECELL  SQUAREPITCH PITCH=1.2751 3 FUELD=0.823 1 CLADD=0.9627 2  END
LATTICECELL  SQUAREPITCH PITCH=1.2751 6 FUELD=0.823 4 CLADD=0.9627 5  END
  CENTRM DATA  DAN2PITCH=0.61    END CENTRM
END CELLDATA
```

EXAMPLE 6. SPHTRIANGP ARRAY.

> Consider an infinite array of spherical pellets of 2.67% enriched UO_2 with a density of 10.3 g/cm^3 and a diameter of 1.0724 cm arranged in a "triangular" pitch, flooded with borated water at 4350 ppm. The boron is natural boron; the borated water is created by adding boric acid, H_3BO_3, and has a density of 1.0078 g/cm^3. The temperature is 15°.

Because the diameter of the fuel pellet, 1.0724 cm, is smaller than the average mean-free path in the UO_2, approximately 1.5 cm, and because the configuration is a regular array, **LATTICECELL** is the appropriate choice for proper cross-section processing.

The density fraction for the UO_2 is the ratio of actual to theoretical density (10.3/10.96 = 0.9398). Assume that the U is all ^{235}U and ^{238}U. See Sect. 7.1.4.1.9 for how to define borated water.

The XSProc data follows:

```
SPHERICAL  PELLETS  IN  BORATED  WATER

MULTIREGION input data

Examples of XSProc input data for **MULTIREGION** problems are given below.

EXAMPLE 1. SPHERICAL.

> Consider a small highly enriched uranium sphere supported by a Plexiglas collar in a tank of water. The uranium metal sphere has a diameter of 13.1075 cm, is 97.67% enriched, and has a density of 18.794 g/cm^3. The cylindrical Plexiglas collar has a 4.1275-cm-radius central hole, extends to a radius of 12.7 cm and is 2.54 cm thick. The water filled tank is 60 cm in diameter.

The density fraction of the uranium metal is the ratio of actual to theoretical density, where the theoretical density is obtained from the *Isotopes in standard composition library* table in section 7.2.1. Thus, the density multiplier is 18.794/19.05 = 0.9866. The abundance of uranium is not stated beyond 97.67% enriched, so it is reasonable to assume the remainder is ^{238}U. The Plexiglas collar is not significantly different from water and does not surround the fuel, so it can be ignored. If it is ignored, the problem becomes a 1-D geometry that can be defined using the **MULTIREGION** type of calculation, and the eigenvalue of the system can be obtained without additional data by executing CSAS1. However, the Plexiglas has been included in this data so it can be passed to a code such as KENO V.a which can describe the geometry rigorously. The XSProc data follow:

```

EXAMPLE 2. BUCKLEDSLAB.

> This example features a 93.2% enriched uranyl-fluoride solution inside a rectangular Plexiglas container immersed in water. The fissile solution contains 578.7 g of UO_2F_2 per liter and has no excess acid. The critical thickness of the fuel is 5.384 cm. The finite height of the fuel slab is 147.32 cm, and the depth is 71.58 cm. The Plexiglas container is 1.905 cm thick and is reflected by 20.32 cm of water.

The half thickness of the fuel (2.692) will be used with a reflected left boundary and a vacuum right boundary (default). The XSProc data follow:

DOUBLEHET input data

EXAMPLE 1: A doubly-heterogeneous spherical fuel element with 15,000 UO_2 particles in a graphite matrix.

Grain fuel radius is 0.025 cm. Grain contains one coating layer that is 0.009-cm-thick. Pebbles are in a triangular pitch on a 6.4-cm-pitch. Fuel pebble fuel zone is 2.5 cm in radius and contains a 0.5-cm-thick graphite clad that contains small amounts of ^{10}B. Pebbles are surrounded by ^{4}He. In this case we designated the homogenized mixture as mixture 10. If we have a KENO V.a or KENO-VI input section, we would use mixture 10 in that section. Note that the keyword "FUELR=" is followed by the fuel dimension only, i.e., no mixture number. That is because the fuel mixture number is specified with "FUELMIX=" and therefore need not be repeated.

EXAMPLE 3: A doubly-heterogeneous slab fuel element with flibe salt coolant

Grain fuel radii for UO_2 particles are 0.025 cm. The UO_2 grains contain four coating layers with thicknesses of 0.01, 0.0035, 0.003, and 0.004 cm, respectively. The fuel grains are embedded in a carbon matrix material to form the fuel compact. The x-dimension of fuel plate consists of a 0.5 cm (half-thickness) fuel compact region, a carbon clad with outer dimension of 1.27, followed by the flibe coolant with an outer reflected dimension of 1.62 cm. The width (y-dimension) of the slab plate is 22.5 cm and the height (z-dimension) is 500 cm. The y and z dimensions are only used to define volumes for the fuel plate.

Two methods of specifying a fissile solution

The standard composition specification data offer flexibility in the choice of input data. This section illustrates two methods of specifying the same fissile solution.

Create a mixture 3 that is aqueous uranyl nitrate solution:

$UO_2(NO_3)_2$, solution density = 1.555 g cm^3/

0.2669 g U/g-soln., 0.415 g U/ cm^3; excess nitrate = 0.39 mg/g-soln

Uranium isotopic content: 92.6 wt % U-235 5.9 wt % U-238

1.0 wt % U-234 and 0.5 wt % U-236

The SCALE atomic weights used in this problem are listed as follows:

H 1.0078

O 15.999

N 14.0067

U-234 234.041

U-235 235.0439

U-236 236.0456

U-238 238.0508

Two methods of describing the uranyl nitrate solution will be demonstrated. Method 1 is more rigorous, and method 2 is easier and as accurate.

METHOD 1:

This method involves breaking the solution into its component parts [(HNO_3, $UO_2(NO_3)_2$, and H_2O)] and entering the basic standard composition specifications for each.

1. Calculate the density of the HNO_3 0.39×10^{-3} g NO_3/g soln × [(62.997 g HNO_3/mole HNO_3)/(61.990 g NO_3/mole NO_3)] × 1.555 g soln/ cm^3soln = 6.16×10^{-4} g HNO_3/cc soln.
2. Calculate the density fraction of HNO_3 (actual density/theoretical density). In the Standard Composition Library the theoretical density of HNO_3 is 1.0. $6.16 \times 10^{-4}/1.0 = 6.16 \times 10^{-4}$.
3. Calculate the molecular weight of the uranium

The number of atoms in a mole of uranium is the sum of the number of atoms of each isotope in the mole of uranium.

Let AU = the average molecular weight of uranium, g U/mole U

GU = the density of uranium in g/cm^3.

Then the number of atoms in a mol of uranium =

$(6.023 \times 10^{+23} * 10^{-24} * GU)/AU$

or 0.6023 * GU/AU.

The weight fraction of each isotope is the weight % * 100.

Therefore, F235 = 0.926, the weight fraction of U-235 in the U

F238 = 0.059, the weight fraction of U-238 in the U

F236 = 0.005, the weight fraction of U-236 in the U

F234 = 0.010, the weight fraction of U-234 in the U

A235 = 235.0442, the molecular weight of U-235

A238 = 238.0510, the molecular weight of U-238

A236 = 236.0458, the molecular weight of U-236

A234 = 234.0406, the molecular weight of U-234.

Then the number of atoms of isotopes in a mol of uranium =

$6.023 \times 10^{+23} * 10^{-24} * ((GU*F235/A235) + (GU*F238/A238) +$

GU*F236/A236) + (GU*F234/A234))

or

0.6023*GU * (0.926/235.0442 + 0.059/238.0510 +

0.005/236.0458 + 0.010/234.0406).

Because the number of atoms of uranium equals the sum of the atoms of isotopes,

0.6023 * GU/AU = 0.6023 * GU *(0.926/235.0442 + 0.059/238.0510 +

0.005/236.0458 + 0.010/234.0406)

1/AU = 0.926/235.0442 + 0.059/238.0510 + 0.005/236.0458 + 0.010/234.0406

AU = 235.2144.

4. Calculate the molecular weight of the $UO_2(NO_3)_2$.

   $235.2144 + (8 \times 15.9954) + (2 \times 14.0033) = 391.184$ g $UO_2(NO_3)_2$/mole

5. Calculate the density of $UO_2(NO_3)_2$

   0.415 g U/cc × [(391.184 g $UO_2(NO_3)_2$/mol)/(235.2144 g U/mole)] =

   0.69018 g $UO_2(NO_3)_2$/ cm^3.soln.

Calculate the density fraction (actual density/theoretical density) of $UO_2(NO_3)_2$.

[In the Standard Composition Library the theoretical density of $UO_2(NO_3)_2$ is given as 2.2030 g/cm^3.]

The density fraction is 0.69018/2.2030 = 0.31329.

6. Calculate the amount of water in the solution

   1.555 g soln/ cm^3. soln - 6.16 × 10^{-4} g HNO_3/cm^3 soln - 0.69018 g $UO_2(NO_3)_2$LL/ cm^3. soln = 0.8642 g H_2O/cc soln.

7. Calculate the density fraction (actual density/theoretical density) of water.

```
HNO3        3   6.16-4   293  END
UO2(NO3)2   3  .31329  293  92235  92.6  92238  5.9  92234  1.0
                   92236   0.5  END
H2O         3    .86575  293  END
```

METHOD 2:

This method utilizes the solution option available in the standard composition specification data. Because the density is specified in the input data, this method should yield correct number densities that should agree with method 1 except for calculational round-off.

1. Calculate the fuel density

   0.415 g U/cc is 415 g U/L.

2. The molecular weight of nitrate NO_3 is 61.9895.

3. Calculate the molarity of the solution.

   0.39 mg nitrate/g soln × 1000 cm^{3}soln/L soln × 1 g/1000 mg × 1.555 g soln/ cm^{3}soln = 0.60645 g excess nitrate/L soln.

   A 1-molar solution is 1 mole of acid/L of solution:

   (For nitric acid 1 molar is 1 normal because there is only one atom of hydrogen per molecule of acid in HNO_3.)

   (0.60645 g nitrate/L soln)/(61.9895 g NO_3/mole NO_3) = 9.783 × 10^{-3} mole nitrate/L is identical to mole of acid/L, which is identical to molarity.

4. The density fraction of the solution is 1.0. Do not try to use the density of the solution divided by the theoretical density of $UO_2(NO_3)_2$ from the Standard Composition Library for your density multiplier. The $UO_2(NO_3)_2$ listed there is the solid, not the solution.

   The solution specification data follow:

```
SOLUTION      MIX=1   RHO[UO2(NO3)2] = 415    92235   92.6    92238   5.9
                      92234    1.0    92236   0.5
              MOLAR [HNO3] = 9.783-3
              TEMP = 293      DENSITY = 1.555 END SOLUTION
```

Comparison of number densities from the two methods

The number densities of methods 1 and 2 should agree within the limits of the input data. The density multipliers in method 1 are 5 digits and the density multipliers in method 2 are 4 digits. Therefore, the number densities calculated by the two methods should agree to 4 or 5 digits.

	Method 1	Method 2
Nuclide number	Atom density	Atom density
92235	9.84603E-04	9.84603E-04

Multiple unit cells in a single problem

Consider a problem that involves three different UO_2 fuel assemblies: a 1.98%-enriched assembly, a 2.64%-enriched assembly, and a 2.96%-enriched assembly. All fuel rods are UO_2 at 10.138 g/cm^3 and are 0.94 cm in diameter. The Zircaloy-4 clad has an inside radius of 0.4875 cm and an outside radius of 0.545 cm. The rod pitch is 1.44 cm. Each fuel assembly is a 15 × 15 array of fuel pins with water holes, instrumentation holes, and burnable poison rods. For cross-section processing, the presence of the water holes, instrumentation holes, and burnable poison rods in the assemblies are ignored.

The following XSProc input use the CENTRM/PMC method for self-shielding three latticecells with different fuel enrichments. The remaining mixture (SS-304), not specified in a unit cell, is processed as an infinite homogeneous medium using the BONAMI method. Each mixture can appear only in a single zone of one unit cell. For square pitch latticecells the default CENTRM transport solver is MoC with P0 scatter; however in this input, the solver for the 3rd cell is modified through CENTRM DATA to use the two-region approximation for the CE calculation [npxs=5], and discrete S_N transport calculation with P1 anisotropic scatteringfor the MG solutions in the fast and thermal energy ranges [nfst=0, nthr=0].

Multiple fissile mixtures in a single unit cell

The following problem involves large units having the bulk of their fissile material more than one mean-free path away from the surface of the unit. The interaction between the units that occurs in the resonance range is a very small fraction of the total interaction because an overwhelming percentage of the interaction occurs deep within each unit. Therefore, the resonance range interaction between the units can be ignored, and the default infinite homogeneous medium cross-section processing in the resonance range can be considered adequate for this particular application.

Consider a problem that consists of four 20.96-kg 93.2%-enriched uranium metal cylinders, density 18.76 g/cm^3, and four 5-liters Plexiglas bottles filled with highly enriched uranyl nitrate solution at 415 g/L, a specific gravity of 1.555, and 0.39 mg of excess nitrate per gram of solution. The isotopic content of the uranium metal is 93.2 wt % ^{235}U, 5.6 wt % ^{238}U, 1.0 wt % ^{234}U, and 0.2 wt % ^{236}U. The uranium isotopic content of the nitrate solution is 92.6 wt % ^{235}U, 5.9 wt % ^{238}U, 1.0 wt % ^{234}U and 0.5 wt % ^{236}U. The size of the metal cylinders is between 10 and 12 cm in diameter and height, and the size of the nitrate solution is on the order of 16 and 20 cm in diameter and height. The average mean-free path in the uranium metal is on the order of 1.5 cm, and the average mean free path in the nitrate solution is on the order of 0.5 cm. Therefore, infinite homogeneous medium is an appropriate choice for this problem and the use of CENTRM/PMC is valid.

See Examples 1–4 of Sect. 7.1.4.1.2 for data input details for the Plexiglas and uranium metal. See Example 1 of Sect. 7.1.4.1.5 for data input details for the uranyl nitrate solution. The XSProc data for this problem follow:

Cell weighting an infinite homogeneous problem

Cell weighting an infinite homogeneous medium has no effect on the cross sections because there is only one zone and one set of cross sections. However, a cell-weighted mixture number can still be supplied using the keyword **CELLMIX**= followed by an unique mixture number. This cell-weighted mixture number can be used in subsequent codes and will produce results similar to the cross sections of the original mixture.

EXAMPLE 1

This problem would probably be run with CSAS1 to provide the k-infinity of 20%-enriched UO_2.

```

Cell weighting a LATTICECELL problem

Cell weighting used with a **LATTICECELL** problem creates cell-weighted homogeneous cross sections that represent the characteristics of the heterogeneous unit cell. This cell-weighted mixture can then be used in a subsequent code for the overall volume where the cells are located without having to mock up the actual 3-D heterogeneous array of cells. This cell-weighted homogeneous mixture is designated by the user with the keyword **CELLMIX**= immediately followed by an unused mixture number. This needs to follow immediately after the cell description. Note that the mixtures used in the unit cell data cannot be used in a subsequent code because they have been flux weighted to create the user specified mixture. Therefore, if a mixture used in the unit cell description is also to be used in a subsequent code, another mixture must be created that is identical except for the mixture number. Every mixture that is to be used in a subsequent code except zero (i.e., void) must be defined in the standard composition data.

A byproduct of the cell-weighting calculation is the eigenvalue (k-effective) of an infinite array of the cell described as the unit cell.

EXAMPLE 1

Consider a cylindrical stainless steel tank filled with spherical pellets of 2.67%-enriched UO_2 arranged in a close-packed "triangular" pitch, flooded with borated water at 4350 ppm. The cylindrical stainless tank is sitting in a larger tank filled with borated water at 4350 ppm.

The data for the UO_2 and borated water were developed in detail in Example 3 of Sect. 7.1.4.3.2. The stainless steel must be defined, and mixture 3 was chosen because mixture 1 was the UO_2 and mixture 2 was the borated water. Because the borated water will be used as a reflector for the stainless steel tank and has been used in the unit cell data, it must be repeated with a different mixture number (in this case, as mixture 4).

In the subsequent calculation, user specified cell mixture 100 will be used to represent the UO_2 pellets in the borated water, mixture 3 will represent the stainless steel tank, and mixture 4 will represent the borated water reflector around the stainless-steel tank.

The XSProc data for creating the cell-weighted cross sections on mixture 100 follow:

```

Cell weighting a MULTIREGION problem

A **MULTIREGION** problem is cell weighted primarily to obtain a cell-weighted homogeneous cross section that represents the characteristics of the heterogeneous unit cell. The eigenvalue obtained for a **MULTIREGION** problem with cylindrical or spherical geometry having a white boundary condition specified on the right boundary approximates an infinite array of the cells. A vacuum boundary condition would represent a single cell. A slab with reflected boundary conditions for both boundaries represents an infinite array of slab cells. The cell-weighted cross sections for spherical or cylindrical geometries with a white right boundary condition do not use a Dancoff correction and thus may not be accurate for representing a large array of the specified units.

EXAMPLE 1

Consider a small, highly enriched uranium sphere supported by a Plexiglas collar in a tank of water. The uranium metal sphere has a diameter of 13.1075 cm, is 97.67% enriched, and has a density of 18.794 g/cm^3. The cylindrical Plexiglas collar has a 4.1275-cm radius central hole, extends to a radius of 12.7 cm and is 2.54 cm thick. The water-filled tank is 60 cm in diameter.

The Plexiglas collar is not significantly different from water and does not surround the fuel, so it will be ignored. Because this makes the problem a 1-D geometry, it can be defined using the **MULTIREGION** type of calculation and the eigenvalue of the system can be obtained without additional data by executing CSAS1 with CENTRM/PMC, if PARM=CENTRM is specified on the command line. The abundance of uranium is not stated beyond 97.67% enriched, so assume the remainder is ^{238}U. The XSProc data follow:

7.2 STANDARD COMPOSITION LIBRARY

L. M. Petrie, R. A. Lefebvre, and D. Wiarda

ABSTRACT

The SCALE Standard Composition Library provides a flexible and convenient means of generating models that include many types of materials. Users may specify materials as individual nuclides; elements with tabulated natural abundances; compounds, alloys, mixtures, and fissile solutions commonly encountered in engineering practice.

ACKNOWLEDGMENTS

This work was originally funded by the U.S. Nuclear Regulatory Commission through the Office of Nuclear Material Safety and Safeguards and the Office of Nuclear Regulatory Research. Continuing support is provided by the U.S. Department of Energy Nuclear Criticality Safety Program.

7.2.1 INTRODUCTION

The Standard Composition Library has been included within the SCALE system to provide the user with a simple and straightforward method of specifying the material mixtures for a given problem. The library consists of over 700 mixtures and isotopes commonly used within criticality safety, shielding, and reactor physics models. This library is tabulated in Sect. 7.2.2 with the various features of each composition. Additionally, a number of standard fissile solutions available for use are tabulated in Sect. 7.2.3.

The Standard Composition Library is created using the COMPOZ module, and can be updated by users as desired.

7.2.2 THE STANDARD COMPOSITION LIBRARY

The Standard Composition Library describes the various isotopes, elements (both symbols and full name), and compounds/alloys that can be used to define the material mixtures for a given problem. Typically, the alphanumeric description of one or more of these materials will be used to define a material mixture.

When formulating a mixture, it is often necessary to know the density (g/cm^3) of the various constituent materials. For convenience, the reference values given in the library have been listed in Table 7.2.2 through Table 7.2.5. Note that the given reference values represent the actual theoretical density, except in the case of isotopes and some individual nuclides where a default value of 1.0 g/cm^3 is used. The actual theoretical densities are fixed values at naturally occurring or nominal conditions. These default densities should not be used for materials containing enriched isotopes, especially light elements with isotopes that are strong absorbers such as boron, B_4C, or lithium. When densities are recalculated by other codes such as KENO, the recalculated densities may differ slightly from those given in the Standard Composition Library depending on the cross-section library specified in the calculation. Note that the recalculated mixture densities are presented for information purposes and are not used in the calculations.

Note that not all nuclides in the Standard Composition Library are available on each cross-section library, and user are encourage to review the code output for warning messages regarding composition data. Refer to the cross section library chapter for listings of available nuclides in each cross-section library.

Multiple sets of iron, nickel, and chromium nuclides are available in the Standard Composition Library. These sets correspond to different weighting functions used in generating the multigroup cross sections. One special weighting function corresponds to $1/[E\ \sigma_t(E)]$, where $\sigma_t(E)$ is the total cross section of the referenced nuclide or alloy. Entries have been added to the isotopic distribution table so that standard weighted isotopes will be requested if the desired nuclide is not on the specified library.

The nuclide identifying numbers (IDs) are listed in Table 7.2.1. Typically, the ID is 1000*Z + A, where Z and A are the charge and mass numbers for the nuclide (e.g., 1001 for ^{1}H and 8016 for ^{16}O). Exceptions to this rule include metastable nuclides, nuclides with bound thermal scattering data, and nuclides whose cross sections have a special weighting. Also, elements with isotopic mixtures (typically natural abundance) have IDs of Z* 1000.

If a nuclide identifier is listed in Table 7.2.1, it can be accessed and used in a user-specified material (a.k.a., arbitrary material). User-specified materials require the user to provide all the information normally found in the Standard Composition Library. Refer to the XSProc manual for details on how to input user-specified materials.

Several materials contain multiple isotopes of a single element. For these materials, the user is free to specify the isotopic distribution as discussed in the XSProc chapter. Alternatively, the user may elect not to enter this data, thereby telling the code to assume the default values shown in the tables. In describing a user-specified material, a multiple isotope ID of Z * 1000 can be used to denote the elements of Table 7.2.2. Note that even if the natural abundances from Table 7.2.2 are accessed through elemental specification, not all nuclides are necessarily present on each cross-section library. Refer to the Cross Section Library chapter for listings of available nuclides in each cross-section library.

Atomic masses for the isotopes were taken from "The Ame2003 atomic mass evaluation (II)" by G. Audi et al. [STDCOMPAWT03]. The atom percents of the isotopic distribution table were taken from "Isotopic Compositions of the Elements, 2001" by J. K. Bohlke [STDCOMPBDLDB+05]. Densities were taken from several sources, including the CRC Handbook of Chemistry and Physics [STDCOMPWea01]. Gases and explicit isotopes were changed to all have a theoretical density of 1.0 g/cm^3.

To more fully document the composition of each compound and/or document the assumptions used in producing the associated cross-section data, a brief description is given in the tables where needed.

*If the column for the chemical symbol has a value, the name and the chemical symbol refer to the same composition. Otherwise, the chemical symbol refers to a different composition. In case of monoisotopic elements, such as ^{209}Bi, the chemical symbol refers directly to SCALE ID 83209 instead of 83000. See Table 7.2.3 for details.

Table 7.2.3: Elements and special nuclide symbols.

Name	Description	ID	Density
activities		900	1.0
1/vabsorber		999	1.0
d	Deuterium in heavy water with S(α,β) thermal kernel	1002	1.0
h-liquid_ch4	Liquid methane at 100 K	1001001	1.0
albound	Al metal with S(α,β) thermal kernel	1013027	2.702
zr90-zr5h8	Zr-90 with the S(α,β) thermal kernel for Zr in zrh2 and zr5h8	1040090	1.0
zr91-zr5h8	Zr-91 with the S(α,β) thermal kernel for Zr in zrh2 and zr5h8	1040091	1.0
zr92-zr5h8	Zr-92 with the S(α,β) thermal kernel for Zr in zrh2 and zr5h8	1040092	1.0
zr93-zr5h8	Zr-93 with the S(α,β) thermal kernel for Zr in zrh2 and zr5h8	1040093	1.0
zr94-zr5h8	Zr-94 with the S(α,β) thermal kernel for Zr in zrh2 and zr5h8	1040094	1.0
zr95-zr5h8	Zr-95 with the S(α,β) thermal kernel for Zr in zrh2 and zr5h8	1040095	1.0
zr96-zr5h8	Zr-96 with the S(α,β) thermal kernel for Zr in zrh2 and zr5h8	1040096	1.0
h-solid_ch4	Solid methane at 22 K	2001001	1.0
bebound	Beryllium metal with a S(α,β) thermal kernel	3004009	1.85
h-cryo_ortho	H at cryogenic temperatures with ortho form	4001001	1.0

7.2.3 TABLE OF FISSILE SOLUTIONS

The Standard Composition Library (through) describes the various compounds, alloys, elements, and isotopes one may use in defining the material mixtures for a given problem. In addition to the various materials listed there, one is also free to use any of the fissile solutions listed in Table 7.2.6. Indeed, the user is encouraged to treat the solutions listed in Table 7.2.6 as he would any other standard composition. Using empirical fits to experimental data, the code will then automatically calculate the density of the solution, or the user can explicitly specify the density. The code then calculates the volume fraction corresponding to the heavy metal, acid, and water components of the solution. A fissile solution starts with the keyword, SOLUTION, after which one or two salts and the corresponding acid may be specified. Input specifications for fissile solutions can be found in the XSPROC chapter.

7.3 BONAMI: RESONANCE SELF-SHIELDING BY THE BONDARENKO METHOD

U. Mertyurek, M. L. Williams, and K. S. Kim

ABSTRACT

BONAMI is a module of the SCALE code system that is used to perform Bondarenko calculations for resonance self-shielding. BONAMI obtains problem-independent cross sections and Bondarenko shielding factors from a multigroup (MG) AMPX master library, and it creates a MG AMPX working library of self-shielded, problem-dependent cross sections. Several options may be used to compute the background cross section values using the narrow resonance or intermediate resonance approximations, with and without Bondarenko iterations. A novel interpolation scheme is used that avoids many of the problems exhibited by other interpolation methods for the Bondarenko factors. BONAMI is most commonly used in automated SCALE sequences and is fully integrated within the SCALE cross section processing module, XSProc. New spatially dependent self-shielding capability has been incorporated into BONAMI for SCALE 6.3.

Acknowledgments

The authors express gratitude to W. A. Wieselquist and M. A. Jessee for their supervision of the SCALE project and review of the manuscript. The authors acknowledge N. M. Greene, formerly of ORNL, for his original development of and contributions to the BONAMI module and methodology.

7.3.1 INTRODUCTION

BONAMI (**BON**darenko **AM**PX **I**nterpolator) is a SCALE module that performs resonance self-shielding calculations based on the Bondarenko method [BONAMIIB64]. It reads Bondarenko shielding factors ("f-factors") and infinitely dilute microscopic cross sections from a problem-*independent* nuclear data library processed by the AMPX system [BONAMIWWCD15], interpolates the tabulated shielding factors to appropriate temperatures and background cross sections for each nuclide in the system, and produces a self-shielded, problem-dependent data set.

The code performs self-shielding for an arbitrary number of mixtures using either the narrow resonance (NR) or intermediate resonance (IR) approximation [BONAMIGC62]. The latter capability was introduced in SCALE 6.2. BONAMI has several options for computing background cross sections, which may include Bondarenko iterations to approximately account for the impact of resonance interference for multiple resonance absorbers. Heterogeneous effects are treated using equivalence theory based on an "escape cross section" for arrays of slabs, cylinders, or spheres. During the execution of a typical SCALE computational sequence using XSProc, Dancoff factors for uniform lattices of square- or triangular-pitched units are calculated automatically for BONAMI by numerical integration over the chord length distribution. However, for non-uniform lattices-such as those containing water holes, control rods, and so on-the SCALE module MCDancoff can be run to compute Dancoff factors using Monte Carlo for an arbitrary 3D configuration, and these values are then provided in the sequence input.

The conventional BONAMI approach in SCALE 6.2 introduces significant biases of reactivity and intra pin self-shielded cross sections for multiple fuel rings with uniform or nonuniform temperature profile. New spatially dependent resonance self-shielding method [BONAMIKHW21] has been developed and implemented into BONAMI for SCALE 6.3.

The major advantages of the Bondarenko approach are its simplicity and speed compared with SCALE's more rigorous CENTRM/PMC self-shielding method, which performs a pointwise (PW) deterministic transport calculation "on the fly" to compute multigroup (MG) self-shielded cross sections. With the availability of IR theory in BONAMI, accurate results can be obtained for a variety of system types without the computation expense of CENTRM/PMC.

7.3.2 BONDARENKO SELF-SHIELDING THEORY

In MG resonance self-shielding calculations, one is interested in calculating effective cross sections of the form

$$\sigma_{X,g}^{(r)} = \frac{\int_g \sigma_X^{(r)}(E)\Phi(E)\mathrm{dE}}{\int_g \Phi(E)\mathrm{dE}}, \tag{7.3.1}$$

where $\sigma_{X,g}^{(r)}$ is the shielded MG cross section for reaction type X of resonance nuclide r in group g; $\sigma_X^{(r)}(E)$ is a PW cross section; and $\Phi(E)$ is the PW weighting function, which approximates the flux spectrum per unit of energy for the system of interest. PW cross section values are known from processing evaluated data in ENDF/B files; therefore, resonance self-shielding depends mainly on determining the problem-dependent flux spectrum $\Phi(E)$, which may exhibit significant fine structure variations as a result of resonance reactions.

The essence of the Bondarenko method is to parameterize the flux spectrum corresponding to varying degrees of self-shielding, represented by the background cross section parameter σ_0 (called "sigma-zero") and the Doppler broadening temperature T. Hence,

$$\Phi(\mathrm{E}) \rightarrow \Phi(\mathrm{E}; \sigma_{0,\mathrm{g}}^{(\mathrm{r})}, \mathrm{T}) \quad , \quad \mathrm{E} \in \mathrm{g} \; ; \text{and } \sigma_{X,g}^{(r)} \rightarrow \sigma_{X,g}^{(r)}(\sigma_{0,g}^{(r)}, \mathrm{T}) \tag{7.3.2}$$

With this approach, it is possible to preprocess MG data for different background cross sections representing varying degrees of resonance self-shielding. This allows the MG averaging to be performed during the original MG library processing, so that BONAMI can do a simple interpolation on the background cross section and temperature to obtain self-shielded cross sections. This procedure is much faster than the CENTRM/PMC method in SCALE, which computes a PW flux spectrum by solving the neutron transport equation on a PW energy mesh in CENTRM and then evaluates Eq. (7.3.1). in PMC "on the fly" during a sequence execution.

BONAMI performs two main tasks: (a) computation of background cross sections for all nuclides in each mixture in the system and (b) interpolation of shielded cross sections from the library values tabulated vs. background cross sections and temperature. The BONAMI calculation is essentially isolated from the computation of the tabulated shielded cross sections, which is performed by the AMPX processing code system-the only connection is through the definition of the background cross section used in processing the library values. Various approximations can be used to parameterize the flux spectrum in terms of a background XS, as required by the Bondarenko method. We will first consider several approaches to representing the flux in an infinite medium, which lead to different definitions of the background cross section. BONAMI's use of equivalence theory to extend the homogeneous methods to address heterogeneous systems, such as reactor lattices, is discussed in the following section.

7.3.2.1 Parameterized Flux Spectra

Several approximations can be applied to the infinite medium transport equation to parameterize the flux spectrum in terms of a background XS, as required by the Bondarenko method. The resulting homogeneous spectra are used in AMPX to process MG cross sections which can also can be applied to heterogeneous systems (i.e., lattices) by using equivalence theory; thus the key step is determining approximations that provide parameterized solutions for homogeneous media. The neutron transport equation for a homogeneous medium at temperature T, containing a resonance nuclide r mixed with other nuclides can be expressed as

$$\left(\Sigma_t^{(r)}(E,T) + \sum_{j\neq r}\Sigma_t^{(j)}(E,T)\right)\Phi(E,T) = S^{(r)}(E,T) + \sum_{j\neq r} S^{(j)}(E,T), \tag{7.3.3}$$

where $\Sigma_t^{(r)}(E,T)$, $S^{(r)}(E,T)$ are the macroscopic total XS and elastic scattering source for r, respectively; and $\Sigma_t^{(j)}(E,T)$, $S^{(j)}(E,T)$ are the macroscopic total cross section and elastic source, respectively, for a nuclide j. The cross sections in all these expressions are Doppler-broadened to the temperature of the medium. The nuclides in the summations (i.e., all nuclides except r) are called background nuclides for the resonance absorber r.

The NR approximation can be used to approximate scattering sources of nuclides for which the neutron energy loss is large compared with the practical widths of resonances for the absorber materials of interest. Applying the NR approximation for the scattering source of background material j gives

$$S^{(j)}(E,T) \rightarrow \Sigma_p^{(j)} C(E) \text{for j = a NR-scatterer nuclide} \tag{7.3.4}$$

where C(E) is a slowly varying function representative of the asymptotic (i.e., no absorption) flux in a homogeneous medium, which approximates the flux between resonances. In the resolved resonance range of most important resonance absorbers, the asymptotic flux per unit energy is represented as,

$$C(E) = \frac{\Phi_\infty}{E}, \tag{7.3.5}$$

where Φ_∞ is an arbitrary normalization constant that cancels from the MG cross section expression. In the thermal range a Maxwellian spectrum is used for C(E), and in the fast range a fission spectrum is used. The

SCALE Cross Section Libraries section of the SCALE documentation gives analytical expressions for C(E) used in AMPX to process MG data with the NR approximation. AMPX also has an option to input numerical values for C(E), obtained for example from a PW slowing-down calculation with CENTRM. This method has been used to process MG data for some nuclides on the SCALE libraries.

Conversely, the wide resonance (WR) approximation has been used to represent elastic scattering sources of nuclides for which the neutron energy loss is small compared with the practical width of the resonance. This approximation tends to be more accurate for heavy nuclides and for lower energies. The limit of infinite mass is usually assumed, so the WR approximation is sometimes called the infinite mass (IM) approximation. Because of the assumption of IM, there is no energy loss due to collisions with WR scatterers. Applying the WR approximation for the slowing-down source of background nuclide *j* gives

$$\mathrm{S}^{(j)}(\mathrm{E,T}) \rightarrow \Sigma_s^{(j)}(\mathrm{E,T})\Phi(\mathrm{E,T}); \text{for } j = \text{a WR-scatterer nuclide} \tag{7.3.6}$$

The IR approximation was proposed in the 1960s for scatterers with slowing-down properties intermediate between those of NR and WR scatterers [BONAMIGC62]. The IR method represents the scattering source for arbitrary nuclide *j* by a linear combination of NR and WR expressions. This is done by introducing an IR parameter usually called lambda, such that

$$\mathrm{S}^{(\mathrm{j})}(\mathrm{E,T}) \;\rightarrow\; \underbrace{\lambda_{\mathrm{g}}^{(\mathrm{j})}\Sigma_{\mathrm{p}}^{(\mathrm{j})}\,C(E)}_{\textbf{NRscatterer}} \;+\; (1-\lambda_{\mathrm{g}}^{(\mathrm{j})})\;\underbrace{\Sigma_{\mathrm{s}}^{(\mathrm{j})}(\mathrm{E,T})\Phi(\mathrm{E,T})}_{\textbf{WRscatterer}} \quad ; \quad \mathrm{E}\in \mathrm{g}\,. \tag{7.3.7}$$

A value of $\lambda = 1$ reduces Eq. (7.3.7) to the NR expression, whereas math:*lambda = 0* reduces the equation to the WR expression. Fractional math:*lambda*s are for IR scatterers. Since the type of scatterer can change with the energy, the IR lambdas are functions of the energy group as well as the nuclide. The math:*lambda* values represent the moderation "effectiveness" of a given nuclide, compared to hydrogen. The AMPX module LAMBDA was used to compute the IR parameters on the SCALE libraries. (See AMPX documentation distributed with SCALE) Substituting Eq. (7.3.7) into Eq. (7.3.3) and then dividing by the absorber number density *N(r)* gives the following IR approximation for the infinite medium transport equation in energy group g

$$\left(\sigma_{\mathrm{t}}^{(\mathrm{r})}(\mathrm{E,T}) + \sigma_0^{(\mathrm{r})}(\mathrm{E,T})\right)\Phi^{(\mathrm{r})}(\mathrm{E,T}) \;=\; \frac{1}{\mathrm{N}^{(\mathrm{r})}}\mathrm{S}^{(\mathrm{r})}(\mathrm{E,T}) \;+\; \frac{1}{\mathrm{N}^{(\mathrm{r})}}\sum_{j\neq r}\lambda_{\mathrm{g}}^{(\mathrm{j})}\,\Sigma_{\mathrm{p}}^{(\mathrm{j})}C(E) \tag{7.3.8}$$

where the background cross section of *r* in the homogeneous medium is defined as

$$\sigma_0^{(\mathrm{r})}(\mathrm{E,T}) \;=\; \frac{1}{\mathrm{N}^{(\mathrm{r})}}\;\sum_{j\neq r}\left(\Sigma_{\mathrm{a}}^{(\mathrm{j})}(\mathrm{E,T}) + \lambda_{\mathrm{g}}^{(\mathrm{j})}\,\Sigma_{\mathrm{s}}^{(\mathrm{j})}(\mathrm{E,T})\right) \tag{7.3.9}$$

Although Eq. (7.3.8) provides the flux spectrum as a function of the background cross section $\sigma_0^{(r)}(u,T)$ it is not in a form that can be preprocessed when the MG library is generated, because the energy variation of $\sigma_0^{(r)}(E,T)$ must be known. If the total cross sections of the background nuclides in Eq. (7.3.9) have different energy variations, the shape of $\sigma_0^{(r)}(E,T)$ depends on their relative concentrations-which are not known when the MG library is processed. However, if the cross sections in Eq. (7.3.9) are independent of energy, so that the background cross section is *constant*, Eq. (7.3.8) can be solved for any arbitrary value of $\sigma_0^{(r)}$ as a parameter. This obviously occurs for the special case in which nuclide *r* is the only resonance nuclide in the mixture; i.e., the background materials are nonabsorbing moderators for which the total cross section is equal to the potential cross section. In this case, $\sigma_0^{(r)}(E,T) \;\rightarrow\; \sigma_{0,g}^{(r)}$, where

$$\sigma_{0,g}^{(r)} \;=\; \frac{1}{N^{(r)}}\sum_{j\neq i}N^{(j)}\,\lambda_g^{(j)}\sigma_p^{(j)} \tag{7.3.10}$$

If the mixture contains multiple resonance absorbers, as is usually the case, other approximations must be made to obtain a constant background cross section.

The approximation of "no resonance interference" assumes that resonances of background nuclides do not overlap with those of nuclide *r*, so their total cross sections can be approximated by the potential values within resonances of *r* where self-shielding occurs. In this approximation, the expression in Eq. (7.3.10) is also used for the background cross section.

Another approximation is to represent the energy-dependent cross sections of the background nuclides by their group-averaged (i.e., self-shielded cross) values; thus

$$\sigma_a^{(j)}(E,T) \quad \rightarrow \quad \sigma_{a,g}^{(j)} \quad ; \qquad \sigma_s^{(j)}(E,T) \quad \rightarrow \quad \sigma_{s,g}^{(j)} \text{ for } E \in g \tag{7.3.11}$$

In this case, the background cross section in Eq. (7.3.9) for nuclide *r* is the group-dependent expression,

$$\sigma_{0,g}^{(\mathrm{r})} \;=\; \frac{1}{\mathrm{N}^{(\mathrm{r})}} \sum_{j \neq r} \left(\Sigma_{\mathrm{a,g}}^{(\mathrm{j})} + \lambda_{\mathrm{g}}^{(\mathrm{j})} \Sigma_{\mathrm{s,g}}^{(\mathrm{j})} \right) \tag{7.3.12}$$

An equation similar to Eq. (7.3.12) is used for the background cross sections of all resonance nuclides; thus the self-shielded cross sections of each resonance absorber depend on the shielded cross sections of all other resonance absorbers in the mixture. When self-shielding operations are performed with BONAMI for this approximation, "Bondarenko" iterations are performed to account for the inter-dependence of the shielded cross sections.

Assuming that $\sigma_0^{(r)}$ is represented as a groupwise-constant based on one of the previous approximations, several methods can be used to obtain a parameterized flux spectrum for preprocessing Bondarenko data in the MG libraries. In the simpliest approach, the scattering source of the resonance nuclide *r* in Eq. (7.3.8) is represented by the NR approximation, $\mathrm{S}^{(\mathrm{r})}(\mathrm{E,T})$ to $\Sigma_{\mathrm{p}}^{(\mathrm{r})} C(E)$. In this case, Eq. (7.3.8) can be solved analytically to obtain the following expression for the flux spectrum used to process MG data as a function of $\sigma_0^{(r)}$:

$$\Phi^{(\mathrm{r})}(\mathrm{E};\sigma_0^{(\mathrm{r})},\mathrm{T}) \;=\; \frac{\sigma_{\mathrm{p}}^{(\mathrm{r})} \;+\; \frac{1}{\mathrm{N}^{(\mathrm{r})}} \sum\limits_{j \neq r} \Sigma_{\mathrm{p}}^{(\mathrm{j})}}{\sigma_{\mathrm{t}}^{(\mathrm{r})}(\mathrm{E,T}) + \sigma_0^{(\mathrm{r})}} C(E) \quad \rightarrow \quad \frac{C(E)}{\sigma_{\mathrm{t}}^{(\mathrm{r})}(\mathrm{E,T}) + \sigma_0^{(\mathrm{r})}} \tag{7.3.13}$$

where C(E) includes is an arbitrary constant multiplier that cancels from Eq. (7.3.1).

A more accurate approach that does not require using the NR approximation is to directly solve the IR form of the neutron transport equation using PW cross sections, with the assumption of no interference between mixed absorber resonances. The IRFfactor module of AMPX uses XSProc to calculate the self-shielded flux spectrum for MG data processing using one of two options:

(a) A homogeneous model corresponding to an infinite medium of the resonance nuclide mixed with hydrogen, in which the ratio of the absorber to hydrogen number densities is varied in CENTRM to obtain the desired background cross section values;

(b) A heterogeneous model corresponding to a 2D unit cell from an infinite lattice, in which the cell geometry (e.g., pitch) as well as the absorber number density is varied in CENTRM to obtain the desired background cross section values.

Both of these models provide a numerical solution for the flux spectrum. Details on these approaches are given in reference 2.

7.3.2.2 Self-Shielded Cross Section Data in SCALE Libraries

The AMPX code system processes self-shielded cross sections using the flux expressions described in the preceding section. For MG libraries in SCALE-6.2 and later versions, the NR approximation in Eq. (7.3.13) is used to represent the flux spectrum for nuclides with masses below A=40, since the NR approximation is generally accurate for low-mass nuclides and/or high energies. The standard AMPX weight functions are used to represent C(E) over the entire energy range for all nuclides with A<40, except for hydrogen and oxygen which use a calculated C(E) from CENTRM. The NR approximation with a calculated C(E) function is also used to represent the spectrum above the resolved resonance range for nuclides with A>40; but in the resolved resonance range of these nuclides, AMPX processes shielded cross sections with flux spectra obtained from CENTRM calculations using either a homogeneous or heterogeneous model. Regardless of the method used to obtain the flux spectrum, the parameterized shielded cross sections for absorber nuclide "r" are computed from the expression,

$$\sigma_{\mathrm{X,g}}^{(\mathrm{r})}(\sigma_0^{(r)},T) \quad = \quad \frac{\int_g \ \sigma_X^{(r)}(E,T)\ \Phi(E;\ \sigma_0^{(r)},T)\,dE}{\int_g \ \Phi(E;\ \sigma_0^{(r)},T)\ dE} \quad , \tag{7.3.14}$$

where $\Phi(E;\ \sigma_0^{(r)},T)$ is the flux for a given value of $\sigma_0^{(r)}$ and T.

Rather than storing self-shielded cross sections in the master library, AMPX converts them to Bondarenko shielding factors, also called f-factors, defined as the ratio of the shielded cross section to the infinitely dilute cross section. Thus the MG libraries in SCALE contain Bondarenko data consisting of f-factors defined as

$$f_{\mathrm{X,g}}^{(\mathrm{r})}(\sigma_0,T) \quad = \quad \frac{\sigma_{\mathrm{X,g}}^{(\mathrm{r})}(\sigma_0,T)}{\sigma_{\mathrm{X,g}}^{(\mathrm{r})}(\infty)} \quad , \tag{7.3.15}$$

and infinitely dilute cross sections defined as,

$$\sigma_{\mathrm{X,g}}^{(\mathrm{r})}(\infty) \quad = \quad \sigma_{\mathrm{X,g}}^{(\mathrm{r})}(\sigma_0=\infty, T=T_{ref}) \rightarrow \quad \frac{\int_g \ \sigma_X^{(r)}(E,T_{ref})\,C(E)\ dE}{\int_g \ C(E)\ dE} \quad . \tag{7.3.16}$$

In AMPX, the reference temperature for the infinitely dilute cross section is normally taken to be 293 K. Bondarenko data on SCALE libraries are provided for all energy groups and for five reaction types: total, radiative capture, fission, within-group scattering, and elastic scatter. Recent SCALE libraries include f-factors at ~10–30 background cross section values (depending on nuclide) ranging from ~10^{-3} to ~10^{10} barns, which span the range of self-shielding conditions. Typically the f-factor data are tabulated at five temperature values. Background cross sections and temperatures available for each nuclide in the SCALE MG libraries are given in the SCALE Cross Section Libraries chapter.

7.3.2.3 Background Cross Section Options in BONAMI

To compute self-shielded cross sections for nuclide *r*, BONAMI first computes the appropriate background cross section for the system of interest and then interpolates the library Bondarenko data to obtain the f-factor corresponding to this σ_0 and nuclide temperature. Several options are available in BONAMI to compute the background cross section, based on Eq. (7.3.10) and Eq. (7.3.12) in the preceding section. The options are specified by input parameter "**iropt**" and have the following definitions:

(a) iropt = 0 => NR approximation with Bondarenko iterations:

Background cross sections for all nuclides are computed using Eq. (7.3.12) with math:*lambda = 1*; therefore,

$$\sigma_0^{(\mathrm{r})} = \frac{1}{\mathrm{N}^{(\mathrm{r})}} \sum_{j \neq r} \Sigma_{\mathrm{t,g}}^{(\mathrm{j})}. \tag{7.3.17}$$

Since the background cross section for each nuclide depends on the shielded total cross sections of all other nuclides in the mixture, "Bondarenko iterations" are performed in BONAMI to obtain a consistent set of shielded cross sections. Bondarenko iterations provide a crude method of accounting for resonance interference effects that are ignored by the approximation for $\sigma_0^{(r)}$ in Eq. (7.3.10). The BONAMI iterative algorithm generally converges in a few iterations. Prior to SCALE-6.2, this option was the only one available in BONAMI, and it is still the default for XSProc.

(b) iropt = 1 => IR approximation with no resonance interference (potential cross sections):

Background cross sections for all nuclides are computed using Eq. (7.3.10). No Bondarenko iterations are needed.

(c) iropt t = 2 => IR approximation with Bondarenko iterations, but no resonance scattering:

Background cross sections for all nuclides are computed using Eq. (7.3.12) with the scattering cross section approximated by the potential value; therefore,

$$\sigma_0^{(\mathrm{r})} = \frac{1}{\mathrm{N}^{(\mathrm{r})}} \sum_{j \neq r} \left(\Sigma_{\mathrm{a,g}}^{(\mathrm{j})} + \lambda_{\mathrm{g}}^{(\mathrm{j})} \Sigma_{\mathrm{p}}^{(\mathrm{j})} \right) \tag{7.3.18}$$

Since the background cross section for each resonance nuclide includes the shielded absorption cross sections of all other nuclides, Bondarenko interactions are performed.

(d) iropt = 3 => IR approximation with Bondarenko iterations:

Background cross sections for all nuclides are computed using the full IR expression in Eq. (7.3.12). Bondarenko interactions are performed.

Computation of the background cross sections in BONAMI generally requires group-dependent values for the IR parameter math:*lambda*. These are calculated by a module in AMPX during the library process and are stored in the MG libraries under the reaction identifier (MT number), MT=2000.

7.3.2.4 Self-Shielded Cross Sections for Heterogeneous Media

Equivalence theory can be used to obtain shielded cross sections for heterogeneous systems containing one or more "lumps" of resonance absorber mixtures separated by moderators, such as reactor lattices. It can be shown that if the fuel escape probability is represented by the Wigner rational approximation, the collision probability formulation of the neutron transport equation for an absorber body in a heterogeneous medium can be reduced to a form identical to Eq. (7.3.3). This can be done for an "equivalent" infinite homogeneous medium consisting of the same absorber body mixture plus an additional NR scatterer with a constant cross section called the "escape cross section" [BONAMILam66]. Equivalence theory states that the self-shielded cross section for resonance absorber *r* in the heterogeneous medium is equal to the self-shielded cross section of *r* in the equivalent infinite homogeneous medium; therefore the f-factors that were calculated for homogenous mixtures can also be used to compute self-shielded cross sections for heterogeneous media by simply interpolating the tabulated f-factors in the library to the modified sigma-zero value of

$$\hat{\sigma}_0^{(r)} = \sigma_0^{(r)} + \sigma_{esc}^{(r)} \tag{7.3.19}$$

where,

$\hat{\sigma}_0^{(r)}$ = background cross section of r in the absorber lump of the heterogeneous system;

$\sigma_0^{(r)}$ = background cross section defined in Sect. 7.3.2.1 for an infinite homogeneous medium of the absorber body mixture;

$\sigma_{esc}^{(r)}$ = microscopic escape cross section for nuclide *r*, defined as

$$\sigma_{esc}^{(r)} = \frac{\Sigma_{esc}}{N^{(r)}} \tag{7.3.20}$$

Σ_{esc} = macroscopic escape cross section for the absorber lump defined in BONAMI as

$$\Sigma_{esc} = \frac{(1 - c)A}{\bar{\ell}\ [1 + (A - 1)\, c]} \tag{7.3.21}$$

where

$\bar{\ell}$ = average chord length of the absorber body = $4 \times \frac{volume}{surface\ \ area}$;

A = Bell factor, used to improve the accuracy of the Wigner rational approximation;

c = lattice Dancoff factor, which is equal to the probability that a neutron escaping from one absorber body will reach another absorber body before colliding in the intervening moderator.

Values for the mean chord length $\bar{\ell}$ are computed in BONAMI for slab, sphere, and cylinder absorber bodies. In the most common mode of operation where BONAMI is executed through the XSProc module in SCALE, Dancoff factors for uniform lattices are computed automatically and provided as input to BONAMI. For nonuniform lattices-such as those containing water holes, control rods, etc.-it may be desirable for the user to run the SCALE module MCDancoff to compute Dancoff factors using Monte Carlo for an arbitrary 3D configuration. In this case the values are provided in the MORE DATA input block of XSProc. The Bell factor "A" is a correction factor to account for errors caused by use of the Wigner rational approximation to represent the escape probability from a lump. Two optional Bell factor corrections are included in BONAMI. The first uses expressions developed by Otter that essentially force the Wigner escape probability for an isolated absorber lump to agree with the exact escape probability for the particular geometry by determining a value of A as a function of $\Sigma_T \bar{\ell}$ for slab, cylindrical, or spherical geometries. Since the Otter expression was developed for isolated bodies, it does not account for errors in the Wigner rational approximation due to lattice effects. BONAMI also includes a Bell factor correction based on a modified formulation developed by Leslie [BONAMILHJ65] that is a function of the Dancoff factor.

7.3.3 INTERPOLATION SCHEME

After the background cross section for a system has been computed, BONAMI interpolates f-factors at the appropriate σ_0 and temperature from the tabulated values in the library. Fig. 7.3.1 shows a typical variation of the f-factor vs. background cross sections for the capture cross section of ^{238}U in the SCALE 252 group library.

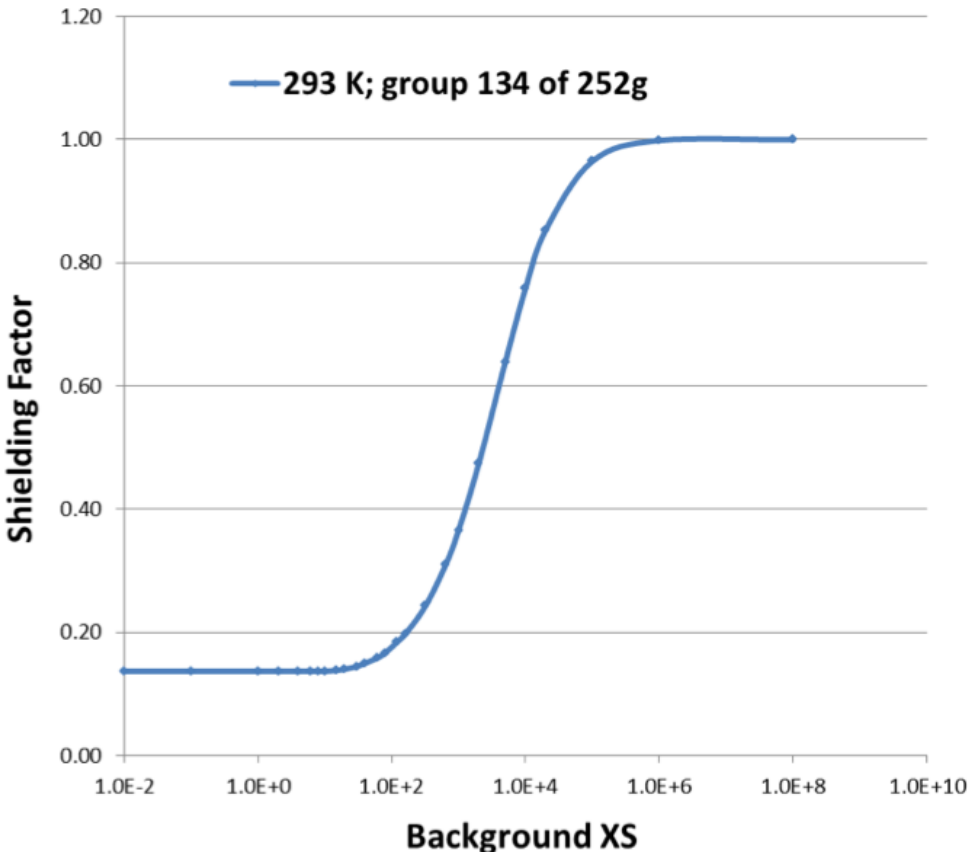

Fig. 7.3.1: Plot of f-factor variation for ^{238}U capture reaction.

Interpolation of the f-factors can be problematic, and several different schemes have been developed for this purpose. Some of the interpolation methods that have been used in other codes are constrained Lagrangian, [BONAMIDYB77] arc-tangent fitting, [BONAMIKid74] and an approach developed by Segev [BONAMISeg81]. All of these were tested and found to be inadequate for use with the SCALE libraries, which may have multiple energy groups within a single resonance. BONAMI uses a unique interpolation method developed by Greene, which is described in [BONAMIGre82]. Greene's interpolation method is essentially a polynomial approach in which the powers of the polynomial terms can vary within a panel, as shown in Eq. (7.3.25):

$$f(\sigma) = f(\sigma_1) + \frac{\sigma^{q(\sigma)} - \sigma_1^{q(\sigma)}}{\sigma_2^{q(\sigma)} - \sigma_1^{q(\sigma)}} (f(\sigma_2) - f(\sigma_1)) , \qquad (7.3.22)$$

where

$$q(\sigma) = q(\sigma_1) + \frac{\sigma - \sigma_1}{\sigma_2 - \sigma_1} (q(\sigma_2) - q(\sigma_1)) . \qquad (7.3.23)$$

Fig. 7.3.2 illustrates the expected behavior of Eq. (7.3.22) caused by varying the powers in a panel.

By allowing the power q to vary as a function of independent variable *sigma*, we can move between the various monotonic curves on the graph in a monotonic fashion. Note that when p crosses the $p = 1$ curve, the shape changes from concave to convex, or vice versa.

This shape change means that we can use the scheme to introduce an inflection point, which is exactly the situation needed for interpolating f-factors.

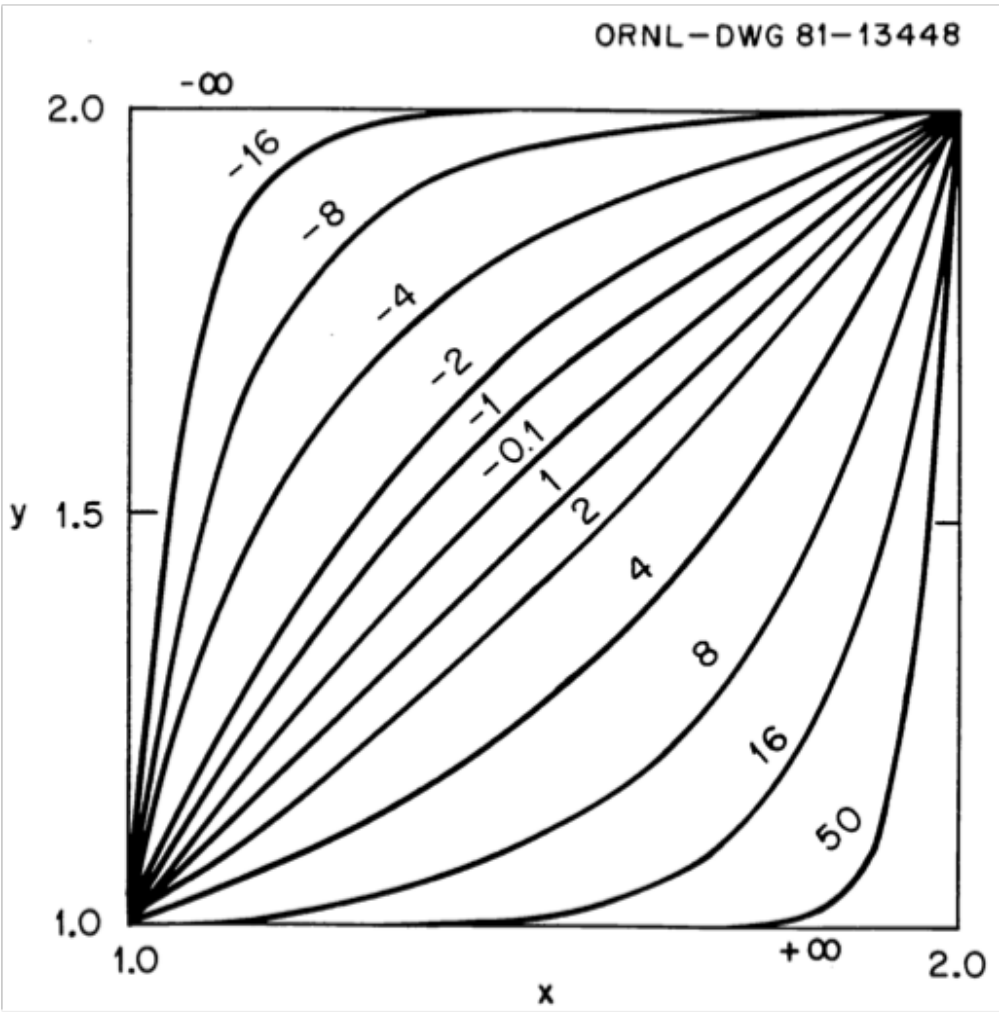

Fig. 7.3.2: Illustration of the effects of varying "powers" in the Greene interpolation method.

Fig. 7.3.3 and Fig. 7.3.3 show typical "fits" of the f-factors using the Greene interpolation scheme for two example cases. Note, in particular, that since this scheme has guaranteed monotonicity, it easily accommodates the end panels that have the smooth asymptotic variation. Even considering the extra task of having to determine the powers for temperature and σ_0 interpolations, the method is not significantly more time-consuming than the alternative schemes for most applications.

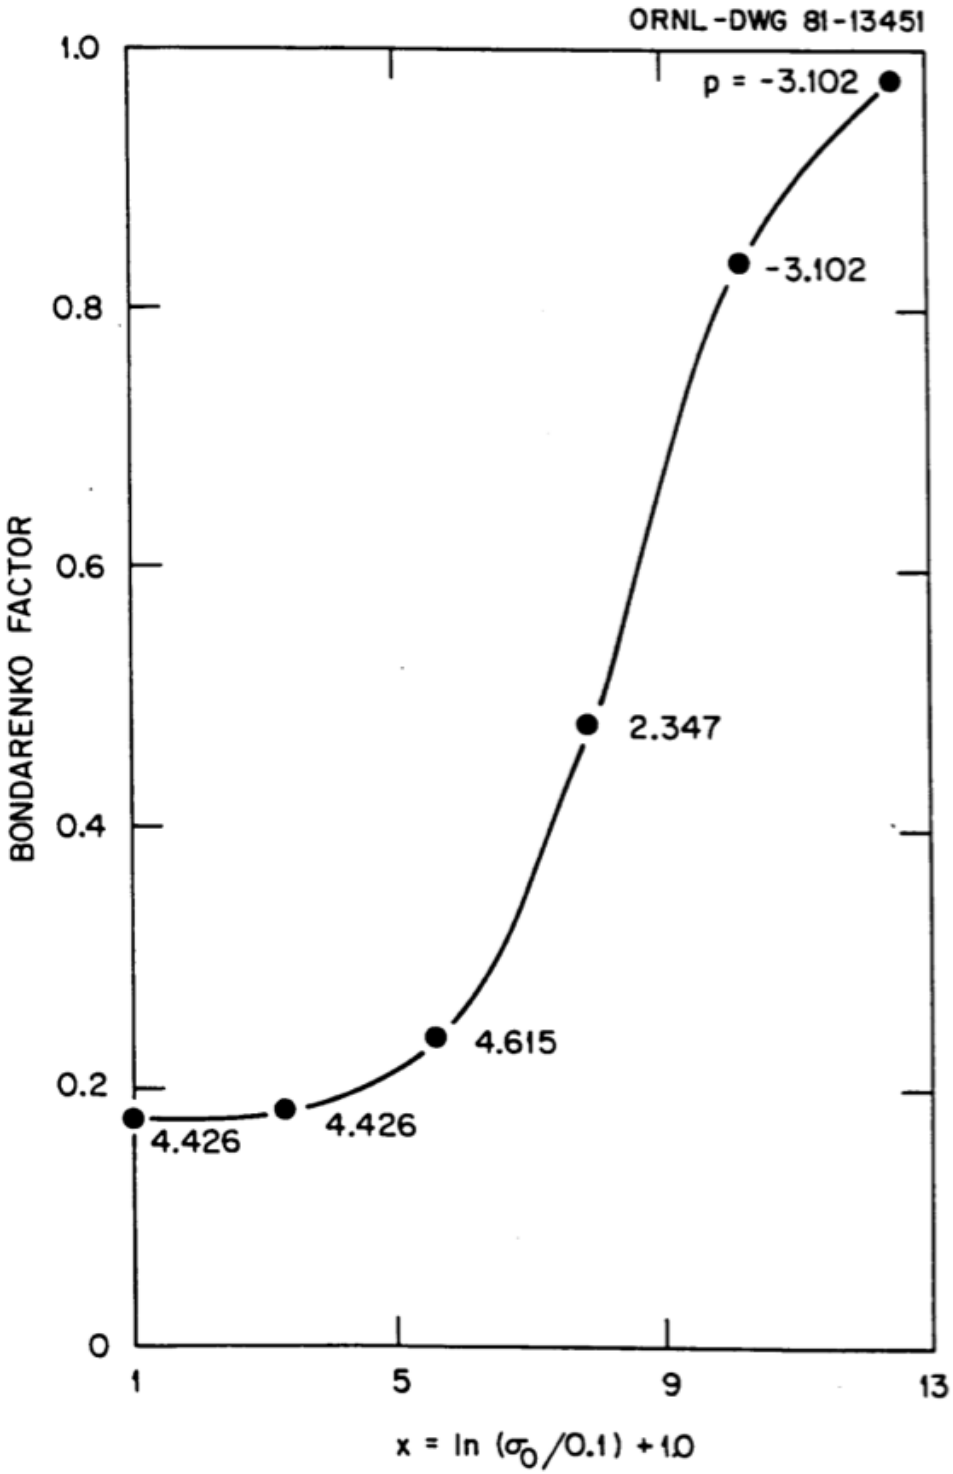

Fig. 7.3.3: Use of Greene's method to fit the σ_0 variation of Bondarenko factors for case 1.

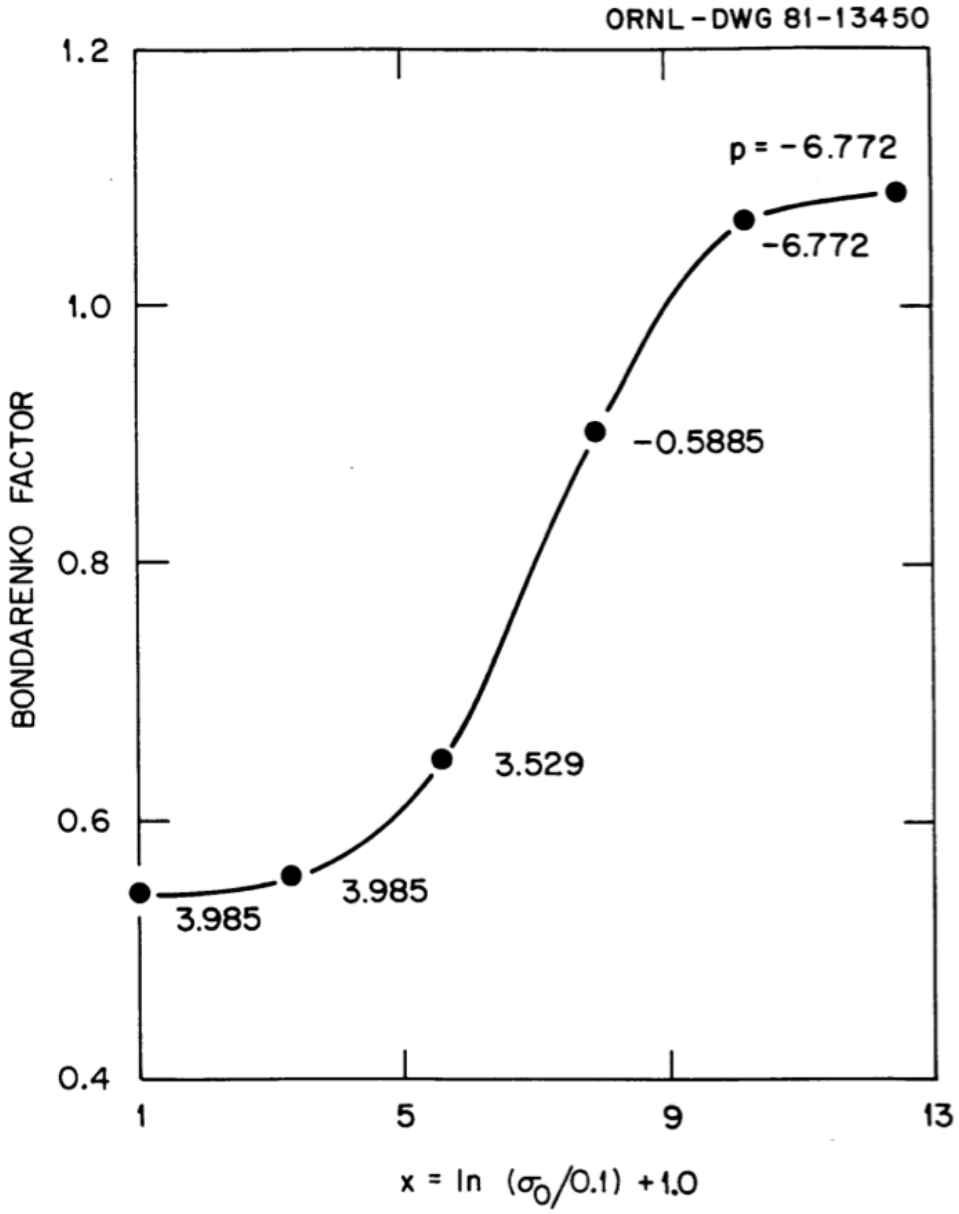

Fig. 7.3.4: Use of Greene's method to fit the σ_0 variation of Bondarenko factors for case 2.

7.3.4 INPUT INSTRUCTIONS

BONAMI is most commonly used as an integral component of XSProc through SCALE automated analysis sequences. XSProc automatically prepares all the input data for BONAMI and links it with the other self-shielding modules. During a SCALE sequence execution, the data are provided directly to BONAMI in memory through XSProc. Some of the input parameters can be modified in the MOREDATA block in XSProc.

However, the legacy interface to execute stand-alone BONAMI calculations has been preserved for expert users. The legacy input to BONAMI uses the FIDO schemes described in the FIDO chapter of the SCALE manual. The BONAMI input for standalone execution is given below, where the MOREDATA input keywords are marked in bold.

T Terminate Data Block 2.

This concludes the input data required by BONAMI.

7.3.4.1 Notes on input

In the 1$ array, *cellgeometry* specifies the geometry. The geometry information is used in conjunction with the 7* array to calculate mean chord length *Lbar* if it is not provided by the user in the 14* array.

numzones, the number of zones, may or may not model a real situation. It may, for example, be used to specify *numzones* independent media to perform a cell calculation in parallel with one or more infinite medium calculations. The geometry description in 1$ array applies only to mean chord length calculations unless it is provided in 14*.

In the 2* array, *bonamieps* is used to specify the convergence expected on all macroscopic total values by zone, that is, each $\Sigma_t(g, j)$ in group g and zone j is converged so that

$$\frac{\left|\Sigma_t^i(g,j) \quad - \quad \Sigma_t^{i-1}(g,j)\right|}{\Sigma_t^i(g,j)} \quad \leq \quad bonamieps \quad . \tag{7.3.24}$$

The "Bell" factor in the 2* array is the parameter used to adjust the Wigner rational approximation for the escape probability to a more correct value. It has been suggested that if one wishes to use one constant value, the Bell factor should be 1.0 for slabs and 1.35 otherwise. In the ordinary case, BONAMI defaults the Bell factor to zero and uses a prescription by Otter [BONAMIOtt64] to determine a cross-section geometry-dependent value of the Bell factor for isolated absorber bodies. It uses a prescription by Leslie[6] to determine

the Dancoff factor–dependent values of the Bell factor for lattices, which are much more accurate than the single value. The user who wishes to determine the constant value can, however, use it by inputting a value other than zero.

The 3$, 4$, and 5* arrays are used to specify the concentrations of the constituents of all mixtures in the problem as follows:

Entry 3$ (Mixture Number) 4$ (Nuclide ID) 5* (Concentrations)

1

2

.

.

.

.

mixlength

.

Because of the manner in which BONAMI references the nuclides in a calculation, each nuclide in the problem must have a unique entry in the mixing table. Thus one cannot specify a mixture and subsequently load it into more than one zone, as can be the case with many modules requiring this type of data.

The 12* array is used to allow varying the temperatures by nuclide within a zone. In the event this array is omitted, the 12* array will default by nuclide to the temperature of the zone containing the nuclide.

The mixture numbers in each zone are specified in the 6$ array. Mixture numbers are arbitrary and need only match up with those used in the 3$ array.

The radii in the 7* array are referenced to a zero value at the left boundary of the system.

In the event the temperatures in the 8* array are not bounded by temperature values in the Bondarenko tables, BONAMI will extrapolate using the three temperature points closest to the value. For example, a request for 273 K for a nuclide with Bondarenko sets at 300, 900, and 2,100 K would use the polynomial fit from those three temperature points to extrapolate the 273 K value.

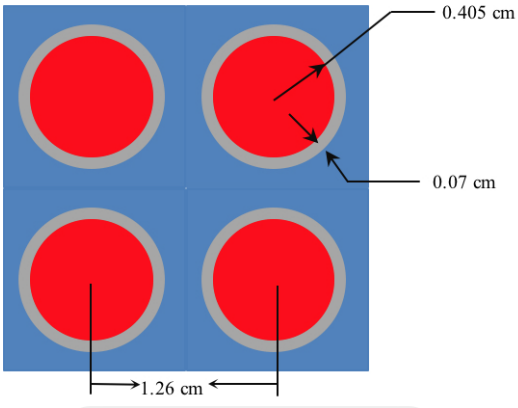
The escape cross sections in the 9* array allow a macro escape cross section (Σ_e^{input}) to be specified by zone. (This array can be ignored if Dancoff factors are provided.) If the Dancoff factor for a zone is specified as -1 in the input, then the user-specified escape cross section is used in calculating the background cross sections σ_0 as follows:

$$\sigma_0 = \frac{\sum_{n \neq i} N_n \sigma_t^n + \Sigma_e^{input}}{N_i} \tag{7.3.25}$$

7.3.5 SAMPLE PROBLEM

In most cases, the input data to BONAMI are simple and obvious because the complicated parameters are determined internally based on the options selected. The user describes his geometry, the materials contained therein, the temperatures, and a few options.

This problem is for a system of iron-clad uranium (U^{238} – U^{235}) fuel pins arranged in a square lattice in a water pool.



Our number densities are

Fuel:

$$N_{^{235}U} = 1.4987 \times 10^{-4}$$

$$N_{^{238}U} = 2.0664 \times 10^{-2}$$

Clad:

$$N_{^{56}Fe} = 9.5642 \times 10^{-5}$$

Water:

$$N_H = 6.6662 \times 10^{-2}$$

$$N_O = 3.3331 \times 10^{-2}$$

For the problem, we choose *iropt* = 1 (IR approximation with scattering approximated by math:*lambda*Σ_p) and *crossedt* = 4 for the most detailed output edits. An 8-group test library is used for fast execution and a short output file.

The XSProc/CSAS1X SCALE sequence input file, the corresponding i_bonami FIDO input file created by the sequence under the temporary working directory, and an abbreviated copy of the output from this case follows.

7.4 CENTRM: A NEUTRON TRANSPORT CODE FOR COMPUTING CONTINUOUS-ENERGY SPECTRA IN GENERAL ONE-DIMENSIONAL GEOMETRIES AND TWO-DIMENSIONAL LATTICE CELLS

M. L. Williams and K. S. Kim

Abstract

CENTRM computes continuous-energy neutron spectra for infinite media, general one-dimensional (1D) systems, and two-dimensional (2D) unit cells in a lattice, by solving the Boltzmann transport equation using a combination of pointwise and multigroup nuclear data. Several calculational options are available, including a slowing-down computation for homogeneous infinite media, 1D discrete ordinates in slab, spherical, or cylindrical geometries; a simplified two-region solution; and 2D method of characteristics for a unit cell within a square-pitch lattice. In SCALE, CENTRM is used mainly to calculate problem-specific fluxes on a fine energy mesh (10,000–70,000 points), which may be used to generate self-shielded multigroup cross sections for subsequent radiation transport computations.

ACKNOWLEDGMENTS

Several current and former ORNL staff made valuable contributions to the CENTRM development. The author acknowledges the contributions of former ORNL staff members D. F. Hollenbach and N. M. Greene; as well as current staff member L. M. Petrie. Portions of the original code development were performed by M. Asgari as partial fulfillment of his PhD dissertation research at Louisiana State University (LSU); and Riyanto Raharjo from LSU made significant programming contributions for the inelastic scattering and thermal calculations.

7.4.1 INTRODUCTION

CENTRM (**C**ontinuous **EN**ergy **TR**ansport **M**odule) computes "continuous-energy" neutron spectra using various deterministic approximations to the Boltzmann transport equation. Computational methods are available for infinite media, general one-dimensional (1-D) geometries, and two-dimensional (2D) unit cells in a square-pitch lattice. The purpose of the code is to provide fluxes and flux moments for applications that require a high resolution of the fine-structure variation in the neutron energy spectrum. The major function of CENTRM is to determine problem-specific fluxes for processing multigroup (MG) data with the XSProc self-shielding module (Introduction in XSProc chapter), which is executed by all SCALE MG sequences. XSProc calls an application program interface (API) to perform a CENTRM calculation for a representative model (e.g., a unit cell in a lattice), and then utilizes the spectrum as a *problem-dependent* weight function for MG averaging. The MG data processing is done in XSProc by calling an API for the PMC code, which uses the CENTRM continuous-energy (CE) flux spectra and cross-section data to calculate group-averaged cross sections over some specified energy range. The resulting application-specific library is used for MG

neutron transport calculations within SCALE sequences. In this approach the CENTRM/PMC cross-section processing in XSProc becomes an active component in the overall transport analysis. CENTRM can also be executed as a standalone code, if the user provides all required input data and nuclear data libraries; but execution through XSProc is much simpler and less prone to error.

7.4.1.1 Description of problem solved

CENTRM uses a combination of MG and pointwise (PW) solution techniques to solve the neutron transport equation over the energy range ~0 to 20 MeV. The calculated CE spectrum consists of PW values for the flux per unit lethargy defined on a discrete energy mesh, for which a linear variation of the flux between energy points is assumed. Depending on the specified transport approximation, the flux spectrum may vary as a function of space and direction, in addition to energy. Spherical harmonic moments of the angular flux, which may be useful in processing MG matrices for higher order moments of the scattering cross section, can also be determined as a function of space and energy mesh.

CENTRM solves the fixed-source (inhomogeneous) form of the transport equation, with a user-specified fixed source term. The input source may correspond to MG histogram spectra for volumetric or surface sources or it may be a "fission source" which has a continuous-energy fission-spectrum distribution (computed internally) appropriate for each fissionable mixture. Note that eigenvalue calculations are *not* performed in CENTRM-these must be performed by downstream MG transport codes that utilize the self-shielded data processed with the CENTRM spectra.

7.4.1.2 Nuclear data required for CENTRM

A MG cross section library, a CE cross section library, and a CE thermal kernel [S(α, β)] library are required for the CENTRM transport calculation. During XSProc execution for a given unit cell in the CELL DATA block, the MG library specified in the input is processed by BONAMI prior to the CENTRM calculation, in order to provide self-shielded data based on the Bondarenko approximation for the MG component of the CENTRM solution. The shielded MG cross sections are also used in CENTRM to correct infinitely dilute CE data in the unresolved resoance range. The CRAWDAD module is executed by XSProc to generate the CENTRM CE cross section and thermal kernel libraries, respectively, by concatenating discrete PW data read from individual files for the nuclides in the unit cell mixtures. CE resonance profiles are based strictly on specifications in the nuclear data evaluations; e.g., Reich-Moore formalism is specified for most materials in ENDF/B-VII. PW data in the CENTRM library are processed such that values at any energy can be obtained by linear interpolation within some error tolerance specified during the library generation (usually ~0.1% or less). CRAWDAD also interpolates the CE cross section data and the Legendre moments of the thermal scattering kernels to the appropriate temperatures for the unit cell mixtures. The format of the CENTRM library is described in Sect. 7.4.6.1.

7.4.1.3 Code assumptions and features

As shown in Fig. 7.4.1, the energy range of interest is divided into three intervals called the Upper Multigroup Range (UMR), Pointwise Range (PW), and Lower Multigroup Range (LMR), respectively, which are defined by input. MG fluxes are computed using standard multigroup techniques for the UMR and LMR, and these values are then divided by the group lethargy width to obtain the average flux per lethargy within each group. This "pseudo-pointwise" flux is assigned to the midpoint lethargy of the group, so that there is one energy point per group in the UMR and LMR energy intervals. However, for each group in the PW range there are generally several, and possibly many, energy points for which CENTRM computes flux values. In this manner a problem-dependent spectrum is obtained over the entire energy range.

The default PW range goes from 0.001 eV to 20 keV, but the user can modify the PW limits. The energy range for the PW transport calculation is usually chosen to include the interval where the important absorber nuclides

have resolved resonances, while MG calculations are performed where the cross sections characteristically have a smoother variation or where shielding effects are less important. In the SCALE libraries the thermal range is defined to be energies less than 5.0 eV. Above thermal energies, scattering kinematics are based on the stationary nucleus model, while molecular motion and possible chemical binding effects are taken into account for thermal scattering, which can result in an incease in the neutron incident energy. The CENTRM thermal calculation uses Legendre coefficients from the CE kernel library that describes point-to-point energy transfers for incoherent and coherent scattering, as function of temperature, for all moderators that have thermal scattering law data provided in ENDF/B. Thermal kernels for all other materials are generated internally by CENTRM based on the free-gas model.

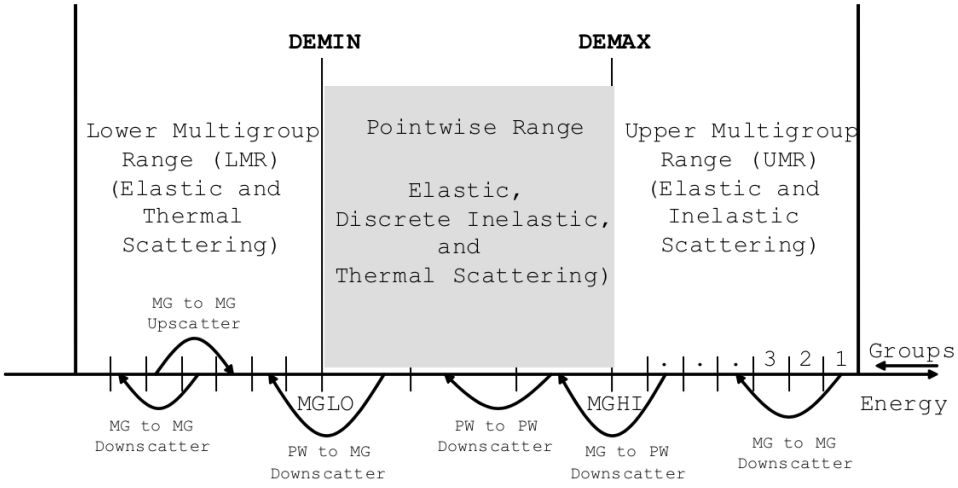

Fig. 7.4.1: Definition of UMR, PW, and LMR energy ranges.

Several transport computation methods are available for both MG and PW calculations. These include a space-independent slowing down calculation for infinite homogeneous media, 1D discrete ordinates or P1 methods for slab, spherical, and cylindrical geometries, and a 2D method of chracateristics (MoC) method for lattice unit cells. A simplified two-region collision-probablity method is also available for ther pointwise solution. In general the user may specify different transport methods for the UMR, PW, and LMR, respectively; however, if the 2D MoC method is specified for any range, it will be used for all.

The CENTRM 1D discrete ordinates calculation option has many of the same features as the SCALE MG code XSDRNPM. It represents the directional dependence of the angular flux with an arbitrary symmetric-quadrature order, and uses Legendre expansions up to P_5 to represent the scattering source. No restrictions are placed on the material arrangement or the number of spatial intervals in the calculation, and general boundary conditions (vacuum, reflected, periodic, albedo) can be applied on either boundary of the 1D geometry. Lattice cells are represented in the CENTRM discrete ordinates option by a 1D Wigner-Sitz cylindrical or spherical model with a white boundary condition on the outer surface.

Starting with SCALE-6.2, CENTRM also includes a 2D MoC solver for lattice cell geometries consisting of a cylindrical fuel rod (fuel/gap/clad) contained within a rectangular moderator region. The MoC calculation is presently limited to square lattices. The 2D unit cell uses a reflected boundary condition on the outer square surface, which provides a more rigorous treatment than the 1D Wigner-Seitz model; however the MoC option requires a longer execution time than the 1D discrete ordinates method. The MoC option has been found to improve results compared to the 1D Wigner-Seitz cell model for many cases, but in other cases the improvement is marginal.

A variable PW energy mesh is generated internally to accurately represent the fine-structure flux spectrum for the system of interest. This gives CENTRM the capability to rigorously account for resonance interference effects in systems with multiple resonance absorbers. Because CENTRM calculates the space-dependent PW flux spectrum, the spatial variation of the self-shielded cross sections within an absorber body can be obtained. A radial temperature distribution can also be specified, so that space-dependent Doppler broadening can be treated in the transport solution. Within the epithermal PW range, the slowing-down source due to elastic and discrete-level inelastic reactions is computed with the analytical scatter kernel based upon the neutron kinematic relations for *s*-wave scattering. Continuum inelastic scatter is approximated by an analytical evaporation spectrum, assumed isotropic in the laboratory system. For many thermal reactor and criticality safety problems, self-shielding of inelastic cross sections has a minor impact, and by default these options are turned off for faster execution. As previously discussed, the thermal scatter kernel is based on the ENDF/B scattering law data for bound moderators, and uses the free-gas model for other materials.

7.4.2 THEORY AND ANALYTICAL MODELS

This section describes the coupled MG and PW techniques used to solve the neutron transport equation.

7.4.2.1 Energy/lethargy ranges for MG and PW calculations

The combined MG/PW CENTRM calculation is performed over the energy range spanned by the group structure in the input MG library. The energy boundaries for the "IGM" neutron groups specified on the MG library divide the entire energy range into energy intervals. The lowest energy group contained in the UMR is defined to be "MGHI"; while the highest energy group in the LMR is designated "MGLO." The boundary between the PW and UMR energy intervals is set by the energy value "DEMAX," while "DEMIN" is the boundary between the PW and LMR. The default values of 0.001 eV and 20 keV for DEMIN and DEMAX, respectively, can be modified by user input, but the input values are altered by the code to correspond to the closest group boundaries. Hence, DEMAX is always equal to the lower energy boundary of group MGHI and DEMIN the upper energy boundary of MGLO. The PW calculation is performed in terms of lethargy (u), rather than energy (E). The origin (u=0) of the lethargy coordinate corresponds to the energy E=DEMAX, which is the top of the PW range. See Fig. 7.4.2.

The highest energy group of the thermal range is defined by the parameter "IFTG," obtained from the MG library. If DEMIN is less than the upper energy boundary of IFTG, the PW range extends into thermal. In this case, scattering in the PW region of the thermal range is based on the PW scattering kernel data; and the LMR calculation uses 2D transfer matrices for incoherent and coherent scattering on the MG library. Coupling between the MG and PW thermal calculations is treated, and outer iterations are required to address effects of upscattering.

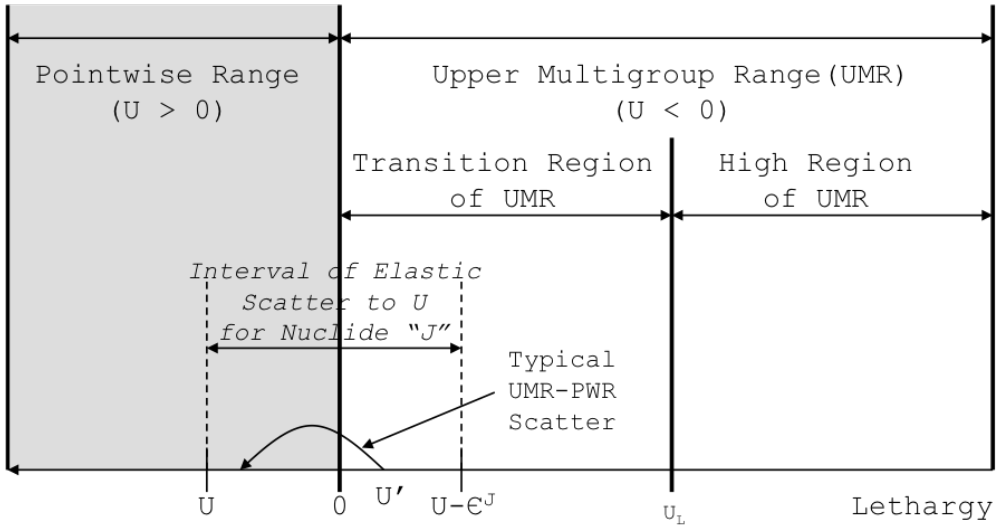

Fig. 7.4.2: Definition of *High* and *Transition* regions in upper multigroup region.

With the exception of hydrogen moderation, elastic down-scattering coupling the UMR and PW ranges, occurs only within a limited sub-range of the UMR called the "transition region". The highest energy group in the transition region is designated "MGTOP." The precise definition of the transition region is given in Sect. 7.4.2.6.1.

Energy boundaries of the group structure on the input MG library correspond to the IGM+1 values, { G_1, G_2, ... G_g, G_{g+1}, ..., G_{IGM+1}}. It is convenient to designate the number of groups in the UMR, PW, and LMR ranges equal to NG_U, NG_P, and NG_L, respectively, so that IGM = NG_U + NG_P + NG_L; or in terms of the parameters MGHI and MGLO introduced previously:

NG_U = MGHI; NG_P = MGLO - MGHI - 1; NG_L = IGM - MGLO + 1.

The flux per unit lethargy is calculated for a discrete energy (or lethargy) mesh spanning the MG structure. Groups in the UMR and LMR each contain a single energy mesh point, while groups in the PW range generally contain several points. The number of mesh *points* in the UMR, PW, and LMR is equal respectively to NG_U, N_P, and NG_L; and the total number of points in the entire energy mesh is designated as "N_T," which is equal to NG_U + N_P + NG_L. Thus the lethargy (u) mesh consists of the set of points: {u:sub:*1*,... u_{NGU}, u_{NGU+1},... u_{NGU+NP}, $u_{NGU+NP+1}$,... u_{NT}}. Based on the lethargy origin at E=DEMAX, the lethargy "u_n" associated with any energy point "E_n" is equal to,

$u_n = \ln(DEMAX/E_n)$.

Lethargy points are arranged in order of increasing value. The lethargy origin is at point NG_U+1, the lower energy boundary of group MGHI; i.e., $\mathbf{u}_{NGU+1}$=0. Note that the entire UMR (E>DEMAX) corresponds to negative lethargy values. Lethargy values for the first NG_U and the last NG_L points in the mesh are defined to be the midpoint lethargies of groups in the UMR and LMR ranges, respectively. For example, for the NG_U groups within the UMR,

$u_1 = 0.5[\ln(DEMAX/G_1) + \ln(DEMAX/G_2)]$;

$u_{NGU} = 0.5[\ln(DEMAX/G_{MGHI}) + \ln(DEMAX/G_{MGHI+1})]$;

and similarly for the NG_L groups in the LMR,

$u_{NGU+NP+1} = 0.5[\ln(DEMAX/G_{MGLO}) + \ln(DEMAX/G_{MGLO+1})]$

$u_{NT} = 0.5[\ln(DEMAX/G_{IGM}) + \ln(DEMAX/G_{IGM+1})]$

The remaining N_P points in the mesh (i.e., values u_{NGU+1} to u_{NGU+NP}) are contained within the NG_P groups that span the PW range. By definition the first point in the PW range is the lower energy boundary of group MGHI. The other mesh points are computed internally by CENTRM, based on the behavior of the macroscopic PW total cross sections and other criteria.

The neutron flux, as a function of space and direction, is calculated for each energy/lethargy point in the mesh by solving the Boltzmann transport equation. The transport equation at each lethargy point generally includes a source term representing the production rate due to elastic and inelastic scatter from other lethargies, which couples the solutions at different lethargy mesh points. Except in the thermal range, neutrons can only gain lethargy (lose energy) in a scattering reaction; thus the PW flux is computed by solving the transport equation at successive mesh points, sweeping from low to high lethargy values.

7.4.2.2 The Boltzmann equation for neutron transport

The steady state neutron transport equation shown below represents a particle balance-per unit phase space, at an arbitrary point :math:` ho` in phase space,

$$\Omega \cdot \nabla\Psi(\rho) + \sum_t (r, u)\Psi(\rho) = \int_0^{\infty} \int_0^{4\pi} \Sigma\left(u' \rightarrow u; \mu_0\right) \Psi\left(u', \Omega'\right) du' + Q_{ext}(\rho) \tag{7.4.1}$$

where:

$\psi(\rho)$ = angular flux (per lethargy) at phase space coordinate ρ;

$\rho = (r, u, \Omega)$ = phase space point defined by the six independent variables;

$r = (x_1, x_2, x_3)$ = space coordinates;

$u = \ln(E_{ref}/E)$ = lethargy at energy E, relative to an origin (u=0) at E_{ref};

$\Omega = (\mu, \zeta)$ = neutron direction defined by polar cosine μ and azimuthal angle ζ;

$\Sigma_t(r, u)$ = macroscopic total cross section;

$\Sigma(u' \rightarrow u; \mu_0)$ = double differential scatter cross section;

μ_0 = cosine of scatter angle, measured in laboratory coordinate system;

$Q_{ext}(\rho)$ = external source term, including fission source;

The left and right sides of Eq. (7.4.1) respectively, are equal to the neutron loss and production rates, per unit volume-direction-lethargy. In CENTRM the spatial distribution of the fission source is input as a component of the external source Q; hence, a fixed source rather than an eigenvalue calculation is required for the transport solution.

The angular dependence of the double-differential macroscopic scatter cross section of an arbitrary nuclide "j" is represented by a finite Legendre expansion of arbitrary order L:

$$\Sigma^{(j)}\left(u' \rightarrow u; \mu_0\right) = \sum_{\ell=0}^{L} \frac{2\ell + 1}{2} \Sigma_{\ell}^{(j)}\left(u' \rightarrow u\right) \quad P_{\ell}\left(\mu_0\right) \tag{7.4.2}$$

where $P_\ell(\mu_0)$ = Legendre polynomial evaluated at the laboratory scattering cosine mu_0; and

$\Sigma^{(j)}(u' \rightarrow u)$ = cross section moments of nuclide j, defined by the expression

$$\sum_{\ell}^{(\mathrm{j})}(\mathrm{u}' \rightarrow \mathrm{u}) = \int_{-1}^{1} \sum^{(\mathrm{j})}(\mathrm{u}' \rightarrow \mathrm{u}; \mu_0)\, \mathrm{P}_{\ell}(\mu_0)\, \mathrm{d}\mu_0 \tag{7.4.3}$$

After substitution of the above Legendre expansions for the scattering data of each nuclide, and applying the spherical harmonic addition theorem in the usual manner, the scattering source on the right side of Eq. (7.4.1) becomes [CENTRM-BG70]:

$$\mathrm{S}(\mathrm{r}, \mathrm{u}, \Omega) \equiv \int_0^{\infty} \int_0^{4\pi} \Sigma(\mathrm{u}' \rightarrow \mathrm{u}; \mu_0)\, \Psi(\mathrm{u}', \Omega')\, \mathrm{d}\Omega' \mathrm{d}u' = \sum_{\ell \mathrm{k}=1}^{\mathrm{LK}} \frac{2\ell + 1}{2} \mathrm{Y}_{\ell \mathrm{k}}(\Omega) \mathrm{S}_{\ell \mathrm{k}}(\mathrm{r}, \mathrm{u}) \tag{7.4.4}$$

wherein,

$\mathrm{Y}_{\ell \mathrm{k}}(\Omega) = \mathrm{Y}_{\ell \mathrm{k}}(\mu, \zeta)$ = the spherical harmonic function evaluated at direction Ω

$\mathrm{S}_{\ell \mathrm{k}}$ = spherical harmonic moments of the scatter source, per unit letharagy.

The summation index "ℓk" indicates a double sum over ℓ and k indices; in the most general case it is defined as:

$$\sum_{\ell \mathrm{k}=1}^{\mathrm{LK}} = \sum_{\ell=0}^{\mathrm{L}} \sum_{\mathrm{k}=0}^{\ell} \tag{7.4.5}$$

where "L" is the input value for the maximum order of scatter (input parameter "ISCT").

Due to symmetry conditions, some of the source moments may be zero. The parameter LK is defined to be the total number of non-zero moments (including scalar flux) for the particular geometry of interest, and is equal to,

LK = L + 1 for 1D slabs and spheres;

LK = L*(L+4)/4+1 for 1D cylinders, and

LK = L*(L+3)/2+1 for 2D MoC cells

More details concerning the 1-D Boltzmann equation can be found in the XSDRNPM chapter of the SCALE manual.

7.4.2.3 Legendre moments of the scattering source

The $S_{\ell k}$ moments in Eq. (7.4.4) correspond to expansion coefficients in a spherical harmonic expansion of the scatter source. These can be expressed in terms of the cross section and flux moments by

$$\mathrm{S}_{\ell \mathrm{k}}(\mathrm{u}) = \sum_{\mathrm{j}} \int_{\mathrm{u}'} \mathrm{S}_{\ell \mathrm{k}}^{(\mathrm{j})}(\mathrm{u}' \rightarrow \mathrm{u})\, \mathrm{d}u' = \sum_{\mathrm{j}} \int_{\mathrm{u}'} \Sigma_{\ell}^{(\mathrm{j})}(\mathrm{u}' \rightarrow \mathrm{u})\, \Psi_{\ell \mathrm{k}}(\mathrm{u}')\, \mathrm{d}u' \tag{7.4.6}$$

where $\psi_{\ell k} = (u)$ = spherical harmonic moments of the angular flux;

$$= \int_0^{4\pi} Y_{\ell \mathrm{k}}(\Omega) \quad \Psi(\Omega) \mathrm{d}\Omega \tag{7.4.7}$$

and $S_{\ell k}^{(j)}(u' \rightarrow u)$ = moments of the differential scatter rate from lethargy u′ to u, for nuclide "j";

$$= \Sigma_{\ell}^{(j)}(u' \rightarrow u)\, \Psi_{\ell k}(u') \tag{7.4.8}$$

The $\psi_{\ell k}$ flux moments are the well known coefficients appearing in a spherical harmonic expansion of the angular flux. These usually are the desired output from the transport calculation. In particular, the $\ell = 0, k = 0$ moment corresponds to the scalar flux [indicated here as $\phi\,(r, u)$],

$$\Psi_{0,0}(\mathrm{r,\,u}) = \Phi(\mathrm{r,\,u}) = \int_0^{4\pi} \Psi(\mathrm{r,\,u},\Omega) d\Omega \tag{7.4.9}$$

In general the epithermal component of the scatter source in Eq. (7.4.4) contains contributions from both elastic and inelastic scatter reactions; however, inelastic scatter is only possible above the threshold energy corresponding to the lowest inelastic level. The inelastic Q values for most materials are typically above 40 keV; therefore, elastic scatter is most important for slowing down calculations in the resolved resonance range of most absorber materials of interest. For example, the inelastic Q values of ^{238}U, iron, and oxygen are approximately 45 keV, 846 keV, and 6 MeV, respectively; while the upper energy of the ^{238}U resolved resonance range is 20 keV in ENDF/B-VII. The inelastic thresholds of some fissile materials like ^{235}U and ^{239}Pu are on the order of 10 keV; however, with the exception of highly enriched fast systems, these inelastic reactions usually contribute a negligible amount to the overall scattering source. CENTRM assumes that continuum inelastic scatter is isotropic in the laboratory system, while discrete level inelastic scatter is isotropic in the *center of mass* (CM) coordinate system.

Over a broad energy range, *elastic* scatter from most moderators can usually be assumed isotropic (*s*-wave) in the neutron-nucleus CM coordinate system. In the case of hydrogen, this is true up to approximately 13 MeV; for carbon up to 2 MeV; and for oxygen up to 100 keV. However, it is well known that isotropic CM scatter does not result in isotropic scattering in the laboratory system. For *s*-wave elastic scatter the average scatter-cosine in the laboratory system is given by: $\bar{\mu}_0 = 0.667/\ \mathrm{A}$;[3] where "A" is the mass number (in neutron mass units) of the scattering material. This relation indicates that *s*-wave, elastic scattering from low A materials tends to be more anisotropic in the laboratory, and that the laboratory scattering distribution approaches isotropic ($\bar{\mu}_0 = 0; \theta_0 = 90$) as A becomes large. For example, the $\bar{\mu}_0$ of hydrogen is 0.667 (48.2°); while it is about 0.042 (87.6°) for oxygen. Because *s*-wave scattering from heavy materials is nearly isotropic in the laboratory system, the differential scattering cross section (and thus the scattering source) can usually be expressed accurately by a low order Legendre expansion. On the other hand light moderators like hydrogen may require more terms-depending on the flux anisotropy-to accurately represent the elastic scatter source in the laboratory system. The default settings in CENTRM are to use P0 (isotropic lab scatter) for mass numbers greater than A=100, and P1 for lighter masses.

An analytical expression can be derived for the cross-section moments in the case of two-body reactions, such as elastic and discrete-level inelastic scattering from "stationary" nuclei. Stationary here implies that the effect of nuclear motion on neutron scattering kinematics is neglected.

Note: The stationary nucleus approximation for treating scattering kinematics does not imply that the effect of nuclear motion on Doppler broadening of resonance cross sections is ignored, since this effect is included in the PW cross-section data.

In CENTRM the stationary nucleus approximation is applied above the thermal cutoff, typically around 3-5 eV, but is not valid for low energy neutrons. CENTRM has the capability to perform a PW transport calculation in the thermal energy range using tabulated thermal scattering law data for bound molecules, combined with the analytical free-gas kernel for other materials. In this case the cross-section moments appearing in Eq. (7.4.3) include upscattering effects. The expressions used in CENTRM to compute the PW scatter source moments in the thermal range are given in Sect. 7.4.2.6.

The following two sections discuss the evaluation of the scatter source moments for epithermal elastic and inelastic reactions, respectively.

Epithermal Elastic Scatter

Consider a neutron with energy E′, traveling in a direction Ω′, that scatters elastically from an arbitrary material "j," having a mass $A^{(j)}$ in neutron-mass units. Conservation of kinetic energy and momentum requires that there be a unique relation between the angle that the neutron scatters (relative to the initial direction) and its final energy E after the collision. If the nucleus is assumed to be stationary in the laboratory coordinate system, then the cosine (μ_0) of the scatter angle (θ_0) measured in the laboratory system, as a function of the initial and final energies, is found to be

$$\mu_0 \equiv \Omega' \cdot \Omega = G^{(j)}(E', E), \tag{7.4.10}$$

where the kinematic correlation function G relating E′, E, and μ_0 for elastic scatter is equal to

$$\begin{gathered} G^{(j)}(E', E) = a_1^{(j)} \times [E/E']^{\frac{1}{2}} - a_2^{(j)} \times [E'/E]^{\frac{1}{2}} \\ \text{and } a_1^{(j)} = \left(A^{(j)} + 1\right)/2 \quad ; \quad a_2^{(j)} = \left(A^{(j)} - 1\right)/2 \end{gathered} . \tag{7.4.11}$$

The final energy E of an elastically scattered neutron is restricted to the range,

$$\alpha^{(j)} E' \leq E \leq E' \tag{7.4.12}$$

where $\alpha^{(j)} =$ maximum fractional energy lost by elastic scatter

$$= \left[a_2^{(j)}/a_1^{(j)}\right]^2 \tag{7.4.13}$$

The corresponding range of scattered neutrons in terms of lethargy is equal to

$$u' \leq u \leq u' + \varepsilon^{(j)} \tag{7.4.14}$$

where

$$\begin{aligned} u, u' = u(E), u'(E') &= \text{ lethargies corresponding to E and E}', \text{ respectively; and} \\ \varepsilon^{(j)} &= \text{ maximum increase in lethargy, per elastic scatter } = \ln\left[1/\alpha^{(j)}\right] \end{aligned} \tag{7.4.15}$$

The double-differential scatter kernel of nuclide j (per unit lethargy and solid angle) for *s*-wave elastic scatter of neutrons from stationary nuclei, is equal to

$$\begin{aligned} \Sigma^{(j)}(u' \to u; \mu_0) &= \frac{E\Sigma^{(i)}(u')}{E'\left(1 - \alpha^{(j)}\right)} \delta\left[\mu_0 - G^{(j)}(E', E)\right], \text{ for } u' \leq u \leq u' + \varepsilon^{(j)} \\ &= 0 \quad u < u' \text{ or } u > u' + \varepsilon^{(j)} \end{aligned} \tag{7.4.16}$$

The presence of the Dirac delta function completely correlates the angle of scatter and the values of the initial and final energies. Substituting the double differential cross-section expression from Eq. (7.4.16) into Eq. (7.4.3) gives the single-differential Legendre moments of the cross section, per final lethargy:

$$\begin{aligned} \Sigma_\ell^{(j)}(u' \to u) &= \frac{EP_\ell\left[G^{(j)}\right]\Sigma^{(j)}(u')}{E'\left(1 - \alpha^{(j)}\right)}, \text{ for } u' \leq u \leq u' + \varepsilon^{(j)} \\ &= 0 \quad u' \text{ or } u > u' + \varepsilon^{(j)} \end{aligned} \tag{7.4.17}$$

where P_ℓ = Legendre polynomial evaluated at argument $G^{(j)}$ equal to the scatter cosine.

When the above expressions are used in Eq. (7.4.6), the following is obtained for the ℓk moment of the epithermal elastic scattering source at lethargy u:

$$S_{\ell k}{}^{(j)}(u) = \sum_j \int_{u-\varepsilon^{(j)}}^{u} S_{\ell k}(u' \to u)\, du' = \sum_j \int_{u-\varepsilon^{(j)}}^{u} \frac{E\Sigma^{(j)}(u') P_\ell\left[G^{(j)}\right]}{E'\left(1 - \alpha^{(j)}\right)} \Psi_{\ell k}(u')\, du'. \tag{7.4.18}$$

Epithermal Inelastic Scatter

If the input value of DEMAX is set above the inelastic threshold of some materials in the problem, then inelastic scattering can occur in the PW range. The pointwise transport calculation may optionally include discrete-level and continuum inelastic reactions in computing the PW scatter source moments. The multigroup calculations always consider inelastic reactions.

Discrete-level inelastic reactions are two-body interactions, so that kinematic relations can be derived relating the initial and final energies and the angle of scatter. It can be shown that the kinematic correlation function for discrete-level inelastic scatter can be written in a form identical to that for elastic scatter by redefining the parameter a_1 in Eq. (7.4.11) to be the energy dependent function [CENTRM-Wil00],

$$a_1^{(\,m,j)} = \frac{\left(A^{(j)} + 1\right)}{2} + \frac{\left(-Q^{(m,j)}\right) A^{(j)}}{2E} \tag{7.4.19}$$

The parameter $Q^{(m,\,j)}$ is the Q-value for the m_{th} level of nuclide "j". The Q value is negative for inelastic scattering, while it is zero for elastic scatter. The threshold energy in the laboratory coordinate system is proportional to the Q-value of the inelastic level, and is given by:

$$E_T^{(m,j)} = \frac{A^{(j)} + 1}{A^{(j)}} \times \left(-Q^{(m,j)}\right) \tag{7.4.20}$$

The range of energies that can contribute to the scatter source at E, due to inelastic scatter from the m_{th} level of nuclide j is defined to be [E:sub:*L* , E:sub:*H*], where E_H >E:sub:*L* >E:sub:*T*. This energy range has a corresponding lethargy range of [u:sub:*LO* , u:sub:*HI*] which is equal to,

$$\begin{aligned} u_{LO} &= u - \ln\left(\frac{1}{\alpha_1^{(j)}(E_H)}\right) = u - \varepsilon_1^{(j)} \\ u_{HI} &= u - \ln\left(\frac{1}{\alpha_2^{(j)}(E_L)}\right) = u - \varepsilon_2^{(j)} \end{aligned} \tag{7.4.21}$$

The energy-dependent alpha parameters in the above expressions are defined as,

$$\begin{aligned} \alpha_1(E) &= \left(\frac{A\Delta^{(m,j)}(E)-1}{A+1}\right)^2 \\ \alpha_2(E) &= \left(\frac{A\Delta^{(m,j)}(E)+1}{A+1}\right)^2 \end{aligned} \tag{7.4.22}$$

where

$$\Delta^{(m,j)}(E) = \sqrt{1 - \frac{E_T^{(m,j)}}{E}} \tag{7.4.23}$$

Modifying the epithermal elastic scatter source in Eq. (7.4.18) to include discrete-level inelastic scatter gives the following expression

$$S_{\ell k}(u) = \sum_{m,j} \int_{u_{LO}}^{u_{HI}} \frac{E}{E'} \frac{\Sigma^{(m,j)}(E')\, P_\ell\left[G^{(m,j)}\right]}{(1-\alpha^j)\,\Delta^{(m,j)}(E')} \Psi_{\ell k}(u')\, du' \tag{7.4.24}$$

Detailed expressions for the lethargy limits are given in [CENTRM-Wil00]. Since $\Delta^{(m,j)}$ is equal to unity for elastic scatter, the above equation reduces to Eq. (7.4.15) if there is no discrete-level inelastic contribution.

At high energies, the inelastic levels of the nucleus become a continuum. In this case CENTRM represents the energy distribution of the scattered neutrons by an evaporation spectrum with an isotropic angular distribution in the lab system; thus, only the P_0 moment appears in the continuum inelastic scattering source. Including continuum inelastic reactions in the PW calculation usually has a small impact on the spectrum used for resonance self-shielding, and may adversely impact the computer memory requirements and execution time. Therefore, by default, CENTRM does not include continuum inelastic reactions in the pointwise solution; however, it is always included in the UMR solution.

Thermal Scatter

Since thermal neutrons have energies comparable to the mean kinetic energy of molecules in thermal equilibrium, the scattering kernels must account for molecular motion. The scatter moments include both downscatter as well as upscatter contributions; hence, the integration limits appearing in Eq. (7.4.18) must be extended from the lowest to the highest energy of the thermal range. Furthermore the cross-section moments correspond to the Legendre expansion coefficients of the thermal scatter kernel, which has a substantially different form than the epithermal kernel discussed in the previous two sections. In general the ℓ^{th} Legendre moment of the thermal scattering kernel at temperature T, describing scattering from E to E', is given by

$$\sigma_\ell(\mathrm{E}' \rightarrow \mathrm{E}; \mathrm{T}) = \frac{\sigma_b}{T}\sqrt{\frac{\mathrm{E}}{\mathrm{E}'}}e^{-\frac{\beta(\mathrm{E}'\rightarrow\mathrm{E})}{2}}\int \mathrm{P}_\ell(\mu_0)\,\mathrm{S}[\alpha,\beta;T]d\mu_0 \tag{7.4.25}$$

where $\beta(E' \rightarrow E)$ and $\alpha(E', E, \mu_0)$ are dimensionless variables (functions of temperature) defining the energy and momentum exchange, respectively, of the collision [CENTRM-BG70]; σ_b is the rigidly bound scatter cross section, which is proportional to the free atom cross section; and S(α, β; T) describes the temperature-dependent thermal scattering law.

If atomic bonding effects are neglected, the atoms of a material behave like a gas in thermal equilibrium at the temperature of the medium. In this case S(α, β) can be expressed by an analytical function. CENTRM uses the free gas model for all nuclides except those materials that have thermal scattering laws available in the ENDF/B nuclear data files. The ENDF/B scattering law data account for the effects of molecular bonding and possible polyatomic crystalline structure. While free-gas kernels are computed internally in CENTRM, the kernel moments describing bound thermal scatterers are stored in a data file that can be accessed by CENTRM.

Bound thermal kernels

Thermal scattering from bound atoms is classified either as an "inelastic reaction," in which the neutron energy may change, or an "elastic reaction," in which the neutron changes direction, but does not change energy. In ENDF/B the former reactions are treated as incoherent inelastic scattering with a doubly differential kernel describing the secondary neutron energy and angle distribution. The latter reactions are usual treated as coherent elastic scatter characterized by diffractive interference of the scattered deBroglie waves, although a few materials are modeled by the incoherent elastic approximation. Legendre moments for thermal elastic kernels describe the secondary angular distribution with no energy exchange, at a given neutron energy. Bound scatter kernels have been processed by the AMPX code system for most of the ~25 compounds with thermal scatter laws in ENDF/B, and are stored in individual kinematics files distributed with the SCALE code system. These include materials such as: H in water, H and C in polyethylene, H and Zr in ZrH, C in graphite, deuterium in heavy water, Be metal, Be in BeO, etc. The CRAWDAD module processes scattering kernel data for individual nuclides into a combined library used in CENTRM, and also interpolates the kernels to the appropriate temperatures.

The bound scatter kernels are tabulated at different energy points from the flux solution mesh; therefore it is necessary to map the data onto the desired energy mesh in the CENTRM calculation. Because thermal

elastic scattering results in no energy loss, the elastic moments only appear in the within-point term of the scattering source in the CENTRM thermal calculation. Thus the coherent elastic data is easily interpolated since it only involves a single energy index and temperature. However, the incoherent inelastic moments are 2-D arrays in terms of the initial and final energies, so that a 2-D interpolation must be done for each temperature. CENTRM uses a simple type of "unit-base transform" method to interpolate incoherent inelastic kernels onto the flux solution mesh. The method attempts to preserve the absolute peak of the secondary energy distribution, at given initial energy. For water-bound hydrogen and several other moderators, this is quite adequate, since the kernel generally has only a single maximum. However, if more than one local extrema is present, such as for graphite, the other local peaks are not explicitly preserved in the interpolation method. For this reason it is necessary to include a fairly dense set of initial energies in the tabulated kernels of graphite and similar materials, to avoid gross changes in the kernel shape at adjacent initial energy panels.

Free gas thermal kernels

CENTRM computes free-gas kernels using the approach proposed by Robinson [CENTRM-Rob81] as a modification to the original FLANGE [CENTRM-HF71] methodology. Legendre moments of the free-gas scatter kernel per unit lethargy are expressed as,

$$\Sigma_{\ell}^{(j)}\left(u' \rightarrow u\right) = A^{(j)}\Sigma_{free}^{(j)} \quad \frac{E}{E'}e^{-\beta/2}\sum_{n=0}^{\ell} W_{\ell n}H_n\left(E', E\right) \tag{7.4.26}$$

where $W_{\ell n}$ are constant coefficients associated with the Legendre polynomial of order ℓ; Σ_{free} is the constant free-atom cross section for the material; and H_n are the α-moments of the free-gas scatter law, given as

$$H_n\left(E', E\right) = \frac{1}{\sqrt{\pi}}\int_{\alpha_L}^{\alpha_H} \alpha^n \times \left(\frac{e^{-\frac{\alpha^2+\beta^2}{4\alpha}}}{2\sqrt{\alpha}}\right) d\alpha \tag{7.4.27}$$

The limits on the above integral correspond to:

$$\alpha_L\left(E', E\right) = \alpha\left(E', E, \mu_0 = -1\right) \quad \text{and} \quad \alpha_H\left(E', E\right) = \alpha\left(E', E, \mu_0 = 1\right). \tag{7.4.28}$$

The alpha moments for $n > 0$ can be evaluated very efficiently using a recursive relation [CENTRM-Wil00]:

$$H_n\left(E', E\right) = 2(2n-1)H_{n-1} + \beta^2 H_{n-2} - \left[F_n\left(\sqrt{\alpha_H}, \beta\right) - F_n\left(\sqrt{\alpha_L}, \beta\right)\right] \tag{7.4.29}$$

where F_n is the function,

$$F_n(t, \beta) = \frac{t^{2n-1}e^{-\frac{1}{4}\left(\frac{\beta^2}{t^2}+t^2\right)}}{\sqrt{\pi}/2} \tag{7.4.30}$$

Analytical expressions for the initial two moments, H_0 and H:sub:` -1`, are given in [CENTRM-Rob81].

The standard free-gas kernel is based on the assumption of a constant free atom cross section. When averaged over the molecular velocity distribution, this gives a 1/v variation in the effective free-gas cross section at low energies. To approximately account for nuclear structure effects on the energy dependence of the thermal cross section (e.g., low energy resonances), the free-gas moments are multiplied by the ratio $\sigma_s(E)/\sigma_{FG}(E)$, where σ_s is the Doppler broadened scatter cross section processed from ENDF/B data; and σ_{FG} is the effective free-gas cross section,

$$\sigma_{FG}\left(E'\right) = \frac{\sigma_{free}}{y^2}\left[\left(y^2 + 1/2\right)\mathrm{erf}(y) + \frac{ye^{-y^2}}{\sqrt{\pi}}\right] \tag{7.4.31}$$

where $y^2 = A\frac{E}{kT}$.

7.4.2.4 Sub-moment expansion of the epithermal scattering source

One difficulty in computing the epithermal scatter source moments is that the Legendre polynomial in the integrand of Eq. (7.4.18) and Eq. (7.4.24) is a function of both the initial and final lethargy (or energy) of the scattered neutrons, due to the correlation function $G^{(j)}(E, E')$). At each lethargy u this requires that the u'-integral be recomputed over all lower lethargies, for every nuclide and moment. A more efficient algorithm would be possible if the differential scattering moments appearing in the integrand could be factored into a product of a function of u multiplied by a function of u' such as

$$S_{\ell k}{}^{(j)}(u' \to u) = F^{(j)}(u') \quad H^{(j)}(u) \tag{7.4.32}$$

where F and H are the two factors (to be specified later).

If this is done, the u-function can be factored from the scatter source integrals, leaving only integrals over the u$\prime$-function as shown below:

$$S^{(j)}(u) = \int_{u'} S^{(j)}_{\ell k}(u' \to u)\, du' = H^{(j)}(u) \int_{u'} F^{(j)}(u')\, du' \tag{7.4.33}$$

Because the factored integrand does not depend on the variable u, a running summation over all u' points can be accumulated and saved as the calculation sweeps from low to high lethargy. For example, note that the $\ell = 0$ moment in Eq. (7.4.18) is already separable into a product of u times u' because P_0 is equal to one at all values of G. Thus the isotropic component of the elastic differential scatter rate (per unit lethargy) from u' to u is proportional to *E/E^{prime}*, where

$$E = E(u) = E_{ref} e^{-u}, \quad \text{and} \quad E' = E'(u') = E_{ref} e^{-u'} \tag{7.4.34}$$

Therefore, the two separable factors in the lowest moment, $S^{(j)}_{0.0}(u' \to u)$ are identified as,

$$\begin{aligned} H(u) &= E/\left(1 - \alpha^{(j)}\right), \quad \text{and} \\ F(u') &= \Sigma^{(j)}(u')\, \Psi_{00}(u')\, /E' \end{aligned} \tag{7.4.35}$$

However, the higher order Legendre moments contain the term $P_\ell(G)$ in the integrand; and the expression for $G(E', E)$ is a difference of two terms that depend on both E and E'. A new method called a "sub-moment expansion" has been developed for CENTRM that allows the Legendre polynomials appearing in the differential scatter moments to be factored into the desired separable form. Each spherical harmonic moment of the scattering source appears expanded in a series of factored "sub-moments."

The Legendre polynomial of order ℓ is a polynomial containing terms up to the *ell*$^{\text{th}}$ power. Applying the binomial expansion theorem and some algebraic manipulation, the standard expression for P_ℓ evaluated at "G" can be expressed as

$$P_\ell(G) = \frac{E'}{E} \times a_1^\ell \sum_{K=-\ell}^{\ell} \tilde{g}_{\ell,K}(E) \quad h_K(E) h_K^{-1}(E') \tag{7.4.36}$$

where $h_k(E) = E^{1+K/2}$; and the expansion coefficients $\tilde{g}_{\ell,k}$ are equal to, $\tilde{g}_{\ell K} = \frac{g_{\ell K}}{N_\ell \times \alpha_1^\ell}$ where the $g_{\ell,K}$ (no tilde) parameters were defined in [CENTRM-WA95] to be:

$$\begin{aligned} g_{\ell,K} &= \frac{\left(1 + (-1)^{\ell+K}\right)}{2} \sum_{K'=0}^{\frac{\ell-K}{2}} (-1)^{K'} b_{2K'+K,\ell} \begin{pmatrix} 2K'+K \\ K' \end{pmatrix} \quad a_1^{K+K'} a_2^{K'}; \quad \text{for} \quad K \geq 0 \\ &\text{and} \\ &= (-a_2/a_1)^{|K|} \quad g_{\ell,|K|} \quad ; \text{ for } K < 0. \end{aligned} \tag{7.4.37}$$

In Eq. (7.4.36)-Eq. (7.4.37), the constants $b_{m,\ell}$ and N_ℓ are the standard Legendre constants and normalization factors, respectively, which are tabulated in Table 7.4.1 for orders through P_7; and $\begin{pmatrix} m \\ i \end{pmatrix}$ = the binomial expansion coefficients[20] = $\frac{m!}{(m-i)!\quad i!}$

The explicit dependence of the constants a_1 and a_2 on the nuclide index j [see Eq. (7.4.11)] has been suppressed to simplify notation. For discrete-level inelastic scatter the parameter a_1 is an energy dependent function given by Eq. (7.4.19), but for elastic scatter this reduces to the constant in Eq. (7.4.11). Note that the $g_{\ell,K}$ value is zero unless ℓ and K are both even or both odd, respectively, so that about half the terms appearing in the summation of Eq. (7.4.36) vanish. Table 7.4.2 through Table 7.4.4 give values for the submoment expansion coefficients for several nuclides.

The sub-moment expansion of the scattering source, including both elastic and discrete-level inelastic reactions, is obtained by substituting the expansion of the Legendre polynomial from Eq. (7.4.36) into Eq. (7.4.26), giving

$$S_{\ell k}(u) = \sum_{m,j} \sum_{K=-\ell}^{\ell} Z_{\ell,K}^{(m,j)}(E) h_K(E) \int_{u_{LO}^{(m,j)}}^{u_{HI}^{(m,j)}} \psi_{\ell k}(u') \Sigma^{(m,j)}(E') \frac{h_K^{-1}(E')}{\Delta^{(m,j)}(E')} du' \tag{7.4.38}$$

where $Z_{\ell K}^{(m,j)}(E) = a_1^{\ell}(E) \frac{\tilde{g}_{\ell,K}^{(m,j)}(E)}{(1-\alpha^{(j)})}$. For elastic scatter, the Z coefficients are independent of energy.

With this approach the scatter source moments in Eq. (7.4.39) have been further expanded into a summation of "submoments" identified by index K (although some of these terms are equal to zero, due to the behavior of the $g_{\ell,K}$ coefficients). Each term has the desired factored form expressed in Eq. (7.4.32); i.e., separable in terms of the variables u and u' with

$$H_{\ell,K}^{(i)}(u) = Z_{\ell,K}^{(j)}(E) h_K(E), \quad \text{and} \quad F_{\ell k,K}^{(j)}\left(u^j\right) = \frac{h_K^{-1}(E') \Psi_{\ell k}(u') \Sigma^{(j)}(u')}{\Delta^{(m,j)}(E')} \tag{7.4.39}$$

so that the lk_{th} moment of the scatter source can be written as

$$S_{\ell k}(u) = \sum_{m,j} \sum_{K=-1}^{\ell} H_{\ell,K}^{(j)}(u) \int_{u_{LO}^{(m,j)}}^{u_{HI}^{(m,j)}} F_{\ell k,K}^{(j)}(u') du' \tag{7.4.40}$$

Characteristics and Properties of the Sub-Moment Expansion

The expansion in Eq. (7.4.36) becomes numerically unstable for heavy nuclides (large A), with high Legendre orders. Using double precision arithmetic, it was found that the accuracy of the expansion begins to break down for heavy nuclides (A100) if the order of scatter exceeds P_5; although the expansion for lighter nuclides (viz, moderators) is very accurate even for scattering orders as high as P_7 or more. For this reason CENTRM has an option to restrict the Legendre expansion to lower orders for heavy masses, while using the input value of "ISCT" for lighter nuclides. The restricted Legendre order and mass cut-off value can be controlled by user input, but the default is P_0 (i.e., isotropic lab scattering) for A>100. Table 7.4.5 shows the maximum error observed in the series representation of Legendre polynomials up to P_5, for selected mass numbers. These values were obtained by evaluating the series expansion for $P_\ell(G(x))$ in Eq. (7.4.36), and comparing to the exact value computed at 11 equally spaced values for E/E'. The observed error in the P_5 polynomial expansion is < 1% even for heavy materials such as ^{238}U, while nuclides whose mass is < 100 are computed nearly exactly by the expansion.

Although the accuracy of the submoment expansion is good through P_7 scattering in moderators, Legendre expansions above P3 are not recommended because the number of terms in the expansion increases rapidly with increasing scattering order, especially for 2D MoC and 1D cylindrical systems. The number of spherical

harmonic moments appearing in the scattering source depends on the order (L=ISCAT) of the Legendre expansion used to represent the differential scatter cross section, as well as on the type of geometry (slab, spherical, cylindrical, or 2D MoC) used in the transport calculation. The submoment method further expands each source moment. Table 7.4.6 shows the number of moments in the cross-section expansion, and the number of moments and submoments in the scatter source expansion, as a function of scatter order and geometry type. Although the use of cumulative integrals discussed below allows the sub-moments to be evaluated rapidly, the large number of terms becomes prohibative for high scattering orders. Fortunately a P_1 Legendre order is sufficient for most self-shielding calculations, and orders beyond P_2 should seldom be required for reactor physics and criticality applications.

Scattering moments expressed with cumulative integral operator

It will be convenient to express the scatter source moments in terms of an integral operator $\mathbb{C}$, designated here as the "cumulative integral." The domain of this operator is the vector space of all integrable lethargy functions. The operator is defined for an arbitrary domain element $f(u')$, at an arbitrary lethargy limit U, to be:

$$\mathbb{C}(\mathrm{f};\mathrm{U}) = \int_{\mathrm{u_0}}^{\mathrm{U}} \mathrm{f}(\mathrm{u}')\,\mathrm{du}' \tag{7.4.41}$$

where u_0 is an arbitrary reference point. In implementing this method in CENTRM, it is convenient to set u_0=u_L; i.e., the negative lethargy value corresponding to highest energy of the transition range.

The cumulative integral at some lethargy mesh point u_n is related to the value at the previous lethargy mesh point u_{n-1} by the expression

$$£(f;u_n) = £(f;u_{n-1}) + \int_{u_{n-1}}^{u_n} f(u')\,du' \tag{7.4.42}$$

where $u_n > u_{n-1}$.

Note that only *a single panel of integration* over the interval $[u_{n-1}, u_n]$ must be performed to update the cumulative integrals.

The sub-moment expansion of the scatter source in Eq. (7.4.38) can be expressed in terms of the cumulative integral operator as follows:

$$\mathrm{S}^{(\mathrm{j})}_{\ell\mathrm{k}}(\mathrm{u}) = \sum_j \sum_{K=-\ell}^{\ell} \mathrm{H}^{(\mathrm{j})}_{\ell,\mathrm{K}}(\mathrm{u}) \times \left[£\left(\mathrm{F}^{(\mathrm{j})}_{\ell\mathrm{k},\mathrm{K}}; u^{(m,j)}_{HI} \right) - £\left(\mathrm{F}^{(\mathrm{j})}_{\ell\mathrm{k},\mathrm{K}}; u^{(m,j)}_{LO} \right) \right] \tag{7.4.43}$$

For elastic scatter the value of $\mathrm{u}^{(\mathrm{m,j})}_{\mathrm{LO}}$ is equal to $u - \varepsilon^{(j)}$, and $\mathrm{u}^{(\mathrm{m,j})}_{\mathrm{HI}}$ is equal to u.

7.4.2.5 Multigroup Boltzmann equation

The MG form of the transport equation used in the UMR and LMR is derived by integrating Eq. (7.4.1) over the energy intervals defined by the group structure in the MG library. Details concerning the MG transport equation, including its solution using the discrete ordinates method, can be found in the SCALE documentation of XSDRNPM. The CENTRM MG solution is similar to the XSDRNPM method: however; the outer iteration loop in CENTRM is limited to the thermal groups, since no eigenvalue calculation is performed in CENTRM. The MG scatter source in the thermal range has upscatter contributions that depend on group fluxes from lower energy groups in the LMR, so that outer iterations are performed over thermal groups in the LMR until the upscatter portion of the MG scatter source converges.

Multigroup data for CENTRM calculation

Group cross-section data for the MG calculations are taken from the input MG library which should include a combined 2D transfer matrix representing all pertinent scatter reactions (viz, elastic, inelastic, coherent and incoherent thermal reactions, n-2n, etc). MG cross sections also should be problem-dependent values. This is done by processing the data with BONAMI prior to the CENTRM calculation. BONAMI converts the problem-independent cross-sections into problem-dependent values by using the Bondarenko factors on the MG library.

Conversion of multigroup fluxes to pseudo-pointwise values

The MG flux solution provides the integrated flux over lethargy, for each group interval. The average flux within a group is assumed to approximate the value of the flux per unit lethargy at the midpoint lethargy of the group; thus a set of "pseudo-pointwise" angular fluxes and moments can be obtained for the NG_U and NG_L mesh points in the UMR and LMR, respectively. For lethargy point u_n , corresponding to the midpoint lethargy of group g contained within the LMR and UMR, a PW flux value is computed from the expression,

$$\Psi(u_n) = \Psi_g/\Delta u_g \tag{7.4.44}$$

where Δu_g is the lethargy width of group g. Eq. (7.4.44) provides PW flux values for lethargy mesh points,

$$u_1 \ldots u_{NGU,} \quad \text{and} \quad u_{NGU+NP+1} \cdots \ldots u_{NT} \tag{7.4.45}$$

A linear variation of the flux per unit lethargy is assumed between lethargy points to obtain a continuous representation in the UMR and LMR.

7.4.2.6 The Boltzmann equation within the PW range

In contrast to the "pseudo-pointwise" fluxes obtained from the MG transport calculation, a true PW solution is performed for the N_P lethargy points between DEMAX and DEMIN. The PW solution is performed within a loop over energy groups: i.e., for each of the NG_P groups in the PW range there is an additional loop over all lethargy mesh points contained inside the group. This approach facilitates coupling of the scatter source from the UMR to the PW range and from the PW and LMR.

Evaluating Eq. (7.4.1) at each of the N_P energy mesh-points in the PW range gives a system of integro-differential equations that can be solved to obtain the PW flux moments, per lethargy, for the N_P energy mesh points in the range DEMAX to DEMIN-which correspond to the lethargy points, $U_{NGU+1}, \ldots U_{NGU+NP}$. Again linear variation of the flux between lethargy points is assumed, to obtain a continuous spectrum. Substituting Eq. (7.4.4) into Eq. (7.4.1), the PW transport equation at mesh point n is found to be,

$$\Omega \bullet \nabla\Psi_n(r,\Omega) + \Sigma_{t,n}(r)\Psi_n(r,\Omega) = \sum_{\ell k} \frac{2\ell+1}{2} Y_{\ell k}(\Omega) S_{\ell k,n}(r) + Q_n(r,\Omega) \tag{7.4.46}$$

for $n = (NG_U + 1), \ldots., (NG_U + N_P)$

where

$$\begin{aligned} \sum_{t,n}(\mathbf{r}) &= \sum_{t}(\mathbf{r}, u_n) \\ \Psi_n(\mathbf{r},\Omega) &= \Psi(\mathbf{r},\Omega,u_n) \\ S_{\ell k,n}(\mathbf{r}) &= S_{\ell k}(\mathbf{r},u_n) \end{aligned} \tag{7.4.47}$$

Aside from the definition of the cross-section data, the above equation appears identical in form to the MG transport equation, and can be solved with virtually the same algorithm as the MG solution, once the scatter source moments are determined. The same computer routines in CENTRM calculate both the MG and PW fluxes. However, a major conceptual difference between the PW and MG transport equations is that the PW equation describes a differential neutron balance per unit lethargy *at an energy point*, while the MG equation represents an integral balance over an interval of lethargy points. Although this type of point solution is not inherently conservative over the intervals defined by the energy mesh, the particle balance for each interval has been found to be very good. It should also be noted that exact particle conservation is not a

strict requirement for this type of application where flux spectra rather than particle balances are primarily of interest.

In the PW range the scatter source is composed of (a) MG-to-PW scatter from the UMR and possibly upscatter from the LMR if the PW range extends into thermal, and (b) PW-to-PW scatter from points in the PW range. The submoment expansion method described previously is used in CENTRM to provide an efficient method of evaluating the PW-to-PW downscatter source for the epithermal range, which includes most of the resolved resonances.

Scattering sources for the PW range

In the case of elastic scatter from nuclide "j," only the lethargy interval below $u_n - \varepsilon^{(j)}$ can scatter to a lethargy point u_n in the PW range. If $u_n - \varepsilon^{(j)}$ is negative, then some portion of the source at u_n is due to UMR-to-PW from energies above DEMAX, since zero-lethargy is equal to the top energy of the PW range. Otherwise, the elastic source is entirely PW-to-PW.

For any given nuclide j, the lowest lethargy in the UMR range that contributes to the elastic scatter source in the PW range is equal to $-\epsilon^{(j)}$. Let "jL" represent the lightest *non-hydrogen* nuclide (i.e., having the smallest A value greater than unity) in the system. The associated fractional energy loss for this material is indicated as α_L, so that the highest energy neutron in the UMR range that can scatter into the PW range from an elastic collision with any non-hydrogenous moderator will have an energy equal to DEMAX/α_L. The corresponding lethargy is equal to be the negative value $-\epsilon^{(L)}$, or -ln(α_L). The value of $-\epsilon^{(L)}$ is actually adjusted in CENTRM to coincide with the immediately preceding multigroup boundary, which has a lethargy value designated as u_L. The interval of negative lethargy in the UMR between u_L and 0 has been defined previously to be transition range, because the elastic slowing-down source from this interval provides a transition between the UMR and PW solutions, respectively. The transition range always contains an integer number of groups, corresponding to MGTOP to MGHI. The total downscatter source from the UMR to lethargy u_n is composed of elastic and inelastic contributions from the transition range between [u_L,0]; and contributions from the "*high*" energy range from lethargies below u_L. The high contribution comes from inelastic and hydrogen elastic reactions in the energy interval above the transition range.

The downscatter source at u_n in the PW range can thus be expressed as the sum of three distinct contributions - S_{HI}, S_{Tr}, and S_{PW} -, that correspond to scatter from the high region of the UMR, the transition region of the UMR, and the PW ranges, respectively. The source moments appearing in Eq. (7.4.46) can thus be expressed as:

$$\begin{aligned} S_{\ell k,n}(r) &= S_{\ell k,HI}(r, u_n) + S_{\ell k,Tr}(r, u_n) + S_{\ell k,PR}(r, u_n) \\ &= \int_{-\infty}^{u_L} S_{\ell k}(u' \to u)\, du' + \int_{u_L}^{0} S_{\ell k}(u' \to u)\, du' + \int_{0}^{u_n} S_{\ell k}(u' \to u)\, du' \end{aligned} \tag{7.4.48}$$

Downscatter source from high region of the UMR to the PW range (SHI)

The high region of the UMR corresponds to groups 1 through MGTOP-1. The MG-to-PW scattering source (S_{HI}) from high energy region originates in the energy range above DEMAX/α_L; i.e., lethargies below u_L (see Fig. 7.4.2). In this region, inelastic reactions may scatter neutrons to the PW range; but due to the definition of u_L, the only elastic reactions that scatter to the PW range are due to hydrogen. Therefore in general, the MG matrices describing scatter from groups in high region to groups in the PW range correspond to discrete and continuum inelastic reactions, and elastic scatter from hydrogen. If g' is an arbitrary group in the UMR range above the transition interval and g is a fixed group interval in the PW range, then the rate that neutrons

scatter from all groups g' in the high region to all energy points in g, for a given direction Ω, is obtained from the usual expression for MG-to-MG transfers, and is equal to

$$S_g(r,\Omega) = \sum_{\ell k} \frac{2\ell+1}{2} Y_{\ell k}(\Omega) S_{\ell k,g} \tag{7.4.49}$$

where MGLO > g > MGHI, and the MG source moments are,

$$S_{\ell k,g} = \sum_{g'=1}^{MGTOP-1} \Sigma_{\ell,g'\to g} \Psi_{\ell k,g'} \tag{7.4.50}$$

while Eq. (7.4.50) gives the moments of the overall scatter rate from all groups in the high range into the *entire* PW group g, it is necessary to determine how the group source should be distributed over the PW energy mesh contained within the group; i.e., it is desired to extract the PW source moments, from the group moments by applying some "intra-group" distribution $H_{\ell k,g}(E)$ such that,

$$S_{\ell k,HI}(u) = S_{\ell k,g} H_{\ell k,g}(E), \qquad \text{for } u(E)\varepsilon \text{ group } g \tag{7.4.51}$$

The intra-group distribution has units of "per unit lethargy," and its integral over the group is normalized to unity. This form of the scatter source preserves the MG moments $S_{\ell k,g}$, whenever $S_{\ell k,HI}(u)$ is integrated over group g, ensuring that the correct number of neutrons (as determined from the UMR calculation) will always be transferred from the high range into the PW group. Only the distribution within the group is approximate.

Recall that the scatter source of concern here is due only to elastic scatter from hydrogen and inelastic scatter from all other materials. In the case of *s*-wave elastic scatter from hydrogen, the P_0 and P_1 moments per unit lethargy, respectively, can be rigorously expressed in the form of Eq. (7.4.51) with

$$H_0 \propto E \quad , \quad \text{and} \quad H_1 \propto E^{3/2} \tag{7.4.52}$$

These expressions can be inferred directly from the moments of the scatter kernel in Eq. (7.4.17). The higher order scatter moments for hydrogen have a somewhat more complicated form containing sums of energy functions; but since these moments are usually less important than the first two moments, a less rigorous treatment of their intra-group distribution is used. The intra-group distribution due to inelastic scatter depends on the Q values for the individual levels, and these are not available on the multigroup libraries. Fortunately, the scatter source in the PW range is not very sensitive to the assumed intra-group distribution for inelastic scatter, as long as the total inelastic source for the group is computed correctly. As a reasonable trade-off between rigor and complexity, the high energy component of the UMR-to-PW scatter source is approximated using H_0 for the intra-group distribution of all P_0 moments, and H_1 for all higher order moments. This approximation produces the correct intra-group variation for the lowest two moments of the hydrogen scatter source, but the higher order moments of hydrogen and the inelastic scatter source are not distributed exactly throughout the group. However, the integrated source moments are correct in all cases. Again, it should be emphasized that the approximations discussed here only apply to the UMR-to-PW component designated as S_{HI}, which comes from reactions above the transition range (energies above E_{HI}/α_L). This is often a small contribution to the overall PW source term.

Scattering sources from UMR transition region and epithermal PW range

Most coupling between the UMR and the PW range is due usually to elastic scatter from energies immediately above DEMAX. The contribution to the PW source due to downscatter source from this transition range has been designated $S_{Tr}(u_n)$. The other component of the PW source, $S_{PW}(u_n)$, accounts for the scattering source coming from all lethargies lower than u_n in the PW range. It is convenient to combine the two sources together as the PW epithermal source called "S_{Ep}," which has an lk_{th} moment given by Eq. (7.4.32),

$$\begin{aligned} S_{\ell k,Ep} &= \int_{u_L}^{u_n} S_{\ell k}(r, u' \rightarrow u)\, du' \\ &= \sum_j \sum_{K=-\ell}^{\ell} Z_{\ell,k}^{(j)} h_K(E) \int_{u_n-\varepsilon^{(j)}}^{u_n} \Psi_{\ell k}(u') \quad \Sigma^{(j)}(u') \quad h_K^{-1}(E')\, du'. \end{aligned} \tag{7.4.53}$$

This is done because CENTRM uses the submoment expansion technique to compute both the PW-to-PW epithermal source from the PW range as well as the MG-to-PW source from the transition range of the UMR. Note that elastic scattering from the transition range only impacts the PW scatter source at the initial mesh points in the PW range; i.e., those contained in the interval $0 < u_n < \epsilon^{(j)}$, for nuclide j. Beyond these mesh points the elastic scatter source is due only to PW-to-PW scatter, as illustrated in Fig. 7.4.2.

The epithermal elastic source at u_n, coming from the range u_L to u_n, is expressed as an integral over the immediately preceding lethargy mesh interval from u_{n-1} to u_n plus the integral over the remaining lethargy interval, as illustrated in Fig. 7.4.3. The former integral is designated as $I(u_{n-1},u_n)$ and the latter as $I(u_L,u_{n-1})$, so that

$$S_{\ell k,E\ell}(u_n) = I(u_{n-1}, u_n) + I(u_L, u_{n-1}) \tag{7.4.54}$$

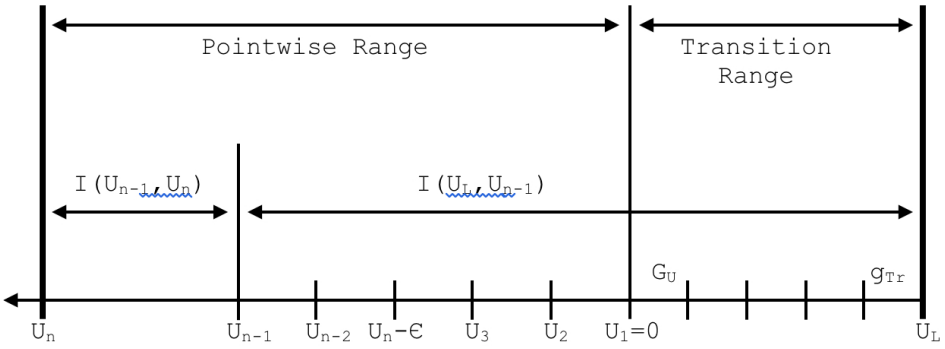

Fig. 7.4.3: Definition of cumulative integral elements.

The lethargy mesh in CENTRM is constrained such that the maximum lethargy gain in an elastic reaction ($\epsilon^{(j)}$) is always greater than the maximum mesh interval size, which insures that $I(u_{n-1},u_n)$ always includes the full panel from u_{n-1} to u_n. In the above and subsequent equations the explicit dependence of S_{Ep} on independent variables other than lethargy is not shown for notational convenience. The integral $I(u_{n-1},u_n)$ is evaluated approximately by applying the trapezoidal rule, which leads to,

$$I(u_n, u_{n-1}) = \int_{u_{n-1}}^{u_n} S_{\ell k}(u' \rightarrow u_n)\, du' \sim \frac{[S_{\ell k}(u_n \rightarrow u_n) + S_{\ell k}(u_{n-1} \rightarrow u_n)]}{2} \times (u_n - u_{n-1}) \tag{7.4.55}$$

Using the submoment expansion from Eq. (7.4.38), Eq. (7.4.55) can be written for elastic scatter as

$$I(u_{n-1}, u_n) = \Sigma_{n\to n}\Psi_{\ell k,n} + \sum_K Z^{(j)}_{\ell K} h_K(E_n)\, h_K^{-1}(E_{n-1})\, \Sigma^{(j)}(u_{n-1})\, \Psi_{\ell k,n-1}\frac{\Delta u_{n-1}}{2}. \tag{7.4.56}$$

The first term on the right side of Eq. (7.4.56) corresponds to the "within-point" component of elastic scatter from u_n to u_n, which only occurs for straight ahead scatter ($\mu_0 = 1$). The within-point cross section is defined as,

$$\Sigma_{n\to n} = \frac{\Delta u_{n-1}}{2}\sum_j \frac{\Sigma^{(j)}_n}{(1-\alpha^{(j)})}. \tag{7.4.57}$$

In deriving this term the following relation has been used for each nuclide:

$$\sum_K Z_K = \frac{1}{1-\alpha}. \tag{7.4.58}$$

The $I(u_L,u_{n-1})$ portion of the integral in Eq. (7.4.53) is equal to

$$I(u_L, u_{n-1}) = \sum_j \sum_{K=-\ell}^{\ell} Z^{(j)}_{\ell,K} \quad h_K(E_n) \int_{u_n-\varepsilon^{(j)}}^{u_{n-1}} \Psi_{\ell k}(u') \quad \Sigma^{(j)}(u')\, h_K^{-1}(E')\, du'. \tag{7.4.59}$$

Note that the lower lethargy limit of the integral is restricted to $u_n - \epsilon^{(j)}$, since this is the maximum limit of lethargy that can scatter to u_n in an elastic reaction. In terms of the cumulative integral operator, the integral in Eq. (7.4.59) over the interval $\left[u_n - \epsilon^{(j)}, u_{n-1}\right]$ is equal to:

$$\int_{u_n-\varepsilon(j)}^{u_n-1} \Psi_{\ell k}(u')\,\Sigma^{(j)}(u')\, h_K(E')^{-1}\, du' = \left[£\left(F^{(j)}_{\ell k,K}; u_{n-1}\right) - £\left(F^{(j)}_{\ell k,K}; u_n - \varepsilon^{(j)}\right)\right] \tag{7.4.60}$$

where $F_{\ell k,K}$ has been defined in Eq. (7.4.39). In order to evaluate Eq. (7.4.60) it is necessary to determine the cumulative integral values at u_{n-1} and $u_n - \varepsilon^{(j)}$. The lethargy u_{n-1} will always correspond to a mesh point value, but in general $u_n - \varepsilon^{(j)}$ can fall between mesh points. Evaluation of the cumulative integrals at an arbitrary limit such as $u_n - \varepsilon^{(j)}$ is performed in CENTRM by interpolation of previously calculated values stored for all the mesh points below u_n during the transport calculation at lower lethargies. The interpolated value of the cumulative integral at $u_n - \varepsilon^{(j)}$ that is subtracted in Eq. (7.4.60) is called the "*excess integral*" in CENTRM. At each lethargy point, excess integrals must be found as a function of space, nuclide, moment, and submoment. Also note that for some initial mesh points (i.e., $u_n < \varepsilon^{(j)}$) the value $u_n - \varepsilon^{(j)}$ can be negative, indicating that a portion of the PW scatter source at u_n is due to elastic scattering from the negative lethargy range above DEMAX. This means that cumulative integrals must be known for mesh intervals in the transition as well as in the PW range. Values of the cumulative integrals at all points within the transition range are first computed from the results from the UMR calculation, prior to the PW transport calculation (but after the UMR calculation). Additional cumulative integrals are then calculated successively during the PW transport solution at all mesh points and are stored as the calculation proceeds from low to high lethargy. Thus in evaluating $S_{\ell k,Ep}(u_n)$, the cumulative integrals at every space interval already will have been stored at all energy points up to (n-1), in an array called $CUM^j_{\ell k,K}$, for each nuclide j, moment ℓk, and submoment K:

$$CUM^{(j)}{}_{\ell k,K} = \left\{£\left(F^{(j)}_{\ell k,K}; u_{n'}\right), n' = 1, n-1\right\}, \tag{7.4.61}$$

so that the excess integral values can be interpolated from the above array. The first N_{Tr} elements of the array $CUM^j_{\ell k,K}$, correspond to lethargy points in the transition range, and the remainder are in the PW range, where

$\mathbf{N}_{\mathrm{Tr}} = \mathrm{G_U} - \mathrm{g_{Tr}} + 1$;

$\mathbf{g}_{\mathrm{Tr}}$ = MGTOP, the highest energy group in the transition range; (i.e., the group whose high energy boundary corresponds to u_L

$\mathrm{G_U}$ = Lowest energy group in the transition range.

Elastic cumulative integrals contained in array $\mathrm{CUM}^{j}_{\ell k,K}$, are calculated at each lethargy point $\mathrm{u_n}$ with the expression:

$$\begin{aligned} \pounds\left(\mathrm{F}^{(\mathrm{j})}_{\ell \mathrm{k,K}}; \mathrm{u_n}\right) &= \pounds\left(\mathrm{F}^{(\mathrm{j})}_{\ell \mathrm{k,K}}; \mathrm{u_{n-1}}\right) + \int_{u_{\mathrm{n-1}}}^{\mathrm{u_n}} \mathrm{F}^{(\mathrm{j})}_{\ell \mathrm{k,K}}(\mathrm{u}')\,\mathrm{du}' \\ &= \pounds\left(\mathrm{F}^{(\mathrm{j})}_{\ell \mathrm{k,K}}; \mathrm{u_{n-1}}\right) + \int_{\mathrm{u_n}-1}^{\mathrm{u_n}} \Psi_{\ell \mathrm{k}}(\mathrm{u}') \quad \Sigma^{(\mathrm{j})}(\mathrm{u}') \quad \mathrm{h_K}(\mathrm{E}')^{-1}\,\mathrm{du}' \end{aligned} \tag{7.4.62}$$

After completing the calculation of PW angular fluxes and moments at $\mathrm{u_n}$ the integral over the most current lethargy panel [$\mathrm{u_{n-1}}$,$\mathrm{u_n}$] is evaluated with the trapezoidal approximation, resulting in an updated cumulative integral array containing the value at lethargy $\mathrm{u_n}$:

$$\pounds\left(\mathrm{F}^{(\mathrm{j})}_{\ell \mathrm{k,K}}; \mathrm{u_n}\right) \approx \quad \pounds\left(\mathrm{F}^{(\mathrm{j}}_{\ell \mathrm{k,K}}; \mathrm{u_{n-1}}\right) + \Delta \mathrm{u_{n-1}} \frac{\left[\mathrm{h_K}^{-1}(\mathrm{E_{n-1}})\,\Sigma^{(\mathrm{j})}_{\mathrm{n-1}}\Psi_{\ell \mathrm{k,n-1}} + \mathrm{h_K^{-1}}(\mathrm{E_n})\,\Sigma^{(\mathrm{j})}_{\mathrm{n}}\Psi_{\ell \mathrm{k,n}}\right]}{2}, \tag{7.4.63}$$

where the cumulative integrals at the preceding mesh point are known from the previous calculation, and the flux moments $\psi_{\ell k}(u_n)$ are determined from the transport calculation at the current lethargy point. Only a single panel of integration is required to update the cumulative integrals, significantly reducing the amount of computation compared to recomputing the entire summation again at each new energy point. The integration is performed rapidly with the trapezoidal approximation, which should be accurate since the energy mesh is defined to reproduce the macroscopic cross sections linearly between mesh points. In order to avoid loss of numerical significance, the set of stored cumulative integrals is periodically "renormalized," by translating to a new reference lethargy point (recall that only the *differences* of cumulative integrals is needed).

Elastic cumulative integrals for the transition range are calculated with a slightly different expression, using MG flux moments obtained in the UMR calculation. Because the transition interval is part of the UMR, it is convenient to evaluate cumulative integrals at lethargy values corresponding to group boundaries. This requires approximating the energy distribution of the flux spectrum within each group in the transition range. To evaluate the cumulative interval in the transition range of some nuclide j, the scalar flux per energy (at a given space location) within a transition group is approximated as: $\Phi(\mathrm{E}) = \mathrm{M}^{(\mathrm{j})}/\mathrm{E}$, where $\mathrm{M}^{(\mathrm{j})}$ is a normalization constant defined so that the MG outscatter rate (i.e., slowing-down density) from the group is preserved. It can be shown that this normalization condition requires that

$$\mathbf{M}^{(j)} = \frac{\left[\Sigma^{(j)}_{t,g'} - \Sigma^{(j)}_{a,g'} - \Sigma^{(j)}_{g'},\right]\Delta u_{g'}}{\xi^{(j)}\Sigma^{(j)}_{s,g'}} \times \left[\phi_{g'}/\Delta u_{g'}\right] \tag{7.4.64}$$

where ξ is the average lethargy gain in an elastic reaction and $\Sigma_{g'g'}$ is the within-group MG scatter cross section. Thus the scalar flux per unit lethargy used to evaluate cumulative integrals of nuclide j is:

$$\phi(\mathrm{u}') = \mathrm{M}^{(\mathrm{j})}; \quad \text{for } \mathrm{u}' \in \mathrm{g}', \text{ and } \mathrm{g}' \in \text{ Transition region of UMR} \tag{7.4.65}$$

Within-group energy spectra for the higher order flux-moments could be approximated in similar manner by preserving the higher order Legendre moments of the slowing-down density, but CENTRM simply uses the

same form in Eq. (7.4.64) for all flux moments, so that in general the within-group energy distribution for any ℓk_{th} moment in the transition range is approximated as,

$$\Psi_{\ell k}(u') = \frac{\left[\sum_{t,g'}^{(j)} - \Sigma_{a,g'}^{(j)} - \Sigma_{g'g'}^{(j)}\right] \Delta u_{g'}}{\xi^{(j)} \sum_{s,g'}^{(j)}} \times \left[\Psi_{\ell k,g'} / \Delta u_{g'}\right] \tag{7.4.66}$$

for $u' \in g'$, and$g' \in$ transition region of UMR. Therefore the following integrals can be evaluated:

$$\int_{u_{g'}}^{u_{g'+1}} h_K^{-1}(E') \Sigma^{(\mathrm{j})}(\mathrm{u}') \Psi_{\ell \mathrm{k}}(\mathrm{u}')\, \mathrm{du}' = \frac{\sum_{\mathrm{r,g'}}^{(\mathrm{j})} \Delta \mathrm{u_{g'}}}{\xi^{(\mathrm{j})}} \frac{\Psi_{\ell \mathrm{k,g'}}}{\Delta \mathrm{u_{g'}}} \int_{\mathrm{u_{g'}}}^{\mathrm{u_{g'+1}}} \mathrm{h_K^{-1}}(\mathrm{E}')\, \mathrm{du}'. \tag{7.4.67}$$

Integration of the $\mathrm{h_k}^{-1}$ function is performed analytically to give the cumulative integral at any group boundary $\mathrm{u_g}$ in the transition range:

$$\begin{aligned} &£\left(\mathrm{F}_{\ell \mathrm{k,K}}^{(\mathrm{j})}; \mathrm{u_g}\right); \sum_{\mathrm{g'=g}}^{\mathrm{G_U}} \frac{\Sigma_{\mathrm{r,g'}}^{(\mathrm{j})} \Delta \mathrm{u_{g'}}}{\xi^{(\mathrm{j})}} \frac{\Psi_{\ell \mathrm{k,g'}}}{\Delta \mathrm{u_{g'}}} \times \left[\frac{2}{\mathrm{K}+2}\right] \left[\mathrm{h_K^{-1}}\left(\mathrm{E_{g'+1}}\right) - \mathrm{h_K^{-1}}\left(\mathrm{E_{g'}}\right)\right] \\ &\mathrm{g} = \mathrm{g_{Tr}}, \quad \mathrm{g_{Tr+1}}, \ldots\ldots \mathrm{G_U} \end{aligned} \tag{7.4.68}$$

Eq. (7.4.68) is used to obtain the initial $\mathrm{N_{Tr}}$ values of the cumulative integrals, corresponding to the transition range. If the lower limit of the integral in Eq. (7.4.60) is negative, then the cumulative integral at $u_n - \varepsilon^{(j)}$ is interpolated from among the set of $\mathrm{N_{Tr}}$ tabulated values generated by Eq. (7.4.68); otherwise it is interpolated from the values that were computed with Eq. (7.4.63). The following algorithm is used to interpolate cumulative integrals for negative lethargy arguments (i.e., in the transition range):

$$\begin{aligned} £\left(F_{\ell k,K}^{(j)}; u\right) &= £\left(F_{\ell k,K}^{(j)}; u_g\right) + \frac{h_K^{-1}(E) - h_K^{-1}\left(E_g\right)}{h_K^{-1}\left(E_{g+1}\right) - h_K^{-1}\left(E_g\right)} \\ &\times \left[£\left(F_{\ell k,K}^{(j)}; u_{g+1}\right) - £\left(F_{\ell k,K}^{(j)}; u_g\right)\right] \end{aligned} \tag{7.4.69}$$

or $u(E) \in g$; and g $\in$ transition range of UMR.

Because the energy mesh in the PW range is very fine, simple linear interpolation of the cumulative integrals is used for positive lethargy arguments.

The complete epithermal elastic scatter source $S(r, \Omega, u_n)$ appearing in Eq. (7.4.46) at any mesh point $\mathrm{u_n}$ corresponds to a spherical harmonic expansion using the previously derived moments of $\mathrm{S_{HI}}$ and $\mathrm{S_{Ep}}$. This angular scatter source is equal to,

$$\begin{aligned} &\mathrm{S}(\mathbf{r}, \Omega, \mathrm{u_n}) = \Sigma_{\mathrm{n}\to\mathrm{n}} \Psi_{\mathrm{n}}(\mathbf{r}, \Omega) \\ &+ \sum_{\ell \mathrm{k}} \frac{2\ell+1}{2} \mathrm{Y}_{\ell \mathrm{k}}(\Omega) \left\{ \mathrm{H}_\ell(\mathrm{E_n}) \sum_{\mathrm{g'=1}}^{\mathrm{g_{Tr}-1}} \sum_{\ell, \mathrm{g'} \to \mathrm{g}} \psi_{\ell \mathrm{k,g'}} \right. \\ &\left. + \sum_{\mathrm{j}} \sum_{\mathrm{K}} \mathrm{Z}_{\ell \mathrm{K}}^{(\mathrm{j})} \mathrm{h_K}(\mathrm{E_n}) \left[0.5 \Delta \mathrm{u_{n-1}}\, \mathrm{F}_{\ell \mathrm{k,K}}^{(\mathrm{j})}(\mathrm{u_{n-1}}) + £\left(\mathrm{F}_{\ell \mathrm{k,K}}^{(\mathrm{j})}; \mathrm{u_{n-1}}\right) - £\left(\mathrm{F}_{\ell \mathrm{k,K}}^{(\mathrm{j})}; \mathrm{u_n} - \varepsilon^{(\mathrm{j})}\right)\right] \right\} \end{aligned} \tag{7.4.70}$$

The above expression was written explicitly for the case of elastic scatter; however, the discrete level inelastic PW source can be incorporated with little modification. The only changes are that additional cumulative integral terms corresponding to each inelastic level will appear in Eq. (7.4.70); the cumulative integrals

for the inelastic levels must be computed by integrating the more general expression in Eq. (7.4.39); and the lethargy arguments for the inelastic cumulative integrals are the generalized lethargy limits u_{LO} and u_{HI} defined in Sect. 7.4.2.4 and [CENTRM-Wil00].

Note that Eq. (7.4.70) contains the term $\Sigma_{n\to n} \quad \Psi_n(r,\Omega)$ which can be subtracted from both sides of the transport equation in Eq. to give a slightly altered form of the PW transport equation that contains a modified scatter source and a modified total cross section. The modified source component is identical to the expression in Eq. (7.4.70) with the within-point term $\Sigma_{n\to n}\Psi_n(r,\Omega)$ removed. The modified total cross section, represented by $\tilde{\Sigma}_{t,n}$ has the appearance of a "transport-corrected" cross section given below:

$$\tilde{\Sigma}_{t,n} = \Sigma_{t,n} - \Sigma_{n\to n} \tag{7.4.71}$$

An interesting and significant consequence of this operation is that the right side of Eq. (7.4.70) no longer contains the unknown flux $\psi_n(r,\Omega)$ since the within-point term is eliminated. The resulting modified transport equation has the same form as a purely absorbing medium with a known source term; and thus can be solved without requiring scatter-source iterations in the epithermal range. However, iterations may still be required for cell cases with two reflected or albedo boundary conditions.

PW thermal scatter source

There are significant differences in the CENTRM epithermal and thermal PW transport solutions. In the epithermal range neutrons can only lose energy in scattering reactions, so that a single sweep from high to low energy (i.e., low to high lethargy) is required in the solution. On the other hand, since low energy neutrons may gain as well as lose energy in scattering reactions, outer iterations are required to converge the thermal scattering source. Furthermore, the PW scatter kernels $\Sigma_\ell(u'\to u)$ in the epithermal range represent two-body interactions (such as elastic and discrete-level inelastic reactions) between a neutron and a stationary nucleus. The simple kinematic relations for these cases allow the efficient sub-moment expansion method to be utilized in computing scattering source moments. Thermal scattering reactions are not two body reactions, but rather represent an effective average over the molecular velocity distribution; thus, there is no simple kinematic relationship between neutron energy loss and the angle of scatter relative to its initial direction. In solving the transport equation for thermal neutrons, the scatter source at lethargy u_n is approximated as a summation over the "N" mesh points in the thermal range,

$$\int_{\text{thermal}} \Sigma_\ell^{(j)}(u'\to u_n)\,\Psi_{\ell k}(u')\,du' = \sum_{m=1}^{N} W_m \Sigma_\ell^{(j)}(u_m\to u_n)\,\Psi_{\ell k}(u_m) \tag{7.4.72}$$

where

m = 1 is the thermal/epithermal boundary point;

m = N is the lowest thermal energy point; and

W_m are standard quadrature weights for trapezoidal integration with N-1 lethargy panels:

$$\begin{aligned} W_m =& 0.5\times(\Delta u_m + \Delta u_{m+1}) \quad ; \quad \text{for m} = 2,3,\ldots N-1 \\ & 0.5\times\Delta u_m \quad ; \quad \text{for m} = 1 \quad \text{or} \quad N \end{aligned} \tag{7.4.73}$$

Point-to-point cross-section moments in the thermal range are computed from the free-gas or bound kernels evaluated at the desired initial (u_m) and final (u_n) lethargy mesh points. For a given outer iteration, the summation in Eq. (7.4.72) is evaluated using the most recently computed flux moments. In many instances the main purpose of the CENTRM calculation will be to obtain a PW spectrum for resonance self-shielding calculations. In these cases the thermal flux does not have to be converged very tightly to obtain a reasonable

thermal spectrum for self-shielding low energy resonances, so that only a few outer iterations are typically employed.

An additional complication in the thermal calculation is that inner iterations are necessary to converge the "within-point" (no energy loss) contribution of the thermal scattering source, due to the presence of PW flux moments at lethargy point m = n. No inner iterations are required to converge the within-point elastic scatter term in the epithermal PW calculation because there can be no change in the neutron direction if there is no energy loss, unlike the thermal range.

A space-dependent rebalance calculation for the entire thermal energy band is performed between outer iterations in order to speed up convergence of the solution. Reaction rates and leakage values appearing in the thermal-band rebalance equation are obtained by integrating PW values over the thermal range. Other acceleration techniques, such as over-relaxation, extrapolation, and renormalization, are also employed.

Downscatter source from the epithermal PW range to the LMR

MG transport calculations performed in the energy range below DEMIN, which includes the thermal energy range, are coupled to the epithermal PW range transport calculations by the slowing down source. The epithermal PW-to-LMR scatter source represents the contribution to the multigroup source in some fixed group g contained in the LMR, from scatter reactions in the epithermal range above DEMIN. The lethargy value corresponding to the energy DEMIN (i.e., the bottom energy of the PW range) will be indicated as u_{PW}, thus u_{PW} = ln(DEMAX/DEMIN); while the lethargy corresponding to the thermal energy boundary will be designated as u_{TH}. The cut-off lethargy for the epithermal PW range will correspond to: $u_{cut} = \min(u_{PW}, u_{TH})$. If there is no PW thermal calculation in CENTRM, then $u_{cut} = u_{PW}$; otherwise, u_{cut} = u:sub:*TH*. For a given nuclide j, the lowest lethargy in the epithermal PW range from which a neutron can scatter elastically into the LMR is equal to $(u_{cut} - \varepsilon^{(j)})$ If the value of $(u - \varepsilon^{(j)})$ is greater than u_{cut}, then an elastic collision with nuclide j cannot moderate an epithermal neutron from the PW range to u. Therefore in general for a given material zone, only a limited number of nuclides (possibly none) and a limited portion of the epithermal PW energy range may be able to scatter neutrons elastically to any particular group in the LMR. Utilizing the elastic scatter kernel and applying a sub-moment expansion to the resulting expression, the source moment describing scatter from the PW epithermal range to a lethargy u in the LMR is found to be

$$S_{\ell k}^{(j)}(u) = \sum_{K} Z_{\ell K}^{(j)} \quad h_K(E) \int_{u-\varepsilon^{(j)}}^{u_{\text{cut}}} F_{\ell k,K}^{(j)}(u')\, du' \tag{7.4.74}$$

where u is in group g; and $g \in$ LMR.

The integral in the above expression can be evaluated from cumulative integrals stored during the epithermal PW transport calculation. Thus the source moment per unit lethargy at u in the LMR range, due to epithermal scattering from nuclide j, can be written as,

$$S_{\ell k}{}^{(j)}(u) = \sum_{K} Z_{\ell K}^{(j)} h_K(E) \left[£\left(F_{\ell k,K}^{(j}; u_{cut} \right) - £\left(F_{\ell k,K}^{(j)}; u - \varepsilon^{(j)} \right) \right], \tag{7.4.75}$$

for u in group g and $u - \varepsilon(j) < u_{PW}$.

The source per unit lethargy in Eq. (7.4.75) is integrated over the "sink group" g in the LMR to determine the desired MG scatter source moment due to reactions in the epithermal PW range. The actual integral over group g is performed numerically by introducing a three-point (two panel) integration mesh within the group,

as follows:

$$\begin{aligned} u_I &= \text{initial integration point in group g} = \text{lethargy at top energy of group g} = u_g \\ u_F^{(j)} &= \text{final integration point in group g} \\ &= \text{MIN}\left\{u_{g+1}; u_{cut} + \varepsilon^{(j)}\right\}, \quad \text{where } u_{g+1} = \text{lethargy at bottom of energy of group g} \\ u_A^{(j)} &= \text{middle integration point in group g} = 0.5\left(u_F^{(j)} + u_I\right) \end{aligned} \tag{7.4.76}$$

Note that the final and middle points of integration (i.e., $u_F^{(j)}$ and $u_A^{(j)}$) may be nuclide dependent; and if $u_I - \varepsilon^{(j)} > u_{cut}$, then nuclide j does not contribute to the pointwise-to-LMR scatter source in g. Applying the two-panel Simpson's approximation for integration over group g results in

$$S_{\ell k,g}^{(j)} = \Delta^{(j)}/3\left[\, S_{\ell k}^{(j)}(u_I) + 4\, S_{\ell k}^{(j)}\left(u_A^{(j)}\right) + S_{\ell k}^{(j)}\left(u_F^{(j)}\right)\right] \tag{7.4.77}$$

where $\Delta^{(j)} = 0.5\left(u_F^{(j)} - u_I\right)$.

The values for

$S_{\ell k}^{(j)}(u_I)$, $S_{\ell k}^{(j)}\left(u_A^{(j)}\right)$, and $S_{\ell k}^{(j)}\left(u_F^{(j)}\right)$ in Eq. (7.4.77) are obtained by evaluating Eq. (7.4.75) at the lethargy values u_I, $u_A^{(j)}$, and $u_F^{(j)}$, respectively. Use of more than two panels for the group integration was found to have an insignificant impact.

The complete epithermal PW-to-LMR source in group g is finally obtained by summing Eq. (7.4.75) over all nuclides and then substituting the spherical harmonic moments into the Legendre expansion of the MG scatter source, resulting in

$$S_{PW\to g} = \sum_{\ell k} \frac{2\ell+1}{2} Y_{\ell k}(\Omega) \sum_j \Delta^{(j)}/3 \quad \left[\, S_{\ell k}^{(j)}(u_I) + 4\, S_{\ell k}^{(j)}\left(u_A^{(j)}\right) + S_{\ell k}^{(j)}\left(u_F^{(j)}\right)\right] \tag{7.4.78}$$

Thermal scatter sources from LMR and PW range

If the value of DEMIN is specified to be below the thermal energy boundary, the portion of the PW range between DEMIN and the thermal cutoff, as well as the entire LMR, will be contained in the thermal range. In this case thermal neutrons will downscatter from the thermal PW range to the LMR, and upscatter from the LMR to the thermal PW range.

The latter thermal source (LMR-to-PW) is computed in exactly the same manner as used to compute the UMR-to-PW source S_{HI}, described in Sect. 7.4.2.6.2. On the other hand, the scatter source from the thermal PW to the LMR is computed with a similar approach as given in the previous section for epithermal PW-to-LMR scatter. In this case Eq. (7.4.78) is used as before, except the source moments are not obtained from the submoment expansion in Eq. (7.4.75), but rather by evaluating the PW thermal scatter expression in Eq. (7.4.72).

In performing the transport calculation for any group g in the LMR range, the PW-to-MG source component in Eq. (7.4.78) is added to the MG-to-MG scattering into g from all groups in the UMR and LMR ranges, respectively, to obtain the total scatter source.

7.4.2.7 Determination of energy mesh for PW flux calculation

The energy mesh for the PW flux computation is determined for a specific problem as follows: (a) for each zone-composition, microscopic cross-section data are interpolated (if necessary) to the desired zone-temperature, and a union energy mesh is formed from the energy meshes of PW total cross sections of all materials in that zone, plus the MG boundaries; (b) macroscopic total cross sections are computed for the union meshes in each zone; (c) union meshes for each zone are thinned (i.e., some energy points eliminated) in a manner that allows the zone macroscopic cross section to be interpolated linearly, within some input error tolerance; (d) a union mesh is created from the thinned energy meshes for each zone thus producing a "global" energy mesh; (e) the global mesh is checked to insure that it still contains group boundaries and midpoint-energies of the input MG library, and finally, (f) still more points may be added to constrain the maximum interval width between successive lethargy points to be less than some fraction of the maximum lethargy gained by elastic scatter from a fictitious nuclide having a mass of approximately 400. The fraction used in limiting the maximum size of any lethargy interval can be set by the input value of "FLET," but is defaulted to a value of 1/3.

The mesh thinning procedure is effective in reducing the number of energy points in the PW transport calculation, while preserving essential features of the macroscopic cross-section data that affect the flux spectrum; viz, the mesh is typically fine in energy regions corresponding to important resonances, but coarser where there is little variation in the macroscopic cross-section data. The default thinning tolerance is 0.1%. A less stringent thinning tolerance may give a large reduction in computation time, but also can affect the accuracy.

7.4.2.8 CENTRM cross sections and fixed sources

CENTRM PW cross-section libraries

SCALE includes CE nuclear data for all materials and all reaction types available in ENDF/B, processed for several different temperatures. The CE data, spanning the energy range from 10^{-5} eV to 20 MeV, are stored in separate files for individual nuclides, which can be used for CENTRM as well as CE Monte Carlo calculations. The CRAWDAD module reads these files and merges the data to form a single CENTRM formatted library containing only the particular materials, cross section types, temperatures, and energy range needed for a given calculation (see Sect. 8.1.6). In general the CENTRM library includes CE data for the unresolved, as well as the resolved, resonance range. Unresolved resonance data typically have rather smooth variations, but in reality the cross sections represent average values for very closely spaced resonances that can not be measured individually.

Linearization of MG cross sections and fixed sources

Shielded group cross sections from the input MG library are always required for the UMR and LMR portions of the CENTRM calculation. Two approaches are available to translate multigroup cross sections into pseudo-PW data at energy points within a group. The first is a "step" approximation in which $\sigma) = \sigma_g$, where E_n is any energy point contained in group g. This leads to a histogram representation of σ(E) that is discontinuous at the group boundaries. If the multigroup data show significant variation between adjacent groups, then the histogram approach can introduce discontinuities and oscillations into the pointwise flux. An alternative approach is to "linearize" the multigroup cross sections, using a linear representation that preserves the group-average values and is continuous at the group boundaries. Although the resulting cross section is continuous and does not cause distortions in the flux spectrum, the data does not necessarily represent the actual energy variation of the cross section.

Input fixed source terms are treated in a similar manner. The multigroup spectra that are input by the user may be converted either to a discontinuous histogram function in lethargy; or may be linearized by group. In

the latter case the resulting groupwise-linear function is evaluated at the energy mesh points to obtain the pointwise source term.

7.4.3 AVAILABLE METHODS FOR SOLVING TRANSPORT EQUATION

CENTRM offers several calculation options for solving the Boltzmann equation. Some of these are only available for either the MG or PW calculations, respectively. In the case of the MG methods, the calculation procedures are similar to those described in the XSDRNPM documentation. The following sections briefly describe the PW transport approximations available in CENTRM.

7.4.3.1 Discrete ordinates

The discrete ordinates method can be used for both MG and PW solutions. The main difference in the solution is the computation of the scattering sources: the multigroup method uses group-to-group scatter matrices, while the PW method uses the submoment expansion technique described earlier. Also, as previously discussed, the pointwise discrete ordinates equation has the same form as the transport equation for a purely absorbing medium; so that inner iterations are not required to converge the pointwise scattering source. The XSDRNPM documentation shows the finite-difference form of the discrete ordinate equations, and includes a discussion of S_N quadratures, the weighted-difference model, angular streaming coefficients, treatment of boundary conditions, and other standard procedures used in the CENTRM 1-D discrete ordinates solution.

Homogenized infinite medium

A homogenized infinite medium calculation can be performed for either the MG or the PW energy ranges. This method is essentially a "zero-dimensional" model that has no spatial or angular variation in the flux (only energy dependence). The materials contained in all zones are "smeared" into a single homogenized mixture using volume weighting of the number densities, and the effective external source is defined to be the volume-weighted source density. The resulting homogenized composition is then solved as an infinite medium, so that the PW scalar flux is equal to,

$$\Phi(\mathrm{u_n}) = \frac{\int \tilde{\Sigma}(u' \rightarrow \mathrm{u_n})\,\Phi(u')\,du' + \tilde{Q}_{ext}(E)}{\tilde{\Sigma}_t(\mathrm{u_n})} = \frac{\tilde{S}(\mathrm{u_n}) + \tilde{Q}_{\mathrm{ext}}(\mathrm{u_n})}{\tilde{\Sigma}_t(\mathrm{u_n})} \tag{7.4.79}$$

where $\tilde{\Sigma}_t, \tilde{S}, \tilde{Q}_{ext}$ = homogenized cross section, scatter source, and external source, respectively.

The total cross section in the PW calculation is reduced by the value of the "within-point" cross section, as discussed in Sect. 7.4.2.6. The PW scattering source is computed from a P_0 submoment expansion using cumulative integrals, as described in Sect. 7.4.2.4. The scalar flux at all space-intervals and the angular flux in all directions are set to the above value, while higher order flux moments are equal to zero.

7.4.3.2 Zonewise infinite medium

The zonewise infinite medium solution is an option for the both PW and MG calculations. This method is similar to the homogenized infinite medium option, except each zone is treated independently as an infinite medium, so that no spatial homogenization is required; i.e., Eq. is solved for each individual zone. The zonewise source corresponds to the *input* external source within the respective zone.

Note: *THERE IS NO COUPLING BETWEEN THE CALCULATIONS FOR EACH ZONE.*

Hence, any zones that do not contain an input external source will have zero fluxes, since there is no leakage between zones in the zonewise infinite medium model. To avoid this problem the user must either input a volumetric source, or specify a fission source and add a minute amount of fissionable material to generate a fission spectrum source.

7.4.3.3 Collision probability method

A collision probability (CP) solution of the 1-D integral transport equation is available in CENTRM as an alternative to the pointwise discrete ordinates approach. This option is only available for the pointwise solution, and has the following additional restrictions compared to the pointwise S_N method:

(a) only 1-D cylindrical or slab geometry is treated (no spherical geometry);

(b) periodic boundary conditions have not been implemented;

(c) interior surface sources cannot be treated;

(d) P_0 scattering (isotropic *laboratory* scatter) is assumed; no transport correction is applied to the pointwise cross sections in CENTRM.

(e) due to assumption (d), computation of the angular flux is not required in order to obtain the scalar flux; therefore, only the P_0 flux moment (scalar flux) of the angular flux is calculated.

(f) PW thermal calculations are not supported for the CP method.

This method has only had a limited amount of testing, and has not been validated as extensively as the discrete ordinates and MoC options.

The PW scattering source for the integral transport equation is similar to that for the discrete ordinates method, except that only the P_0 source moment is considered, and the "within point" correction is not applied to the total cross section for the collision probability method. Therefore only the spatial and directional treatment is substantially different in the two transport approaches. In the collision probability method the total interaction rate within a space interval is expressed in terms of collision probabilities $P_{i\prime\rightarrow i}$ corresponding to the probability that neutrons born uniformly in volume $V_{i\prime}$, at lethargy u_n will collide in interval i with volume V_i. The scalar flux in space interval "i," at lethargy point u_n obeys the integral transport equation,

$$\Sigma_i(u_n)\,\phi_i(u_n)\,V_i = \sum_{i'} P_{i'\rightarrow i}(u_n)\left[\Sigma_{i';n\rightarrow n} \quad \Phi_i(u_n) + Q_{\text{eff},i'}(u_n)\right] V_{i'} \tag{7.4.80}$$

where

$\sum_{i',n\rightarrow n}$ is the within-point cross section at i$\prime$, defined in Eq. (7.4.57); and

$Q_{\text{eff},i'}$ is the external source (Q_n) plus the P_0 downscatter source in i$\prime$ and at u_n, which is computed in a similar manner as for the discrete ordinates solution.

The boundary condition at the center of a cylinder is assumed to be reflected; while the outer boundary condition can either be vacuum or albedo. An albedo boundary condition returns a fraction of the outward leakage, using a cosine distribution for the return-current. An albedo of unity corresponds to a "white" boundary condition.

Unlike the integro-differential transport equation used by the discrete ordinates method, the integral equation at space interval i, contains the unknown fluxes at *all other* space intervals i$\prime$. This requires that inner iterations be performed for the PW solution using the CP option.

Collision Probabilities (CP) in 1-D cylindrical geometry are computed using the method developed by Carlvik [CENTRM-Car64]. The CPs for a vacuum outer boundary condition are first computed. In this case the probability that a neutron born in annular interval i with outer radius R_i, will have its next collision in annular interval j with outer radius R_j , is computed from the expression:

$$P_{i\rightarrow j} = \delta_{ij}\Sigma_j V_j + 2\left(S_{i-1,j-1} - S_{i-1,j} - S_{i,j-1} - S_{i,j}\right) \tag{7.4.81}$$

where δ_{ij} represents the Kronecker delta function and

$$S_{ij} = \int_0^{R_t} \left[Ki_3\left(\tau_{ij}^{+}\right) - Ki_3\left(\tau_{ij}^{-}\right) \right] dy \tag{7.4.82}$$

In the above expression Ki_3 corresponds to a 3rd order Bickley function, and $\tau_{ij}^{+}$and τ_{ij}^{-} are,

$$\tau_{if}^{\pm} = \Sigma \times \left(\sqrt{R_j^2 - y^2} \pm \sqrt{R_i^2 - y^2} \right) \tag{7.4.83}$$

Integration of the Bickley functions is performed numerically using Gauss-Jacobi quadrature.

The probability that a neutron born in interval "i" will escape uncollided from a cell with a vacuum outer boundary is equal to one minus the probability that it has a collision in any interval of the cell, so that

$$P_{esc,i} = 1 - \sum_j P_{i \to j} \tag{7.4.84}$$

The "blackness" (γ_i) of interval i is defined to be the probability that neutrons entering the cell with a cosine-current angular distribution on the surface will collide within interval i. The total blackness (γ) is the probability that a neutron entering the outer boundary will collide anywhere in the cell. The blackness is computed from the escape probability:

$$\Gamma_i = \frac{4V_i\Sigma_i}{S} \times P_{esc,i} \quad ; \quad \text{and} \quad \Gamma = \sum_i \Gamma_i \tag{7.4.85}$$

where S is the outer surface area of the cell.

The vacuum CPs can be modified to account for the effect of an albedo condition on the outer surface. In these cases a fraction of the neutrons reaching the outer boundary are returned isotropically back into the cell, and "bounce" back and forth between the two boundaries, with each traverse reducing the number of uncollided neutrons. Mathematically this corresponds to a converging geometric series that accounts for the cumulative effect of the "infinite" number of traverses through the cell. Evaluating the geometric sum, the collision probability (P^A) for an albedo of α can be expressed as

$$P_{i \to j}^{A} = P_{i \to j} + \frac{S}{4V_i\Sigma_i} \times \frac{\alpha\Gamma_i\Gamma_j}{1 - \alpha(1 - \Gamma)} \tag{7.4.86}$$

In the case of a slab with two vacuum boundaries, the CP's are expressed in terms of transmission probabilities $T_{i \to j}$, corresponding to the probability that a neutron born in volume i will reach surface j without a collision. The transmission probability is equal to,

$$T_{i \to j} = \frac{E_3\left(\tau_{ij}\right) - E_3\left(\tau_{ij} + \tau_i\right)}{2\tau_i} \tag{7.4.87}$$

where:

τ_{ij} is the optical distance between surface S_j and the surface volume V_i that is closest to S_j;

τ_i is the optical thickness of volume V_i; and

E_3 is the third order Exponential Function.

In a slab with vacuum boundaries, the CP for a neutron born in interval i to have its next collision in some interval j bounded by surfaces S_j and S_{j+1}, is given by the expression,

$$P_{i\to j} = T_{i\to j} - T_{i\to j+1} \tag{7.4.88}$$

A slab with a specular-reflected boundary condition on one side and a vacuum on the other can be represented as an "expanded" geometry with two vacuum boundaries, simply by adding the cell's mirror image at the reflected boundary. Hence, collision probabilities for these cases can also be obtained from the expressions for two vacuum boundaries. For slabs with an albedo (or white) boundary on one side and a reflected boundary on the other, the same expression in Eq. (7.4.86) presented earlier for cylinders can also be used to obtain albedo-corrected collision probabilities from the vacuum values. However, unlike cylindrical geometry, a slab may have specular-reflected boundary conditions on both sides, corresponding to an infinite array of repeating cells. In CENTRM the collision probabilities for a doubly-reflected slab geometry are obtained by explicitly including two reflected cells in addition to the "primary" cell, and then applying a white boundary condition on the outer surface of the expanded geometry. The resulting modified geometry, consisting of three cells (i.e., the primary plus two reflected cells) with a reflected center and outer albedo boundary, can be treated as described previously.

7.4.3.4 P_1 ("Diffusion Theory") method

The CENTRM MG calculation has an option for a P_1 calculation; however, this option is not available for the PW calculation. The method is essentially identical to that used in XSDRNPM. The P_1 option is called diffusion theory in both XSDRNPM and CENTRM input descriptions; but since the P_1 component of the scatter source is explicitly treated and since Fick's Law is not assumed, the method is actually more closely related to the P_1 spherical harmonic solution approach. The P_1 method is also used in CENTRM to generate a flux guess for the thermal flux distribution in an S_N calculation. Several outer iterations over the thermal groups are always performed with P_1 theory, prior to beginning the discrete ordinates calculation for the thermal range. In the case of PW thermal calculations, the multigroup thermal flux guess is converted in PW flux values by multiplying by the ratio of MG to PW cross-section values at each lethargy point.

7.4.3.5 Two-region (2R) method

A two-region (2R) calculation similar to the Nordheim method is also available as a PW option in CENTRM. In general the PW S_N or MoC solutions provide a more rigorous approach to compute self-shielded cross sections than the 2R method; however the 2R approximation gives accurate results for a wide range of "conventional cases." Verification studies have shown that the 2R option produces eigenvalues comparable to those obtained with the S_N and MoC options for numerous cases of interest, and the execution time is often significantly faster since only the zone-averaged PW scalar flux is computed. Thus the CENTRM 2R option is an adequate and attractive alternative for many applications.

The CENTRM 2R solution provides several advantages over the original Nordheim method. CENTRM uses pre-processed PW nuclear data, rather than the Nordheim approach of using input resonance parameters for a built-in resonance formula (Breit-Wigner). This allows the CENTRM-2R calculation to utilize PW cross sections processed from Reich-Moore resonance data in ENDF/B, while the conventional Nordheim method is limited to Breit-Wigner resonance formulae that do not treat level-level interference. Other advantages of the CENTRM-2R calculation include a rigorous treatment of resonance overlap from mixed absorbers, ability to address mixtures of arbitrary moderators with energy dependent cross sections, and capability to include inelastic and thermal scattering effects in the flux calculation.

The 2R approximation, which is a simplified version of the general collision probability method, represents the system by an interior region containing the mixture of materials to be self-shielded, and an exterior

moderator region where the asympototic flux per lethargy is approximated by a simple analytical expression (e.g., constant for epithermal energies).

CENTRM performs a separate 2R calculation for each zone. For example, if a problem consists of fuel and moderator zones, then two 2R calculations are done: one has fuel as the interior region and moderator as the exterior, and the other has moderator as interior and fuel as exterior. In the case of lattices, multiple bodies composed of the same mixture are addressed by introducing a Dancoff factor.

The 2R equation solved by CENTRM for interior region "I" is equal to,

$$\Sigma_I(u_n)\,\phi_I(u_n) = \left(1 - P_I^{(esc)}(u_n)\right)\left(S_I(u_n) + Q_I^{ext}(u_n)\right) + \Sigma_I(u_n)\,P_I^{(esc)}(u_n)\,\varphi_{asy}(u_n) \tag{7.4.89}$$

In the above equation, S_I and Q_I are the scatter and fixed sources, respectively, for interior region "I"; and $P_I^{(esc)}$ is the probability that a neutron born in the interior region will escape and have its next collision in the external region. For an interior region consisting of multiple bodies of the same composition separated by an exterior region, the escape probability is equal to

$$P_I^{(esc)}(u_n) = \frac{P_0^{(esc)}(u_n)\,[1 - C_I]}{[1 - C_I] + C_I\bar{\ell}_I\Sigma_I(u_n)\,P_0^{(esc)}(u_n)} \tag{7.4.90}$$

where $P_0^{(esc)}$ is the escape probability from a single, isolated body in the interior region; $\bar{\ell}_I$ is the average chord length of bodies in the interior region; and C_I is the Dancoff factor, corresponding to the probability that a neutron escaping one interior body will pass through the exterior region and have its next collision in another body of the interior region. Values for $P_0^{(esc)}$ are computed internally by the code at each energy mesh point, but Dancoff factors must be provided by input for each zone. In the standard XSProc computational sequence, Dancoff values are automatically computed and provided to CENTRM.

The asymptotic flux φ_{asy} for the exterior region is represented by analytical expressions in the fast, epithermal, and thermal energy ranges, respectively, as summarized in Table 7.4.7. The constants C_1, C_2 and C_3 are defined to impose continuity at the energy boundaries, and also include the overall normalization condition that the PW asymptotic flux at DEMAX is equal to the MG flux for group MGHI obtained from the UMR calculation.

Table 7.4.7: Asymptotic flux representation.

Upper energy	**Description**	**Distribution (per unit energy)**	**Distribution (per unit lethargy)**
20 MeV	Fission spectrum	$C_3E^{1/2}\,e^{-E/\theta}$ (*)	$C_3E^{3/2}\,e^{-E/\theta}$ (*)
200 keV	Slowing-down	C_2/E	C_2
5kT	Maxwellian	$C_1E\,e^{-E/kT}$	$C_1E^2\,e^{-E/kT}$
(*) θ = fission spectrum "temperature" = 1 MeV.			

Equation Eq. (7.4.89) is solved similarly to the zonewise infinite medium equation; the only difference being that the interior sources are multiplied by (1-$P_0^{(esc)}$), and the presence of an inhomogeneous source term coming from the exterior region. Like all CENTRM transport options, the PW scattering source is computed using cumulative integrals as given in Eq. (7.4.43) In the 2R option, only the P_0 scatter-source moment is needed.

7.4.3.6 Method of characteristics for a 2D unit cell

The 2D MoC option is available for square-lattice unit cell cases, with both multigroup and pointwisecross sections. The geometry for the MoC cell calculation consists of a number of concentric cylindrical zones contained within a square outer surface with reflected boundary conditions. The MoC calculation is not currently functional for triangular lattices. A multiregion cell may be used in the MoC option, but it must correspond to a similar geometry as a square lattice cell. Because the 2D MoC solution is limited to 2D rectangular lattice cell geometries, the code performs a number of internal checks to verify the input geometry is permitted. The energy mesh generation, scattering source calculation, etc. are performed in the same manner as for the discrete ordinates option, except that only P_0 scatter is treated. Unlike the CENTRM discrete ordinates method which solves the 1D transport equation, the MoC option solves the 2D transport equation for planar XY slice through a square-pitch lattice of cylindrical pins. Because the the MoC calculation treats the outer rectangular boundary of the unit cell correctly, it provides a more rigorous calculation than using an equivalent 1D cylindrical Wigner-Seitz cell. The geometry input for the MoC calculation is identical to the input for the 1D cylindrical model— the code internally converts the input value for the equivalent cylindrical radius into the outer rectangular cell dimension (pitch) by preserving the total cell area. Thus the length (L) of a side of the rectangular cell in the MoC calculation is computed form the relation $L = \sqrt{\pi R_{eq}^2}$, where Req is the equivalent outer radius of the Wigner-Seitz cell, given in the CENTRM input array of radial dimensions. Due to symmetry conditions, the MoC calculation is performed for only 1/8 of the rectangular cell (i.e., a 45 degree sector) and for the upward directions.

MoC uses a integrating factor to convert the divergence term in the transport equation into a directional derivative along the direction of neutron transport (Ω). For a given direction in the angular quadrature set, the spatial domain is spanned by a set of parallel characteristic rays originating at one boundary and terminating at the opposite boundary. The default separation distance between the parallel rays is 0.02 cm. in CENTRM. The angular flux in given direction is computed by integrating the directional derivative along the characteristic direction. A reflected boundary condition is normally applied along the rectangular outer surface of the unit cell. The default directional quadrature, which defines the characterstic directions and is used for integration, consists of 8 azimuthal angles for the 45 degree sector in the X-Y plane and 3 postive polar angles relative to the Z-axis.

The spatial domain of the unit cell is defined by zones of uniform mixtures (e.g., fuel, clad, moderator) in which the cross section at a fixed energy point or group is constant. These uniform composition regions may be further divided into sufficiently small "flat-source" sub-divisons in which the sources (scattering and external) can be approximated as being constant. The MoC computes the average flux in the flat-source region by summing over all characteristics in the volume.

[CENTRM-KW12] gives more information about the CENTRM MoC solution method.

7.4.4 CENTRM INPUT DATA

The standard mode for executing CENTRM is through the XSProc self-shielding module which automatically defines the CENTRM options, mixing table, and geometry, and also prepares the necessary MG and PW nuclear data files and passes the CENTRM PW flux results to the downstream code PMC [see section describing XSProc]. However CENTRM can also be executed in standalone using the FIDO input provided in this section. When executed through XSProc, the user can set values for most CENTRM input parameters given in this section by using keywords in the CENTRM DATA block [see XSProc section]. Note that if CENTRM is run as a standalone module, the input data files defined in Table 7.4.8 must be provided, and the default values for some input parameters are different.

FIDO INPUT FOR STANDALONE CENTRM CALCULATIONS

14. NTHR = Multigroup Calculation Option in Lower MG Range [E<DEMIN] (3)

    0/1/2/3/4/5/6 = S_N / diffusion / homogenized infinite medium /

    zonewise infinite medium/(option 5 deprecated)/2D MoC cell

    [see Note 3]

15. NPXS = Calculation Option in PW Range [DEMIN<E<DEMAX] (4)

    0/1/2/3/4/5/6 = none (do NFST multigroup calculation) / S_N / collision-probability/homogenized infinite medium /zonewise infinite medium/ 2-region/

    2D MoC cell method of characteristics (only for square lattice cells)

    [see Note 3]

16. ISVAR = Multigroup Source & Cross-Section Linearization Option (3)

    0/1/2/3 = none /linearize MG source /linearize MG XS's /both [see Note 4]

17. mocMesh = Mesh Options for MoC Calculation; npxs=6 only:

    0/1/2 = coarse/regular/fine mesh/input by zone (0)

18. mocPol = Number of Polar Angles for MoC Quadrature; npxs=6 only:

    2/3/4 = allowable values (3)

19. mocAzi = Number of Azimuthal Angles for MoC Quadrature; npxs=6 only:

    1 -> 16 = allowable values (8)

20. kern = Thermal Neutron Scattering Treatment:

    0/1 = all free-gas kernels/use bound S(alpha, beta) data if available (1)

21. ISCTI = P_N Order of Scattering for PW inelastic [<= ISCT] (1)

22. NMF6 = PW Inelastic Scatter Option (-1)

    -1/0/1 = no inelastic/ discrete level inelastic/ discrete and continuum

2$ $ EDITING AND OTHER OPTIONS (12 entries. Defaults shown in parenthesis)

1. IPRT = Mixture Cross-Section Print Option: (-3)

   -3/-2/-1/N = none / write PW macro cross sections to output file, in tab1 format/

   print 1-D MG cross sections /print $P_0 \rightarrow P_N$ MG scatter matrices

2. ID1 = Flux Print/Punch Options (-1)

   -1/0/1/2/ = none / print MG flux / also print M.G moments

   /save PW zone-average flux in ascii file

3. IPBT = Balance Tables Print Option (PW thermal B.T. edit not functional) (0)

   0/1 = none / print balance tables

4. IQM = Use Volumetric Sources: 0/N = No / Yes (0)
5. IPM = Use Boundary Source: 0/N = No / Yes (0)
6. IPN = Group Diffusion Coefficient Option (2)

   0/1/2 = [*see XSDRNPM input*]

7. IDFM = Use Density Factors 0/1 = No / Yes (0)
8. IXPRT = Extra Print Option:

0/1 = minimum print /regular print (0)

9. MLIM = Mass Value Restriction on Order of Scattering (100)

   0/M = no effect / restrict nuclides with mass *geq* M to have scatter

   order *leq* NLIM

10. NLIM = Restrictive Scatter Order (0)

3** CONVERGENCE CRITERIA AND OTHER CONSTANTS (9 entries. Defaults in parenthesis)

1. EPS = Upscatter Integral Convergence Criterion (0.001)
2. PTC = Point Convergence Criterion (0.001) [see Note 5]
3. XNF = Source Normalization Factor (1.0) [see Note 1]
4. B2 = Material Buckling Value [units of cm^{-2}] (0.0)
5. DEMIN = Lowest Energy of Pointwise Flux Calculation, in eV (0.001)
6. DEMAX = Highest Energy of Pointwise Flux Calculation, in eV (2.0E4)
7. TOLE = Tolerance Used in Thinning Pointwise Cross Sections (0.001) [see Note 7]
8. MOCRAY = Distance (cm) Between MoC Rays; only for npxs=6 (0.02)
9. FLET = Lethargy-Gain Fraction For Determining Energy Mesh (0.1) [see Note 7]
10. ALUMP = 0.0→1.0, Criterion for Lumping of Materials by Mass (0.0) [see Notes]

7.4.4.1 CENTRM data notes

1. If ISRC = 0, an external volumetric or boundary source is used, as specified in the 30$$, 31**, and 32** arrays (these are similar to same arrays in XSDRNPM). This option is only available for standalone CENTRM calculations; it is not an option for XSProc execution. If ISRC=1, the magnitude of the fission source density (neutrons/cm^3-s) is input in the 34** array, and the source energy spectrum is assumed to be χchi`=0 regardless of value in 34** array). Both external and fission sources may be used if ISRC = 2. The source normalization parameter XNF in the 3* array applies to the combined sources specified in data block 3.

2. If the value of DEMIN in the 3* array is set lower than the thermal cutoff energy of the AMPX MG library, a PW thermal calculation is performed over the energy range between DEMIN and the thermal cutoff. A MG thermal calculation is performed over the remainder of the thermal range. PW thermal calculations always start with ten outer iterations of MG theory to obtain an initial flux guess. The value "IUP" indicates how many *additional* outer iterations are to be performed.

3. The solutions in the upper and lower MG ranges, as well as the PW solution, provide several calculational options in addition to the default method. These are described in Sect. 7.4.3.

4. The parameter ISVAR indicates how MG values for sources and cross sections are mapped onto the PW energy mesh. See Sect. 7.4.2.8.

5. "Point Convergence" refers to the worst convergence over all space intervals, between successive iterations. It is applied to (a) inner iterations for MG S_N solution; (b) inner iterations of doubly-reflected boundary conditions in PW S_N solution; and (c) outer iterations of MG and PW solution in thermal range.

6. The values for DEMAX and DEMIN determine the energy range of the PW calculation. If the purpose of the CENTRM calculation is to obtain PW fluxes for resonance self-shielding calculations with PMC, then the PW energy range should at least span the resolved resonance ranges of all materials for which self shielding is significant.

7. The energy mesh for the PW flux calculation is based on several factors, as described in Sect. 7.4.2.7.

8. If parameter alump > 0, epithermal and thermal scattering sources for individual nuclides with similar masses are combined into macroscopic "lumps," based on a fractional mass deviation of "alump." For example, alump=0.2 means that materials are combined into one or more lumps such that their masses are within +/- 20% of the effective mass of the lump. The effective mass of the lump is defined to preserve the macroscopic slowing down power. Mass lumping up to 0.2 will often reduce execution time with little impact on the results.

7.4.4.2 CENTRM I/O files

Table 7.4.8 shows filenames used by CENTRM. Some files are not required for some calculations.

Table 7.4.8: Default File Names

File Name	Description
ft04f001	Input MG library (only for standalone execution)
ft81f001	Input PW cross-section library from Crawdad PW
lib_cen_kern	Input PW thermal scatter kernels from Crawdad
_centrm.pw.flux	Output PW flux by zone (only for standalone)
_centrm.pw_macro_xs	Output PW macro cross-section (optional)

7.4.4.3 Description of the CENTRM CE cross section file

The CENTRM CE cross section library is typically created using the CRAWDAD module. CRAWDAD is executed automatically during XSProc cases; but when CENTRM run standalone, the CE library must be pre-generated prior to the CENTRM calculation (e.g., by running CRAWDAD). CRAWDAD reads the SCALE CE data files for individual nuclides, and creates a combined CENTRM library in the binary format shown below.

Table 7.4.9: Header Records.

Record No.	Parameters	Description
1	IDTAPE	Tape Identifier.
1	NNUC	Number of Nuclides on pointwise file.
1	MTMP	Maximum Number of Temperatures for any Nuclide on file.
1	MAXMT	Maximum Number of Reactions for any Nuclide on file.
1	MAXPT	Maximum Number of Energy Points for any Nuclide (any MT) on File.
1	IX(10)	Unused for Now.
1	TITLE	Title (Character*72)
2	NZAPT(NNUC)	ZA's for Each Nuclide.
3	IDPT(NNUC)	MAT ID's for Each Nuclide.
4	NTEM(NNUC)	Number of Temperatures for Each Nuclide.
5	EMAX(NNUC)$^{(DP)}$	Highest Energy of Pointwise Data for Each Nuclide.
6	EMIN(NNUC)$^{(DP)}$	Lowest Energy of Pointwise Data for Each Nuclide.
7	EUPUR(NNUC)$^{(DP)}$	Upper Energy of Unresolved range.
8	EUPRR(NNUC)$^{(DP)}$	Upper Energy of Resolved range
9	ELORR(NNUC)$^{(DP)}$	Lower Energy of Resolved range.
10	MPT(NNUC)	Number of Energy Points for Total Cross Sections of Each Nuclide.
11	MPS(NNUC)	Number of Energy Points for Elastic Scatter Cross Sections of Each Nuclide.
12	NFIRST(NNUC)	Starting Record Number of Data for Each Nuclide.
13	MPIN(NNUC)	Number of inelastic levels for Each Nuclide.
14	POTXS(NNUC)	Potential Cross Sections for Each Nuclide.
15	MAX_INEL(NNUC)	Maximum Number of Energy Points for any Inelastic Discrete or Continuum Level.
16	NTHERM(NNUC)	Thermal Scattering Kernel IDs for Each Nuclide (0 = free gas).
17	Free	Not Used

Table 7.4.10: Nuclide Dependent Records (repeat for each nuclide)

Parameters	Description
DTEXT	Descriptive Text (Character*72).
ID	Nuclide ID.
IZA	Nuclide ZA.
NMT	Total Number of MT's.

7.4.5 EXAMPLE CASE

In this section an example standalone CENTRM calculation is demonstrated for a 1-D slab geometry model of a highly enriched uranium solution with an iron-56 reflector. To execute CENTRM in standalone mode, nuclear data libraries must be provided for MG cross sections (file ft04f001), PW cross sections (file ft81f001), and PW thermal scatter kernels (lib_cen_kernel). The shell script (=shell) in front of the CENTRM input is used to link the necessary nuclear data libraries to the CENTRM calculation. Here it is assumed that the Crawdad module has been previously run to produce the PW cross section and thermal kernel libraries, which are located in the same directory from which that the job is submitted, while the MG library is the 8 group test library from the SCALE data directory.

7.4.6 CENTRM PW LIBRARY AND FLUX FILE FORMATS

Sect. 7.4.6.1 below describes the format for the input CENTRM PW data library (binary). The subsequent Sect. 7.4.6.2, describes the format of the output PW flux file (binary) produced by CENTRM, which is input to the PMC code.

7.4.6.1 CENTRM CE cross section file

The CENTRM CE cross section library is typically created using the CRAWDAD module in SCALE. CRAWDAD reads the SCALE CE data files for individual nuclides, and creates the combined CENTRM library.

Table 7.4.12: 17 Header Records described below.

Record No.	Parameters	Description
1	IDTAPE	Tape Identifier.
1	NNUC	Number of Nuclides on PW file.
1	MTMP	Maximum Number of Temperatures for any Nuclide on file.
1	MAXMT	Maximum Number of Reactions for any Nuclide on file.
1	MAXPT	Maximum Number of Energy Points for any Nuclide (any MT) on File.
1	IX(10)	Unused for Now.
1	TITLE	Title (Character*72)
2	NZAPT(NNUC)	ZA's for Each Nuclide.
3	IDPT(NNUC)	MAT ID's for Each Nuclide.
4	NTEM(NNUC)	Number of Temperatures for Each Nuclide.
5	EMAX(NNUC)$^{(DP)}$	Highest Energy of Pointwise Data for Each Nuclide.
6	EMIN(NNUC)$^{(DP)}$	Lowest Energy of Pointwise Data for Each Nuclide.
7	EUPUR(NNUC)$^{(DP)}$	Upper Energy of Unresolved range.
8	EUPRR(NNUC)$^{(DP)}$	Upper Energy of Resolved range
9	ELORR(NNUC)$^{(DP)}$	Lower Energy of Resolved range.
10	MPT(NNUC)	Number of Energy Points for Total Cross Sections of Each Nuclide.
11	MPS(NNUC)	Number of Energy Points for Elastic Scatter Cross Sections of Each Nuclide.
12	NFIRST(NNUC)	Starting Record Number of Data for Each Nuclide.
13	MPIN(NNUC)	Number of inelastic levels for Each Nuclide.
14	POTXS(NNUC)	Potential Cross Sections for Each Nuclide.
15	MAX_INEL(NNUC)	Maximum Number of Energy Points for any Inelastic Discrete or Continuum Level.
16	NTHERM(NNUC)	Thermal Scattering Kernel IDs for Each Nuclide (0 = free gas).
17	Free	Not Used

Table 7.4.13: [NUCLIDE DIRECTORY : 1 RECORD/NUCLIDE].

Parameters	Description
DTEXT	Descriptive Text (Character*72).
ID	Nuclide ID.
IZA	Nuclide ZA.
NMT	Total Number of MT's.
(NTOMT(K),K=1,NMT)	Number of Temperatures.
NRRP	Number of Resolved Resonances Processed.(not used)
NTOTR	Total Number of Records for This Nuclide.
IX(6)	Unused for Now.
(MT(N),N=1,NMT)	MT's for This Nuclide.
((TEMP(M,MN), →	Temperatures for This Nuclide.
M=1, NTOMT(MN)), MN=1,NMT))	
(NPT(J),J=1,NMT)	Number of Energy Points for Each MT.

7.4.7 CENTRM ERROR MESSAGES

CENTRM prints several of the same error messages as the XSDRNPM code. Users should refer to the XSDRNPM chapter for these. CENTRM also prints the additional error messages shown below.

STATEMENT IN PRINTOUT	USER ACTION
ERROR. DEMIN exceeds maximum energy in working library STOP 400	Reduce input value of DEMIN
ERROR. DEMAX exceeds DEMIN STOP 401	Check input values for PW energy limits
***CALCULATION TERMINATED. No neutron groups in working library	Check AMPX working library
WARNING: Thermal Source is 0 in ACCEL **–OR-** WARNING: Thermal Absorption + Leakage is 0 in ACCEL	Check input source and thermal cross-section data (often caused by using Zonewise Infinite Medium option with no source in some zone)
Requests nuclide *XXX* which is not on your working library.	Check nuclide ID's and composition numbers in mixing table to make sure they are on MG library; Verify that PW and MG libraries are consistent

7.5 PMC: A PROGRAM TO PRODUCE MULTIGROUP CROSS SECTIONS USING POINTWISE ENERGY SPECTRA FROM CENTRM

M. L. Williams, D. F. Hollenbach, U. Merteryuk, and K. S. Kim

ABSTRACT

PMC generates problem-dependent multigroup cross sections from an existing multigroup cross-section library, a pointwise nuclear data library, and a pointwise neutron flux file produced by the CENTRM continuous-energy transport code. In the SCALE sequences, PMC is a computational module called from XSProc to produce self-shielded multigroup (MG) cross-sections over a specified energy range (e.g., resolved resonance range) of individual nuclides in the system of interest. The self-shielded cross sections are obtained by integrating the pointwise (PW) nuclear data using the CENTRM problem-specific, continuous-energy flux as a weight function for each spatial mixture in the system. Several options are available in PMC to specify various types of weighting methods for the one-dimensional and two-dimensional MG data. PMC outputs problem-dependent self-shielded cross sections that can be used in XSDRNPM, KENO, NEWT or other MG transport codes.

ACKNOWLEDGMENTS

The authors acknowledge the suggestions and direct contributions of L. M. Petrie of Oak Ridge National Laboratory, and former ORNL staff N. M. Greene, and R. M. Westfall.

7.5.1 INTRODUCTION

PMC is a computational module used for the CENTRM/PMC self-shielding method performed by the XSProc driver module. It can also be run in standalone mode. PMC (**P**roduce **M**ultigroup **C**ross sections) computes multigroup (MG) cross sections by utilizing the pointwise (PW) neutron spectra calculated in CENTRM [PMCWA95] to weight cross sections in a continuous-energy (CE) library file. This provides problem-dependent, self-shielded MG data representative of the fine-structure variation in the neutron energy spectrum for the system of interest. PMC only computes shielded cross sections within the energy interval of the CENTRM PW flux calculation, defined by the energy limits DEMIN and DEMAX. By default the lower limit is DEMIN=0.001 eV, and the upper energy is DEMAX=20,000 eV; however these parameters can be modified by the user in the CENTRM DATA input block. Outside of this energy interval, the shielded cross sections previously computed with the Bondarenko method in BONAMI are retained. PMC is automatically called from the XSProc driver module during execution of a SCALE sequence, and the resulting zone-averaged, problem-dependent cross sections can be passed to MG transport solvers (e.g., KENO, NEWT, XSDRNPM, etc.) called by the sequence.

7.5.1.1 Description of PMC input nuclear data

The nuclear data input to PMC consists of both MG and CE cross sections. Input MG data are obtained from the MG library specified in the sequence input. During SCALE execution, CE data used by both CENTRM and PMC are prepared by the code CRAWDAD, which reads CE files for individual nuclides, interpolates the data to the appropriate temperatures for the specified mixtures, and concatenates the data into a one problem-specific, multiple-nuclide CENTRM PW library. In general each nuclide has its own unique energy mesh defined such that the cross section at any energy value can be interpolated linearly from the library point data to accuracy better than 0.1%. Although cross sections in the original CE data files include values over the full energy range of 0-20 MeV, CRAWDAD reduces the energy range to interval of the CENTRM PW calculation (i.e., DEMIN→DEMAX). It is this combined PW library that is accessed by PMC. The format of the CENTRM PW library is described in CENTRM: A Neutron Transport Code for Computing Continuous-Energy Spectra in General One-Dimensional Geometries and Two-Dimensional Lattice Cells.

7.5.1.2 Description of PMC input pointwise flux data

In addition to the input nuclear data, PMC also requires PW flux values calculated in CENTRM to be provided. Depending on the CENTRM transport approximation, the flux data includes the PW scalar flux spectrum as a function of energy and spatial-zone, and also may include PW spherical harmonic moments of the angular flux (e.g., the current), which can be used in processing MG scattering matrices for higher-order Legendre moments. The non-uniform energy-mesh of the PW flux is determined during the CENTRM calculation in order to represent the spectrum variation with a minimum number of energy points. Like the CE cross section data, the flux spectrum at any energy value can be obtained within a specified tolerance by linear interpolation of the PW flux values.

7.5.2 CODE FEATURES

Two types of MG data are processed by PMC: 1-D cross sections and 2-D scatter matrices. The 1-D cross sections are weighted-average values over each energy group, by nuclide and reaction type. If there are "G" energy groups on the input library, then the 1-D cross section for each reaction type can be viewed as a 1-D vector with G values (of course some may be zero). Depending on the options and PW energy range specified, PMC will generally only re-compute and replace some of the G-group data. The 2-D cross sections correspond to group-to-group transfers (and corresponding Legendre moments) associated with various types of scatter reactions. These data can be arranged into a 2-D G by G matrix. For most materials this matrix is quite sparse. The 2-D data depend not only on the cross-section data, but also on the

energy/angular distributions of the secondary neutrons, which are represented by Legendre moments. PMC always re-normalizes the 2-D elastic and inelastic scattering matrices (including moments) to be consistent with the respective self-shielded 1-D data. In the case of elastic scattering, PMC also has rigorous options that can be used to modify the secondary energy distribution to account for self-shielding effects, such as by correcting the group removal cross section.

7.5.2.1 Options for treatment of 1-D cross sections

PMC computes new MG data for each reaction type (MT) and each nuclide on the input MG library, which also has CE data on the CENTRM PW library. Cross sections for reactions on the input MG library which do not have corresponding PW reaction data are not replaced; i.e., the original MG values are retained. SCALE CE library files for individual nuclides contain all reaction types included in the ENDF/B data; however the CRAWDAD module, executed prior to PMC, only includes certain ones when it produces the problem-specific CENTRM library. By default the CENTRM PW nuclear data library always includes cross sections for the total (MT-1), radiative capture (MT-102), and elastic scattering reactions (MT-2) of all nuclides; as well as fission (MT-18), and prompt, delayed, and total-nubar values (MTs-456, 455, 452, respectively) for fissionable nuclides. The (n,alpha) cross sections (MT-107) for B-10 and Li-6 are also always included if these nuclides are present in a mixture. If the CENTRM PW transport calculation includes the inelastic scattering option, indicated by CENTRM input parameter nmf6 >= 0, the discrete-level PW inelastic (MTs 50-90) and continuum inelastic (MT-91) data are also included in the CENTRM PW library.

PW data for the unresolved resonance range are infinitely dilute on the CENTRM library; therefore PMC does not use PW cross sections to compute self-shielded data for the unresolved range. Instead, self-shielded cross sections in the unresolved range are calculated using the Bondarenko method in BONAMI prior to the CENTRM and PMC calculations. This step is automatically performed by XSProc in the SCALE calculation sequences.

PMC offers two methods to compute the total cross section. In the first method the MG value for the total cross section (MT=1) is processed directly from the PW MT-1 data on the CENTRM library. Total cross sections are generally considered the most accurate type of evaluated reaction data (due to measurement techniques); however if PW data for MT-1 are processed as an independent cross section, there is no guarantee that the sum of the partial cross sections will sum to the total. These small imbalances in cross sections affect the neutron balance, and may impact eigenvalue calculations. For this reason the PMC default option does not compute the total cross section by weighting the MT-1 PW data, but rather by summing the MG partial cross sections (including the original MG data not re-processed in PMC).

The 1-D cross sections can be weighted using either the P_0 (scalar flux) or P_1 (current) PW Legendre moment. In almost all cases flux weighting is more desirable, since resonance reaction rates are usually the dominant factor in the PW range. However, current-weighting may be more accurate for certain problems where spatial transport and leakage strongly influence the spectrum in the resonance range, such as when the leakage spectrum is greatly impacted by cross section interference minima such as occur in iron media. The current-weighting option has been successfully applied for criticality calculations involving mixtures of highly-enriched uranium and iron. An alternative approach to using the current-weighted total cross section is to include a Legendre expansion of the angular-flux-weighted total cross section, which modifies the diagonal elements of the 2D elastic scattering moments.[7] This option is specified by setting PMC input parameter n2d=±2, as discussed in Sect. 7.5.2.4.

7.5.2.2 Spatial averaging of 1D cross sections

PMC computes MG microscopic cross sections for each material mixture in a given CENTRM calculation, using the spatially averaged PW spectrum within the mixture. In SCALE this method is called "zone-weighting", and it is the default for PMC. Zone-weighted cross sections are generated for every mixture zone in the unit cell. In configurations containing fuel/absorber mixtures (e.g., lattices) in multiple unit cells, CENTRM/PMC calculations may be performed for each mixture, resulting in multiple mixture-weighted cross sections for the same nuclide ID. For this reason, both the nuclide ID and a mixture number are generally required to uniquely identify any specific cross section data generated by PMC.

PMC also has an option to calculate "cell-weighted" (i.e., homogenized) MG data, which applies disadvantage factors to preserve the cell-averaged reaction rates for the entire unit cell. This is not typically done, except for treating doubly-heterogeneous cells with SCALE. In this case the PMC cell-weighting option is performed to produce homogenized MG cross sections for the low level heterogeneity (e.g., fuel grain in a fuel pebble). The XSProc control module automatically sets the correct PMC weighing flag based on the type of unit cell.

7.5.2.3 Energy ranges for multigroup weighting

The energy range of the MG and CE libraries in SCALE typically spans 10^{-5} to $2*10^{7}$ eV. In general this encompasses the (a) thermal region where upscatter is treated, (b) resolved and unresolved resonance ranges, and (c) high energy region above the resonance ranges. The thermal range for the current SCALE libraries is defined to be below 5 eV. Energy limits for the resolved and unresolved resonance ranges are defined by the individual ENDF/B evaluations for each nuclide, and these limits are included in the CENTRM PW library.

As discussed in section 8.3, the CENTRM PW flux file contains values of the zone-flux (and moments) per unit lethargy, calculated over the entire energy range 10^{-5} eV to 20 MeV; however, only the fluxes in the energy range from DEMAX to DEMIN are computed from the PW transport solution and exhibit the spectral fine-structure due to resonance reactions. The flux outside interval [DEMAX, DEMIN] is represented by the smoother "pseudo-pointwise" values obtained from CENTRM's MG solution. PMC provides two options to define the nuclide-specific energy range for computing problem-dependent MG data:

Option (1). Compute MG cross sections of a given nuclide only over the resolved resonance range of the nuclide. If the CENTRM PW calculation does not encompass the entire resolved resonance range for the nuclide, pseudo-point fluxes are be used in the self-shielding calculations for some groups in the resolved regions. The pseudo-point fluxes are generally a good representation for the gross spectrum shape, but do not reflect fine-structure effects caused by resonance absorption; therefore with this option, the user should take care that the CENTRM PW limits are appropriate for the resonance nuclides of interest.

Option (2). Compute MG cross sections for a given nuclide over the entire energy range for which PW flux values are calculated in the CENTRM. In this case PMC computes MG cross sections only over the portion of the PW data that is contained within the PW flux range; i.e., the pseudo PW spectrum is not used to process any data. Shielded cross sections for groups not included in the PW calculation are based on the BONAMI self-shielding method.

Option (2) above is default in PMC. SCALE-6.2 has DEMIN and DEMAX default values of 0.001 eV and 20 keV. This is sufficient for resonance self-shielding of essentially all actinide and important fission product nuclides; but some structural materials such as iron have resonances above 20 keV which would be shielded by BONAMI (Sect. 7.3).

7.5.2.4 Options for treatment of 2-D cross sections

The input parameter N2D defines five PMC options for processing problem-dependent, 2-D elastic scattering matrices. The first approach, N2D=0, simply multiplies the elastic scattering matrices by the ratio of the new to old 1-D elastic cross sections for the specified reaction process, where the "old" data are the 1-D values in the original MG library, and the "new" data are the problem-dependent MG cross sections processed using the PW flux as described above. The P_{ell} Legendre moments as well as the P_0 matrix are scaled by the same ratio for a given group. This method is also always used for discrete-level and continuum inelastic cross sections, as well as any other 2-D data other than elastic. The basic assumption is that the relative group-to-group scattering distribution does not change from the distribution in the original MG library, which is processed with an infinitely dilute spectrum- i.e., self-shielding only affects the total scatter rate. This approach gives good results for many applications, and is very efficient computationally. However, for intermediate and high mass materials, the elastic removal rate from a group may be sensitive to the problem-dependent CE spectrum. In these cases the scaling approximation may not give the correct elastic removal rate from the group, because the within-group elastic cross section will be in error. In these cases the alternate approaches described below can be used.

The option N2D= -1 corrects for the impact of resonance self-shielding on the elastic removal from an energy group. This option recomputes a new value for the within-group cross section by applying a correction factor based on the ratio of shielded versus unshielded removal probabilities for *s*-wave scatter (isotropic center-of-mass scatter). The P_0 out-scattering cross sections are then renormalized to give the correct 1D shielded cross section for the group. This approach provides a reasonable and computationally efficient approximation to process 2D elastic matrices in the resolved resonance range of actinide nuclides. However the assumption of s-wave scatter may not be valid in the resolved resonance range of a structural material such as iron; therefore users should beware when applying the approximation if the PW range is extended above 50 keV, for systems with large sensitivity to structural materials.

Option N2D=1 uses the CENTRM PW flux to recompute the entire set of group-to-group scatter data (including Legendre moments) using PW thermal scattering kernel data for the thermal energy range and assuming *s*-wave kinematics for the epithermal energy range. Since the CENTRM PW flux is used as the weighting function, this approach is sometimes more accurate for groups with large spectral gradients as discussed above. As with the N2D=-1 option, the main limitation is the *s*-wave scattering approximation for the secondary energy distribution. This option requires more computation time than the N2D methods discussed previously, and usually gives similar results as N2D=-1.

A rigorous derivation of the MG transport equation from the CE equation results in a directionally dependent total cross section. PMC option N2D=2 uses the method in [PMCBG70] to address this effect by modifying the Legendre moments of the 2D elastic matrix. For cross section moment "n", the diagonal term (i.e., within-group scatter) is modified by adding a term equal to the difference in the MG total cross section weighted with the PW scalar flux and the MG total cross section weighted with the n_{th} Legendre moment of the PW flux. When using MoC (NPXS=6), since default ISCT is 0, there are no Pn flux moments on CENTRM PW flux file. Therefore, no diagonal P_n correction will be applied to cross section moments.

Option N2D=-2 is essentially a combination of options N2D=2 and N2D=-1. This option applies the elastic removal correction to the diagonal term of the P_0 moment of the elastic 2D matrix, and applies the PL correction described above to the diagonal term of the PL Legendre moment of the elastic matrix.

The thermal energy range presents a particularly difficult challenge for processing problem-dependent 2-D scattering data, due to the complicated kinematics associated with molecular motion, chemical binding, and coherent scattering effects. PMC currently uses the scaling approximation (N2D=0 option) for the thermal energy range with any input value of N2D except for N2D=1.

7.5.3 CALCULATION OF PROBLEM-DEPENDENT MULTIGROUP CROSS SECTIONS

7.5.3.1 1-D cross sections

$$\sigma^{j}_{z,r,g} = \frac{\int_{\Delta E_g} \sigma^{j}_{z,r}(E)\Phi_z(E)dE}{\int_{\Delta E_g} \Phi_z(E)dE} = \frac{\int_{\Delta E_g} \sigma^{j}_{z,r}(E)\Phi_z(E)dE}{\Phi_{z,g}} \tag{7.5.1}$$

where

$\Phi_{z,g}$ is the multigroup zone flux,

$\sigma^{j}_{z,r,g}$ is the zone-average, group cross section, and

ΔE_g is the energy interval of group g.

The integration in Eq. (7.5.1) is performed by summing over a discrete energy mesh within the group boundaries. Since the CE cross section and the PW flux generally have different energy grids, the integration mesh for the numerator is formed by taking the union of the two. The CE cross sections and the PW flux are mapped onto the union mesh, and the integral is evaluated using the trapezoidal method. Eq. (7.5.1) is used to compute weighted group data for all MT's for which CE data are available on the CENTRM library, except in the case of the fission neutron yield ν. Instead of using the PW scalar flux as the weighting function, the MG value for ν is weighted by the product of the PW flux and the PW fission cross section for the material.

7.5.3.2 2-D scattering cross sections

The 2-D MG cross section moments are defined as the weighted group-average of terms appearing in a Legendre (PL) expansion of the CE double-differential scatter cross section, which describes the transfer of neutrons from one energy to another, for a given angle of scatter. The PL Legendre moments on the original MG library are fully consistent with the ENDF/B kinematic specifications. Thus the specified anisotropy in elastic or inelastic data in the center-of-mass (CM) system is reflected in the PL scattering matrices; however the library MG data are processed with an infinitely dilute flux spectrum. PMC provides several options for modifying these data to correct for problem-specific spectral effects, such as self-shielding. First, consider the scaling method (N2D=0) in which all the elements of the original scatter matrix (i.e., on the input Master library) for a given initial group are multiplied by the ratio of 1-D scatter cross sections. This has the effect of normalizing the original scatter matrix to the problem-dependent value calculated for the 1-D scatter data. In this case the l_{th} Legendre moment of the 2-D multigroup cross section for reaction type "s" of nuclide "j" in zone "z" (at a specified temperature), for scatter from initial group g′ to final group g, is computed by:

$$\sigma^{j}_{l,z,s,g'\to g} = \frac{\left(\sigma^{j}_{z,s,g'}\right)_{new}}{\left(\sigma^{j}_{s,g'}\right)_{orig}} \times \left(\sigma^{j}_{l,s,g'\to g}\right)_{orig} \tag{7.5.2}$$

where the subscripts "*orig*" and "*new,*" respectively, refer to the original MG data on the Master library, and the new problem-dependent data computed by PMC. The types of reactions for which problem-dependent 2-D cross sections may be processed using the scaling method are elastic (MT=2), discrete-level inelastic (MT's 50–89), continuum inelastic (MT=90), and (n,2n) (MT=16). This approach is also applied to obtain problem-dependent thermal scatter matrices, which contain upscatter as well as down-scatter reactions. The CENTRM nuclear data libraries include PW cross sections for incoherent (MT=1007) and coherent (MT=1008, if available) thermal scattering reactions, which can be processed into 1-D MG data by PMC in the same manner as other reaction types. The 1-D weighted thermal scattering data are then used to normalize

the 2-D thermal matrices on the input Master library. For materials with both coherent and incoherent thermal scatter data, each matrix is scaled by the corresponding type of 1-D data. The coherent scattering matrix only contains within-group terms.

The option N2D= -1 recomputes the P_0 within-group elastic cross section based on the assumption of s-wave scatter kinematics, and scales the other terms of the original P0 elastic matrix by the modified removal rate. This procedure approximately corrects for effects of resonance self-shielding on the group removal probability, without having to recompute the entire matrix assuming *s*-wave scatter, as done for N2D=1. Suppressing the zone index for simplicity, the P_0 within-group XS is defined as:

$$\sigma_{\mathrm{g,g}} \equiv \frac{\int_{\mathrm{g}} \sigma_{\mathrm{s}}(\mathrm{E}) \left[1 - \mathrm{p_r(E)}\right] \Phi(\mathrm{E}) \mathrm{dE}}{\int_{\mathrm{g}} \Phi(\mathrm{E}) \mathrm{dE}} \tag{7.5.3}$$

where $p_r(E)$ is the probability that a neutron at energy E, within group g, will scatter to an energy below the lower boundary of the group. For *s*-wave scattering this equation becomes,

$$\sigma_{\mathrm{g,g}} = \frac{\int_{\mathrm{E_{Lo}}}^{\min\left(\mathrm{E_{Hi}}, \frac{\mathrm{E_{Lo}}}{\alpha}\right)} \sigma_{\mathrm{s}}(\mathrm{E}) \left[\frac{\mathrm{E}-\mathrm{E_L}}{\mathrm{E}(1-\alpha)}\right] \Phi(\mathrm{E}) \mathrm{dE}}{\int_{\mathrm{g}} \Phi(\mathrm{E}) \mathrm{dE}} \tag{7.5.4}$$

The N2D= -1 option recomputes a modified P_0 within-group cross section from the expression,

$$\left(\sigma_{\mathrm{g,g}}\right)_{\mathrm{new}} = \frac{\widetilde{\sigma}^{(\varphi)}_{\mathrm{g,g}}}{\widetilde{\sigma}^{\infty}_{\mathrm{g,g}}} \left(\sigma_{\mathrm{g,g}}\right)_{\mathrm{orig}} \tag{7.5.5}$$

where

$(\sigma_{\mathrm{g,g}})_{\mathrm{orig}}$ is the original within-group cross section on the MG library, based on actual kinematics and weighted with an infinitely dilute spectrum;

$\widetilde{\sigma}^{(\infty)}_{\mathrm{g,g}}$ is the infinitely dilute within-group cross section based on s-wave kinematics, which is computed from Eq. (7.5.4) using an infinitely dilute spectrum

$\widetilde{\sigma}^{(\varphi)}_{\mathrm{g,g}}$ is the self-shielded within-group based on s-wave kinematics, computed from Eq. (7.5.4) using $\Phi(\mathrm{E}) \rightarrow$ CENTRM PW flux.

If the effects of resonance self-shielding are small, then there will be little change in the original within-group value, since in this case $\widetilde{\sigma}^{(\varphi)}_{\mathrm{g,g}} \sim \widetilde{\mathrm{O}}^{(\infty)}_{\mathrm{g,g}}$.

The P_0 group-to-group out-scatter terms for N2D=-1 are scaled as follows:

$$\sigma_{g \rightarrow g'} = \frac{\left(\sigma_{\mathrm{s,g}}\right)_{\mathrm{new}} - \widetilde{\sigma}^{(\varphi)}_{\mathrm{g,g}}}{\left(\sigma^{\infty}_{\mathrm{s,g}}\right)_{\mathrm{new}} - \widetilde{\sigma}^{\infty}_{\mathrm{g,g}}} \times \left(\sigma_{\mathrm{g \rightarrow g'}}\right)_{\mathrm{orig}} \tag{7.5.6}$$

Again if there is little self-shielding, the change in off-diagonal matrix elements is small, so that the original secondary energy distribution is preserved. Finally the entire modified P_0 scatter matrix is renormalized to correspond to the self-shielded 1-D scatter cross section.

For the option N2D=1, an entirely new PL elastic scattering matrix is computed. The l_{th} Legendre moment of the 2-D MG elastic cross section of nuclide "j" in zone "z" (at a specified temperature), for scattering from initial group g′ to final group g is rigorously defined as, [PMCBG70]

$$\sigma^{j}_{l,g' \rightarrow g} = \frac{\int_{\Delta E_g} \int_{\Delta E_{g'}} \sigma^{j}_{l}(E' \rightarrow E) \Phi_{l,z}(E') \, dE' dE}{\int_{\Delta E_{g'}} \Phi_{l,z}(E') \, dE'} = \frac{\int_{\Delta E_g} \int_{\Delta E_{g'}} \sigma^{j}(E') f^{j}_{l}(E' \rightarrow E) \Phi_{l,z}(E') \, dE' dE}{\int_{\Delta E_{g'}} \Phi_{l,z}(E') \, dE'} \tag{7.5.7}$$

where σ_z(E) is the CE elastic cross-section data from the CENTRM nuclear data file, evaluated at the appropriate temperature for zone z; f_l^j (E′ → E) is the secondary neutron energy distribution from elastic scattering; and $\Phi_{l,z}$(E) is the lth PW flux moment averaged over zone Z. PMC assumes *s*-wave scattering from stationary nuclei to evaluate the scattering distribution, and uses the P_0 flux moment (i.e., scalar flux) as for the weighting function for all PL matrices; therefore the expression evaluated by PMC for N2D=1 is:

$$\sigma^j_{l,z,g'\to g} = \frac{\int_{g'}\int_g \frac{\sigma^j_z(\mathrm{E})\Phi_z(E')P_l(G^j)}{(1-\alpha^j)E'}dE'dE}{\int_g \Phi_z(E')\,dE'} \tag{7.5.8}$$

here Pl is the l_{th} order Legendre polynomial; and G^j is the kinematics relation expressing the cosine of the scattering angle as a function of E and E', for elastic scattering from nuclear mass A^j. The kinematics function for nuclide j is defined as,

$$\mathrm{G^j}(\mathrm{E'},\mathrm{E}) = \frac{\mathrm{A^j}+1}{2}\sqrt{\frac{\mathrm{E}}{\mathrm{E'}}} - \frac{\mathrm{A^j}-1}{2}\sqrt{\frac{\mathrm{E'}}{\mathrm{E}}}, \tag{7.5.9}$$

where G^j(E′,E) is equal to the cosine of the angle of scatter between the initial and final directions. The integral over the final group (g) is evaluated analytically using routines developed by J. A. Bucholz [PMCBuc78]. Integration over the initial group (g′) is then performed numerically using the same method as for evaluating the problem-dependent 1-D cross sections.

Option N2D=2 adds the following term to the diagonal of the l_{th} moment of the PL elastic scatter matrix,

$$\left(\sigma^j_{l;g,g}\right)_{new} = \left(\sigma^j_{l;g,g}\right)_{orig} + \sigma^j_{t;g} - \sigma^j_{t,l;g}; \quad 0 < l < isct \tag{7.5.10}$$

where isct is the order of scatter specified in CENTRM calculation; $\sigma^j_{t;g}$ is the standard 1D total cross section weighted with the scalar flux, and $\sigma^j_{t,l;g}$ is the total cross section weighted with the l^{th} Legendre moment of the angular flux; i.e.,

$$\sigma^j_{t,l;g} = \frac{\int_g \sigma^j_t(E)\Phi_l(E)dE}{\int_g \Phi_l(E)dE} \tag{7.5.11}$$

7.5.3.3 Problem-dependent fission spectra

Fission spectra (chi) describing the energy distribution of secondary neutrons produced by fission depend upon the energy of the neutron causing the fission, thus the MG chi data should be a 2-D matrix, $\chi_{g\to g'}$. However, neutron transport codes in SCALE expect a 1-D distribution, $\chi_{g'}$; therefore the production of fission neutrons in group g′ by neutrons in group g is approximated as,

$$\mathrm{P_{g\to g'}} = \chi_{\mathrm{g'}}\nu_{\mathrm{g}}\sigma_{\mathrm{f,g}}\Phi_{\mathrm{g}} \tag{7.5.12}$$

and the total number of secondary neutrons generated in group g' is,

$$\mathrm{P_{g'}} = \chi_{\mathrm{g'}}\sum_{\mathrm{g}}\nu_{\mathrm{g}}\sigma_{\mathrm{f,g}}\Phi_{\mathrm{g}} \tag{7.5.13}$$

SCALE MG libraries contain "generic" 1-D chi distributions for each fissionable nuclide. These are processed from the evaluated ENDF/B fission data, weighted by the standard weighting function used to process the SCALE MG libraries (i.e., Maxwellian in thermal energy range, 1/E in epithermal range, fission spectrum in

fast range). The SCALE MG libraries also contain 2-D chi distributions processed from ENDF/B fission data, can be processed with a problem-dependent weighting function to create a more representative 1-D chi. This procedure is done in PMC for each fissionable nuclide, using the following equation that preserves the secondary neutron energy distribution:

$$\chi_{g'} = \frac{\sum_g \chi_{g\to g'} \nu_g \sigma_{f,g} \Phi_g}{\sum_g \nu_g \sigma_{f,g} \Phi_g} \tag{7.5.14}$$

In the above equation, $\nu_g, \sigma_{f,g},$ and Φ_g are problem-dependent 1-D data computed by PMC using the PW fluxes calculated by CENTRM, and $\chi_{g\to g'}$, are the 2-D MG fission spectra data on the AMPX multigroup Master library. The 1D prompt chi computed by PMC includes all fission components (first-chance-fission, second-chance-fission, etc) given in the ENDF/B files, weighted by the relative fission-source fraction associated with each channel. PMC also computes an effective delayed neutron fission spectra, and this is combined with the prompt chi, using the appropriate delayed neutron fraction, to obtain the final 1-D fission spectra. The 1-D chi computed by PMC replaces the generic 1-D values for MT-1018 that were originally in the Master library.

7.5.3.4 Definition of background cross sections

The value of the "background cross section (σ_0)" may be used in PMC to determine which materials are considered to be infinitely dilute, in which case no cross section processing is done for the material. No processing is performed for material "j" if its background cross section exceeds the value of input parameter *XS_dilute* ; i.e., if $\sigma_0^{(j)}$ > XS_dilute. The expression used in PMC to compute the background cross section $\sigma_0^{(j)}$ is given in the BONAMI section.

7.5.4 PMC INPUT DATA

The Fido input blocks shown in this section are only required when executing PMC as a standalone module. In the more typical case where PMC is executed through the XSProc module during a SCALE sequence calculation, the default parameter values are automatically defined within XSProc. Default values for XSProc execution can be overridden using keyword input in the CENTRM DATA block (see Sect. 7.4.4). The keyword input names correspond to the variable names given in this section.

DATA BLOCK 1

0$ $ LOGICAL UNIT ASSIGNMENTS (8 entries. Default values given in parenthesis)*

1. LIBM = Input AMPX Master nuclear data library (22)
2. LIBX = Input CENTRM pointwise nuclear data library (90)
3. LIBF = Pointwise flux file produced by CENTRM (91)
4. LIBNM = Output problem-dependent Master library created by PMC (92)
5. LIBSC = Scratch unit (18)
6. LIBSX = Scratch unit (24)

(*) Parameters in the 0$ $ array cannot be modified for XSProc execution.

1$ $ INTEGER PARAMETERS (10 entries)

1. MRANGE

= 0, obsolete option

= 1, Compute new group cross sections over resolved resonance range of pointwise nuclides [from EUPR to ELOR given in CENTRM data library]

= 2, Compute new group cross sections over pointwise flux range [from DEMAX to DEMIN in CENTRM flux calculation] (2).

2. N2D

   = -2, Apply removal correction to P0 elastic scatter matrix AND apply consistent PN correction to higher order Legendre components; normalize to 1D.

   -1, Apply elastic removal correction to P0 elastic scatter matrix; normalize to 1D.

   = 0, Normalize P_N components of original elastic scattering matrix to new 1-D elastic value.

   = 1, Compute new P_N components of elastic matrix, using scalar flux as weighting function.

   = 2, Modify diagonal elements of the PN moments of the elastic matrix using the consistent PN method (-1).

3. NTHRM

   = 0 Treatment of thermal scatter kernels [not functional] (0)

4. NPRT

   = -1, Minimum printed output;

   = 0, Standard print out;

   = 1, Also print new weighted cross sections for MT's 1, 2, 18, and 102.

   = 2, Maximum amount of printed output includes 2D matrices (-1).

5. NWT

   = 0, Generate zone-weighted multigroup data;

   = 1, Generate cell-weighted multigroup data (0).

6. MTT

   = 0, Process all MT's included in LIBX. [**NOTE:** With this option, total cross section may not equal to sum of partials];

   = 1, Process all MT's except 1, 27, 101; then compute:

      MT 101 = sum of MT's 102-114,

      MT 27 = sum of MT's 18 and 101,

      MT 1 = sum of MT's 2, 4, 16, 17, and 27 (1).

7. PMC_OMIT

   = 0, Process all pointwise nuclides used in CENTRM calculation;

   = 1, Process only nuclides in fuel zones.

   > 1, Process all materials except those in 2$$ array

8. IXTR2

   = 0, PMC run in CSAS standard sequence;

   = 1, PMC run in stand-alone mode (1);

   = 2 PMC run in CSAS double-heterogeneous cell sequence

9. IXTR3

   = -1, Process new data for all Legendre components on the input AMPX master library up to P_7.

   = N, Process new data through P_N moments. [N=Scattering Order+1] (-1).

10. N1D

    = 0 Use CENTRM scalar flux for weighting function;

    = 1, Use the absolute value of CENTRM current for weighting function (0).

*1** REAL PARAMETERS** (10 entries)

1. XS_DILUTE = background cross section (barns) considered to be infinitely dilute (10^{10})

2-10. Fill with 0.0

7.5.4.1 Notes for PMC users

1. N2D specifies the method used to process the P_N components of the 2-D elastic scattering matrices. In the option N2D=0, the P_N components of the original elastic scattering matrix are simply re-normalized using the new, problem-dependent 1-D elastic values. This simple scaling approach often works well, but it does not account for the impact of resonance self-shielding on the group removal probability. The default option N2D= -1 approximately corrects the P0 elastic matrix for removal self-shielding effects on and is usually preferred to N2D=0, except for fast systems. Option N2D=1 re-computes all the P_N components of 2-D elastic cross sections using the scalar flux as a weighting function, along with the the use of PW thermal scattering kernel data and assumption of *s*-wave scattering within the epithermal PW energy range. This approach takes significantly more execution time than N2D=-1, and usually is not necessary. Option N2D=2 corrects the diagonal terms of the Legendre moments, using the consistent PN expression. Option N2D=-2 is similar to N2D=2, except the elastic removal correction is applied to the P0 moment (Like for N2D=-1). Option N2D=-2 has been found to improve results for many infinite lattice cases.

2. NWT specifies whether the new multigroup cross sections are zone-weighted or cell-weighted. When PMC is executed through XSProc, nuclides are always zone-weighted unless the double-heterogeneous

option is specified in the CELLDATA block of the sequence input. Except for double-heterogeneous cells, cell-weighting of the MG cross sections should be done by the multigroup XSDRNPM calculation.

3. PMC_OMIT is used to indicate which pointwise nuclides are processed when computing new group cross sections. If PMC_OMIT=1, only nuclides in fuel mixtures are processed. Fuel mixtures are defined as having at least one material with Z ≥ 90. Option PMC_OMIT>1 only works for PMC standalone runs, since there is no mechanism for inputting the 2$$ array in sequences.

4. IXTR3 is used to indicate through what Legendre order the scattering matrices are to be processed. By default, in stand-alone mode all P_N moments on the Master library are processed, where as in a SCALE sequence only through order N=5 are processed. With few exceptions, the SCALE multigroup libraries contain scattering data through P_5.

5. If input parameter XS_DILUTE > 0.0, PMC computes background cross sections (σ_0) for each material, and bypasses processing materials with σ_0 > XS_DILUTE. The default of XS_DILUTE =10^{10} barns causes essentially all materials to be processed regardless of dilution. Smaller XS_DILUTE values may reduce the number of materials being processed, and hence reduce the execution time; however, XS_DILUTE should not be so low that important absorbers are not shielded.

7.5.5 EXAMPLE CASE

Usually PMC is executed through one of the automated SCALE sequences such as CSAS or TRITON where it is called by XSProc in conjunction with other SCALE modules, such as CRAWDAD which provides the pointwise nuclear data library and CENTRM which provides pointwise fluxes. In such cases the user does not have to prepare input directly for PMC.

7.5.5.1 PMC input for example case

An example of PMC stand-alone execution is given below, but it should be noted that this PMC case cannot be executed unless it is linked to the output data files produced by other modules. The example problem given in the CENTRM chapter shows the coupled execution of several stand-alone modules, including PMC, which mimics the function of XSProc.

```
=pmc
0$$      -42      81      15      -42      18      19      17
1$$     2   -1    0   0    0    1    0    0    5    0
 1t
end
```

7.5.5.2 PMC output for example case

Only the printed output produced by PMC for the example problem is shown here. In this case the "standard" PMC editing option (NPRT=0) was specified. The XSProc default of "minimum" print in the SCALE sequences produces considerably less output.

7.5.6 FORMATS OF DATA FILES

The CENTRM chapter of the SCALE manual describes the format for the CENTRM PW nuclear data library and the format of the output PW flux file produced by CENTRM, which is input to the PMC code.

7.5.7 APPENDICES

7.5.7.1 Alphabetical Index of Subroutines

This section provides a convenient alphabetical index of the subroutines used in PMC, the subroutines that call them and the subroutines they call.

Subroutine Name	Calling Subroutine	Called Subroutine
add2d	xscal	pint
addpxs	xscal	
boss	pmc	flxrec

zonefl	boss	

7.5.7.2 Alphabetical Index of Modules

This section provides a list of the modules used in PMC and the subroutines that reference them.

ARRAY Format: READ ARRAY array parameters data type orientation data END ARRAY See Sections on ARRAY Data, Geometry, and alternative sample problem mockups

Repeat the sequence ARRAY PARAMETERS DATA TYPE ORIENTATION DATA for each array used in the problem.

ARRAY PARAMETERS

KEYWORD	DEFAULT	DEFINITION
ARA=	none[a]	no. defining the array
TYP=	Cuboidal[a]	array type (cuboidal or square, hexagonal or triangular, rhexagonal, rhexagonal, dodecahedral)
NUX=	none[a]	no. of units in X direction
NUY=	none[a]	no. of units in Y direction
NUZ=	none[a]	no. of units in Z direction
GBL=	none[b]	global or overall array number
PRT=	YES	print any label
COM=	none	delim comment delim optional, maximum of 132 characters

ORIENTATION DATA FOR FILL

Enter unit numbers to define every position in the array. When entering data using the options in this table, the count and option fields must be adjacent with no imbedded blanks. The operand field may be separated from the option field by one or more blanks. Orientation data for FILL is terminated by entering END FILL.

COUNT FIELD	OPTION FIELD	OPERAND FIELD	COMMENTS
		j	stores j at the current position in the array
i	R, *, $	j	stores j in the next i positions in the array
	F	j	fills remainder of the array with unit no. j starting with the current array position
	A	j	sets the current position in the array to j
i	S		increments current position in the array by i (This allows skipping i positions. The value of i may be positive or negative.)
i	Q	j	repeats the previous j entries i times. The default value of i is 1
i	N	j	repeats the previous j entries i times, inverting the sequence each time. The default value of i is 1.
i	B	j	starting with the entry at -i from the current position, store entries in inverse order until position -(i+j) is reached. Default value of i=1.
i	I	j k	provides the end points (j, k) with i entries linearly interpolated between them (i.e., a total of i+2 points). At least one blank must separate j and k. When used for an integer array, the i option should only be used to generate integer steps (i.e., (k-j)/(i+1) should be a whole number).

ORIENTATION DATA FOR LOOP

Enter the unit number and nine numbers that define the position(s) of that unit. Data for each of these ten entries are repeated until every position in the array has been defined. Orientation data for LOOP are terminated by entering END LOOP.
ENTER DATA IN THE FORM:

DATA ENTRY	COMMENTS
LTYPE	The unit type. LTYPE must be greater than 0.
IX1	Starting position in the X direction. IX1 must be at least 1 and no larger than the value entered for NUX.
IX2	Ending position in the X direction. IX2 must be at least 1 and no larger than the value of NUX.
INCX	The number of units by which increments are made in the X direction.
IY1	The starting position in the Y direction. IY1 must be at least 1 and less than the value entered for NUY.
IY2	Ending position in the Y direction. IY2 must be at least 1 and no larger than the value of NUY.
INCY	The number of units by which increments are made in the positive Y direction.
IZ1	Starting position in the Z direction. IZ1 must be at least 1 and no larger than NUZ.
IZ2	Ending position in the Z direction. IZ2 must be at least 1 and no larger than NUZ.
INCZ	The number of units by which increments are made in the positive Z direction.

[a] In KENO Va the default is 1

[b] In KENO Va the default is the largest array number, *nuxnuy*

7.6 CHOPS: MODULE TO COMPUTE POINTWISE DISADVANTAGE FACTORS AND PRODUCE A CELL-HOMOGENIZED CENTRM LIBRARY

M. L. Williams and L. M. Petrie

7.6.1 INTRODUCTION

CHOPS (**C**ompute **HO**mogenized **P**ointwise **S**tuff) computes pointwise (PW) disadvantage factors from the PW zone fluxes on a CENTRM output file, and then multiples the disadvantage factors by continuous-energy (CE) cross section data in a CENTRM library to generate a new cell-homogenized CENTRM CE library. The PW disadvantage factor for zone "Z", as a function of energy E, is calculated from the expression,

$$D_Z(E) = \frac{\Phi_Z(E)}{\Phi_C(E)} \tag{7.6.1}$$

where $\Phi_Z(E)$ is the CENTRM PW flux spectrum averaged over the volume of zone Z in the cell, and $\Phi_C(E)$ is the PW flux averaged over the entire cell volume. The cell-homogenized CE cross section for a nuclide "j"

is equal to

$$\sigma_C^{(j)}(E) = \sum_Z F_Z^{(j)} D_Z(E) \sigma_Z^{(j)}(E) \tag{7.6.2}$$

where $F_Z^{(j)}$ is the fraction of all nuclide–j atoms contained in zone Z, and $\sigma_Z^{(j)}(E)$ is the CE cross section for nuclide-j at the temperature of zone Z. When multiplied by the cell-homogenized number density of nuclide-j and by the cell-average flux, the cross section expression in Eq. (7.6.2) gives the correct average reaction rate at energy E.

CHOPS is used in the automated double heterogeneity sequence in SCALE, in which a low-level heterogeneity, such as microspheres in a granular fuel element, are smeared into a homogenized absorber region appearing in the second level heterogeneity, such as fuel pellet or pebble appearing in a lattice. The disadvantage factors provide for flux weighting of the PW XS data so that the spatial self-shielding is treated correctly in the homogenized geometry. A second CENTRM PW transport calculation is performed with the cell-averaged PW library output by CHOPS in order to account for the additional self-shielding of the absorber pellets/pebbles in the lattice. CHOPS is called automatically by the XSProc module for double-heterogeneous unit cells, or it can run as a standalone code.

7.6.2 CHOPS INPUT DATA

DATA BLOCK 1

0$ $ LOGICAL UNIT ASSIGNMENTS (10 entries. Default values given in parentheses)

1. lold – logical unit number of input CENTRM XS library (1)

2. lnew – logical unit number of output CENTRM homogenized XS library (2)

3. lflx – logical unit number of input CENTRM PW flux library (3)

4. ldis – logical unit number for edit of PW disadvantage factors (0)

5. n15 – logical unit number for scratch (15)

6. n16 – logical unit number for scratch (16)

7. n17 – logical unit number for scratch (17)

8. n18 – logical unit number for scratch (18)

9. n19 – logical unit number for scratch (19)

10. nsq – sequence number used in filename on unit “lnew” (1)

[Example: if *lnew=11* and *nsq=3*: output filename of homogenized library= *ft11f003]*

1$ $ INTEGER PARAMETERS (5 entries)

1. idtap – identifier for the new library (55555)

[for macro library, the value of *idtap* is made negative]

2. nprt – output print option: 0 = > min print; 1 = > normal; 2 = > max print (0)

3. iden – if=0 = > define homogenized XS id = id on CENTRM flux file (0)

if>0 = > define homogenized XS id to be, ($iden$*10^6 + ZA)

4. macr – type of XS output: 0 = > microscopic ; 1 = > macroscopic (0)

5. icorr – not used (0)

2 REAL PARAMETERS** (3 entries)

1. tole – tolerance used to thin pointwise cross-sections (0.0025)

(0.0 means no thinning is done)

2. cleth – maximum lethargy between thinned pointwise cross-sections

points that allow a point to be discarded (0.25)

3. vfrac – multiplier applied to all output XS's [eg, grain fraction] (1.0)

T [TERMINATE DATA BLOCK 1]

7.6.3 CHOPS I/O UNITS

Table 7.6.1 shows default logical unit numbers used by CHOPS. These values may be changed in the 0$$ array of input.

Table 7.6.1: Default I/O unit assignments for CHOPS.

Unit number	Description
1	Input CENTRM CE data library
2	Output homogenized CENTRM CE data library
3	Input pointwise CENTRM flux file
15	Scratch file
16	Scratch file
17	Scratch file
18	Scratch file
19	Scratch file

7.6.4 CHOPS SAMPLE INPUT

The sample case in Example 7.6.1 first executes a CENTRM unit cell geometry calculation using the CSAS-MG sequence, which by default generates the PW flux file on unit 15, as well as the CE nuclear data library on unit 81 for input to CHOPS. The standalone CHOPS code then computes a cell-homogenized CE library for the unit cell. The new homogenized CENTRM CE library is output on unit 91with filename: *ft91f001*

Example 7.6.1: CHOPS sample input.

7.7 CRAWDAD: MODULE TO PRODUCE CENTRM-FORMATTED CONTINUOUS-ENERGY NUCLEAR DATA LIBRARIES

M. L. Williams, D. Wiarda, and S. W. D. Hart

ACKNOWLEDGMENTS

The authors would like to acknowledge the important contributions to CRAWDAD made by former ORNL staff N. M. Greene and D. F. Hollenbach.

7.7.1 INTRODUCTION

SCALE uses the code CRAWDAD (Code to Read And Write DAta for Discretized solution) to read nuclear data from the SCALE-6 continuous (CE) library files, and write it to an output file in the particular format needed for the discretized energy solution in CENTRM. Prior to SCALE-6, the CE data used by the CENTRM and PMC modules were distributed directly in the CENTRM library format. However beginning with SCALE-6, the same CE data are used by both CENTRM/PMC and by the CE versions of the KENO and Monaco Monte Carlo codes. CE nuclear data for each nuclide are stored in individual files contained in the SCALE permanent data directory. CRAWDAD reads the files for each material appearing in a problem and combines all data into a single problem-dependent CENTRM library file stored in the temporary directory for execution.

All SCALE-6 calculations that use modules CENTRM and PMC for self-shielding multigroup (MG) cross sections must first execute the CRAWDAD computational module. During execution of SCALE sequences, the XSProc self-shielding module automatically executes CRAWDAD whenever the CENTRM/PMC method is specified. CRAWDAD also can be run in stand-alone mode to process and save a CENTRM-formatted library for subsequent CENTRM/PMC calculations.

PMC allows the energy range of the CE data to be selected, as well as which reactions are placed on the output CENTRM library. The output CENTRM library always contains the following "standard" nuclear data types for all materials: total (1); elastic (2); complete inelastic (4); radiative capture (102); fission (18); total/prompt/delayed nubars (452, 455, 456); and (n,:math:*alpha*) cross section for 10B and 7Li. In this list, the number shown in parenthesis corresponds to the ENDF/B "mt numbers."

CE data are obtained for arbitrary energies by linear interpolation of discrete cross sections defined on a pointwise (PW) energy mesh. The PW energy mesh for a given nuclide is sufficiently fine that error introduced by linear interpolation between any two points is less than 0.1%. CRAWDAD also interpolates the CE data to the specific temperatures needed for the problem. The default temperature interpolation method uses square-root of temperature below 1200 Kelvin and a finite difference procedure above this temperature [CRAWDADHCML16].

7.7.2 CRAWDAD INPUT DATA

For standalone CRAWDAD execution, the user prepares the FIDO input deck as described below. However during a SCALE sequence computation, the XSProc module always executes CRAWDAD for CENTRM/PMC self-shielding calculations, and defines appropriate CRAWDAD parameter values based on specified CENTRM and PMC options. This is the recommended mode of operation. Some XSProc default values for CRAWDAD can be changed using keywords in the CENTRM DATA block; e.g., see parameters *mtout*= and *kernel*= in Sect. 7.4.4. Several options available for stand-alone execution cannot be controlled by keywords in the sequence runs, as these are set automatically

7.8 MCDANCOFF: MONTE-CARLO BASED DANCOFF FACTOR CALCULATION

L. M. Petrie, B. T. Rearden, A. M. Holcomb, and K. S. Kim

ABSTRACT

The MCDancoff program is used to calculate Dancoff factors in complicated, three-dimensional (3-D) geometries using Monte Carlo integrations. The geometries are standard SCALE geometry descriptions, with the current restriction that Dancoff factors can only be calculated for regions bounded by cuboids, spheres, or cylinders. Multiple Dancoff factors can be calculated with one input file. New AMPX one group library for MCDancoff was developed for SCALE 6.3 based on ENDF/B-VII.1.

ACKNOWLEDGMENT

This work was sponsored in part by Atomic Energy of Canada, Ltd. Development of new ENDF/B-VII.1 based AMPX one group library for SCALE 6.3 was sponsored by the US Nuclear Regulatory Commision (NRC). The contribution of S. J. Poarch in preparing this document is gratefully acknowledged.

7.8.1 INTRODUCTION

MCDancoff (Monte Carlo Dancoff) is a program that calculates Dancoff factors for complicated, three-dimensional geometries. Its input is a slight modification of a CSAS6 input file which uses the standard SCALE geometry as detailed for KENO-VI. The modifications to the input involve different input in the START data block describing which Dancoff factors are to be calculated. The calculation involves starting histories isotropically on the surface of the region for which the Dancoff factor is to be calculated and following the path of each history until it has encountered all the elements of the material in the region, or until it has exited the system. A one group cross-section library is used to determine the total cross sections of the mixtures in the problem. The one group library has been developed based on ENDF/B-VII.1 for SCALE 6.3 for which various reaction cross sections were obtained by energy group collapsing and elastic cross sections (MT=2) were replaced by potential cross sections.

A current restriction of MCDancoff is that it can only calculate Dancoff factors for regions bounded by cylinders, spheres, or cuboids. Other simple bodies could be added in the future, but a general bounding surface would be impractical.

The Dancoff factors are used in SCALE to correctly self-shield multigroup cross sections for a given problem; either as input to BONAMI or to determine an equivalent cell for CENTRM. This is most typically accomplished through the MORE DATA and CENTRM DATA blocks.

The Dancoff factors are actually calculated by a modified version of the KENO-VI code called KENO_Dancoff. All printed output from these calculations is suppressed by default. If there is a need to see this output (for example, to find an error message), it can be turned on by setting an environment variable **print_dancoff=yes**.

7.8.2 INPUT DATA DESCRIPTION

MCDancoff input data is the same as CSAS6 input data with the following exceptions. A special one group cross-section library will be used. It can be specified as **xn01** in the input but will be set to this if anything else is entered for the library. Because MCDancoff is running a fixed source problem, and the Dancoff factor doesn't need to be calculated with the same accuracy as an eigenvalue, there are useful changes that can be made to the parameters in the PARAMETER data block. Sect. 7.8.3 discusses this in more detail. Finally, the START data block is used to define which Dancoff factors will be calculated. This data block is defined below.

```
READ START Begins the data block

  1. dancoff

  begins defining a new Dancoff factor. Always start
  relative to the global unit in the geometry.

  2. array

  step into an array contained in the current unit - followed
  by karray, nbx, nby, nbz where karray is the
  region containing the array in the current unit, nbx is the x
  position in the array of the next unit, nby is the y position
  in the array of the next unit, and **nbz** is the z position in
  the array of the next unit.

  3. hole

  step into a hole contained in the current unit - followed by
  nhole, the hole number relative to the current unit.

  4. unit

  final unit in the nesting chain - followed by **nn**, the
  unit number

  5. region

  region to calculate the Dancoff factor for - followed by
  k, the relative geometry word in unit nn defining the
  outer bound of the region.

  6. nst

if input, must be 0 (defaults to 0).
Repeat 2 and 3 to get from the global unit to the final unit nn.
Repeat 1-5 for each Dancoff factor to be calculated.

END START Ends the data block
```

7.8.3 CALCULATION AND USE OF 3D DANCOFF FACTORS

1. The 3-D Dancoff factors are computed with KENO-VI geometry. If beginning with CSAS5 model, use C5TOC6 to convert to CSAS6.
2. Change sequence name from CSAS6 to MCDancoff and change cross-section library to **xn01**.
3. Input appropriate parameter data.

   Since the Dancoff calculation is fixed source integration, there is no need to skip generations, and **nsk** should be set to 0. Since small changes to the Dancoff have very minor effects on the cross sections, fewer histories are probably needed for calculating the Dancoff than for calculating *keff*. Thirty thousand histories divided as 100 generations of 300 histories per generation has produced Dancoff factors with deviations of less than 1 percent. It may be advantageous to turn off plots at this point. Since the same parameters can be entered more than once, with the final entry being the one used, adding a separate record with these values immediately before the **end parameter** keywords would override the original KENO-VI parameters.

   Example:

```
read param
        .........
  nsk=0 npg=300 gen=100 nub=no fdn=no flx=yes plt=no
end param
```

4. Identify the region for which Dancoff factors are desired in START data.

   The start type needs to be set to **0** for the Dancoff calculation (this is the default). All KENO-VI START data should be removed or commented out by placing an apostrophe in column 1. Each region for which a Dancoff calculation is desired then starts with the keyword **dancoff**. This is followed by data that specify the relationship of the global unit to the specific geometry description of the region. If the region is nested inside an array, then the keyword, **array**, is specified, followed by four integers. The first integer is the indices of the media record specifying the array relative to the current unit. The next 3 integers are the X, Y, and Z indexes of the position of the next unit in the array. If the region is nested in a hole, then the keyword, **hole**, is specified, followed by the relative count of the correct hole in the unit. The preceding data are repeated (in the correct nesting order starting with the global unit) until reaching the unit where the region is located. Then the keyword, **unit**, followed by the unit number is given, followed by the keyword, **region**, followed by the relative index of the geometry keyword describing the desired region with respect to that unit. Currently, only cylinders, spheres, and cuboids are programmed for calculating Dancoff factors.

   Examples:

```
read start
  nst=0
  dancoff    hole 1    unit=1  reg=1
end start

read start
   dancoff  array  1 1 1 1  array  1 17 17 2  unit 10  region 1
end start
```

5. Execute MCDANCOFF *filename*.input file like any other SCALE input file.

6. Examine *filename*.dancoff file, which will contain Dancoff factors for each nuclide in the specified region

```
index        nuclide        dancoff      deviation
                  1          92234    3.36340E-01    1.81134E-03
                  2          92235    3.36340E-01    1.81134E-03
                  3          92236    3.36340E-01    1.81134E-03
                  4          92238    3.36340E-01    1.81134E-03
                  5           8016    1.00000E+00    0.00000E+00
```

7. Once all desired Dancoff factors are obtained, return to original model and enter CENTRM DATA for each cell with dan2pitch(mix) specified.

```
read celldata
  latticecell triangpitch fuelr=0.633  1 gapr=0.637 0 cladr=0.675 10 hpitch=0.867  14 end
centrm data
  dan2pitch(1)=0.336
end centrm
```

8. If executing TSUNAMI-3D, additional steps are necessary because TSUNAMI-3D does not treat the dan2pitch input parameter.

Return to the original TSUNAMI-3D input file and replace the sequence name to "CSAS-MG PARM=CHECK" and delete all data after the unit cell data to quickly obtain revised pitch values. (Note: CSAS will not modify cell dimensions to more than 20 cm, so a revised moderator density may need to be entered to obtain the desired Dancoff factor.) Search for the word "*desired*" in output file to find new pitch values for each cell.

```
unit cell  =    1
  original pitch               = 1.7340E+00
  Dancoff for orig pitch       = 2.9728E-01
  desired Dancoff              = 3.3600E-01

pitch to produce desired Dancoff= 1.6845E+00
```

9. Enter revised pitch and revised moderator density (for cell calculation only, not for geometry model) in TSUNAMI model.

7.8.4 EXAMPLE CASE

The following is a contrived case to illustrate an input file using both holes, arrays, and multiple sets of Dancoff factors (although both factors apply to the same pin, so only one set can be used). The case represents two fuel assemblies in a cylindrical tank, each assembly having a poisoned central pin, and four water holes. The Dancoff factors are calculated for each central pin. The input file is listed in Example 7.8.1.

Example 7.8.1: Example input file.

7.9 CAJUN: MODULE FOR COMBINING AND MANIPULATING CENTRM CONTINUOUS-ENERGY LIBRARIES

L. M. Petrie and N. M. Greene

7.9.1 INTRODUCTION

CAJUN is a program used to combine continuous-energy (CE) cross section libraries for use in the cross-section processing codes CENTRM and PMC. It is used primarily by SCALE sequences when processing pointwise cross section data for DOUBLEHET unit cells with the XSProc module (see Sect. 7.1.3), although it can also be run standalone in conjunction with CRAWDAD. CAJUN combines multiple CE libraries into a single library, adds selected nuclides from one library into another library, deletes nuclides from a specified library, or renames nuclides in a library. CAJUN performs an analogous function for CE libraries as AJAX does for multigroup libraries.

In order for input CE libraries to be read by CAJUN, they must be assigned a unit number from 1 to 99. The SHELL module can be used to link individual CE libraries to appropriate file names that are accessible by unit number.

7.9.2 CAJUN INPUT DATA

Input data for CAJUN is read into the program using FIDO type input. The data is divided into three data blocks. The first data block provides the output file number and number of libraries processed. The second data block provides input library numbers, number of nuclides in each library, and whether nuclides are selected by MAT or ZA number. The third data block provides current nuclide MAT or ZA numbers and new nuclide MAT or ZA numbers. Detailed description of the CAJUN input data is provided below.

```
Data Block 1

  0$$         unit assignments (1)

      1.      lcen - logical unit number of output CE CENTRM library (1)

  1$$         number of files to process (2)

      1.      nfile - the number of CENTRM CE libraries to process (1)
      2.      idtap - identifier for the new library (0)

      T       terminate data block 1

**************************************************************************
 *** repeat data block(s) 2 and 3 "nfile" times to create new library
**************************************************************************

Data Block 2

      2$$     file selection and treatment option (4)

      1.      log - logical unit number of input CENTRM CE library (77)
      2.      inum - number of nuclides selected from this library (0)
              0 - select all nuclides on the library as is.
              -n - select all nuclides on the library as is except for those indicated in the 3$$ array.
              n - select the "n" nuclides on the library listed in the 3$$ array.
      3.      iopt - select nuclides by 'mat' or 'nza' number   (1)
              0 - mat
              1 - nza (default)
      4.      nsq - sequence number of file opened on unit LOG (1)

      T       terminate data block 2

Data Block 3 (enter if inum is non-zero)

      3$$     nuclide selection list (inum)
              enter a positive identifier to select a nuclide.
              enter a negative identifier to exclude a nuclide.

      4$$     new nuclide identifiers (inum)
              enter the new nuclide identifiers in the locations corresponding
              to the positive identifier entry in the 3$ array.

      5$$     version of the data (-1,0,1,2,3,4/unk,ENDF,JEF,JENDL,BROND,CENDL)  (inum)

      6$$     8-Character Identifier for Thermal Kinematics Data  (inum)

      7$$     ZA-override Values.  Non-zero values will replace the ZA values in the
              Header Record.  The ZA values in the Data Directory records are not changed.  (inum)

      T       terminate data block 3
```

7.9.3 CAJUN I/O UNITS

CAJUN requires the following I/O devices.

Unit No.	Purpose
5	Standard definition input
6	Output
18	Scratch file

8. MONTE CARLO TRANSPORT

Introduction by B. T. Rearden

SCALE Monte Carlo transport capabilities enable criticality safety, shielding, depletion, and sensitivity and uncertainty analysis [Monte-CarloRPP+14]. SCALE provides separate Monte Carlo capabilities for eigenvalue neutronics and fixed-source coupled neutron-gamma calculations, in the KENO code [Monte-CarloGPJD+11] and fixed-source coupled neutron-gamma calculations in the Monaco code [Monte-CarloPep11] Although the eigenvalue and fixed-source capabilities are provided in separate codes, many capabilities are shared between them, including physics and geometry packages. The foundational features shared between the codes are described below, with specific implementations provided in subsequent sections. Generally, the use of the Monte Carlo transport solvers in SCALE are best accessed through the capability-specific sequences: CSAS for criticality safety, MAVRIC for shielding, TRITON for depletion, TSUNAMI-3D for sensitivity and uncertainty analysis, and MCDancoff for three-dimensional Dancoff factor calculations.

Multigroup Physics

The multigroup treatment implemented in SCALE has been in use since the 1960s and provides efficient, effective solutions with superior runtime performance. Problem-dependent multigroup cross section data are temperature interpolated and resonance self-shielded by other SCALE modules before they are used in each Monte Carlo calculation. Without proper resonance self-shielding, accurate multigroup calculations would not be possible for thermal or intermediate energy spectrum systems. After self-shielding has been accomplished and the two-dimensional expansions have been summed into a Legendre expansion of the total group-to-group transfer arrays, individual nuclide cross sections are multiplied by their densities and summed into mixtures. These mixture cross sections can then be used by the deterministic transport codes for their calculations. The Monte Carlo codes convert the Legendre expansion of the transfer arrays into probability distributions for the group-to-group transfers and for the discrete scattering angles and probabilities that preserve the moments of the Legendre expansion of each group-to-group transfer. These transfer probabilities, angles, and angle probabilities are then transformed so that the new group and angle of scatter are efficiently selected through two random numbers with only one multiplication and one addition operation. If the selected new group is negative, it is reset to positive, and the new direction is chosen isotropically. If the problem is run with P_1 scattering, the scattering angle is chosen from a continuous distribution. For higher order scattering, the polar scatter angle is discrete, and the azimuthal angle is randomly selected from a uniform distribution. Multigroup physics is implemented for neutron, photon, and neutron-photon coupled particle transport modes.

Continuous-energy Physics

The continuous energy treatment in SCALE provides high resolution solution strategies with explicit physics representation. The continuous energy data represent thermal scattering using free gas and $s(\alpha, \beta)$, with explicit point-to-point data provided through the thermal region. The resolved resonance region is represented by pointwise data where the energy point density is optimized for each reaction of each nuclide. Data in the unresolved resonance region are represented by probability tables, and data above the unresolved region implement pointwise data with explicit point-to-point representation for secondary particles. Photon yield data represent each discrete photon. Continuous energy physics contains non-transport data handling to support various flux, reaction rate, point detector tallies, and sensitivity analysis. In addition, continuous energy data are converted from a double differential data format to a lab format in a process where fast look-up tables are provided during library generation. In SCALE 6.0–6.1, calculations are performed only at temperatures available on the data libraries by selecting the library temperature nearest to the desired temperature for

the calculation. Resonance upscattering techniques are implemented via the Doppler Broadened Rejection Correction method [Monte-CarloHMGR13]. With SCALE 6.2, problem-dependent continuous energy cross sections at the user specified temperature are generated at the beginning of the calculation. Continuous energy physics is implemented for neutron, photon, and neutron-photon coupled particle transport modes.

Geometry Packages

Two variants of KENO provide identical solution capabilities with different geometry packages. KENO V.a implements a simple and efficient geometry package sufficient for modeling many systems of interest to criticality safety and reactor physics analysts. KENO-VI implements the SCALE Generalized Geometry Package (SGGP), which provides a quadratic-based geometry system with much greater flexibility in solution modeling. Monaco implements only the SGGP geometry package. Both packages are based on solid bodies organized into reusable objects called *units* that are constructed of material *regions*. Units can be conveniently arranged in rectangular or hexagonal *arrays* of repeating units. Additionally, nesting is available so that one unit can contain another unit as a *hole*, or an array can be nested inside of a unit, which itself can be repeated in another array. There is no limit to the number of nesting levels available, so very complex systems can be quickly generated.

KENO V.a models are constructed from regions of specific shapes following strict rules which provide great efficiency in geometry tracking. Allowed shapes are cubes, cuboids (rectangular parallelepipeds), spheres, cylinders, hemispheres, and hemicylinders. These shapes must be oriented along orthogonal axes, and they can be translated, but they cannot be rotated. A major restriction applied to KENO V.a geometry is that intersections are not allowed, and each region of a unit must fully enclose the preceding region. An exception to this rule is in the use of *holes* through which many units can be placed within an enclosing unit. However, there is a runtime penalty in geometry tracking for this flexibility, so this feature should be used judiciously. KENO V.a provides *rectangular* arrays where the outer body of each unit contained in the array must have a cuboidal shape, and adjacent faces must have the same dimensions. The entire array must be fully enclosed by the region in which it is placed.

SGGP is a quadratic-based geometry system that provides predefined bodies including cone, cuboid, cylinder, dodecahedron, ecylinder (elliptical cylinders), ellipsoid, hexprism, hopper (truncated pyramid), parallelepiped, planes, rhombohedron, rhexprism (rotated hexprisms), sphere, and wedge. Bodies not directly provided with SGGP can be constructed from quadratic surfaces defined with coefficients entered by the user. All bodies and surfaces can be rotated and translated to any orientation and position within their respective unit. SGGP also provides intersecting regions.

SGGP arrays may be composed of cuboids, hexprisms, rhexprisms, or dodecahedrons. Like KENO V.a, the faces of adjacent units in an array must have the same dimensions. An array boundary must be specified for each array, and only the portion of the array within the boundary is considered a part of the system. Also, the specified array must fill the entire volume in the specified array boundary. The array boundary may be any shape that can be specified using quadratic equations.

The use of holes is more flexible in SGGP than in KENO V.a. Within a unit, holes cannot intersect other holes or the unit boundary, but they can intersect region boundaries. The use of holes is not necessary to build complex geometries; they are used primarily to more efficiently build complex geometries and improve the tracking efficiency of the simulation. In SGGP the distance to each surface in the unit must be calculated after each collision. By moving some of the surfaces in a unit into another unit that is included as a hole, all the surfaces in the hole unit except the outer boundary are removed from the containing unit. The judicious use of holes in SGGP can significantly speed up the calculation.

Eigenvalue Analysis

KENO performs eigenvalue calculations for neutron transport primarily to calculate multiplication factors and flux distributions of fissile systems in continuous energy and multigroup modes. Both codes allow explicit geometric representation with their respective geometry packages. KENO provides a multigroup adjoint capability which is especially useful for sensitivity analysis. KENO implements standard variance reduction techniques such as implicit capture, splitting, and Russian roulette.

The initial fission source distribution in KENO can be specified with nine options. These options include the default option of a uniform distribution throughout the fissile material; an axially varying distribution input by the user or defined as cos(Z) or (1-cos(Z)):sup:2, where Z is the axial position; several options to initialize the source at a given position (within a given volume, a given unit, or a unit at a specified array index); or to specifically provide the coordinates of each starting point.

KENO approximates the real *keff* variance using an iterative approach and lagging covariance data between generations [Monte-CarloUMN97]. KENO provides a χ^2 test for the normality of *keff* and provides plots of k_{eff} by active and inactive generations. KENO reports a *best estimate* of k_{eff} that is computed as the minimum variance of k_{eff} based on generations skipped and generations run.

KENO provides track-length tallies for scalar flux and angular flux moments needed for sensitivity analysis. Additionally, tallies are provided for reaction rates, with isotopic tallies available only in CE calculations. KENO also provides mesh tallies based on a user-input orthogonal grid.

Matrix k_{eff} calculations provide an additional method of calculating the k_{eff} of the system. Cofactor k_{eff} and source vectors, which describe the contribution to the system $k_{eff}$from each unit, hole, or array, are available.

KENO provides plots of *keff*by generation and average k_{eff} for visual inspection of source convergence, followed by a χ^2 statistical assessment of convergence. Fission source convergence diagnostic techniques are implemented in KENO to provide improved confidence in the computed results and to reduce the simulation time for some cases. Confirming the convergence of the fission source distribution is especially useful to avoid the false convergence of k_{eff} that can be caused by insufficient sampling of important portions of the system [Monte-CarloUB05] KENO source convergence diagnostics rely on Shannon entropy statistics of the mesh-based fission source data.

Parallel computation capabilities are available in both versions of KENO to provide reductions in wall clock time, especially for sensitivity analysis or Monte Carlo depletion on computer clusters. By introducing a simple master-slave approach via message passing interface (MPI), KENO runs different random walks concurrently on the replicated geometry within the same generation. The fission source and other tallied quantities are gathered at the end of each generation by the master process, and then they are processed either for final edits or next generations.

Shielding Analysis

Monaco is a fixed-source Monte Carlo shielding code that calculates neutron and photon fluxes and response functions for specific geometry regions, point detectors, and mesh tallies. Monaco has variance reduction capabilities, such as source biasing and weight windows, which can be automated via the MAVRIC sequence. MAVRIC performs radiation transport on problems that are too challenging for standard, unbiased Monte Carlo methods. Monaco provides multiple methods to enter the radioactive source descriptions. Spatial distribution options include volumetric sources and mesh sources which can be generated by other codes such as KENO. Energy distributions can be entered by the user or imported directly from emission data provided by ORIGEN. Spent fuel analysis is simplified through direct coupling with the ORIGEN binary concentration files.

8.1 KENO: A MONTE CARLO CRITICALITY PROGRAM

K. B. Bekar, C. Celik, M. E. Dunn,[1] *S. Goluoglu,*[1] *D. F. Hollenbach,*[1] *N. F. Landers,*[1] *C. M.Perfetti,*[1] *L. M. Petrie,*[1] *B. T. Rearden,*[1]

KENO is a three-dimensional (3D) Monte Carlo criticality transport program developed and maintained for use as part of the SCALE Code System. It can be used as part of a sequence or as a standalone program. There are two versions of the code currently supported in SCALE. KENO V.a is the older of the two. KENO-VI contains all current KENO V.a features plus a more flexible geometry package known as the SCALE Generalized Geometry Package. The geometry package in KENO-VI is capable of modeling any volume that can be constructed using quadratic equations. In addition, such features as geometry intersections, body rotations, hexagonal and dodecahedral arrays, and array boundaries have been included to make the code more flexible.

The simpler geometry features supported by KENO V.a allow for significantly shorter execution times than KENO-VI, while the additional geometry features supported in KENO-VI make the code appropriate for cases where geometry modeling is not possible with KENO V.a. In particular, KENO-VI allows intersections, body truncations with planes, and a much wider variety of geometrical bodies. KENO-VI also has the ability to rotate bodies so that volumes no longer must be positioned parallel to a major axis. Hexagonal arrays are available in KENO-VI and dohecahedral arrays enable the code to model pebble bed reactors and other systems composed of close packed spheres. The use of array boundaries makes it possible to fill a non-cuboidal volume with an array, specifying the boundary where a particle leaves and enters the array.

Except for geometry capabilities, the two versions of KENO share most of the computational capabilities and the input flexibility specific to most SCALE modules. They can both operate in multigroup or continuous energy mode, run as standalone codes, or integrated in computational sequences such as CSAS, TSUNAMI-3D, or TRITON. Both versions of the code are continually updated and are written in FORTRAN 90.

Computational capabilities shared by the two versions of KENO include the determination of k-effective, neutron lifetime, generation time, energy-dependent leakages, energy- and region-dependent absorptions, fissions, the system mean-free-path, the region-dependent mean-free-path, average neutron energy, flux densities, fission densities, reaction rate tallies, mesh tallies, source convergence diagnostics, problem-dependent continuous energy temperature treatments, parallel calculations, restart capabilities, and many more.

[1]Formerly with Oak Ridge National Laboratory

8.1.1 ACKNOWLEDGMENTS

Many individuals have contributed significantly to the development of KENO. Special recognition is given to G. E. Whitesides, former Director of the Computing Applications Division, who was responsible for the concept and development of the original KENO code. He has also contributed significantly to some of the techniques used in both KENO versions. The late J. T. Thomas offered many ideas that have been implemented in the code. R. M. Westfall, retired from ORNL, provided early consultation, encouragement, and benchmarks for validating the code. The special abilities of J. R. Knight, retired from ORNL, contributed substantially to debugging early versions of the code. S. W. D. Hart was instrumental in implementing continuous energy temperature treatments. W. J. Marshall has provided substantial validation and quality assurance reviews. Appreciation is expressed to C. V. Parks and S. M. Bowman for their support of KENO and the KENO3D visualization tool. The late P. B. Fox provided many of the figures in this document. D. Ilas, B. J. Marshall, and D. E. Mueller consolidated the previous KENO V.a and KENO-VI manuals into this present form. The efforts of L. F. Norris (retired), W. C. Carter (retired), S. J. Poarch, D. J. Weaver (retired), S. Y. Walker and R. B. Raney in preparing this document are gratefully acknowledged.

The authors thank the U. S. Nuclear Regulatory Commission and the DOE Nuclear Criticality Safety Program for sponsorship of the continuous energy, source convergence diagnostics, and grid geometry features in the current version.

8.1.2 INTRODUCTION TO KENO

KENO, a functional module in the SCALE system, is a Monte Carlo criticality program used to calculate k_{eff}, fluxes, reaction rates, and other data for three-dimensional (3-D) systems. Special features include multigroup or continuous energy mode, simplified data input, the ability to specify origins for spherical and cylindrical geometry regions, a P_n scattering treatment, and restart capability.

The KENO data input features flexibility in the order of input. The only restrictions are that the sequence identifier, title, and cross section library must be entered first. A large portion of the data has been assigned default values found to be adequate for many problems. This feature enables the user to run a problem with a minimum of input data.

In addition to the features listed above, KENO-VI uses the SCALE Generalized Geometry Package (SGGP), which contains a much larger set of geometrical bodies, including cuboids, cylinders, spheres, cones, dodecahedrons, elliptical cylinders, ellipsoids, hoppers, parallelepipeds, planes, rhomboids, and wedges. The code's flexibility is increased by allowing: intersecting geometry regions; hexagonal, dodecahedral, and cuboidal arrays; bodies and holes rotated to any angle and translated to any position; and a specified array boundary that contains only that portion of the array located inside the boundary. Users should be aware that the added geometry features in KENO-VI can result in significantly longer run times than KENO V.a. A KENO-VI problem that can be modeled in KENO V.a will typically run about four times as long with KENO-VI as it does with KENO V.a. Therefore KENO-VI is not a replacement for KENO V.a, but rather an additional version for more complex geometries that could not be modeled previously.

Blocks of input data are entered in the form

```
READ XXXX** *input_data* ``END XXXX
```

where `XXXX` is the keyword for the type of data being entered. The types of data entered include parameters, geometry region data, array definition data, biasing or weighting data, albedo boundary conditions, starting distribution information, the cross section mixing table, extra one-dimensional (1-D) (reaction rate) cross section IDs for special applications, energy group boundaries for tallying in the continuous energy mode, a mesh grid for collecting flux moments, and printer plot information.

A block of data can be omitted unless it is needed or desired for the problem. Within the blocks of data, most of the input is activated by using keywords to override default values.

The treatment of the energy variable can be either multigroup or continuous. Changing the calculation mode from multigroup to continuous energy or vice versa is established by simply changing the cross section library used. All available calculated entities in the multigroup mode can also be calculated in the continuous energy mode. If the calculated entity is energy or group dependent, it is automatically tallied into the appropriate group structure in the continuous energy mode.

The KENO V.a geometry input consists of spheres, hemispheres, cylinders, hemicylinders, and cuboids. Although the origin of the cylinders, hemicylinders, spheres, and hemispheres is zero by default, they may be specified to any value that will allow the geometry to fit in the problem. This feature allows the use of nonconcentric cylindrical and spherical shapes and provides a great deal of freedom in positioning them. Another feature that expands the generality of the code is the ability to place the cut surface of the hemicylinders and hemispheres at any distance between the radius and the origin.

An additional convenience is the availability of an alternative method for specifying the array definition unit-location data. This method uses FIDO-like options for filling the array.

As mentioned above, KENO-VI uses the SGGP, which contains a much more flexible geometry package than the one in KENO V.a. In KENO-VI, geometry regions are constructed and processed as sets of quadratic equations. A set of geometric shapes (including all of those used in KENO V.a plus others) is available in KENO-VI, as well as the ability to build more complex geometric shapes using sets of quadratic equations. Unlike KENO V.a, KENO-VI allows intersections between geometry regions within a unit, and it provides the ability to specify an array boundary that intersects the array.

The most flexible KENO V.a geometry features are the "ARRAY-of-ARRAYs" and "HOLEs" capabilities. The ARRAY-of-ARRAYs option allows the construction of ARRAYs from other ARRAYs. The depth of nesting is limited only by computer space restrictions. This option greatly simplifies the setup for ARRAYs involving different UNITs at different spacings. The HOLE option allows a UNIT or an ARRAY to be placed at any desired location within a geometry region. The emplaced UNIT or ARRAY cannot intersect any geometry region and must be wholly contained within a region. As many HOLEs as will snugly fit without intersecting can be placed in a region. This option is especially useful for describing shipping casks and reflectors that have gaps or other geometrical features. Any number of HOLEs can be described in a problem, and HOLEs can be nested to any depth.

The primary difference between the KENO V.a and KENO-VI geometry input is the methodology used to represent the geometry/material regions in a unit. KENO-VI uses two geometry records (cards) to describe a region. The first record, called the GEOMETRY record, contains the geometry (shape) keyword, region boundary definitions, and any geometry modification data. Using geometry modification data, regions can be rotated and translated to any angle and position within a unit. The second record, the CONTENT record, contains the MEDIA keyword; the material, HOLE, or ARRAY ID number; the bias ID number; and the region definition vector. KENO-VI requires that a GLOBAL UNIT be specified in all problems, including single unit problems.

In addition to the *cuboidal* ARRAYs available in KENO V.a, *hexagonal* ARRAYs and *dodecahedral* ARRAYs can be directly constructed in KENO-VI. Also, the ability to specify an ARRAY boundary that intersects the ARRAY makes it possible to construct a lattice in a cylinder using one ARRAY in KENO-VI instead of multiple ARRAYs and HOLEs as would be required in KENO V.a.

Anisotropic scattering is treated by using discrete scattering angles. The angles and associated probabilities are generated in a manner that preserves the moments of the angular scattering distribution for the selected group-to-group transfer. These moments can be derived from the coefficients of a P_n Legendre polynomial expansion. All moments through the 2n - 1 moment are preserved for n discrete scattering angles. A one-to-one correspondence exists such that n Legendre coefficients yield n moments. The cases of zero and one scattering angle are treated in a special manner. Even when the user specifies multiple scattering angles, KENO can recognize that the distribution is isotropic, and therefore KENO selects from a continuous isotropic distribution. If the user specifies one scattering angle, the code selects the scattering angle from a linear function if it is positive between -1 and +1, and otherwise it performs semicontinuous scattering by picking scattering angle cosines uniformly over some range between -1 and +1. The probability is zero over the rest of the range.

The KENO restart option is easy to activate. Certain changes can be made when a problem is restarted, including using a different random sequence or turning off certain print options such as fluxes or the fissions and absorptions by region.

KENO can also compute angular fluxes and flux moments in multigroup calculations, which are required to compute scattering terms for generation of sensitivity coefficients with the SAMS module or the TSUNAMI-

3D sequence. Fluxes can also be accumulated in a Cartesian mesh that is superimposed over the user-defined geometry in an automated manner.

KENO can perform Monte Carlo transport calculations concurrently on a number of computational nodes. By introducing a simple master-slave approach via MPI, KENO runs different random walks concurrently on the replicated geometry within the same generation. Fission source and other tallied quantities are gathered at the end of each generation by the master process and are then processed either for final edits or subsequent generations. Code parallel performance is strongly dependent on the size of the problem simulated and the size of the tallied quantities.

8.1.3 KENO DATA GUIDE

KENO may be run stand alone or as part of a SCALE criticality safety or sensitivity and uncertainty analysis sequence. If KENO is run stand alone in the multigroup mode, cross section data can be used from an AMPX [DG02] working format library or from a Monte Carlo format cross section library. If KENO uses an AMPX working format library, a mixing table data block must be entered. If a Monte Carlo format library is used, a mixing table data block is not entered, and the mixtures specified in the KENO geometry description must be consistent with the mixtures created on the Monte Carlo format library file.

If KENO is run stand alone in the continuous energy mode, a mixing table data block must be provided unless the restart option is used.

If KENO is run as part of a SCALE sequence, the mixtures are defined in the sequence input; therefore, a mixing table data block cannot be entered in KENO. Furthermore, the mixture numbers used in the KENO geometry description must correspond to those defined in the composition data block of the sequence input. To use a cell-weighted mixture in KENO, the keyword `CELLMIX=`, followed by a unique mixture number, must be specified in the cell data input block of the sequence. Note that cell data are applicable only in the multigroup mode. The mixture number used in the KENO input is the unique mixture number immediately following the keyword `CELLMIX`. A cell-weighted mixture is available only in SCALE sequences that use XSDRN to perform a cell-weighting calculation using a multigroup cross section library. Table 8.1.1 through Table 8.1.16 summarize the KENO input data blocks. These input data blocks are discussed in detail in the following sections. See CSAS, TRITON, and TSUNAMI manuals for more details and tips about how KENO is used as part of these sequences.

To run KENO in parallel (standalone execution), the user must provide the module name with the `%` prefix in the input file (e.g., `=%kenovi`), and provide the required arguments in the command line for parallel execution. The `%` prefix is not required if KENO is run as part of a SCALE sequence. Sequences such as CSAS, TRITON, and TSUNAMI-3D automatically initiate parallel KENO execution if the user provides the required arguments in the command line while running this code.

Warning: KENO can be run in parallel if SCALE has been built with MPI. SCALE pre-built binaries disseminated with each SCALE release are usually not MPI-enabled binaries.

Table 8.1.1: Summary of KENO parameter data

PARAMETERS:		Format: `READ PARAM` *parameter_data* `END PARAM` If parameters are entered, they must follow the sequence ID, title, and cross section library name See Sect. 8.1.3.3, Sect. 8.1.4.2, and Sect. 8.1.4.3 for further details.			
KEY	**DEFAULT**	**DEFINITION**	**KEY**	**DEFAULT**	**DEFINITION**

Table 8.1.2: Summary of array data.

ARRAY Format: READ ARRAY array parameters data type orientation data END ARRAY See Sections on ARRAY Data, Geometry, and alternative sample problem mockups

Repeat the sequence ARRAY PARAMETERS DATA TYPE ORIENTATION DATA for each array used in the problem.

ARRAY PARAMETERS

KEYWORD	DEFAULT	DEFINITION
ARA=	none[a]	no. defining the array
TYP=	Cuboidal[c]	array type (cuboidal or square, hexagonal or triangular, shexagonal, rhexagonal, dodecahedral)
NUX=	none[a]	no. of units in X direction
NUY=	none[a]	no. of units in Y direction
NUZ=	none[a]	no. of units in Z direction
GBL=	none[b]	global or overall array number
PRT=	YES	print any label
COM=	none	delim comment delim optional, maximum of 132 characters

ORIENTATION DATA FOR FILL

Enter unit numbers to define every position in the array. When entering data using the options in this table, the count and option fields must be adjacent with no imbedded blanks. The operand field may be separated from the option field by one or more blanks. Orientation data for FILL is terminated by entering END FILL.

COUNT FIELD	OPTION FIELD	OPERAND FIELD	COMMENTS
		j	stores j at the current position in the array
i	R, *, $	j	stores j in the next i positions in the array
	F	j	fills remainder of the array with unit no. j starting with the current array position
	A	j	sets the current position in the array to j
i	S		increments current position in the array by i (This allows skipping i positions. The value of i may be positive or negative.)
i	Q	j	repeats the previous j entries i times. The default value of i is 1
i	N	j	repeats the previous j entries i times, inverting the sequence each time. The default value of i is 1.
i	B	j	starting with the entry at -i from the current position, store entries in inverse order until position -(i+1) is reached. Default value of i=1.
i	I	j k	provides the end points (j, k) with i entries linearly interpolated between them (i.e., a total of i+2 points). At least one blank must separate j and k. When used for an integer array, the i option should only be used to generate integer steps (i.e., (k-j)/(i+1) should be a whole number).

ORIENTATION DATA FOR LOOP

Enter the unit number and nine numbers that define the position(s) of that unit. Data for each of these ten entries are repeated until every position in the array has been defined. Orientation data for LOOP are terminated by entering END LOOP.
ENTER DATA IN THE FORM:

DATA ENTRY	COMMENTS
LTYPE	The unit type. LTYPE must be greater than 0.
IX1	Starting position in the X direction. IX1 must be at least 1 and no larger than the value entered for NUX.
IX2	Ending position in the X direction. IX2 must be at least 1 and no larger than the value of NUX.
INCX	The number of units by which increments are made in the X direction.
IY1	The starting position in the Y direction. IY1 must be at least 1 and less than the value entered for NUY.
IY2	Ending position in the Y direction. IY2 must be at least 1 and no larger than the value of NUY.
INCY	The number of units by which increments are made in the positive Y direction.
IZ1	Starting position in the Z direction. IZ1 must be at least 1 and no larger than NUZ.
IZ2	Ending position in the Z direction. IZ2 must be at least 1 and no larger than NUZ.
INCZ	The number of units by which increments are made in the positive Z direction.

[a] In KENO Va the default is 1

[b] In KENO Va the default is the largest array number, *maxarr*

Table 8.1.3: Summary of biasing data.

BIAS (weighting)

Format: **READ BIAS** keyword correlation data auxiliary data **END BIAS**

See sections on Biasing or weighting data

KEYWORD	DESCRIPTION	MATERIAL	ID	ENERGY GROUPS	THICKNESS/ INCREMENT

ID= CORRELATION DATA will be read next.

CORRELATION DATA

id	material ID. Enter ID from table at right to use	concrete	301	28,56,200,238,252	5 cm
	weighting data from the library	paraffin	400	28,56,200,238,252	3 cm
ibgn	beginning bias ID	water	500	28,56,200,238,252	3 cm
iend	ending bias ID	graphite	6100	28,56,200,238,252	20 cm

WT= AUXILIARY DATA will be read next.

or

WTS= AUXILIARY DATA will be read next.

AUXILIARY DATA

wttitl	material title (12-character maximum)
id	material ID
nsets	number of sets of group structures
REPEAT	(THKINC, NUMINC, NGPWT, WTAVG) NSETS TIMES
thkinc	thickness per increment
numinc	number of increments
ngpwt	number of energy groups for this set of wts
wtavg	enter numinc x ngpwt values of wtavg

For CORRELATION DATA, the material ID is chosen from the material **ID** column above (the keyword is **ID=**).
For AUXILIARY DATA, the material ID is chosen by the user, and the keyword is **WT=** or **WTS=**. When AUXILIARY DATA are entered, CORRELATION DATA must also be entered to use the data.

Beginning and ending bias IDs are defined by the user. The geometry specification that has the bias ID equal to the beginning bias ID uses the wtavg's from the first interval of material ID.

SIMPLE GEOMETRY REGION INPUT DATA REQUIREMENTS

TYPE OF DATA	TYPE 1 DATA	TYPE 2 DATA	TYPE 3 DATA	TYPE 4 DATA	TYPE 5 DATA	TYPE 6 DATA
fgeom	SPHERE HEMISPHERE HEMISPHE+X HEMISPHE−X HEMISPHE+Y HEMISPHE−Y HEMISPHE+Z HEMISPHE−Z	XCYLINDER XHEMICYL+Y XHEMICYL−Y XHEMICYL+Z XHEMICYL−Z	YCYLINDER YHEMICYL+X YHEMICYL−X YHEMICYL+Z YHEMICYL−Z	CYLINDER ZCYLINDER ZHEMICYL+X ZHEMICYL−X ZHEMICYL+Y ZHEMICYL−Y	CUBE	CUBOID
dimensions	R (radius)	R +X −X	R +Y −Y	R +Z −Z	+X −X	+X −X +Y −Y +Z −Z
optional origin coordinates*	Enter the X Y Z coordinates of origin	Enter the Y Z coordinates of centerline	Enter the X Z coordinates of centerline	Enter the X Y coordinates of centerline	omit	omit
optional chord data**	Enter the dist. to plane	Enter the dist. to plane	Enter the dist. to plane	Enter the dist. to plane	omit	omit
optional center data***	Center type	X-offset	X-offset	Z-offset	omit	omit

*Enter ORIG or ORIGIN for *fgeom*.

**Enter CHORD for *fgeom*.

***Center data are only applicable when flux moments (PNM>0) or angular fluxes (NQD>0) are requested with the coordinate transform (TFM) set to YES.

NOTE: Chord data are not applicable for SPHERE, XCYLINDER, YCYLINDER, CYLINDER, ZCYLINDER, CUBE, or CUBOID.
Origin data are not applicable for a CUBE or CUBOID.

GEOMETRY (region) (continued)

ENTER GEOMETRY DATA IN THE FOLLOWING FORM:

fgeom ref. ID bias ID thickness per region origin coordinates nreg

EXTENDED GEOMETRY REGION INPUT DATA REQUIREMENTS

TYPE OF DATA	TYPE 1 DATA	TYPE 2 DATA	TYPE 3 DATA
fgeom	ARRAY	HOLE	REPLICATE REFLECTOR
ref. ID	array no.	emplaced unit number	mixture number in generated regions
bias ID	omit for ARRAY	omit	first bias ID
thickness / region	omit	omit	variable▫
origin coordinates	Enter the X Y Z coordinates of the most negative point of the array	Enter the X Y Z coordinates of the origin	omit
nreg	omit	omit	number of regions to be generated

▫The number of dimensions to be entered is the same as the region preceding the replicate or reflector specification because the g enerated regions have that shape. The value of the dimensions is the thickness of each generated region of material on that surface and must therefore be a positive value.

Table 8.1.9: Summary of geometry data in KENO-VI.

GEOMETRY (region)

Format: READ GEOM enter geometry region data here END GEOM.. See Appendix B.
GEOMETRY REGION DATA consist of SIMPLE GEOMETRY REGION DATA and EXTENDED GEOMETRY REGION DATA.
* *
ENTER DATA IN THE FOLLOWING FORM:
GLOBAL Enter once to specify this unit as the global unit.
UNIT n
COM=delim comment delim This optional comment can be up to 132 characters. It must begin and end with a delimiter (i.e. " , ' , * , ^ , or !).
Geometry Keyword Label Input Parameters Optional origin data (ORIGIN) Optional chord data (CHORD) Optional rotation data (ROTATE degrees)
Media Keyword Input Parameters
Boundary Keyword Input Parameters Each unit must have one boundary record.
Enter as many geometry and content descriptions as necessary to describe the unit and as many units as necessary to describe the system.

GEOMETRY REGION INPUT DATA REQUIREMENTS

TYPE OF DATA	KEYWORD	INPUT PARAMETERS	NOTES
GEOMETRY	CONE	Lbl Rt Zt Rb Zb	
	CUBOID	Lbl +X −X +Y −Y +Z −Z	
	CYLINDER	Lbl R Zt Zb	
	DODECAHEDRON	Lbl R	
	ECYLINDER	Lbl Rx Ry Zt Zb	
	ELLIPSOID	Lbl Rx Ry Rz	
	HEXPRISM	Lbl R Zt Zb	
	HOPPER	Lbl Lxt Lyt Zt Lxb Lyb Zb	
	PARALLELPIPED	Lbl Xdist Ydist Zdist Psi Theta Phi	
	PENTAGON	Lbl R Zt Zb	
	PLANE	Lbl XPL=a YPL=b ZPL=c CON=d	For geometry keywords, PLANE and QUADRATIC data are entered after the = following the respective subordinate keyword. Only nonzero data are required.
	QUADRATIC	Lbl AQU=a BQU=b CQU=c DQU=d EQU=e FQU=f GQU=g HQU=h IQU=i JQU=j	
	RHEXPRISM	Lbl R Zt Zb

	ZPPLANE	Lbl Zt Zb	
MODIFICATION*	CHORD	+X= −X= +Y= −Y= +Z= −Z=	Only nonzero data are required.
	ORIGIN	X= Y= Z=	Only nonzero data are required.
	ROTATE	A1= A2= A3=	The body is rotated about the Origin using the Euler angle X-convention. Only nonzero data are required; input is in degrees.
MEDIA**	MEDIA	Mixture ID Bias ID i1 i2 . . .	
	HOLE	Hole unit number	
	ARRAY	Array ID i1 i2 . . . PLACE nx ny nz xx yy zz	Place positions the array by placing the origin of the unit in array position nx ny nz at xx yy zz. The region boundary containing the array must be enclosed in or on the array boundary.
BOUNDARY	BOUNDARY	i1 i2 ...	Defines the overall volume of the unit.

*Modification data can be entered in any order. Any combination of modification data can follow any geometry record.
**The Region definition vector, i1 i2 . . ., should contain references to all geometry records which share a boundary with t he region being defined.

Table 8.1.10: Summary of mixing table data.

MIXTURES

Format: READ MIXT xsec parameters mixing table data. END MIXT
Multigroup mode: These data are entered only if an AMPX working format library is being used. (LIB=) in the parameter data, s ee section on Title and parameter data. Do not enter if a Monte Carlo mixed library is used, (XSC=) in the parameter data.
Continuous energy mode: Only the mixing table data are entered. See sections on Mixing table and Mixing table data.

XSEC PARAMETERS — consists of keywords and associated values.
These parameters, if entered, only need to be entered once.

KEYWORD	DEFAULT	DEFINITION
SCT=	1	number of discrete scattering angles 0 is isotropic 1 is P1 2 is P3 3 is P5
EPS=	0.1	cross section message cutoff value used to suppress message numbers K5-060 and K6-060.

MIXING TABLE DATA consists of
(1) a keyword and mixture ID for the mixture
The keyword is MIX=
The desired mixture number follows the keyword
(1a) optionally, a keyword and nuclide mixture ID for the rest of the current mixture
The keyword is NCM=
The desired nuclide mixture ID follows the keyword
(1b) optionally, a keyword and temperature for the mixture (used for continuous energy problems)
The keyword is TMP= or TEM=
The desired temperature in Kelvin follows the keyword
(2) nuclide ID**
(2a) optionally a keyword and nuclide mixture ID for this nuclide
The keyword is NCM= and the desired nuclide mixture ID follows the keyword
(3) number density**
(4) continuous energy cross section filename**
** The sequence (2) (3) (4) is repeated for each nuclide in the mixture. Entry (4) is optional and entered with XS= name where name is the filename.

REPEAT the sequence (1) (2)s (3)s (4)s until all the mixtures have been described.

Table 8.1.11: Summary of plot data.

PLOT — Format: READ PLOT plot parameters END PLOT — plot parameters must be entered for each plot that is to be made.
See sections Plot data and Color plots.

KEYWORD	DEFAULT	DEFINITION
TTL=	prob. title	delim ptitl delim — delim is a one-character delimiter (i.e. ' , " , * , / , or !) that signals the beginning and end of the title.
		ptitl is the plot title (max. 132 char.)
PIC=	MAT	Type of plot: MIXTURE NO., UNIT NO. or BIAS ID NO.
		MIXTURE ----------MAT MIX MIXT MIXTURE MEDI MEDIA
		UNIT NO. ----------UNT UNIT UNITTYPE
		BIAS ID NO. -------IMP BIAS BIASID WTS WEIG WEIGHTS WGT WGTS
XUL=	prev. plot	X coord. of upper left corner of plot
YUL=	prev. plot	Y coord. of upper left corner of plot
ZUL=	prev. plot	Z coord. of upper left corner of plot
XLR=	prev. plot	X coord. of lower right corner of plot
YLR=	prev. plot	Y coord. of lower right corner of plot
ZLR=	prev. plot	Z coord. of lower right corner of plot

KEYWORD	DEFAULT	DEFINITION
UAX=	prev. plot 0 IF VAX OR WAX is read	X component of direction cosine for the AX axis of the plot (across)
VAX=	prev. plot 0 IF UAX OR WAX is read	Y component of direction cosine for the AX axis of the plot (across)
WAX=	prev. plot 0 IF UAX OR VAX is read	Z component of direction cosine for the AX axis of the plot (across)
UDN=	prev. plot 0 IF VDN OR WDN is read	X component of direction cosine for the DN axis of the plot (down)
VDN=	prev. plot 0 IF UDN OR WDN is read	Y component of direction cosine for the DN axis of the plot (down)
WDN=	prev. plot 0 IF UDN OR VDN is read	Z component of direction cosine for the DN axis of the plot (down)
DLX=		Horizontal spacing between points on plot
DLD=		Vertical spacing between points on plot
NAX=		No. of intervals to be printed across page
NDN=		No. of intervals to be printed down page
LPI=	8.0 (character plots) 10 (color plots)	Vertical to horizontal scaling factor for plot proportionality.
RUN=	YES	YES allows the problem to execute NO terminates problem after data checking
PLT=	YES	YES allows the plot(s) to be made NO allows reading the plot data without making a plot
SCR=	YES	Display plot method SCR=YES utilizes color plot display SCR=NO utilizes printer plot display
NCH=	CHRS[c]	delim CHRS delim a one character delimiter[b] signals the beginning and end of the character string
CLR=	See Table on default color specifications for the color plot display method	num(i) red(num(i)) green (num(i)) blue (num(i)) num(i) defines mix. no., unit no., or bias ID next 3 entries define red, green, and blue components of the color representing num(i).

PLOT ORIGIN:
(1) SINGLE UNIT - coincides with origin of geometry description.
(2) BASE ARRAY - at the most negative point of the global array
(3) REFLECTED ARRAY - coincides with the origin of the CORE or ARRAY description of the global array.

[c] Default values of CHRS are given below:

MEDIA	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22
CHRS		1	2	3	4	5	6	7	8	9	A	B	C	D	E	F	G	H	I	J	K	L	M

KEYWORD	DEFAULT	DEFINITION
NST=	0	start type
TFX=	0.0	X coordinate
TFY=	0.0	Y coordinate
TFZ=	0.0	Z coordinate
NXS=	0	X index of unit pos.
NYS=	0	Y index of unit pos.
NZS=	0	Z index of unit pos.
KFS=		fissile mixture no.
LNU=	0	number of last neutron
NBX=	0	source unit number
FCT=	0	fraction
XSM=	−X	−X of source cuboid
XSP=	+X	+X of source cuboid
YSM=	−Y	−Y of source cuboid
YSP=	+Y	+Y of source cuboid
ZSM=	−Z	−Z of source cuboid
ZSP=	+Z	+Z of source cuboid
RFL=	NO	start in reflector
PS6=	NO	print start 6 input
PSP=	NO	print starting points
RDU=	0	unit containing start data
WS6=	0	unit to write start data

[1] RFL is no longer supported (obsolete parameter)

[2] LNU must be the last entry for each set of start 6 data. The LNU of each successive set of data must be larger than the last.

Table 8.1.13: Summary of volume data (KENO-VI).

KEYWORD — Format: READ VOLUME enter volume data here END VOLUME
The default type for volume calculation type is NONE. See section Volume Data.

Table 8.1.14: Summary of grid geometry data.

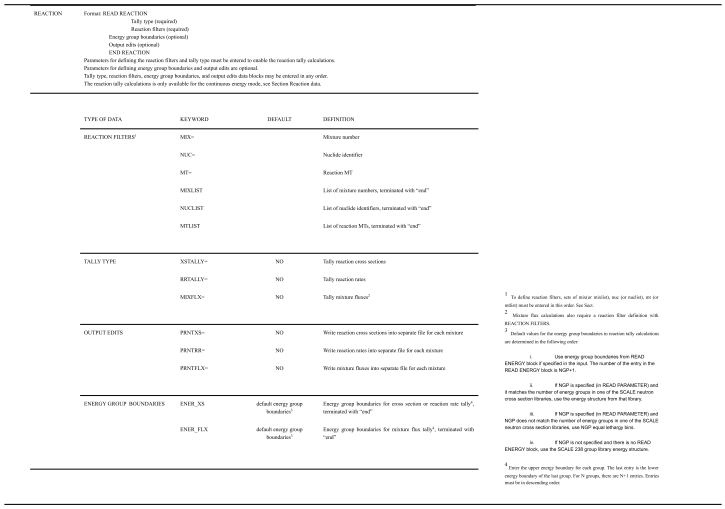
GRID	Format: READ GRID enter grid data here END GRID See Section Grid Geometry Data.		
	KEYWORD	DEFAULT	DEFINITION
	None	-1	grid ID number, required if multiple mesh is defined
	NXCELLS= NUMXCELLS=	1	number of cells in the the X direction
	XMIN=	0	minimum cell boundary in the X direction
	XMAX=	1	maximum cell boundary in the X direction
	or		
	XPLANES	[0,1]	the cell boundaries in the X direction
	XLINEAR		*ncells; xmin; xmax* Number of cells in the X direction; X minimum; X maximum
	NYCELLS= NUMYCELLS=	1	number of cells in the Y direction
	YMIN=	0	minimum cell boundary in the Y direction
	YMAX=	1	maximum cell boundary in the Y direction
	or		
	YPLANES=	[0,1]	the cell boundaries in the Y direction
	YLINEAR		*ncells; ymin; ymax* Number of cells in the Y direction; Y minimum; Y maximum
	NZCELLS= NUMZCELLS=	1	number of cells in the Z direction
	ZMIN=	0	minimum cell boundary in the Z direction
	ZMAX=	1	maximum cell boundary in the Z direction
	or		
	ZPLANES=	[0,1]	the cell boundaries in the Z direction
	ZLINEAR		*ncells; zmin; zmax* Number of cells in the Z direction; Z minimum; Z maximum
	TITLE=	' '	a title for this grid mesh
	TOLERANCE=	1.0E-6	For removing duplicate planes from *PLANES or *LINEAR

Note: The grid must be defined for MG TSUNAMI-3D calculations so that the entire system lies inside the boundaries of the geometry grid. Multiple grids are defined by entering this block multiple times.

Table 8.1.15: Summary of energy group boundaries data.

ENERGY	Format: READ ENERGY energy group boundaries END ENERGY Enter upper energy boundary for each group in eV. The last entry is the lower energy boundary of the last group. For N groups, there are N+1 entries. Entries must be in descending order and in units of eV.

Table 8.1.16: Summary of reaction data.



REACTION

Format: READ REACTION
Tally type (required)
Reaction filters (required)
Energy group boundaries (optional)
Output edits (optional)
END REACTION
Parameters for defining the reaction filters and tally type must be entered to enable the reaction tally calculations.
Parameters for defining energy group boundaries and output edits are optional.
Tally type, reaction filters, energy group boundaries, and output edits data blocks may be entered in any order.
The reaction tally calculations is only available for the continuous energy mode, see Section Reaction data.

TYPE OF DATA	KEYWORD	DEFAULT	DEFINITION
REACTION FILTERS[1]	MIX=		Mixture number
	NUC=		Nuclide identifier
	MT=		Reaction MT
	MIXLIST		List of mixture numbers, terminated with "end"
	NUCLIST		List of nuclide identifiers, terminated with "end"
	MTLIST		List of reaction MTs, terminated with "end"
TALLY TYPE	XSTALLY=	NO	Tally reaction cross sections
	RRTALLY=	NO	Tally reaction rates
	MIXFLX=	NO	Tally mixture fluxes[2]
OUTPUT EDITS	PRNTXS=	NO	Write reaction cross sections into separate file for each mixture
	PRNTRR=	NO	Write reaction rates into separate file for each mixture
	PRNTFLX=	NO	Write mixture fluxes into separate file for each mixture
ENERGY GROUP BOUNDARIES	ENER_XS	default energy group boundaries[3]	Energy group boundaries for cross section or reaction rate tally[4], terminated with "end"
	ENER_FLX	default energy group boundaries[3]	Energy group boundaries for mixture flux tally[4], terminated with "end"

[1] To define reaction filters, sets of mixture number, nuc (or nuclide), mt (or nuclide) must be entered in this order. See Sect.

[2] Mixture flux calculations also require a reaction filter definition with REACTION FILTERS.

[3] Default values for the energy group boundaries in reaction tally calculations are determined in the following order:

i. Use energy group boundaries from READ ENERGY block if specified in the input. The number of the entry in the READ ENERGY block is NGP+1.

ii. If NGP is specified (in READ PARAMETER) and it matches the number of energy groups in one of the SCALE neutron cross section libraries, use the energy structure from that library.

iii. If NGP is specified (in READ PARAMETER) and NGP does not match the number of energy groups in one of the SCALE neutron cross section libraries, use NGP equal-lethargy bins.

iv. If NGP is not specified and there is no READ ENERGY block, use the SCALE 238 group library energy structure.

[4] Enter the upper energy boundary for each group. The last entry is the lower energy boundary of the last group. For N groups, there are N+1 entries. Entries must be in descending order.

8.1.3.1 Keno input outline

The data input for KENO is outlined below. Default data for KENO have been found to be adequate for many problems. These values should be carefully considered when entering data.

Blocks of input data are entered in the form:

`READ XXXX` *input_data* `END XXXX`

where `XXXX` is the keyword for the type of data being entered. The keywords that can be used are listed in Table 8.1.17. A minimum of four characters is required for a keyword, and some keyword names may be as long as twelve characters (`READ PARAMETER`, `READ GEOMETRY`, etc.). Keyword inputs are not case sensitive. Data input is activated by entering the words `READ XXXX` followed by one or more blanks. All input data pertinent to `XXXX` are then entered. Data for `XXXX` are terminated by entering `END XXXX` followed by two or more blanks. Note that multiple `READ GRID` blocks are used if multiple grid definitions are needed.

Table 8.1.17: Types of input data.

Type of data	**Keyword**
Parameters	`PARAMETER`, `PARA` or `PARM`
Geometry	`GEOMETRY`, `GEOM`
Biasing	`BIAS`
Boundary conditions	`BOUNDS`, `BOUN` or `BNDS`
Start	`START`, `STAR` or `STRT`
Energy	`ENERGY` or `ENER`
Array (unit orientation)	`ARRAY` or `ARRA`
Extra 1-D cross sections	`X1DS`
Cross section mixing table[a]	`MIXT` or `MIX`
Plot[a]	`PLOT` or `PLT` or `PICT`
Volumes	`VOLUME`
Grid geometry	`GRIDGEOMETRY`, `GRIDGEOM`, or `GRID`
Reactions	`REACTION`, `REAC`
[a] MIX and PLT must include a trailing blank, which is considered part of the keyword.	

Three data records must be entered for every problem:

(1) the SCALE sequence identifier,

(2) the problem title,

(3) and the `END DATA` to terminate the problem.

KENO V.a or KENO-VI are typically run as part of CSAS, TRITON, or TSUNAMI sequences, but it may also be run standalone. For standalone KENO execution, the sequence identifier is specified using one line similar to:

```
=kenovi
```

A problem title **must be entered** and must immediately follow the sequence identifier (limit 80 characters, including blanks; extra characters will be discarded). See Sect. 8.1.3.3.

The following guidance generally assumes the user is running KENO stand alone. If KENO is to be run using of the other sequences (e.g., CSAS5), see the appropriate manual section for additional guidance.

`READ PARA` *parameter_data* `END PARA`

Enter parameter input as needed to describe a problem. If parameter data are desired in standalone KENO calculations (i.e., non-CSAS), they must immediately follow the problem title. Default values are assigned to all parameters. A problem **can** be run without entering any parameter data if the default values are acceptable.

Parameter data must begin with the words `READ PARA`, `READ PARM`, or `READ PARAMETER`. Parameter data may be entered in any order. If a parameter is entered more than once, the last value is used. The words `END PARA` or `END PARM`, or `END PARAMETER` terminate the parameter data. See Sect. 8.1.3.3.

(n_1)...(n_{13}) The following data may be entered in any order. Data not needed to describe the problem may be omitted.

(n_1) `READ GEOM` *all_geometry_region_data* `END GEOM`

Geometry region data must be entered for every problem that is not a restart problem. Geometry data must begin with the words `READ GEOM` or `READ GEOMETRY`. The words `END GEOM` or `END GEOMETRY` terminate the geometry region data. See Sect. 8.1.3.4.

(n_2) `READ ARRA` *array_definition_data* `END ARRA`

Enter array definition data as needed to describe the problem. Array definition data define the array size and position units (defined in the geometry data) in a 3-D lattice that represents the physical problem being analyzed. Array data must begin with the words `READ ARRA` or `READ ARRAY` and must terminate with the words `END ARRA` or `END ARRAY`. See Sect. 8.1.3.5.

(n_4) `READ BOUN` *albedo_boundary_conditions* `END BOUN`

Enter albedo boundary conditions as needed to describe the problem. Albedo data must begin with the words `READ BOUN`, `READ BNDS`, `READ BOUND`, or `READ BOUNDS`, and it must terminate with the words `END BOUN`, `ENDS BNDS`, `END BOUND`, or `END BOUNDS`. See Sect. 8.1.3.6.

(n_3) `READ BIAS` *biasing_information* `END BIAS`

The *biasing_information* is used to define the weight given to a neutron surviving Russian roulette. Biasing data must begin with the words READ BIAS. The words END BIAS terminate the biasing data. See Sect. 8.1.3.7.

(n_5) READ STAR *starting_distribution_information* END STAR

Enter starting information data for starting the initial source neutrons only if a uniform starting distribution is undesirable. Start data must begin with the words READ STAR, READ STRT or READ START, and it must terminate with the words END STAR, END STRT or END START. See Sect. 8.1.3.8.

(n_6) READ ENER *energy_group_boundaries* END ENER

Enter upper energy boundaries for each neutron energy group to be used for tallying in the continuous energy mode. Energy bin data begin with the words READ ENER or READ ENERGY and terminate with the words END ENER or END ENERGY. The last entry is the lower energy boundary of the last group. The values must be in descending order. This block is only applicable to continuous energy KENO calculations. See Sect. 8.1.3.12.

(n_7) READ MIXT *cross_section_mixing_table* END MIXT

Enter a mixing table to define all the mixtures to be used in the problem. The mixing table must begin with the words READ MIXT or READ MIX and must end with the words END MIXT or END MIX. Do not enter mixing table data if KENO is being executed as a part of a SCALE sequence. See Sect. 8.1.3.10.

(n_8) READ X1DS *extra_1-D_cross_section_IDs* END X1DS

Enter the IDs of any extra 1-D cross sections to be used in the problem. These must be available on the mixture cross section library. Extra 1-D cross section data must begin with the words READ X1DS and terminate with the words END X1DS. See Sect. 8.1.3.9.

(n_9) READ PLOT *plot_data* END PLOT

Enter the data needed to provide a 2-D character or color plot of a slice through a specified portion of the 3-D geometrical representation of the problem. Plot data must begin with the words READ PLOT, READ PLT, or READ PICT and terminate with the words END PLOT, END PLT, or END PICT. See Sect. 8.1.3.11.

(n_{10}) READ VOLUME *volume_data* END VOLUME

Enter the data needed to specify the volumes of the geometry data. Volume data must begin with the words READ VOLUME and end with the words END VOLUME. See Sect. 8.1.3.13.

(n_{11}) READ GRID *mesh_grid_data* END GRID

Enter the data needed to specify a simple Cartesian grid over either the entire problem or part of the problem geometry for tallying fluxes, moments, fission sources, etc. Grid data may be entered using the keywords READ GRID, READ GRIDGEOM, or READ GRIDGEOMETRY, and they are terminated with either END GRID, END GRIDGEOM, or END GRIDGEOMETRY. Multiple grids may be defined by repeating the READ GRID block several times, specifying a different mesh grid identification number for each so defined grid. See Sect. 8.1.3.14 for further information.

(n_{12}) READ REAC *reaction_data* END REAC

Enter the data needed to specify filters for the reaction tally calculations. Reaction data must begin with the words READ REAC and terminate with END REAC. This block is only applicable to calculations in the continuous energy mode. See Sect. 8.1.3.15.

(n_{13}) END DATA must be entered

Terminate the data for the problem.

8.1.3.2 Procedure for data input

For a standalone KENO problem, the first data records **must** be the sequence identifier (e.g., =kenovi or =kenova) and the title. The next block of data **must** be the parameters if they are to be entered. A problem can be run without entering the parameters, which causes KENO to use default values for input parameters. The remaining blocks of data can be entered in any order.

Keywords are deonated using FIXED-WIDTH. A keyword is used to identify the data that follow it. When a keyword is used, it must be entered exactly as shown in the data guide. All keywords except those ending with an equal sign must be followed by at least one blank.

small_italics correlate data with a program variable name. The actual values are entered in place of the program variable name and are terminated by a blank or a comma.

CAPITAL ITALICS identify general data items. General data items are general classes of data including:

(1) geometry data such as *UNIT INITIALIZATION* and *UNIT NUMBER DEFINITION*, *GEOMETRY REGION DESCRIPTION*, *GEOMETRY WORD*, *MIXTURE NUMBER*, *BIAS ID*, and *REGION DIMENSIONS*,

(2) albedo data such as *FACE CODES* and *ALBEDO NAMES*,

(3) weighting data such as *BIAS ID NUMBERS*, etc.

The square brackets, [and], are used to show that an entry is optional.

The broken line, |, is used as a logical "or" symbol to show that the entries to its left and right are alternatives that cannot be used simultaneously.

8.1.3.3 Title and parameter data

A *title*, a character string, must be entered at the top of the input file. The syntax is:

title a string of characters with a length of up to 80 characters, including blanks.

The PARAMETER block may contain parameter initializations for those parameters that need to be changed from their default value. The syntax for the PARAMETER block is:

READ PARA[METER] *p1* ... *pN* END PARA[METER]

or

READ PARM *p1* ... *pN* END PARM

p1 ... *pN* are *N* (*N* greater than or equal to zero) keyworded parameters that together make up the *PARAMETER DATA*

The commonly changed parameters are TME, GEN, NSK, and NPG. Seldom-changed parameters are NBK, NFB, XNB, XFB, WTH, WTL, TBA, BUG, TRK, and LNG.

The *PARAMETER DATA*, *p1 . . . pN*, consists of one or more of the parameters described below. Some of the parameters are valid either for only multigroup or continuous-energy mode. All below parameters and their values are printed in the Numeric Parameters or Logical Parameters output edits, regardless of whether the parameter is valid in the current transport mode (either multigroup or continous energy).

Floating point parameters

`RND` = *rndnum* input hexadecimal random number, a default value is provided.

`TME` = *tmax* execution time (in minutes) for the problem, default = 0.0 (no limit).

> **Caution:** Note that it is only tested at the end of each generation whether the given time limit has been exceeded. The job may be terminated without completing all generations or finalizing all results for output editing if *tmax* has not been entered carefully.

`TBA` = *tbtch* time allotted for each generation (in minutes), default = 10 minutes. If *tbtch* is exceeded in any generation, the problem is assumed to be looping. Execution is terminated, and final edits are performed. The problem can loop indefinitely on a computer if the system-dependent routine to interrupt the problem (PULL) is not functional. `TBA=` is also used to set the amount of time available for generating the initial starting points.

`SIG` = *tsigma* if entered and > 0.0, this is the standard deviation at which the problem will terminate, default = 0.0, which means do not check sigma.

`WTA` = *dwtav* the default average weight given a neutron that survives Russian roulette, *dwtav* default = 0.5.

`WTH` = *wthigh* the default value of *wthigh* is 3.0 and should be changed only if the user has a valid reason to do so. The weight at which splitting occurs is defined to be *wthigh x wtavg*, where *wtavg* is the weight given to a neutron that survives Russian roulette.

`WTL` = *wtlow* Russian roulette is played when the weight of a neutron is less than *wtlow x wtavg*. The *wtlow* default = 1.0/*wthigh*.

Note: The default values of *wthigh* and *wtlow* have been determined to minimize the deviation per unit running time for many problems.

`TTL` = *temperature_tolerance* the continuous energy cross sections must be within the *temperature_tolerance* (in degrees Kelvin) of the requested temperature for the problem to run. A negative value specifies the use of the closest temperature to that requested. TTL is ignored when `DBX` is nonzero. The default = -1.0.

Note:

If a parameter entered is not valid for the current transport mode (either multigroup or continuous energy mode), KENO usually ignores this parameter without a warning. Although a parameter is ignored, its user-defined value may appear in Numeric Parameters or Logical Parameters output edits.

THC = *ethermal_cutoff* the thermal cutoff energy for bound and free-gas moderators in continuous-energy transport. The cutoff energy for the thermal neutron transport treatments is represented by a single energy for all nuclides. If the incident energy is below THC, then thermal scattering kinematics are governed by $S(\alpha,\beta)$ data or the free-gas treatment. If incident energy is greater than THC, then the energy of the motion of the nuclei is considered negligible compared to the neutron energy. See Sect. 8.1.7.2.17 for more details. The default = 10.0 eV.

DBH = *dbrc_high* the energy cutoff (in eV) up to which the Doppler Broadening Rejection Correction (DBRC) method will be used on nuclides for which DBRC is enabled, and cross section libraries are available. DBH is used only in continuous-energy mode. Default = 210.0 eV.

DBL = *dbrc_low* the energy cutoff (in eV) down to which DBRC will be used on nuclides for which DBRC is enabled and cross section libraries are available. Only used in continuous-energy mode. Default = 0.4 eV.

MSH = *mesh_size* length (cm) of one side of a cubic mesh for tallying fluxes, fission source or fission densities. Default = 0.0. A positive non-zero value must be entered if one of MFX, CDS, FIS, or GFX parameters is defined as *YES* and **KENO grid data** input is not entered. See Sect. 8.1.4.11 for more details.

Integer parameters

GEN = *nba* number of generations to be run, default = 203.

NPG = *npb* number of neutrons per generation, default = 1000.

NSK = *nskip* number of generations (1 through *nskip*) to be omitted when collecting results, default = 3.

RES = *nrstrt* number of generations between writing restart data, default = 0. If RES is zero, restart data are not written. When restarting a problem, RES is defaulted to the value that was used when the restart data block was written. Thus, it must be entered as zero to terminate writing restart data for a restarted problem.

BEG = *nbas* beginning generation number, default = 1. If BEG is greater than 1, then restart data must be available. BEG must be 1 greater than the number of generations retrieved from the restart file.

NGP = *ngp* number of neutron energy groups to be used for tallying in continuous-energy mode. If **NGP** corresponds to a standard SCALE group structure, then the SCALE group structure will be used. If it does not correspond to a standard structure, then an equally spaced in lethargy group structure will be used. If nothing is specified for a continuous-energy problem, the SCALE 252-group structure will be used.

Note: In multigroup mode, default energy boundaries used for tallying are always obtained from the multigroup library used by transport, and **NGP** is defaulted accordingly. In continuous-energy mode, energy group boundaries read from **ENERGY** block override the default ngp value. **NGP** value printed in numeric parameters output edit may not reflect this update. The final **NGP** value is correctly printed in additional information output edit (shown as number of energy groups).

DBR = *lusedbrc* use the Doppler broadening rejection correction method. See Sect. 8.1.7.2.18 for more details. Used only in continuous-energy mode. Default = 2.

0 = no DBRC

1 = DBRC for ^{238}U only

2 = DBRC for all available nuclides (^{232}Th, ^{234}U, ^{235}U, ^{236}U, ^{238}U, ^{237}Np, ^{239}Pu, ^{240}Pu)

DBX = *db_xs_mode* option for performing problem-dependent or on-the-fly Doppler Broadening. See Sect. 8.1.7.2.19 for more details. Default = 2.

0 = no problem-dependent or on-the-fly Doppler Broadening

1 = perform problem-dependent Doppler Broadening for 1D cross sections only.

2 = perform problem-dependent Doppler Broadening for both 1D and 2D (thermal scattering data) cross sections.

CET = *ce_tsunami_mode* mode for CE TSUNAMI (See TSUNAMI-3D manual).

0 = no sensitivity calculations

1 = CLUTCH sensitivity calculation

2 = IFP sensitivity calculation

4 = GEAR-MC calculation (with CLUTCH only)

5 = GEAR-MC calculation (with CLUTCH+IFP)

7 = undersampling metric calculation

CFP = *number_of_latent_generations* number of latent generations used for IFP sensitivity or $F^*(r)$ calculations (See TSUNAMI-3D manual). If CET=1 and CFP= -1 then $F^*(r)$ is assumed to equal one everywhere. If CET=4 and CFP= -1 then $F^*(r)$ is assumed to equal zero everywhere.

NQD = *nquad* quadrature order for angular flux tallies, default = 0, which means do not collect. Angular fluxes are typically only needed for TSUNAMI-3D calculations(See TSUNAMI-3D manual).

PNM = *isctr* highest order of flux moment tallies, default = 0. Flux moments are typically only tallied for TSUNAMI-3D calculations (See TSUNAMI-3D manual).

X1D = *numx1d* number of extra 1D cross sections, default = 0.

NB8 = *nb8* number of blocks allocated for the first direct-access unit, default = 1000.

NL8 = *nl8* length of blocks allocated for the first direct-access unit, default = 512.

NBK = *nbank* number of positions in the neutron bank, default = *npb* + 25.

XNB = *nxnbk* number of extra entries in the neutron bank, default = 0.

NFB = *nfbnk* number of positions in the fission bank, default = *npb.*

XFB = *nxfbk* number of extra entries in the fission bank, default = 0.

Alphanumeric parameter data

CEP = *lcep* key for choosing the calculation mode in stand alone KENO calculations. The parameter is set to the appropriate value by the calling sequence if not stand alone KENO. For stand alone KENO, enter NO for multigroup mode, or enter the continuous energy directory filename for the continuous energy mode. The directory file is the file containing pointers to files significant for the continuous energy run.

FNI = *mode_in* extra field in the input restart file name [restart_*mode_in*.keno_input] and [restart_*mode_in*.keno_calculated]. The default is an empty field.

FNO = *mode_out* extra field in the output restart filename [restart_*mode_out*.keno_input] and [restart_*mode_out*.keno_calculated]. The default is an empty field.

Logical parameter data . . . enter *YES* or *NO*

APP = *lappend* key for appending the restart data, default = NO.

ADJ = *nadj* key for running adjoint calculation, default = NO. Adjoint cross sections must be available to run an adjoint problem. If LIB= is specified, the cross sections will be adjointed by the code. If XSC= is specified, the cross sections must already be in adjoint order.

PTB = *ptb* key for using probability tables in the continuous energy mode, default = YES

PNU = *lpromptnu* key for using prompt-only ν in the continuous energy mode, default = NO – use total.

FRE = *lfree_analytic* no longer supported (**obsolete parameter**).

UUM = *lUnionizedMix* use unionized mixture cross section, default = NO. Only used in continuous-energy mode. See Sect. 8.1.7.2.3 for more details.

M2U = *luseMap2Union* store cross sections for each nuclide on a unionized energy grid, default=NO. Only used in the continuous energy mode. See Sect. 8.1.7.2.3 for further details.

CFX = *nflx* collect fluxes, default = NO.

FLX = *nflx* key for collecting and printing fluxes, default = NO.

FDN = *nfden* key for collecting and printing fission densities, default = YES.

FAR = *lfa* key for generating region-dependent fissions and absorptions for each energy group, default = NO.

GAS = *lgas* key for printing region-dependent fissions and absorptions by energy group, applicable only if FAR = YES. Default = FAR. GAS = YES prints region-dependent data by energy group. GAS = NO suppresses region-dependent data by energy group.

NUB = *nubar* calculate the average number of neutrons per fission and the average energy group at which fission occurred, default = YES.

MFP = *mean-free-path* compute and print the mean-free-path of a neutron by region, default = NO.

SMU = *lmult* calculate the average self-multiplication of a unit, default = NO.

MKP = *larpos* calculate and print matrix k-effective by unit location, default = NO. Unit location may also be referred to as array position or position index.

CKP = *lckp* calculate and print cofactor k-effective by unit location, default = NO. Unit location may also be referred to as array position or position index.

FMP = *pmapos* print fission production matrix by array position, default = NO.

MKU = *lunit* calculate and print matrix k-effective by unit type, default = NO.

CKU = *lcku* calculate and print cofactor k-effective by unit type, default = NO.

FMU = *pmunit* print fission production matrix by unit type, default = NO.

MKH = *lmhole* calculate and print matrix k-effective by hole number, default = NO.

CKH = *lckh* calculate and print cofactor k-effective by hole number, default = NO.

FMH = *pmhole* print fission production matrix by hole number, default = NO.

MKA = *lmarry* calculate and print matrix k-effective by array number, default = NO.

CKA = *lcka* calculate and print cofactor k-effective by array number, default = NO.

FMA = *pmarry* print fission production matrix by array number, default = NO.

HHL = *lhhgh* collect matrix information by hole number at the highest hole nesting level, default = NO.

HAL = *langh* collect matrix information by array number at the highest array nesting level, default = NO.

AMX = *amx* key for printing all mixture cross section data. This is the same as activating *XAP, XS1, XS2, PKI*, and *P1D*. If any of these are entered in addition to *AMX*, then that portion of *AMX* will be overridden, default = NO.

XAP = *prtap* key for printing discrete scattering angles and probabilities for the mixture cross sections, default = NO.

XS1 = *prtp0* key for printing mixture 1D cross sections, default = NO.

XS2 = *prt1* key for printing mixture 2D cross sections, default = NO.

XSL = *prtl* key for printing mixture 2D P_L cross sections, default = NO. The Legendre expansion order L is automatically read from the cross section library.

PKI = *prtchi* print input fission spectrum, default = NO.

P1D = *prtex* print extra 1D cross sections, default = NO.

PWT = *lpwt* print weight average array, default = NO.

PGM = *lgeom* print unprocessed geometry as it is read, default = NO.

PAX = *lcorsp* print the arrays defining the correspondence between the cross section energy group structure and the albedo energy group structure, default = NO.

PMF = *prtmore* print angular fluxes or flux moments if calculated, default = NO.

PMS = *print_mesh_flux* print mesh fluxes if computed, default = NO.

PMM = *print_mesh_moments* print the angular moments of the mesh flux, if computed, default = NO.

PMV = *print_mesh_volumes* print the volume of each mesh interval, if computed. Default = NO.

TFM = *ltfm* perform coordinate transform for flux moments and angular flux calculations, default = NO.

FST = *lprint_FStar* create a .3dmap file that contains the F^*(r) mesh used by a CE-TSUNAMI CLUTCH sensitivity calculation.

SCX = *lxsecSave* save CE cross sections to restart file, default=NO.

HTM = *html_output* produce HTML formatted output for interactive browsing, sorting, and plotting of results, default = YES.

BUG = *ldbug* print debug information, default = NO. Enter *YES* for code debug purposes only.

TRK = *ltrk* print tracking information, default = NO. Enter *YES* for code debug purposes only.

RUN = *lrun* key for determining if the problem is to be executed when data checking is complete, default = YES.

PLT = *lplot* key for drawing specified plots of the problem geometry, default = YES.

Note: The parameters RUN and PLT can also be entered in the PLOT data. See Sect. 8.1.3.11. It is recommended that these parameters be entered only in the parameter data to ensure that the data printed in the Logical Parameters table is actually performed. If RUN and/or PLT are entered in both the parameter data and plot data, the results vary depending on whether the problem is run (1) stand alone, (2) as a restarted problem, (3) as CSAS with parm=check, or (4) as CSAS without parm=check. These conditions are detailed below.

KENO standalone and CSAS with PARM=CHECK The values of RUN and/or PLT entered in KENO parameter data are printed in the Logical Parameters table of the problem output. However, values for RUN and/or PLT entered in the **KENO plot data** will override the values entered in the parameter data.

Restarted KENO The values of RUN and/or PLT printed in the Logical Parameters table of the problem output are the final values from the parent problem unless those values are overridden by values entered in the **KENO parameter data** of the restarted problem. If the problem is restarted at generation 1, **KENO plot data** can be entered, and the values for RUN and/or PLT will override the values printed in the Logical Parameters table.

CSAS Without PARM=CHECK The values of RUN and/or PLT entered in the **KENO parameter data** override values entered in the KENO plot data. The values printed in the Logical Parameters table control whether the problem is to be executed and whether a plot is performed.

Parameters that are either Logical or Integer . . . enter YES or NO, or an integer number

SCD= *l_grid_entropy or mp_grid_entropy* score Shannon entropy on a grid, and then perform fission source convergence diagnostics(ScnvgDiag), default=YES, default grid ID = 10001. See Sect. 8.1.7.7 for further details.

CDS = *lgrid_prod_dens or mp_grid_prod_dens* accumulate neutron fissions on a mesh grid either constructed with **MSH** or defined by **KENO grid data** input to use as fission source in subsequent MAVRIC/Monaco shielding calculation or for visualization, default = NO.

FIS = *lgrid_fis_rate or mp_grid_fis_rate* compute fission rates on a mesh grid either constructed with **MSH** or defined by **KENO grid data** input, default = NO.

GFX = *lgrid_flux or mp_grid_flux* compute grid fluxes on a mesh grid either constructed with **MSH** or defined by **KENO grid data** input, default = NO.

MFX = *lgrid_mat_avg_flux or mp_grid_mat_avg_flux* compute mesh fluxes (averaged over the volume of mixtures/materials in each mesh voxel) on a mesh grid either constructed with **MSH** or defined by **KENO grid data** input, default = NO.

CGD = *lgrid_fstar or mp_grid_fstart* compute the F^*(r) mesh tally for continuous-energy CLUTCH sensitivity calculations. This mesh is defined with either **MSH** parameter or **KENO grid data**, default = NO.

The KENO codes in SCALE versions prior to 6.2 allowed for only one mesh definition in the user input, with either the **MSH** parameter or the **KENO grid data** input, and calculation of a single mesh-based quantity, such as MFX (mesh fluxes) or CDS (fission source accumulation on a mesh), per KENO simulation. Either of these mesh-based quantities can be enabled only by entering **MSH=yes** or **CDS=yes** in the parameter input.

Starting with SCALE 6.2, the option to define multiple spatial meshes during a single simulation was implemented in the KENO codes to add flexibility to mesh-based quantity calculations. This enabled computing desired quantities on different spatial meshes in a single KENO simulation: a finer mesh can be used for grid fluxes to increase the resolution while overlaying these data on the geometry for a problem with a full-core reactor model, whereas a coarser mesh can be used for Shannon entropy tally for source convergence diagnostics for the same problem. The new implementation requires that each mesh definition in the **KENO grid data** input have a unique NUMBER (grid ID), which is used for mesh assignment. Users can assign any spatial grid to mesh-based quantities by setting the mesh parameters to this grid NUMBER (e.g., **GFX=id1 MFX=id2**, etc.)

To support both definition formats (logical entries or integer entries), the parameter processor was redesigned for the parameters **SCD**, **CDS**, **GFX**, **MFX** and **CGD** to allow either integer or logical entries. Integer entries are required if multiple mesh-based quantities are requested with different meshes. In this case, each integer entry must point to a grid ID specified in any **KENO grid data**. See Sect. 8.1.4.11 for several examples for the use of these parameter definitions.

KENO codes in SCALE 6.3 introduce a new mesh-based quantity, fission rates on a mesh grid, which is controlled by parameter **FIS** in the parameter block. Like the above parameters, **FIS** also allows both logical and integer entries.

These entries for all above parameters are detailed below.

> **SCD**= yes enable source convergence diagnostics using the fission source accumulation on the default mesh, which is $5 \times 5 \times 5$ Cartesian mesh overlaying the whole problem geometry, generated automatically. See Sect. 8.1.7.7.
>
> **SCD**=*id* enable source convergence diagnostics using the fission source accumulation on the mesh defined with **KENO grid data** with grid ID, *id*.
>
> **CGD**=*id* enable a mesh grid defined by the **KENO grid data** with grid ID, *id* for CLUTCH F^* (r) calculations.
>
> **MFX**=yes compute mesh fluxes on intervals defined by the **MSH** parameter or by the first specified **grid data** block.

MFX=*id* compute mesh fluxes on a mesh grid defined by the **KENO grid data** with grid ID, *id*.

CDS=yes accumulate fission sources on intervals defined by **MSH** or by the first specified **grid data** block.

CDS=*id* accumulate fission source on a mesh grid defined by the specified **KENO grid data** with grid ID, *id*.

FIS=yes compute fission rates on intervals defined by **MSH** or by the first specified **grid data** block.

FIS=*id* compute fission rates on a mesh grid defined by the **KENO grid data** with grid ID, *id*.

GFX=yes compute grid fluxes (fluxes averaged over a voxel volume) on intervals defined by **MSH** or by the first specified **grid data** block.

GFX=*id* compute grid fluxes on a mesh grid defined by the **KENO grid data** with grid ID, *id*.

All of the above quantities may be requested in a single input using either the same or different grids. See Sect. 8.1.4.11 for more details.

I/O Unit Numbers **XSC** = *xsecs* I/O unit number for a Monte Carlo format mixed cross section library. When LIB $\neq 0$, default = 14. To read a mixed cross section library from a Monte Carlo format library file or CSASI, XSC must be specified.

ALB = *albdo* I/O unit number for albedo data, default = 79.

WTS = *wts* I/O unit number for weights, default = 80.

LIB = *lib* I/O unit number for *AMPX* working format cross section library, default = 0.

SKT = *skrt* I/O unit number for scratch space, default = 16.

RST = *rstrt* I/O unit number for reading restart data, default = 0. Enter a logical unit number to restart if *BEG* > 1.

WRS = *wstrt* I/O unit number for writing restart data, default = 0. A non-zero value must be entered if *RES* > 0.

GRP = *grpbs* I/O unit number for an energy group boundary library, default = 77.

Example: Default values for the parameters **NPG** and **FLX** are overridden by the user-defined values. Code continues calculations with 203 particles per generation, and tallies region-averaged fluxes in starting after **NSK** generations skipped.

```
READ PARAM
   NPG=203 FLX=yes
END PARAM
```

Example: **NSK** has been defined more than once. The last **NSK** value 50 is used. A cubic Cartesian mesh grid with 3 cm side length is constructed using the extents of the bounding box enclosing the global unit (or outermost geometry). Then, fluxes (averaged over voxel volumes) are tallied on this mesh grid after 50 generations skipped.

```
READ PARA
   NSK=13
   MSH=3.0 GFX=yes  NSK=50
END PARA
```

8.1.3.4 Geometry data

The *GEOMETRY_ DATA* consists of a series of **UNIT** descriptions, one of which may be the **GLOBAL UNIT**. The **UNIT** is the basic geometry piece in KENO and often corresponds to a well-defined physical entity (e.g., a fuel pin). A **UNIT**, therefore, may consist of multiple *material regions*. Each **UNIT** has its own, local coordinate system. The **UNIT**s are assembled to construct the problem's global geometry for KENO. The *GEOMETRY_ DATA* must be entered unless the problem is being restarted. See Sect. 8.1.4.6 for detailed examples.

UNITS

Geometric arrangements in KENO are achieved in a manner similar to using a child's building blocks. Each building block is called a **UNIT**. An **ARRAY** or lattice is constructed by stacking these **UNIT**s. Once an **ARRAY** or lattice has been constructed, it can be placed in a **UNIT** by using an **ARRAY** specification.

Each **UNIT** in an **ARRAY** or lattice has its own coordinate system. In KENO V.a, all coordinate systems in all **UNIT**s must have the same orientation. This restriction is removed in KENO-VI. All geometry data used in a problem are correlated to the absolute coordinate system by specifying a **GLOBAL UNIT**. **UNIT**s are constructed of combinations from several allowed **shape**s or geometric regions. These regions can be placed anywhere within a **UNIT**. In KENO V.a the regions are oriented along the coordinate system of the **UNIT** and do not intersect other regions. This means, for example, that a **CYLINDER** must have its axis parallel to one of the coordinate axes, while a rectangular parallelepiped must have its faces perpendicular to a coordinate axis. The most stringent KENO V.a geometry restriction is that none of the options allow geometry regions to intersect. In KENO V.a, each region in a unit must entirely contain each preceding region. The orientation, intersection, and containment restrictions are eliminated in KENO-VI. Fig. 8.1.1 shows some situations that are not allowed in KENO V.a, but are allowed in KENO-VI.

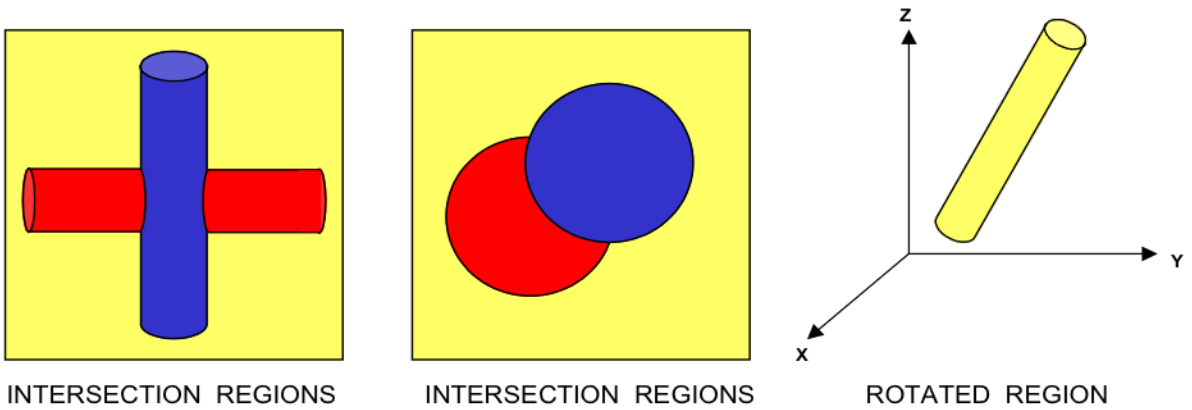


Fig. 8.1.1: Examples of geometry allowed in KENO-VI but not allowed in KENO V.a.

For KENO V.a, unless special options are invoked, each geometric region in a **UNIT** must completely enclose each interior region. Regions may touch at points of tangency and may share faces. See Fig. 8.1.2 for examples of allowable situations.

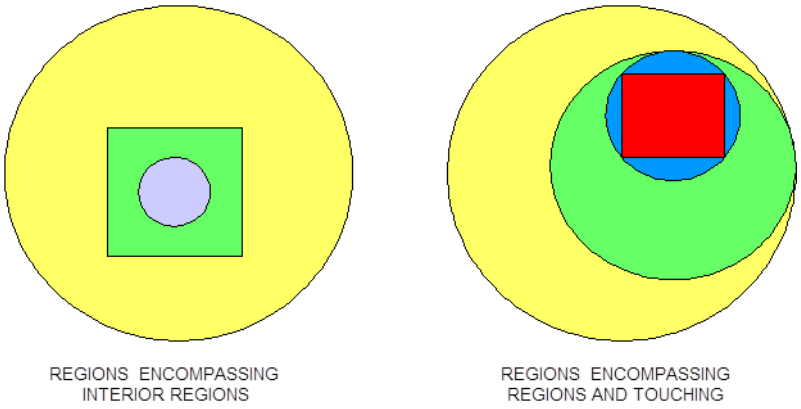

Fig. 8.1.2: Examples of correct KENO V.a units.

Special options are provided to circumvent the complete enclosure restriction in KENO V.a or to enhance the basic geometry package in KENO-VI. These options include **ARRAY** and **HOLE** descriptions. The **HOLE** option is the simplest of these and allows placing a **UNIT** anywhere within a region of another **UNIT.** In KENO V.a, **HOLE**s are not allowed to intersect the region into which they are placed; this restriction does not apply in KENO-VI (see Fig. 8.1.3). In both geometry packages, a **HOLE** cannot intersect the **UNIT** boundary. It is recommended that the outer boundary of a **UNIT** used as a **HOLE** should not be tangent to or share a boundary with another **HOLE** or a region of the **UNIT** containing the **HOLE** because the code may find that the regions are intersecting due to precision and round-off. Since a particle must check every region to determine its location within a **UNIT**, using **HOLE**s to contain complex sections of a problem may decrease the CPU time needed for the problem in KENO-VI. Inclusion of **HOLE**s increases run-time in KENO V.a, but in many cases cannot be avoided. An arbitrary number of **HOLE**s can be placed in a region in combination with a series of surrounding regions. The only restrictions on **HOLE**s are (1) when they are placed in a **UNIT,** they must be entirely contained within the **UNIT**, and (2) they cannot intersect other **HOLE**s or nested **ARRAY**s. **HOLE**s in KENO V.a cannot intersect an **ARRAY**; in KENO-VI, the **HOLE** cannot intersect the **ARRAY** boundary.

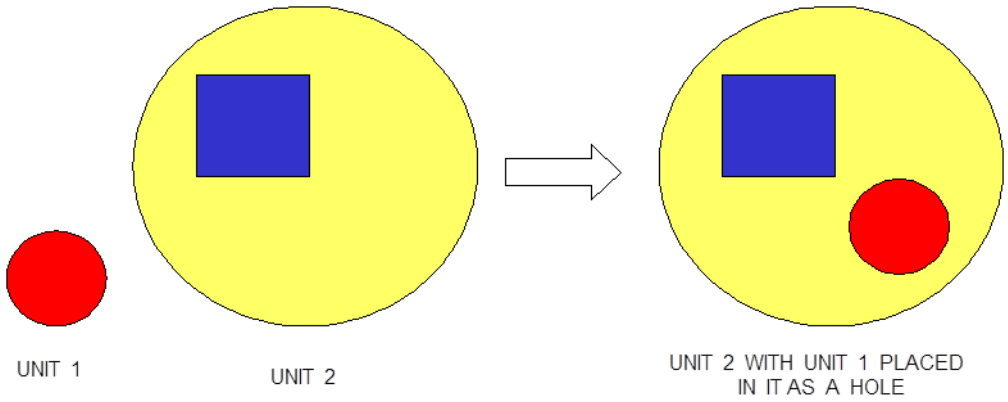

Fig. 8.1.3: Example demonstrating HOLE capability in KENO.

Lattices or arrays are created by stacking **UNIT**s. In KENO V.a, only rectangular parallelepipeds can be organized in an **ARRAY**. **HEXPRISM**s and **DODECAHEDRON**s are allowed in KENO-VI to construct triangular pitched or closed-packed dodecahedral **ARRAY**s, respectively. The adjacent faces of adjacent

UNITs stacked in this manner must match exactly. See Sect. 8.1.4.6.4 for additional clarification and Fig. 8.1.4 and Fig. 8.1.5 for typical examples.

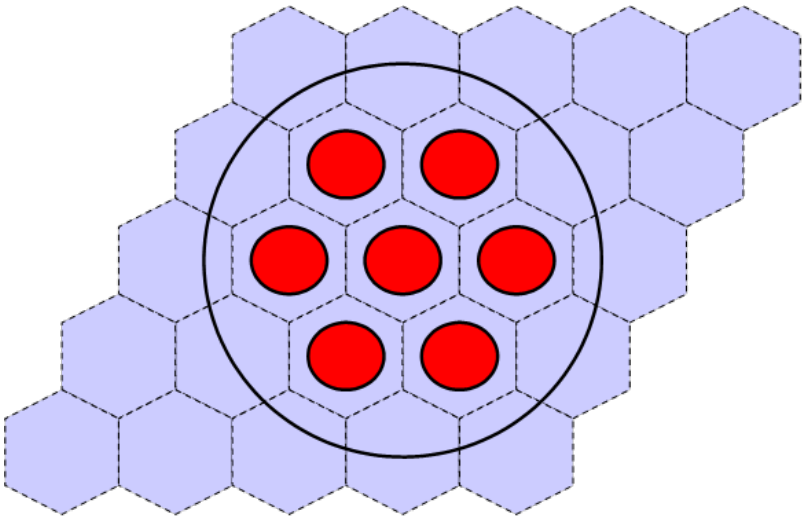

Fig. 8.1.4: Example of triangular pitched ARRAY construction.

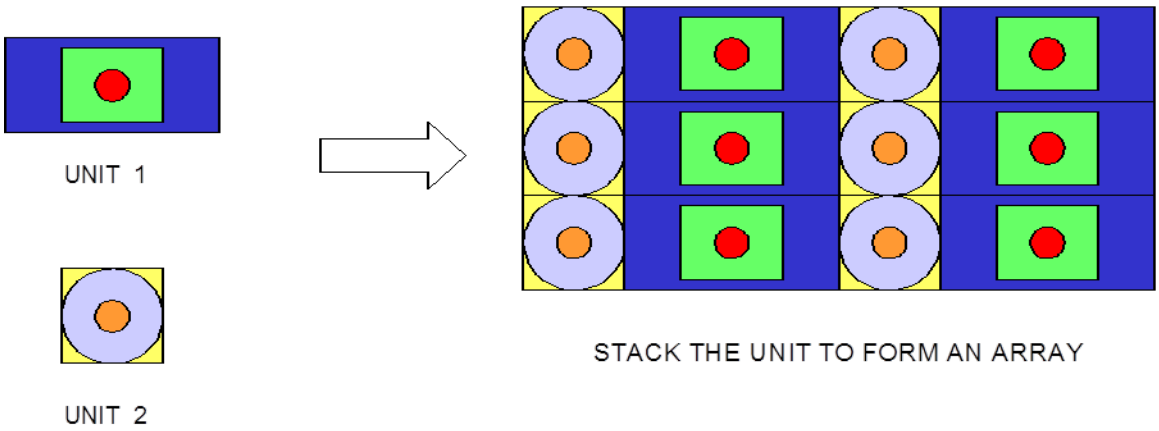

Fig. 8.1.5: Example of ARRAY construction.

The **ARRAY** option is provided to allow for placing an **ARRAY** or lattice within a **UNIT**. In KENO-VI, an **ARRAY** is placed in a **UNIT** by inserting it directly into a geometry/material region as a content record. In KENO V.a, the **ARRAY** is placed directly in the unit like a **CUBOID**: it must be the first region in the **UNIT**, or the **ARRAY** elements must intersect with the smaller region. Subsequent regions in the **UNIT** containing the **ARRAY** must contain it entirely. In KENO-VI, the reverse is true: the region boundary containing the **ARRAY** must coincide with or be contained within the **ARRAY** boundary. Therefore, in KENO-VI the region boundary becomes the **ARRAY** boundary, with the problem ignoring any part of the **ARRAY** outside the boundary. A particle enters or leaves the **ARRAY** when the region boundary is crossed. In KENO V.a, only one **ARRAY** can be placed directly in a UNIT. However, multiple **ARRAY**s can be placed within a **UNIT** by using **HOLE**s. When an **ARRAY** is placed in a **UNIT** via a **HOLE**, the **UNIT** that contains the **ARRAY** (rather than the **ARRAY** itself) is placed in the **UNIT**. **ARRAY**s of dissimilar **ARRAY**s can be created by stacking **UNIT**s that contain **ARRAY**s. In KENO-VI, it is possible to place multiple **ARRAY**s in

a **UNIT** by placing them in separate regions. Also in KENO-VI, using **HOLE**s to insert **ARRAY**s allows the **ARRAY**s to be rotated when placed. See Fig. 8.1.6 for an example of an **ARRAY** composed of **UNIT**s containing **HOLE**s and **ARRAY**s.

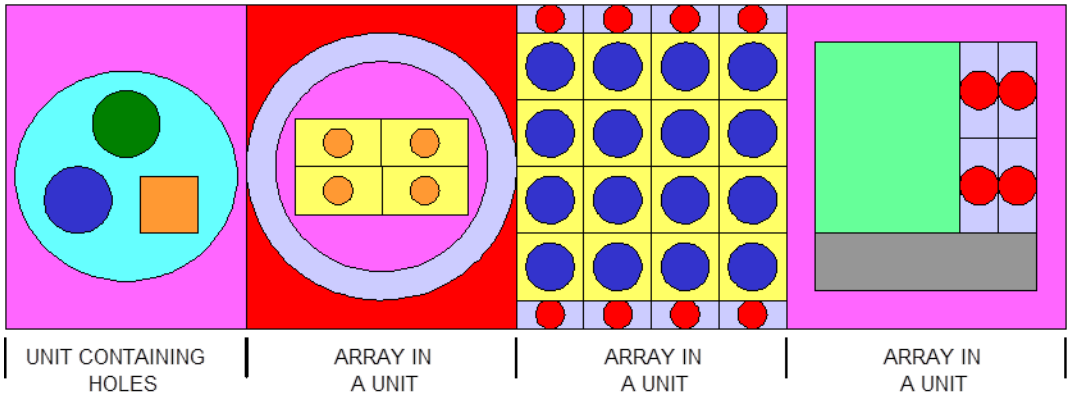

Fig. 8.1.6: Example of an ARRAY composed of UNITs containing ARRAYs and HOLEs.

The method of entering *GEOMETRY_DATA* in the geometry data block follows:

`READ GEOM` *GEOMETRY_ DATA* `END GEOM`

UNIT initialization

The description of a `UNIT` starts out with the `UNIT` *INITIALIZATION* and is terminated by encountering another `UNIT` *INITIALIZATION* or `END GEOM`.

The `UNIT` *INITIALIZATION* has the following format:

`[GLOBAL] UNIT` *u*

u is the identification number (positive integer) assigned to the particular `UNIT`. It may be used later to reference a `UNIT` previously constructed that the user wishes to place in a `HOLE`, or it may be used in an `ARRAY` (see below for more details).

`GLOBAL` is an attribute that specifies that the respective `UNIT` is the most comprehensive `UNIT` in the KENO problem to be solved, the `UNIT` that includes all the other `UNIT`s and defines the overall geometric boundaries of the problem. In general, a `GLOBAL UNIT` must be entered for each problem.

Note: In KENO V.a, the `GLOBAL` specification is optional. If it is used, it can precede either a `UNIT` command or an `ARRAY` *PLACEMENT_DESCRIPTION*. If it is not entered and the problem does not contain `ARRAY` data, `UNIT` 1 is the default `GLOBAL UNIT`. If there is no `GLOBAL UNIT` specified and `UNIT` 1 is absent from the geometry description, an error message is printed. If the geometry description contains an `ARRAY`, KENO V.a defaults the global array to the array referenced by the last `ARRAY` *PLACEMENT_DESCRIPTION* that is not immediately preceded by a unit description. Otherwise, it is the largest array number specified in the array data (Sect. 8.1.3.5).

Examples of initiating a `UNIT`:

1. Initiate input data for `UNIT` No. 6.

UNIT 6

2. Initiate input data for the **GLOBAL UNIT** which is **UNIT** No. 4.

   GLOBAL UNIT 4

For each UNIT, the UNIT's *DESCRIPTION* follows the UNIT's *INITIALIZATION*. The *DESCRIPTION* is realized by combining the commands listed below. The basic principles for constructing a UNIT are different between KENO V.a and KENO-VI. A brief discussion of these principles, together with a few examples, is presented at the end of this section following the description of the basic input used to build the geometry of a UNIT. The keywords that may be used to define a UNIT in KENO are as follows:

shape

COM=

HOLE

ARRAY

REPLICATE (KENO V.a only)

REFLECTOR (KENO V.a only)

MEDIA (KENO-VI only)

BOUNDARY (KENO-VI only)

Shape

Shape is a generic keyword used to describe a basic geometric shape that may be used in building the geometry of a particular **UNIT**. The general format varies between KENO V.a and KENO-VI. In KENO V.a, the **shape** defines a region containing a material, so the user is required to provide both a material and a *bias ID*. In KENO-VI the **shape** is used strictly as a surface, which is later used to define the mono-material regions (using the **MEDIA** card). The user is therefore required to enter a label for this surface so that the **shape** can be referenced later.

KENO V.a:

shape $m\ b\ d_1 \ldots\ d_{\mathrm{N}}\ [a_1 \ldots * [a_{\mathrm{M}}\ ] \ldots]$

KENO-VI:

shape $l\ d_1 \ldots\ d_{\mathrm{N}}\ [a_1 \ldots * [a_{\mathrm{M}}\ ] \ldots]$

shape is a generic keyword that describes a basic predefined KENO shape (e.g., **CUBOID**, **CYLINDER**) that is used to build the geometry of the **UNIT**. The predefined shapes differ between KENO V.a and KENO-VI. See Sect. 8.1.8.1 for a description of the KENO V.a basic shapes and Sect. 8.1.8.2 for the KENO-VI shapes.

m is the mixture number of the material (positive integer) that fills the particular shape in KENO V.a **UNIT** description. A material number of zero indicates a void region (i.e., no material is present in the volume defined by the **shape**).

b is the bias identification number (*bias ID*, a positive integer) assigned to the particular region defined by the **shape** in the KENO V.a **UNIT** description.

l is the label (positive integer) assigned to the particular **shape** in the KENO-VI **UNIT** description. This label is used later to define a certain mono-material region within the **UNIT**.

$d_1 \ldots d_N$ represent the N dimensions (floating point numbers) that define the particular **shape** (e.g., radius of a sphere or cylinder). See Sect. 8.1.8.1 and Sect. 8.1.8.2 for the particular value of N and how each **shape** is described.

$a_1 \ldots a_M$ are M optional *ATTRIBUTES* for the **shape**. The attributes provide additional flexibility in the **shape** description. The attributes that may be used with either KENO V.a or KENO-VI are described below (see shape ATTRIBUTES).

shape ATTRIBUTES

The *ATTRIBUTES* that can be used to enhance the **shape** description are **CHORD**, **ORIG**[**IN**], **CENTER**, and **ROTATE** (KENO-VI only).

The CHORD attribute

This attribute has different formats in KENO V.a and KENO-VI. The user will notice that it is more restrictive in KENO V.a. Only the **HEMISPHERE and HEMICYLINDER shape**s can be **CHORD**ed in KENO V.a, but all 3-D shapes may be **CHORD**ed in KENO-VI.

KENO V.a: **CHORD** ρ

KENO-VI: **CHORD** [**+X**=x+] [-**X**=x-] [**+Y**=y+] [-**Y**=y-] [**+Z**=z+] [-**Z**=z-]

p **is the distance** ρ **from the cut surface to the center of the sphere** or the axis of a hemicylinder. See Fig. 8.1.7 and Fig. 8.1.8. Negative values of ρ indicate that less than half of the **shape** is retained, while positive values indicate that more than half of the **shape** will be retained.

+X=, -X=, +Y=, -Y=, +Z=, -Z= are subordinate keywords that define the axis parallel to the chord. The "+" and "-" signs are used to define the side of the chord which is included in the volume. A "+" in the keyword indicates that the more positive side of the chord is included in the volume. A "-" in the keyword indicates that the more negative side of the chord is included in the volume.

x+, x-, y+, y-, z+, z- are the coordinates of the plane perpendicular to the chord. For each chord added to a body, the keyword **CHORD** must be used, followed by one of the subordinate keywords and its dimension.

In KENO V.a, the CHORD attribute is applicable for only hemispherical and hemicylindrical shapes, *not* for SPHERE, XCYLINDER, YCYLINDER, CYLINDER, ZCYLINDER, CUBE, or CUBOID.

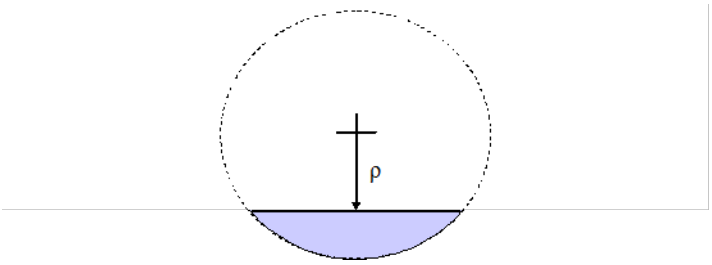

Fig. 8.1.7: Partial hemisphere or hemicylinder; less than half exists (less than half is defined by $\rho < 0$).

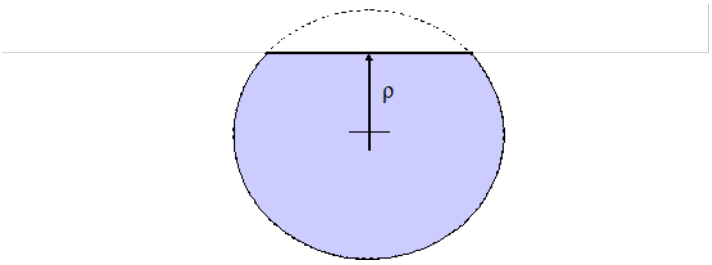

Fig. 8.1.8: Partial hemisphere of hemicylinder; more than half exists (more than half is defined by $\rho > 0$).

Fig. 8.1.9 provides two examples of the use of the CHORD option in KENO-VI.

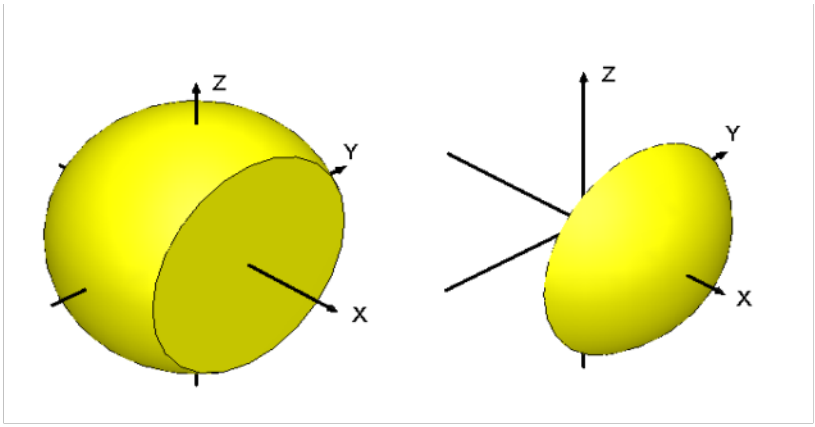

Fig. 8.1.9: Examples of the CHORD option in KENO-VI.

The ORIG[IN] attribute

The format is slightly different between KENO V.a and KENO-VI. Since the entries in KENO-VI are key worded, the user has more flexibility in choosing the order of these entries or in using default values. Only non-zero values must be entered in KENO-VI, but all applicable values, whether zero or non-zero, must be entered in KENO V.a.

KENO V.a: **ORIG**[**IN**] *a b* [*c*]

KENO-VI: **ORIGIN** [**X**=x_0] [**Y**=y_0] [**Z**=z_0]

a is the X coordinate of the origin of a sphere or hemisphere; the X coordinate of the centerline of a Z or Y cylinder or hemicylinder; the Y coordinate of the centerline of an X cylinder or hemicylinder.

b is the Y coordinate of the origin of a sphere or hemisphere; the Y coordinate of the centerline of a Z cylinder or hemicylinder; the Z coordinate of the centerline of an X or Y cylinder or hemicylinder.

c is the Z coordinate of the origin of a sphere or hemisphere; it must be omitted for all cylinders or hemicylinders.

X=, Y=, Z= are the subordinate keywords used to define the new position of the origin of the **shape**. If the a subordinate keyword appears more than once after the **ORIGIN** keyword, the values are summed. If the new value is zero, the particular coordinate does not need to be specified.

x_0, y_0, z_0 are the values for the new coordinates where the origin of the **shape** is to be translated.

The CENTER attribute

This attribute establishes the reference center for the flux moment calculations, which can be useful in TSUNAMI calculations. The syntax for this attribute is:

CENTER *center_type* [*u*] [*x y z*]

center_type is the reference center value, as described in Table 8.1.18. The default value is **global**.

u is the **UNIT** number to be used as a reference center for this region when the *center_type* is **unit**.

x, y, z are the offset from the point specified by the *center_type*. The default is 0.0 for all three entries.

Table 8.1.18: Reference center values

center_type	Reference point
unit	Reference is defined as the origin of **UNIT** *unit_number* plus the offset defined by *x*, *y*, and *z*.
global	Reference is defined as system origin-i.e., (0,0,0) point of the **GLOBAL UNIT**-plus the offset defined by *x*, *y*, and *z*.
local	Reference is defined as the origin of the current **UNIT** plus the offset defined by *x*, *y*, and *z*.
fuelcenter	Reference is defined as the center of all fissile material in the system plus the offset defined by *x*, *y*, and *z*.
wholeunit	When entered for the first region in a unit, the reference for all regions in the unit are defined as the origin of the current unit plus the offset defined by *x*, *y*, and *z*.

The ROTATE attribute

This attribute can only be used in the KENO-VI input. It allows for the rotation of the **shape** or **HOLE** to which it is applied. If **ORIGIN** and **ROTATE** data follow the same **shape** or **HOLE** record, the **shape** is always rotated prior to translation, regardless of the order in which the data appear. Fig. 8.1.10 provides an example of the use of the **ROTATE** option. Its syntax is:

ROTATE [**A1**=a_1] [**A2**=a_2] [**A3**=a_3]

A1=, A2=, A3= are subordinate keywords to specify the angles of rotation of the particular shape with respect to the origin of the coordinate system. The Euler X-convention is used for rotation.

a_1, a_2, a_3 are the values of the Euler rotation angles in degrees. The default is 0 degrees. If a subordinate keyword appears more than once following the ROTATE keyword, the values are summed.

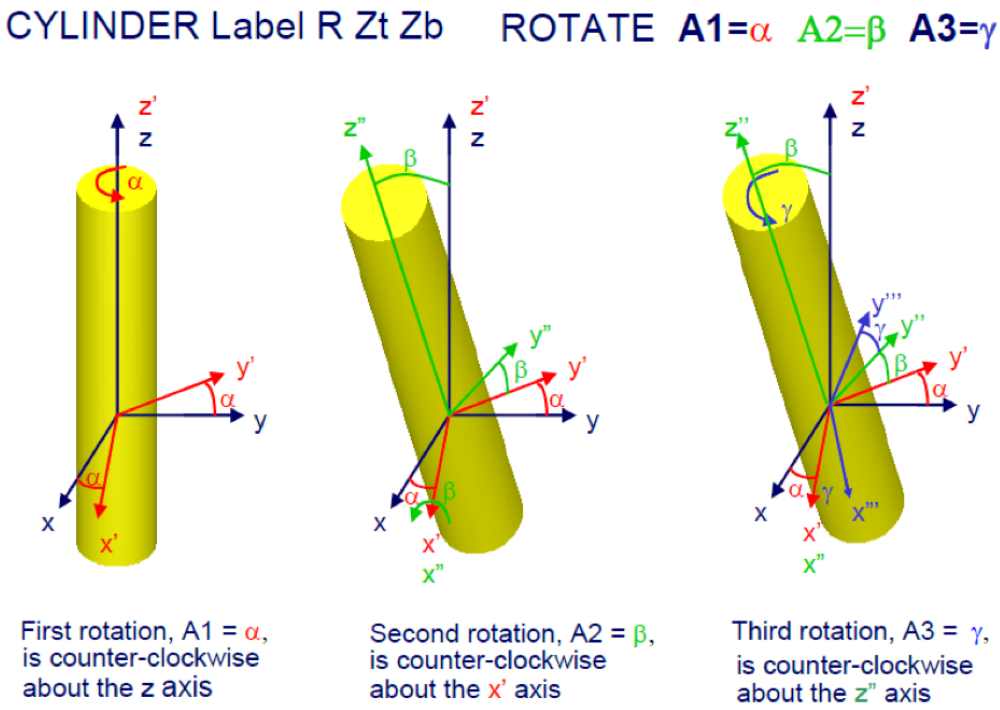

Fig. 8.1.10: Explanation of the ROTATE option.

Examples of **shape**s:

1. Specify a hemisphere labeled 10, containing material 2 with a radius of 5.0 cm which contains only material where Z > 2.0 within the sphere centered at the origin, and its origin translated to X=1.0, Y=1.5, and Z=3.0. KENO V.a (no label, but material and bias ID are the first two numerical entries):

   HEMISPHERE 2 1 5.0 **CHORD** -2.0 **ORIGIN** 1.0 1.5 3.0

   or

   HEMISPHE+Z 2 1 5.0 **CHORD** -2.0 **ORIGIN** 1.0 1.5 3.0

   KENO-VI (no material; this is to be specified with **MEDIA**):

   SPHERE 10 5.0 **CHORD +Z**=2.0 **ORIGIN X**=1.0 **Y**=1.5 **Z**=3.0

2. Specify a hemicylinder labeled 10, containing material 1, having a radius of 5.0 cm and a length extending from Z=2.0 cm to Z=7.0 cm. The hemicylinder has been truncated perpendicular to the X axis at X= -3 such that material 1 does not exist between X= -3 and X= -5. Position the origin of the truncated hemicylinder at X=10 cm and Y=15 cm with respect to the origin of the unit, and rotate it (in KENO-VI input) so it is in the YZ plane at X=10 and at a 45° angle with the Y plane.

   KENO V.a (no rotation possible, no label):

   ZHEMICYL+X 1 1 5.0 7.0 2.0 **CHORD** 3.0 **ORIGIN** 10.0 15.0

   KENO-VI (no material; this is to be specified with **MEDIA** card):

   CYLINDER 10 5.0 7.0 2.0 **CHORD +X**= -3.0 **ORIGIN X**=10.0 **Y**=15.0 **ROTATE A2**= -45

COM=

The keyword **COM**= signals that a comment is to be read. The optional comment can be placed anywhere within a unit definition. Its syntax is:

COM = *delim comment delim*

delim is the delimiter, which may be any one of " , ` , * , ^ , or !

comment is the comment string, up to 132 characters long.

Example of comment within a **UNIT**:

COM="This is a fuel pin"

HOLE

This entry is used to position a **UNIT** within a surrounding **UNIT** relative to the origin of the surrounding **UNIT**. **HOLE**s may share surfaces with but may not intersect other **HOLE**s, the **BOUNDARY** of the **UNIT** which contains the **HOLE**, or an **ARRAY** boundary. In KENO-VI, the **BOUNDARY** record of a **UNIT** placed in a **HOLE** may contain more than one geometry label, but all labels must be positive, indicating inside the respective geometry bodies. The syntax for **HOLE** is:

KENO V.a: **HOLE** *u x y z*

KENO-VI: **HOLE** *u* [a_1 ... [a_M]...]

u is the unit previously defined that is to be placed within the **HOLE**.

x y z is the position of the **HOLE** in the KENO V.a host **UNIT**.

a1 ... aM are optional KENO-VI *ATTRIBUTES* for the **HOLE**. The *ATTRIBUTES* can be **ORIGIN** or **ROTATE** and follow the same syntax previously defined for KENO-VI **shape** *ATTRIBUTES*. These *ATTRIBUTES* allow for the translation and/or rotation of the **HOLE** within the host region.

Examples of **HOLE** use:

Place **UNIT** 2 in the surrounding **UNIT** such that the **ORIGIN** of **UNIT** 2 is at **X**=3, **Y**=3.5, **Z**=4 relative to the origin of the surrounding **UNIT**.

KENO V.a: **HOLE** 2 3 3.5 4

KENO-VI: **HOLE** 2 **ORIGIN X**=3.0 **Y**=3.5 **Z**=4.0

ARRAY

When used within a **UNIT** description, this entry provides an **ARRAY** placement description. In KENO V.a, it always starts a new **UNIT** and generates a rectangular parallelepiped that fits the outer boundaries of the specified **ARRAY**. The specified **ARRAY** is positioned in the **UNIT** according to the most negative point in the **ARRAY** with respect to the coordinate system of the surrounding **UNIT**. Thus, the location of the minimum x, minimum y, and minimum z point in the array is specified in the coordinate system of the **UNIT** into which the **ARRAY** is being placed.

In KENO-VI, the **ARRAY** keyword is used to position an **ARRAY** within a region in a surrounding **UNIT** relative to the origin of the surrounding **UNIT**. When the subordinate keyword **PLACE** is entered, it is followed by six numbers that precisely locate the **ARRAY** within the surrounding **UNIT** as shown in the example below. The first three numbers consist of the element in the **ARRAY** of the **UNIT** selected to position the **ARRAY**. The next three numbers consist of the position of the origin of the selected **UNIT** in

the surrounding **UNIT**. Higher level **ARRAY** boundaries may intersect lower level **ARRAY** boundaries as long as they do not intersect **HOLE**s in the **UNIT**s contained in the **ARRAY** or in **UNIT**s contained in lower level **ARRAY**s.

The syntax for the **ARRAY** card is as follows:

KENO V.a: **ARRAY** *array_id x y z*

KENO-VI: **ARRAY** *array_id* $l_1 \ldots l_N$ [**PLACE** N_x N_y N_z *x y z*]

array_id is the label that identifies the array to be placed.

l1 … lN is the *REGION DEFINITION VECTOR*. These are previously defined **shape** labels, and together they define the region in which the array *array_id* is to be placed. This is used only in KENO-VI.

Nx Ny Nz are three integers that define the element in the **ARRAY** of the **UNIT** selected to position the **ARRAY**. This is used only in KENO-VI.

x y z specify the position of the **ARRAY** in the **UNIT**.

In KENO V.a, the x, y, and z values are the point where the most negative x, y, and z point of the **ARRAY** is to be located in the **UNIT**'s coordinates.

In KENO-VI, the x, y, and z values are the point where the origin of the **UNIT** specified by *Nx*, *Ny*, and *Nz* is to be located in the **shape** specified by the *REGION DEFINITION VECTOR*.

Example of **ARRAY** use:

In KENO V.a, position the most negative point of **ARRAY** 6 at X = 2.0, Y = 3.0, Z = 4.0 relative to the origin of the containing **UNIT**.

ARRAY 6 2.0 3.0 4.0

In KENO-VI, position instead the origin of **UNIT** (1,2,3) of **ARRAY** 6 at X = 2.0, Y = 3.0, Z = 4.0 and specify the **ARRAY** boundary to be the region that is inside the geometry **shape**s labeled 10 and 20 and outside the geometry **shape** labeled 30 used to describe the surrounding **UNIT**.

ARRAY 6 10 20 -30 **PLACE** 1 2 3 2.0 3.0 4.0

REPLICATE and REFLECTOR

These keywords specific to KENO V.a are used to generate additional geometry regions having the **shape** of the previous region. The geometry keyword **REFLECTOR** is a synonym for **REPLICATE**. The desired weighting functions can be applied to those regions by specifying biasing data as described in Sect. 8.1.3.7. The total thickness generated for each surface is the thickness per region for that surface times the number of regions to be generated, *nreg*.

The replicate specification is frequently used to generate weighting regions external to an `ARRAY` placement description. Thus an `ARRAY` placement description followed by a `REPLICATE` description would generate regions of a cuboidal shape. A cylindrical reflector could be generated by following the `ARRAY` placement description with a `CYLINDER` and then a `REPLICATE`. A `HOLE` cannot immediately follow a `REPLICATE`.

Extra regions using default weights can be generated by specifying the first importance region, *imp*, to be one that was not defined in the *BIASING INFORMATION* provided in a `READ BIAS` block. This capability can be used to generate extra regions for collecting information such as fluxes, leakage, etc.

Multiple replicate descriptions can be used in any problem. This capability can be used to model different reflector materials of different thicknesses on different faces.

The number of appropriate region dimensions needed for specifying REPLICATE is determined by the preceding region. For example, if the previous region were a SPHERE, one entry (i.e., t_1) would be required. If the previous region were a CYLINDER, the first entry, t_1, would be the thickness/region in the radial direction, the second entry, t_2, would the thickness/region in the positive length direction, the third entry, t_3, would be the thickness/region in the negative length direction, etc. The REPLICATE specification requirements for a CUBE are the same as for a CUBOID.

Syntax:

REPLICATE|REFLECTOR *m b* $t_1 \ldots t_N$ *nreg*

m is the number of the material (non-negative integer) that fills the particular REPLICATE/REFLECTOR region in the **UNIT** description. A material of zero indicates a void region (i.e., no material is present in the volume defined by the **shape**).

b is the bias identification number (positive integer) assigned to the particular region defined by the shape in the KENO V.a UNIT description. If the specified bias ID is defined in a READ BIAS block, the bias ID number will be incremented automatically, increasing one for each additional region up to *nreg*.

$t_1 \ldots t_N$ represent the thickness (floating point number) per region for each of the *N* surfaces that define the particular shape. If the specified bias ID is one that is defined in the READ BIAS block, the region thicknesses should be consistent with the thicknesses used to generate the bias data being used. See Sect. 9.1.2.7.

nreg is the number of regions (integer) to be generated.

Example:

Create five regions of material 4, each being 3 cm thick, outside a cuboid region (a cuboid has six dimensions). The inner-most of the five generated regions has a *bias id* of 2. The following four regions have *bias id* of 3, 4, 5, and 6.

MEDIA

This card is used in the KENO-VI input file to define the location of a mixture relative to the geometric shapes in the UNIT. Fig. 8.1.11 shows the input for a set of three intersecting SPHEREs in a CUBOID. The total volume data for a region in the problem may be entered as the last entry on the MEDIA card by using the VOL= keyword immediately followed by the volume in cm^3. The volume entered is the volume of the region in the unit multiplied by the number of times the unit occurs in the problem minus any volume excluded from the problem by ARRAY boundaries and HOLEs. The volumes for any or all regions may be entered. If the volume is entered here, this value will be used even if volumes are also entered as a file or calculated (See Sect. 8.1.3.13). Volumes not entered will be determined by the input specified in the VOLUME DATA block. If no volume is supplied, the KENO-VI default volume of -1 will be used. This only affects volume-averaged quantities, i.e., not k_{eff}.

Syntax:

MEDIA *m b* $l_1 \ldots l_N$ [VOL = *v*]

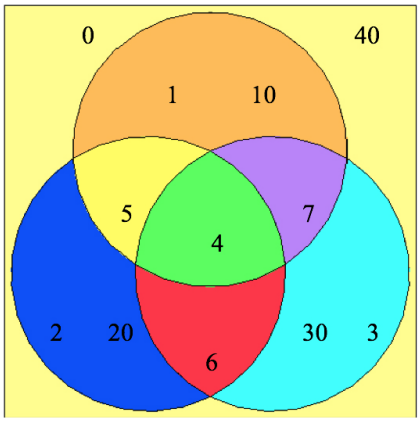
m is the material (positive integer or zero for vacuum) that fills the region defined by MEDIA.

b is the *bias id* for the material sector being defined.

$l_1 \ldots l_N$ is the region definition vector (*N* integers). These are *N* previously defined **shape** labels that together define the material sector.

VOL = is an optional sub-keyword used to input the material sector volume.

v is the volume in cm^3 of the material sector defined by the MEDIA card.



```
GLOBAL UNIT 1

BOUNDARY 40 ]
```

Fig. 8.1.11: Example of the MEDIA record.

BOUNDARY

This card is used in KENO-VI to define the outer boundary of the UNIT. In KENO V.a, the outer boundary of the UNIT is implicitly defined by the last shape in the UNIT. Each UNIT must have one and only one BOUNDARY card.

Syntax:

BOUNDARY *l1 ... lN*

***l*$_1$ ... *l*$_N$** is the UNIT *BOUNDARY DEFINITION VECTOR* (*N* integers). These are *N* previously defined **shape** labels that together define the outer boundary of the **UNIT**. All entries must be positive for the UNIT being defined to be used subsequently as a HOLE.

8.1.3.5 ARRAY Data

The array definition data block is used to define the size of an **ARRAY** and to position **UNIT**s (defined in the geometry data) in a 3-D lattice that represents the **ARRAY** being described. As many arrays as are necessary can be described in a problem, subject to computer storage limitations. In KENO V.a, only one **ARRAY** may be placed directly in a **UNIT**, but as many **ARRAY**s as are needed may be placed in the **UNIT** by using **HOLE**s. In KENO-VI, any number of arrays can be placed in any **UNIT** either directly or indirectly using **HOLE**s. There is no default global array. If a global array is desired it must be explicitly defined.

The **ARRAY** definition data is entered as:

READ ARRAY ARRAY DATA END ARRAY

The *ARRAY_ DATA* consists of *ARRAY_PARAMETERS* and *UNIT_ORIENTATION_DESCRIPTION*.

ARRAY Parameters

The ARRAY parameters that can be used in the definition of an ARRAY are:

ARA=

GBL=

NUX=, **NUY**=, **NUZ**=

PRT=

COM=

TYP= (KENO-VI only)

ARA=

The **ARA**= parameter defines a reference number for an **ARRAY**. It has no default in KENO-VI. In KENO V.a, if is missing, the default is 1.

Syntax:

ARA=*a*

a is the reference number for the **ARRAY**. It has no default in KENO-VI. In KENO V.a, if is missing, the default is 1.

GBL=

This is used to input the number of the global array.

Syntax:

GBL=*g*

g is the reference number for the global **ARRAY**. In KENO V.a it must not be entered more than once. The default is the largest value for *a*, the reference number for the **ARRAY**. In KENO-VI it is no default value and if entered more than once, the last value is used.

PRT=

This entry is used to enable printing the **ARRAY** of **UNIT** numbers.

Syntax:

PRT=*print*

print is a logical constant which defaults to YES, indicating that the **ARRAY** of **UNIT** numbers is printed. If the value is NO, then a summary table is printed instead containing the number of times each unit is used in each array.

NUX=, NUY=, NUZ=

These entries are used to input the number of units in the X, Y, and Z directions, respectively.

Syntax:

NUX=n_x **NUY**=n_y **NUZ**=n_z

$\boldsymbol{n_x}$ $\boldsymbol{n_y}$ $\boldsymbol{n_z}$ are the number of units in the X, Y, and Z directions, respectively. There is no default in KENO-VI. In KENO V.a, each of them defaults to 1.

TYPE=

This entry is used to specify the type of **ARRAY** and is specific to KENO-VI, where more than one type of arrays can be used. It cannot be used in KENO V.a.

Syntax:

TYP=*atyp*

atyp type of array (**cuboidal** or **square**, **hexagonal** or **triangular**, **rhexagonal**, **shexagonal**, **dodecahedral**), default = **cuboidal**

COM=

This keyword is used to enter a comment.

Syntax:

COM=*delim comment delim*

delim is a delimiter. Acceptable delimiters are ", `, * , ^ , or !.

comment is the comment string. Maximum *comment* length is 132 characters.

ARRAY orientation data

There are two methods to enter the **UNIT** numbers constituting an **ARRAY**: **LOOP** and **FILL**.

LOOP Construct

The `LOOP` construct resembles a FORTRAN DO-loop construct. The arrangement of `UNIT`s may be considered as consisting of a 3-D matrix of `UNIT` numbers, with the `UNIT` position increasing in the positive X, Y, and Z directions, respectively.

Syntax:

`LOOP` *u* ix_1 ix_2 incx iy_1 iy_2 incy iz_1 iz_2 *incz* `END LOOP`

u is the `UNIT` identification number (a positive integer).

ix_1 is the starting position in the X direction; ix_1 must be at least 1 and less than or equal to n_x of Sect. 8.1.3.5.5.

ix_2 is the ending position in the X direction; ix_2 must be at least 1 and less than or equal to *nx*.

incx is the number of `UNIT`s by which increments are made in the positive X direction; *incx* must be greater than zero and less than or equal to n_x.

iy_1 is the starting position in the Y direction; iy_1 must be at least 1 and less than or equal to n_y.

iy_2 is the ending position in the Y direction; iy_2 must be at least 1 and less than or equal to n_y.

incy is the number of **UNIT**s by which increments are made in the positive Y direction; *incy* must be greater than zero and less than or equal to n_y.

iz_1 is the starting position in the Z direction; iz_1 must be at least 1 and less than or equal to n_z.

iz_2 is the ending position in the Z direction;, iz_2 must be at least 1 and less than or equal to n_z.

incz is the number of **UNIT**s by which increments are made in the positive Z direction; *incz* must be greater than zero and less than or equal to n_z.

The syntax for ending the **LOOP** construct is:

`END LOOP`

The sequence *u* through *incz* is repeated until the entire **ARRAY** is described. If any portion of an **ARRAY** is defined in a conflicting manner, the last entry to define that portion will determine the **ARRAY**'s configuration. To use this feature, fill the entire **ARRAY** with the most relevant **UNIT** number and superimpose the other **UNIT** numbers in their proper places. An example showing the use of the **LOOP** option is given below. This $5 \times 4 \times 3$ **ARRAY** of **UNIT**s is a matrix of **UNIT**s that has 5 **UNIT**s stacked in the X direction, 4 **UNIT**s in the Y direction, and 3 **UNIT**s in the Z direction. X increases from left to right, and Y increases from bottom to top. Each Z layer is shown separately.

Given:

```
1 2 1 2 1        2 1 2 1 2       1 1 1 1 1
1 1 1 1 1        2 2 2 2 2       1 3 3 3 1
1 1 1 1 1        2 2 2 2 2       1 3 3 3 1
1 2 1 2 1        2 1 2 1 2       1 1 1 1 1
Z Layer 1        Z Layer 2       Z Layer 3
```

The data for this array could be entered using the following entries.

(1) 1 1 5 1 1 4 1 1 3 1 This fills the entire array with 1s.

(2) 2 2 5 2 1 4 3 1 1 1 This loads the four 2s in the first Z layer.

(3) 2 1 5 1 2 3 1 2 2 1 This loads the second and third rows of 2s in the second Z layer.

(4) 2 1 5 2 1 4 3 2 2 1 This loads the desired 2s in the first and fourth rows of the second Z layer.

(5) 3 2 4 1 2 3 1 3 3 1 This loads the 3s in the third Z layer and completes the array data input.

The second layer could have been defined by substituting the following data for entries (3) and (4):

(3) 2 1 5 1 1 4 1 2 2 1 This completely fills the second layer with 2s.

(4) 1 2 4 2 1 4 3 2 2 1 This loads the four 1s in the second layer.

When using the **LOOP** option, there is no single correct method of entering the data. If a **UNIT** is improperly positioned in the **ARRAY** or if some positions in the **ARRAY** are left undefined, it is often easier to add data to correctly define the **ARRAY** than to try to correct the existing data.

FILL Construct

The **FILL** construct enters data by stringing in **UNIT** numbers starting at X=1, Y=1, Z=1, and varying X, then Y, and then Z to fill the **ARRAY**. n_x x n_y x n_z entries are required. FIDO-like input options specified in Table 8.1.19 are also available for filling the **ARRAY**.

Syntax:

`FILL` $u_1 \ldots u_N$ {`END FILL`}|`T`

$u_1 \ldots u_N$ are the N=n_x x n_y x n_z `UNIT` numbers that make up the `ARRAY`

The syntax for ending the `FILL` construct is

`END FILL`

An alternative to end the `UNIT` data in `FILL` is by entering the letter `T`.

Table 8.1.19: FIDO-like input for mixed box orientation fill option.

Count field	Option field	Operand field	Function
		j	stores *j* at the current position in the array
i	R	*j*	stores *j* in the next *i* positions in the array
i	*	*j*	stores *j* in the next *i* positions in the array
i	$	*j*	stores *j* in the next *i* positions in the array
	F	*j*	fills the remainder of the array with unit number *j*, starting with the current position in the array
	A	*j*	sets the current position in the array to *j*
i	S		increments the current position in the array by *i* (This allows for skipping *i* positions; *i* may be positive or negative.)
i	Q	*j*	repeats the previous *j* entries *i* times (default value of *i* is 1)
i	N	*j*	repeats previous *j* entries *i* times, inverting the sequence each time. (default value of *i* is 1)
i	B	*j*	backs *i* entries. From that position, repeats the previous *j* entries in reverse order (default value of *i* is 1)
i	I	*j k*	provides the end points j and k, with i entries linearly interpolated between them (i.e., a total of i+2 points). At least one blank must separate j and k. When used for an integer array, the I option should only be used to generate integer steps-i.e., (k-j)/(i+1) should be a whole number
	T		terminates the data reading for the array

Note: When entering data using the options in this table, the *count field* and *option field* must be adjacent with no imbedded blanks. The operand field may be separated from the option field by one or more blanks.

Example: Consider a $3 \times 3 \times 1$ `ARRAY` filled with 8 `UNIT` 1s and a `UNIT` 2, as shown below.

```
1     1     1
1     2     1
1     1     1
```

The input data to describe this `ARRAY` could be entered as follows:

Option (1) **`1 1 1 1 2 1 1 1 1 T`** This fills the array one position at a time, starting at the lower left corner. The `T` terminates the data.

or

Option (2) **`F1 A5 2 END FILL`** The F1 fills the entire array with 1s, the A5 locates the fifth position in the array, and the 2 loads a 2 in that position. The `END FILL` terminates the data.

8.1.3.6 Albedo data

Albedo boundary conditions are entered using a *FACE CODE* to define where albedo conditions are to be used, and using an *ALBEDO NAME* to indicate which albedo condition is to be used on that face. The default value for each face is vacuum or void. The default values are overridden only on faces for which other albedo names are specified. Albedo boundary conditions are applied only to the outermost region of a problem (global boundaries). Different albedo options are allowed for different global boundaries, and this may show some differences in both KENO V.a and KENO-VI.

In previous SCALE versions, KENO V.a would have allowed the use of albedo boundary conditions to the boundary faces if and only if the outermost geometry region was a cuboid. For non-cuboidal outermost geometries, only the void or vacuum albedo option could have been applied. This limitation has been relaxed in SCALE 6.3; KENO V.a now allows some albedo options for non-cuboidal boundary shapes.

Unlike KENO V.a, KENO-VI allows a combination of geometry shapes to be used to define the boundaries of the global unit. Combinations of more than one geometry shape may result in re-entrant surfaces in the model. KENO-VI users need to be aware that when a neutron reaches a surface with a vacuum albedo, that neutron exits the model and the history ends. If a model contains features that are reentrant, that is a neutron could exit the model and reenter the model on the other side of an unmodeled region, all neutrons passing through the problem boundary are lost when they reach the unmodeled region. Neutrons are not "transported" across unmodeled areas between reentrant surfaces. It is not possible to create a KENO V.a model with reentrant problem outer boundary surfaces.

The syntax for entering the albedo boundary conditions is as follows. Note that `BODY` is no longer considered as a *FACE CODE* in the KENO-VI albedo boundary conditions capability, unlike the previous versions of SCALE.

KENO V.a:

`READ BOUNDS` **fc**$_1$=a_1 [**fc**$_2$=a_2]... [**fc**$_N$=a_N] `END BOUNDS`

KENO-VI:

`READ BOUNDS` [**BODY**=*body_label*] **fc**$_1$=a_1 [**fc**$_2$=a_2]... [**fc**$_N$=a_N] `END BOUNDS`

fc$_1$ ... **fc**$_N$ are **N** *FACE CODE*s, each refers to a single or combination of multiple faces of the global boundaries (faces of the outermost region of a problem). *FACE CODE*s for different outer shapes are defined in Table 8.1.20.

a_1 ... a_N are the *ALBEDO NAME*s as defined in Table 8.1.23.

BODY= refers to the body or shape label in the global unit input. This optional parameter is available only for KENO-VI. The use of **BODY** with any face code combination is an optional feature for the problems in which the boundary definition vector of the global unit consists of a single body label (e.g. **BOUNDARY 10**). However, any face code used to specify an albedo condition on any face of a boundary shape must follow the **BODY=** parameter when the boundary definition vector of the global unit has more than one boundary labels (e.g., **BOUNDARY 10 20 30**). In such a case, all albedo boundary condition specifications following the **BODY=** definition are applied only on the faces of the body given with that **BODY=** definition.

body_label is the integer label of one of the shapes or bodies listed in the boundary definition vector of the global unit.

Albedo boundary conditions may be entered on each face of the global boundaries multiple times. The boundary condition that applies to the boundary face is the last one entered. If no boundary data are entered or if no albedo boundary condition is applied to a boundary face, then this boundary face is assumed to have a void or vacuum boundary condition. Similarly, albedo boundary conditions may be entered on each face of a boundary body listed in the boundary definition vector of the global unit multiple times. In this KENO-VI specific case, the boundary condition that applies to the boundary face of that body is the last one entered.

Example: Apply the reflective albedo boundary condition to all faces of a cuboidal outer boundary except the positive *X* face.

In this sample problem, KENO with the **ALL** face code first applies the reflective albedo boundary condition to all faces of the outermost geometry. Then, the **+XB=** face code overrides the albedo type as *VACUUM* for the positive *X* face of the cuboidal outer boundary.

KENO V.a:

```
READ BOUNDS
   ALL=mirror +XB=vacuum
END BOUNDS
```

KENO-VI:

```
read geometry
   ...
   global unit 1
      CUBOID 10 ...
      ...
      BOUNDARY 10
end geometry

READ BOUNDS
   ALL=mirror +XB=vacuum
END BOUNDS

' following albedo specification is identical with the above one
' READ BOUNDS
'    BODY=10 ALL=mirror +XB=vacuum
' END BOUNDS
```

Example: Apply a material-specific albedo *H2O* to all faces of the global boundaries except the bottom face of the cuboid, which is one of the boundary shapes. Another material-specific albedo *CONC24* is applied to the bottom face of this cuboid.

This sample problem demonstrates the albedo boundary condition specification for a KENO-VI model in which outer boundary of the global unit is defined by a combination of a cuboid and a sphere (CUBOID 10 and SPHERE 20). KENO-VI, with this input, first applies a material-specific albedo,

H2O, to all faces of BODY 10. Then, it overrides the boundary condition of the bottom face of the cuboid with another material-specific albedo, *CONC24*. Finally, material-specific albedo *H2O* is also applied to the spherical face of BODY 20.

KENO-VI:

```
read geometry
   ...
   global unit 1
      CUBOID 10 ...
      SPHERE 20 ...
      ...
      BOUNDARY 10 20
end geometry

READ BOUNDS
   BODY=10 ALL=H2O -ZB=CONC24
   BODY=20 ALL=H2O
END BOUNDS

' following albedo specification is identical with the above one
' READ BOUNDS
'    BODY=10 ALL=H2O
'    BODY=20 ALL=H2O
'    BODY=10 -ZB=CONC24
' END BOUNDS
```

All available **FACE CODE**s are described in Table 8.1.20. Note that the listed **FACE CODE**s are supported by both KENO V.a and KENO-VI.

Table 8.1.20: Face codes and surface numbers for entering boundary (albedo) conditions.

Face codes	Faces defined by face codes
ALL=	All faces of a single or multiple boundary shape(s)
SURFACE(k)=	Albedo surface enumeration indicates any k^{th} face of the boundary shape (Table 8.1.21 and Table 8.1.22 list shape-specific albedo surface numbers)
+XB=	Positive X face of a cuboidal boundary shape
&XB=	Positive X face of a cuboidal boundary shape
-XB=	Negative X face of a cuboidal boundary shape
+YB=	Positive Y face of a cuboidal boundary shape
&YB=	Positive Y face of a cuboidal boundary shape
-YB=	Negative Y face of a cuboidal boundary shape
+ZB=	Positive Z face of a cuboidal boundary shape
&ZB=	Positive Z face of a cuboidal boundary shape
-ZB=	Negative Z face of a cuboidal boundary shape
XFC=	Both positive and negative X faces of a cuboidal boundary shape
YFC=	Both positive and negative Y faces of a cuboidal boundary shape
ZFC=	Both positive and negative Z faces of a cuboidal boundary shape
+FC=	Positive X, Y, and Z faces faces of a cuboidal boundary shape
&FC=	Positive X, Y, and Z faces of a cuboidal boundary shape
-FC=	Negative X, Y, and Z faces of a cuboidal boundary shape

Table 8.1.20 – continued from previous page

XYF=	Positive and negative X and Y faces of a cuboidal boundary shape
XZF=	Positive and negative X and Z faces of a cuboidal boundary shape
YZF=	Positive and negative Y and Z faces of a cuboidal boundary shape
+XY=	Positive X and Y faces of a cuboidal boundary shape
+YX=	Positive X and Y faces of a cuboidal boundary shape
&XY=	Positive X and Y faces of a cuboidal boundary shape
&YZ=	Positive X and Y faces of a cuboidal boundary shape
+XZ=	Positive X and Z faces of a cuboidal boundary shape
+ZX=	Positive X and Z faces of a cuboidal boundary shape
&XZ=	Positive X and Z faces of a cuboidal boundary shape
&ZX=	Positive X and Z faces of a cuboidal boundary shape
+YZ=	Positive Y and Z faces of a cuboidal boundary shape
+ZY=	Positive Y and Z faces of a cuboidal boundary shape
&YZ=	Positive Y and Z faces of a cuboidal boundary shape
&ZY=	Positive Y and Z faces of a cuboidal boundary shape
-XY=	Negative X and Y faces of a cuboidal boundary shape
-XZ=	Negative X and Z faces of a cuboidal boundary shape
-YZ=	Negative Y and Z faces of a cuboidal boundary shape
YXF=	Positive and negative X and Y faces of a cuboidal boundary shape
ZXF=	Positive and negative X and Z faces of a cuboidal boundary shape
ZYF=	Positive and negative Y and Z faces of a cuboidal boundary shape
-YX=	Negative X and Y faces of a cuboidal boundary shape
-ZX=	Negative X and Z faces of a cuboidal boundary shape
-ZY=	Negative Y and Z faces of a cuboidal boundary shape

Warning: In SCALE 6.3:

- Face codes, which are specific to the cuboidal boundary shape, cannot be used with non-cuboidal boundary shapes.
- **SURFACE(..)** face code **cannot be used** together with any cuboidal face codes listed in Table 8.1.20 if the outermost geometry is cube or cuboid.
- The **ALL** face code refers to all faces of the global boundaries.

Unlike the albedo boundary conditions capability in KENO codes of previous SCALE versions, *FACE CODE* definitions and their use are slightly different in SCALE 6.3.

SURFACE(..)= face code is a valid option for both KENO V.a and KENO-VI. **SURFACE(..)=** face code with a corresponding albedo surface number can be used to apply an albedo boundary condition to the specified surface of **any boundary shape** (cuboidal or non-cuboidal). Albedo surface enumerations for all geometric shapes supported by KENO V.a and KENO-VI are listed in Table 8.1.21 and Table 8.1.22, respectively. Note that entering an illegal albedo surface number with **SURFACE(..)** face code in bounds data input block fails the execution (i.e., SURFACE(2)=... for a sphere, SURFACE(9) for a hexprism, etc.)

The **ALL=** face code will apply the listed boundary condition to all surfaces of a single boundary shape, or multiple boundary shapes (KENO-VI only). It can be used with any boundary shape available in both KENO

V.a and KENO-VI. If it follows a **BODY=** definition, then it refers to all the faces of the body given with that **BODY=** definition (KENO-VI only).

All the face codes, which are listed in Table 8.1.20, except **ALL=** and **SURFACE(..)**, are specific to the cuboidal boundary shape, and they may be applied only to the cuboid or cube boundaries.

Table 8.1.21: Albedo surface numbers related to KENO V.a geometry shapes

GEOMETRY SHAPE	ALBEDO SURFACE ENUMERATION

Surfaces refer to the pre-rotation surface of the body that occurs in the indicated quadrant. Refer to Fig. 8.1.1 through Fig. 8.1.28 for illustrations of each geometry body.												

All albedo names available in both KENO codes are given in Table 8.1.23. Table 8.1.23 lists also some material-specific albedo sets. Care must be exercised when using material-specific albedo types. These data sets were generated using a real problem, and they implicitly reflect the neutron energy spectrum, materials, and geometry from that model. Where neutron energy spectra, materials, and geometry vary from that model, the material-specific albedos may give significantly incorrect results. This may be checked by comparing results from a sample of calculations performed with both explicitly modeled reflectors and material-specific albedos. In general, use of material-specific albedos is not recommended.

Warning: The user should thoroughly understand material-specific albedos (e.g., DP0H2O, CON24, etc.) before attempting to use these reflectors. Misapplication of these problem-specific albedo data can cause the code to produce incorrect results without obvious symptoms.

Table 8.1.23: Albedo names available on the KENO albedo library for use with the face codes *

DP0H2O, DPOH2O, DP0, DPO	12 in. (30.48 cm) double P_0 water differential albedo with 4 incident angles
H2O, WATER	12 in. (30.48 cm) water differential albedo with 4 incident angles
PARAFFIN, PARA, WAX	12 in. (30.48 cm) paraffin differential albedo with 4 incident angles
CARBON, GRAPHITE, C	78.74 in. (200.00 cm) carbon differential albedo with 4 incident angles
ETHYLENE, POLY, CH2	12 in. (30.48 cm) polyethylene differential albedo with 4 incident angles
CONC-4, CON4, CONC4	4 in. (10.16 cm) concrete differential albedo with 4 incident angles
CONC-8, CON8, CONC8	8 in. (20.32 cm) concrete differential albedo with 4 incident angles
CONC-12, CON12, CONC12	12 in. (30.48 cm) concrete differential albedo with 4 incident angles
CONC-16, CON16, CONC16	16 in. (40.64 cm) concrete differential albedo with 4 incident angles
CONC-24, CON24, CONC24	24 in. (60.96 cm) concrete differential albedo with 4 incident angles
VACUUM, VOID	Vacuum condition
SPECULAR, MIRROR, REFLECT	Mirror image reflection
PERIODIC	Periodic boundary condition
WHITE	White boundary condition
* Material-specific albedos (differential albedos) may not be used in continuous energy mode	

Note: Differential albedos (material specific albedos), e.g., H2O and CONC, may not be used in continuous energy calculations. In multigroup mode, none of the differential albedos are allowed for the adjoint transport mode.

Different albedo options are allowed for different global boundaries. If the global boundary is a single cube or

cuboids, then any available albedo option is allowed on any face of this cuboidal global boundary. However, if a periodic boundary condition is to be used, then it must be specified on opposing faces simultaneously.

> **Warning:** There is no consistency check for the surfaces on which **PERIODIC** boundary condition has been specified. It is the user's responsibility to specify the **PERIODIC** boundary condition on opposing faces simultaneously.

Albedo options for non-cuboidal global boundaries may show some differences in KENO V.a and KENO-VI:

KENO V.a:

- Albedo boundary conditions other than **VACUUM** are not allowed if the outermost geometry is either a hemisphere or a hemicylinder.
- Material-specific albedos cannot be applied to the curvilinear faces of the outermost geometry.
- **MIRROR** and **PERIODIC** boundary conditions are not allowed on the curvilinear faces of the outermost geometry.
- Whereas **WHITE** or **VACUUM** may be applied to the radial face of a cylinder, any albedo options can be used for the top and bottom faces.

Example: Use a 24-in. concrete albedo boundary condition on the -Z face of the problem and use mirror image reflection on the +X and -X faces to represent an infinite linear array on a 2 ft thick concrete pad.

```
READ BOUNDS
   XFC=mirror -ZB=CONC24
END BOUNDS
```

Example: A cylinder with arbitrarily chosen length is specularly reflected on the top and bottom faces to create an infinitely long cylinder.

```
READ BOUNDS
   SURFACE(2)=mirror SURFACE(3)=mirror
END BOUNDS
```

KENO-VI:

- Any CHORDed surfaces that are global unit boundaries will use the default (VOID) boundary condition, and this cannot be changed. Because KENO-VI does not provide any input method to assign a non-vacuum albedo boundary condition to the CHORDed surface(s), this restriction may need to be considered when building the geometry of the global unit.
- If the boundary definition vector of the global unit contains only a single body label, then all albedo boundary conditions are allowed on any face of the global boundary.
- If the boundary definition vector of the global unit contains multiple body labels and all these body labels are positive numbers (e.g. **BOUNDARY 10 20 30**), then all albedo boundary conditions may be applied to any of the faces of each body.
- If the boundary definition vector of the global unit contains multiple body labels and any of these body labels are negative numbers (e.g. **BOUNDARY 10 20 -30**), then only the **VACUUM** albedo is allowed on the faces of all bodies.

Caution: No non-vacuum albedo boundary conditions can be applied to a CHORDed surface that is global unit boundary.

Example: A cylinder with an arbitrarily chosen length is specularly reflected on the top and bottom faces to create an infinitely long cylinder.

```
read geometry
   ...
   global unit 1
      CYLINDER 10 ...
      ...
      BOUNDARY 10
end geometry

READ BOUNDS
   ALL=mirror SURFACE(1)=void
END BOUNDS

' identical boundary condition can be applied with another definition
' READ BOUNDS
'    BODY=10 SURFACE(2)=reflective SURFACE(3)=mirror
' END BOUNDS
```

Example: Use a 24 in. concrete albedo boundary condition on the -Z face of the problem and use mirror image reflection on the +X and -X faces to represent an infinite linear array on a 2 ft thick concrete pad.

```
read geometry
   ...
   global unit 1
      CUBOID 101 ...
      ...
      BOUNDARY 101
end geometry

READ BOUNDS
   SURFACE(1)=mirror SURFACE(2)=mirror SURFACE(6)=CON24
END BOUNDS

' identical boundary condition can be applied with another definition
' READ BOUNDS
'    BODY=101 XFC=reflective -ZB=CONC24
' END BOUNDS
```

Example: Use a 24-in. concrete albedo boundary condition on the -Z face of a problem with a hexagonal boundary and use mirror image reflection on all side faces of the hexprism to represent an infinite planar array on a 2-ft-thick concrete pad.

```
read geometry
   ...
   global unit 1
      HEXPRISM 201 ...
      ...
      BOUNDARY 201
end geometry

READ BOUNDS
   SURFACE(1)=mirror SURFACE(2)=mirror
   SURFACE(3)=mirror SURFACE(4)=mirror
   SURFACE(5)=mirror SURFACE(6)=mirror
   SURFACE(7)=vacuum SURFACE(8)=conc24
```

(continues on next page)

(continued from previous page)

```
END BOUNDS

' an alternative albedo specification for the same boundary conditions
' READ BOUNDS
'    ALL=mirror SURFACE(7)=vacuum SURFACE(8)=con24
' END BOUNDS
'

' an alternative albedo specification for the same boundary conditions
' READ BOUNDS
'    BODY=201 ALL=mirror SURFACE(7)=vacuum SURFACE(8)=con24
' END BOUNDS
'

' an alternative albedo specification for the same boundary conditions
' READ BOUNDS
'    ALL=mirror
'    BODY=201 SURFACE(7)=vacuum SURFACE(8)=con24
' END BOUNDS
'
```

Example: The outer boundary of the global unit consists of a cuboid (body label 10) and a sphere (body label 20). The sphere is large enough to cut the corners of the cuboid leaving most of the cuboid intact. Use a 24 in. concrete albedo boundary condition on the -Z face of the cuboid to represent a 2 ft. thick concrete pad. Use the DP0H2O on the other surfaces to represent an infinite water reflector.

```
read geometry
   ...
   global unit 1
      CUBOID 10 ...
      SPHERE 20 ...
      ...
      BOUNDARY 10 20
end geometry

READ BOUNDS
   BODY=10 ALL=DP0H2O -ZB=CONC24
   BODY=20 SURFACE(1)=DPOH2O
END BOUNDS

' an alternative albedo specification for the same boundary conditions
' READ BOUNDS
'    ALL=DPOH2O
'    BODY=10 -ZB=CONC24
' END BOUNDS
```

Note that the **ALL** face code is used in two different ways in the above example: (1) Used with body 10 to apply **DPOH2O** albedo *to all faces of this body* (2) Used without body, which is legitimate for KENO-VI, to apply **DPOH2O** albedo *to all faces of both body 10 and 20* (global unit boundaries defined by CUBOID 10 and SPHERE 20).

Example: KENO geometry specification allows modeling the same physical problem with different geometry definitions. For some cases, boundary condition specification becomes more critical to represent the same problem with different geometry configurations. Users must be extra cautious when building their model and examine the limitations listed in this section carefully to prevent unexpected results.

This example was designed to demonstrate how ignoring such limitations for albedo boundary condition setup affects results in analysis. In this example, a model of a simplified version of a GODIVA sphere was attempted with three different geometry definitions as shown below.

KENO-VI, full GODIVA sphere:

```
...

READ GEOMETRY
   global unit 1
          sphere 30 8.75
      media 1 1 30
      boundary 30
END GEOMETRY

READ BOUNDS
   ALL=vacuum
END BOUNDS
```

KENO-VI, half GODIVA sphere defined by combination of a sphere and a cuboid:

```
...

READ GEOMETRY
   global unit 1
          sphere 30 8.75
      cuboid 40 8.75 0.0 4p8.75
      media 1 1 30 40
      boundary 30 40
END GEOMETRY

READ BOUNDS
   ALL=mirror
       BODY=30 surface(1)=void
END BOUNDS
```

KENO-VI, half GODIVA sphere defined by a sphere and a CHORD modifier:

```
...

READ GEOMETRY
   global unit 1
          sphere 30 8.75 chord +x=0.0
          media 1 1 30
          boundary 30
END GEOMETRY

READ BOUNDS
   ALL=mirror surface(1)=void
END BOUNDS
```

The first geometry definition uses only a sphere to define the Godiva sphere. The second sample input uses the combination of a sphere and a cuboid to define a hemisphere and an appropriate boundary condition on each outer boundary to simulate the Godiva sphere. Similarly, in the third sample input, a modified CHORD was used with a sphere to define a hemisphere and an appropriate boundary condition on each outer boundary to simulate the Godiva sphere.

But even if the sample input with the CHORDed surface given above seems correct at first glance, it cannot model the same physical problem as the other two because the albedo boundary condition specification with ALL=MIRROR is not applied to the CHORDed surface. Therefore, that CHORDed sphere models a half GODIVA sphere rather than a full one. Results from these three models, presented in Table 8.1.24, indicate that using code capabilities improperly might result in significant bias in the results.

Table 8.1.24: k-eff results of GODIVA models used in this example

Model	k-eff
Full sphere	1.02680 +/- 0.00100
Half sphere defined by a sphere and a cuboid	1.02962 +/- 0.00075
Half sphere defined by a sphere and a CHORD	0.78745 +/- 0.00078

Unlike KENO codes in previous versions, in SCALE 6.3, KENO codes print several warning messages to remind the user about such limitations and their potential effects if ignored.

Caution: There is no input method to assign a non-vacuum boundary condition to a CHORDed boundary surface (external boundary). Therefore, KENO-VI always applies VACUUM boundary condition to the CHORDed boundary surfaces, and this cannot be changed.

8.1.3.7 Biasing or weighting data

The biasing data block is used (in only multigroup mode) to define the weight that is given to a neutron surviving Russian roulette. The average weight of a neutron that survives Russian roulette, *wtavg*, is defaulted to *dwtav* (**WTA**= in the parameter data [see Sect. 8.1.3.3]) for all *BIAS IDs* and can be overridden by entering biasing information.

The *biasing_information* is used to relate a *BIAS ID* to the desired energy-dependent values of *wtavg*. This concept is similar to the way the *MIXTURE ID, mat*, is related to the macroscopic cross section data.

The weighting functions used in KENO are energy-dependent values of *wtavg* that are applicable over a given thickness interval of a material. For example, the weighting function for water is composed of sets of energy-dependent values of *wtavg* for 11 intervals, each interval being 3 cm thick. The first set of *wtavg's* is for the 0–3 cm interval of water, the second set of *wtavg's* is for the 3–6 cm interval of water, etc. The eleventh set of *wtavg's* is for the 30–33 cm interval of water.

To input biasing information, a *BIAS ID* must be assigned to correspond to a set of *wtavg*. Biasing data can specify a *MATERIAL ID* from the existing KENO V.a weighting library or from the *AUXILIARY DATA* input. The materials available from the KENO weighting library are listed in Table 8.1.25.

The *biasing_information* is entered in one of the following two forms. The first set is said to input the *CORRELATION DATA*, while the second form is said to input the *AUXILIARY DATA*.

`READ BIAS ID**\ =\ *m ib ie* ``END BIAS`

or

`READ BIAS WT[S]=`*wttitl id s* t_1 i_1 g_1 $w_{1,1}$ ... $w_{1,i1xg1}$ ... t_s i_s g_s $w_{s,1}$ ... $w_{s,isxgs}$ `END BIAS`

`ID=` specifies that *CORRELATION DATA* will be entered next.

`WT=` or `WTS=` specifies that *AUXILIARY DATA* will be entered next.

m is the identification (material ID) for the material whose weighting function is to be used. A material ID can be chosen from the existing KENO weighting library (Table 8.1.25) or from the *auxiliary data* input using the second form of the **BIAS** block as described later. If a material ID appears in both the KENO weighting library and the *auxiliary data*, the *weights* from the *auxiliary data* will be used.

ib is the bias ID of the weighting function for the first interval of material *m*. The geometry record having the bias ID equal to *ib* will use the group-dependent *weights* from the first interval of material *m*.

ie is the bias ID of the group-dependent *weights* from the (*ie* - *ib* + 1)*th* interval of material *m*.

wttitl is an arbitrary title name (12 characters maximum), such as CONCRETE, WATER, SPECIALH2O, etc., to identify the material for which the user is entering data. Embedded blanks are not allowed.

id is an identification number (material ID). The value is arbitrary. However, if the data are to be utilized in the problem, this ID must also be used at least once in the first form of the **BIAS** block.

s is the number of sets of group structures for which *weights* will be read for this ID.

$t_1 \ldots t_s$ are *s* thicknesses of each increment for which *weights* will be read for this ID.

$i_1 \ldots i_s$ are *s* numbers of increments for which *weights* will be read for this ID.

$g_1 \ldots g_s$ are *s* numbers of energy groups for which *weights* will be read.

$w_{1,i1xg1} \ldots w_{s,isxgs}$ are *s* sets of *weights*, each set containing a number of *weights* equal to the product of number of increments times the number of groups for that set. The group index varies the fastest.

Table 8.1.25: IDs, group structure and incremental thickness for weighting data available on the KENO weighting library.

Material	Material ID	Group structure for which weights are available	Increment [a] thickness (cm)	Total number of increments available
Concrete	301	27	5	20
		28	5	20
		56	5	20
		200	5	20
		238	5	20
		252	5	20
Paraffin	400	27	3	10

		238	20	10
		252	20	10

continues on next page

Table 8.1.25 – continued from previous page

[a] Group-dependent weight averages are supplied for each increment of the specified incremental thickness (i.e., for any given material) the first ngp (number of energy groups) weights apply to the first increment of the thickness specified here, the next ngp weights apply to the next increment of that thickness, etc CAUTION–If bias IDs defined in the weighting information data are used in the geometry, the region thickness should be consistent with the incremental thickness of the weighting data in order to avoiid overbiasing or underbiasing.

Warning: The user should thoroughly understand weighted tracking before attempting to generate and use auxiliary data for biasing. Incorrect weighting can cause the code to produce incorrect results without obvious symptoms.

Caution: 1. Each set of *AUXILIARY* or *CORRELATION* data must be completely described in conjunction with its keyword. Complete sets of these data can be interspersed in an arbitrary order but data within each set must be entered in the specified order.

2. *AUXILIARY DATA*: If the same *m* is specified in more than one set of data, the last set having the group structure used in the problem is the set that will be utilized. When *AUXILIARY DATA* are entered, *CORRELATION DATA* must also be entered in order to use the *AUXILIARY DATA*.

3. *CORRELATION DATA*: If biasing data define the same bias ID (from the geometry data) more than once, the value that is entered last supersedes previous entries. *Be well aware that multiple definitions for the same bias ID can cause erroneous answers due to overbiasing.*

4. Bias data may not be used in continuous energy mode.

Examples

1. Use the first form of the **BIAS** block to utilize the water biasing factors in bias IDs 2 through 11. From Table 8.1.25, water has material ID m=500 and has bias parameters for 10 intervals that are each 3 cm thick.

```
READ BIAS ID=500 2 11 END BIAS
```

2. Use the second form of the `BIAS` block to specify biasing factors for `SPECIALWATER` to be used in bias IDs 6 and 7. The `SPECIALWATER` biasing factors have a value of 0.69 for BIAS ID 6 and 0.86 for bias ID 7 in each energy group. Sixteen-group cross sections are being used. Each weighting region is 3.048 cm thick. The material ID is arbitrarily chosen to be 510. Note that the first form of the `BIAS` block must be entered to allow the second form of the `BIAS` block to be used for BIAS IDs 6 and 7.

```
READ BIAS WT = SPECIALWATER 510 1 3.048 2 16 16*0.69 16*0.86 ID=510 6 7 END BIAS
```

3. An example of multiple definitions for the same bias ID follows:

```
READ BIAS ID=400 2 7 ID=500 5 7 END BIAS
```

The data for paraffin (`ID`=400) will be used for bias IDs 2, 3, and 4, and the data for water (`ID`=500) will be used for bias IDs 5, 6, and 7. The paraffin data for bias IDs 5, 6, and 7 have been overwritten by water data.

Multiple definitions for the same bias ID are not necessarily incorrect, but the user should be cautious about using multiple definitions and should ensure that the desired biasing or weighting functions are used in the desired geometry regions.

4. An example of how the *bias ID* relates to the energy-dependent values of *weights* is given below.

Assume that a paraffin reflector is to be used, and it is desirable to use the weighting function from the KENO weighting library to minimize the running time for the problem. Also assume that these weighting functions are to be used in the volumes defined in the geometry records having the *bias ID* (defined on a **shape** or `MEDIA` card for KENO V.a and KENO-VI, respectively) equal to 6, 7, 8, and 9. *Correlation data* are then entered and *auxiliary data* will not be entered.

The biasing data would be:

```
READ BIAS ID=400 6 9 END BIAS
```

The results of these data are

(1) the group-dependent *weights* for the 0–3 cm interval of paraffin will be used in the volume defined by the geometry region having *bias ID*= 6.

(2) the group-dependent *weights* for the 3–6 cm interval of paraffin will be used in the volume defined by the geometry region having *bias ID*= 7.

(3) the group-dependent *weights* for the 6–9 cm interval of paraffin will be used in the volume defined by the geometry region having *bias ID*= 8.

(4) the group-dependent *weights* for the 9–12 cm interval of paraffin will be used in the volume defined by the geometry region having *bias ID*= 9.

8.1.3.8 Start data

Special start options are available for controlling the initial neutron distribution. The default starting distribution for **a global array** is flat over the overall array dimensions, in fissile material only. The default starting distribution for a single unit is flat over the system, in fissile material only. See Table 8.1.26 for the starting distributions available in KENO. The syntax for the **START** block is:

`READ START` *p1 ...pN* `END START`

$p_1 \ldots p_N$ are N initializations for the parameters listed below.

The starting information that can be entered is given below. Enter only the data necessary to describe the desired starting distribution.

NST = ***ntypst*** start type, default = 0 Table 8.1.26 lists the available options under the heading, "Start type."

TFX = ***tfx*** the X coordinate of the point at which neutrons are to be started. Default = 0.0. Use for start types 3, 4, and 6.

TFY = ***tfy*** the Y coordinate of the point at which neutrons are to be started. Default = 0.0. Use for start types 3, 4, and 6.

TFZ = ***tfz*** the Z coordinate of the point at which neutrons are to be started. Default = 0.0. Use for start types 3, 4, and 6.

NXS = ***nbxs*** the x index of the unit's position in the global array. Default = 0. Use for start types 2, 3, and 6.

NYS = ***nbys*** the y index of the unit's position in the global array. Default = 0. Use for start types 2, 3, and 6.

NZS = ***nbzs*** the z index of the unit's position in the global array. Default = 0. Use for start types 2, 3, and 6.

KFS = ***kfis*** the mixture whose fission spectrum is to be used for starting neutrons that are not in a fissionable medium. Defaulted to the fissionable mixture having the smallest mixture number. Available for start types 3, 4, and 6.

LNU = ***lfin*** the final neutron to be started at a point. Default = 0. Each *lfin* should be greater than zero, and each successive *lfin* should be greater than the previous one. Use only for start type 6.

NBX = ***nboxst*** the unit in which neutrons will be started. Default = 0. Use for start types 4 and 5.

FCT = ***fract*** the fraction of neutrons that will be started as a spike or the relative fraction of each segment when using to specify a segmented distribution in z. Default = 0. Use for start type 2 and type 8.

XSM = ***xsm*** the -X dimension of the cuboid in which the neutrons will be started. Default = 0.0. For an array problem, XSM is defaulted to the minimum X coordinate of the global array. If the outermost geometry is a cube or cuboid, then XSM is defaulted to the minimum X coordinate of this cuboid. Use for start types 0, 1, 2, 7, and 8.

XSP = ***xsp*** the +X dimension of the cuboid in which the neutrons will be started. Default = 0.0. For an array problem, XSP is defaulted to the maximum X coordinate of the global array. If the outermost geometry is a cube or cuboid, then XSP is defaulted to the maximum X coordinate of this cuboid. Use for start types 0, 1, 2, 7, and 8.

YSM = ***ysm*** the -Y dimension of the cuboid in which the neutrons will be started. Default = 0.0. For an array problem, YSM is defaulted to the minimum Y coordinate of the global array. If the outermost geometry is a cube or cuboid, then YSM is defaulted to the minimum Y coordinate of this cuboid. Use for start types 0, 1, 2, 7, and 8.

YSP = ***ysp*** the +Y dimension of the cuboid in which the neutrons will be started. Default = 0.0. For an array problem, YSP is defaulted to the maximum Y coordinate of the global array. If the outermost geometry is a cube or cuboid, then YSP is defaulted to the maximum Y coordinate of this cuboid. Use for start types 0, 1, 2, 7, and 8.

ZSM = ***zsm*** the -Z dimension of the cuboid in which the neutrons will be started. Default = 0.0 for only start types 0, 1, 2, and 7. For an array problem, ZSM is defaulted to the minimum Z coordinate of the global array. If the outermost geometry is a cube or cuboid, then ZSM is defaulted to the minimum Z coordinate of this cuboid. Use for start types 0, 1, 2, 7, and 8.

ZSP = ***zsp*** the +Z dimension of the cuboid in which the neutrons will be started. Default = 0.0 for only start types 0, 1, 2, and 7. For an array problem, ZSP is defaulted to the maximum Z coordinate of the global array. If the outermost geometry is a cube or cuboid, then ZSP is defaulted to the minimum Z coordinate of this cuboid. Use for start types 0, 1, 2, 7, and 8.

RFL = ***rflkey*** No longer supported (obsolete parameter).

PS6 = ***lprt6*** the key for printing start type 6 input data. If the key is YES, then start type 6 data are printed. If it is NO, then start type 6 data are not printed. Enter YES or NO. Default = NO. Available for start type 6.

PSP = ***lpstp*** the key for printing the neutron starting points using the tracking format. If the key is YES, then print the neutron starting points. If it is NO, then do not print the starting points. Enter YES or NO. Default = NO. Available for all start types.

RDU = ***rdu*** the file from which ASCII start data are to be read for start type 6.

WS6 = ***ws6*** the file to which ASCII start data are written. Available for all start types.

MSS = ***filename.msl*** the file from which ASCII start data are to be read. *filename* may include a valid pathname. Available for start type 9.

Note: All start types can write the initial neutron starting points at the last generation to an ASCII start data file specified by WS6. However, only start type 6 can read starting data from an ASCII start data file specified by RDU. The ASCII start data file format is described in Sect. 8.1.3.8.1.

Table 8.1.26: Starting distributions available in KENO.

Start type	Required data	Optional data	Starting distribution
0	None	NST XSM XSP YSM YSP ZSM ZSP PSP WS6 RFL [a]	Uniform throughout fissile material within the volume defined by (1) the outer region of a single unit, (2) the boundary of the global array, or (3) a cuboid specified by XSM, XSP, YSM, YSP, ZSM, and ZSP.
1	NST	XSM XSP YSM YSP ZSM ZSP PSP WS6 RFL [a]	The starting points are chosen according to a cosine distribution throughout the volume of a cuboid defined by XSM, XSP, YSM, YSP, ZSM, and ZSP. Points that are not in fissile material are discarded.
2	NST NXS NYS NZS FCT	XSM XSP YSM YSP ZSM ZSP PSP WS6 RFL [a]	An arbitrary fraction (FCT) of neutrons are started uniformly in the unit located at position NXS, NYS, NZS in the global array. The remainder of the neutrons is started in fissile material, from points chosen from a cosine distribution throughout the volume of a cuboid defined by XSM, XSP, YSM, YSP, ZSM, ZSP.
3	NST TFX TFY TFZ NXS NYS NZS	KFS PSP WS6	All neutrons are started at position TFX, TFY, TFZ within the unit located at position NXS, NYS, NZS in the global array.

continues on next page

Table 8.1.26 – continued from previous page

4	NST TFX TFY TFZ NBX	KFS PSP WS6	All neutrons are started at position TFX, TFY, TFZ within units NBX in the global array.
5	NST NBX	PSP WS6	Neutrons are started uniformly in fissile material in units NBX in the global array.
6	NST TFX TFY TFZ LNU [b]	NXS NYS NZS KFS PS6 PSP RDU [c] WS6	The starting distribution is arbitrarily input. LNU is the final neutron to be started at a point TFX, TFY, TFZ relative to the global coordinate system or at a point TFX, TFY, TFZ, relative to the unit located at the global array position NXS, NYS, NZS.
7		XSM XSP YSM YSP ZSM ZSP PSP WS6	The starting points are chosen according to a flat distribution in the X- and Y-dimensions and a $(1.0 - \cos(z))^2$ distribution in the Z-dimension throughout the volume of a cuboid defined by XSM, XSP, YSM, YSP, ZSM, and ZSP. Points that are not in fissile material are discarded.
8	NST ZSM ZSP FCT	XSM XSP YSM YSP PSP WS6	Neutrons are started with flat distribution in X and Y, and a segmented distribution in Z, with the X-Y limits defined by XSM, XSP, YSM, YSP and the relative fraction in ZSP-ZSM defined by FCT. FCT must be the last **entry** for each segment.
9	NST MSS		Mesh source from Sourcerer [d]. The starting distribution is read from a previously created mesh source file declared with MSS=*filename.msl*, where *filename* may include a valid pathname.

continues on next page

Table 8.1.26 – continued from previous page

[a] RFL parameter is no longer supported (obsolete parameter)
[b] When entering data for start 6, LNU must be the last entry for each set of data, and the LNU in each successive set of data must be larger than the previous value of LNU. A set of data consists of required and optional data.
[c] Starting points can be read from either a single or multiple ASCII start data file(s) specified with RDU. Each set of data with RDU must be followed by LNU that controls the number of starting points read from each file. Starting points read from an ASCII start data file can be also combined with any set of starting data specified with TFX/TFY/TFZ and/or NXS/NYS/NZS.
[d] Sourcerer sequence has temporarily been removed from SCALE 6.3 because its design relied on legacy SCALE components. A new development has been in progress to redesign Sourcerer capability as a new START data type for both KENO and Shift transport codes, which will be available in next SCALE release.

Warning: Start data input block does not allow multiple start types defined together. Both KENO V.a and KENO-VI only process the start data entered in the first start data input block and discard the others if multiple start data input block defined in user input.

Example-1:

Both KENO V.a and KENO-VI read only start data from the first start data input block and ignore the second one. All starting points are uniformly sampled throughout the fissile materials iside the user-defined box (+x=3.0 -x=-3.0 +y= 1.0 -y=-1.0 +z= 2.0 -z=-2.0).

```
...

  READ START
     NST=0 XSP=3.0 XSM=-3.0 YSP=1.0 YSM=-1.0 ZSP=2.0 ZSM=-2.0
  END START

  READ START
     NST=6 TFX=2.0 TFY= 3.0 TFZ=0.0  LNU=25
  END START

end data
end
```

Optional parameters, **XSM**, **XSP**, **YSM**, **YSP**, **ZSM**, and **ZSP** allowed in start types 0, 1, 2, 7, and 8 are defaulted to 0.0. The default values are internally updated for the problems either with a global array or with a global unit with cuboid booundary shape as described above. User-defined values always override these defaults, and the last user entry always overrides the previous one. See Sect. 8.1.4.8 for details and more examples.

Note: User input specification with **XSM** > **XSP** or **YSM** > **YSP** or **ZSM** > **ZSP** is **not** considered as an error, and calculation is continued by swapping the values. Start type edit in output does not reflect the swapping operations.

Note: KENO-VI and KENO V.a has different interpretation for the source sampling when the user-defined cuboid is not inside the outermost geometry. In such a case, some starting points could be outside the global

geometry, even though they are sampled inside the user-defined cuboid, and these points are considered as an error by KENO V.a; therefore, code terminates the execution after a couple errors have occurred. In contrast, rather than terminating execution, KENO-VI discards the points sampled outside the global geometry, and continues source sampling until all starting points have been sampled in the fissile regions inside the global unit.

Note: Unlike KENO V.a, the outer boundary can be any shape (or combination of shapes) in KENO-VI. For such a case, KENO-VI samples starting positions in the volume of **the first body** entered in the boundary definition vector of the global unit if and only if none of translation and transformation operations are performed on this body.

The start type 6 capability allows neutrons to be started at the arbitrary starting points defined by a set of data. The last entry for each start 6 data set must be LNU, and the LNU value of each successive set of data must be larger than the last. Start 6 data set with any of TFX, TFY, and TFZ, followed by LNU defines points relative to the global coordinate system, and with any of NXS, NYS, NZS, TFX, TFY, and TFZ followed by LNU defines points relative to the unit located at global array position (NXS, NYS, NZS).

In the start type 6 capabilitiy, TFX, TFY, and TFZ values are defaulted to 0.0, and NXS, NYS, and NZS values are defaulted to 0. This capability does not allow multiple entries of NXS, NYS, NZS, TFX, TFY, and TFZ in the same start 6 data set. NXS, NYS, NZS, TFX, TFY, and TFZ values entered in each start type 6 data set override their default values. A start type 6 data set with one or more missing TFX, TFY, and TFZ entries does not halt the execution. Instead, the last updated values of TFX, TFY, and TFZ are used for the missing one.

Start type 6 is capable of reading starting points from an ASCII start data file, which could be created by writing starting points from a previous calculation, defined by RDU in a start type 6 data set. See Sect. 8.1.3.8.1 for the details about a typical ASCII start data file currently supported, and Sect. 8.1.4.8 for more examples.

The following example was designed to illustrate the starting source distributions provided by start data types. Note that only start types 0, 1, 2, 5, 7, and 8 was used for this specific example.

Example-2:

In this example, a $2 \times 2 \times 1$ rectangular array filled with four different units is used to demonstrate the different starting point distributions that can be generated by the starting types available in the start data capability. Spatial distribution of the starting points sampled with only start types 0, 1, 2, 5, 7, and 8 are overlayed on the problem geometry.

```

- **start type 0** (default starting type), samples neutrons initial starting points uniformly throughout four

fissile cylinders inside the global unit. Fig. 8.1.12 shows spatial distributions of the initial neutrons.

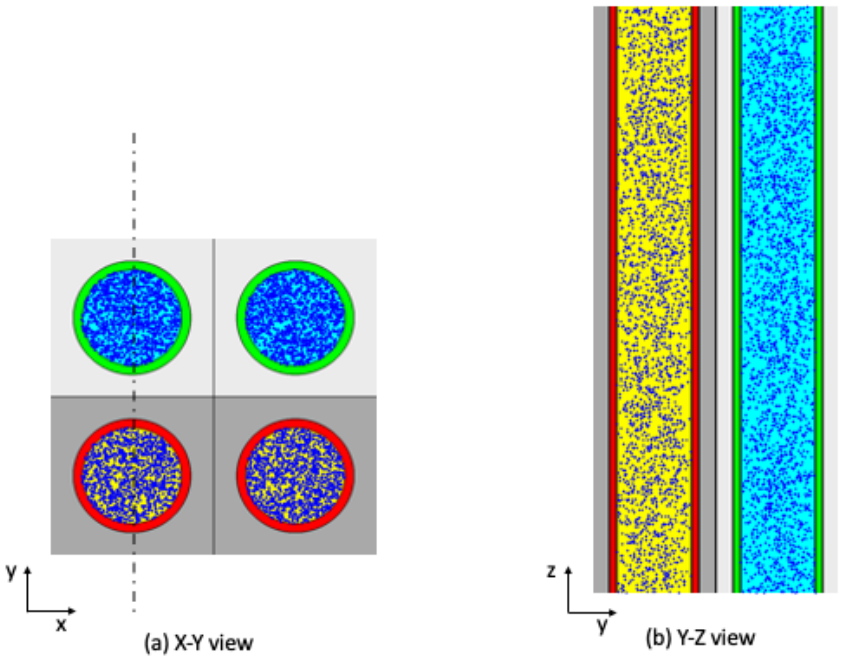

Fig. 8.1.12: Starting point distribution obtained with start type 0 overlayed on the geometry

---

Note: Overlaying starting distribution on Fulcrum-visualized geometry is not currently implemented in Fulcrum. Initial starting points obtained with **PSP** option for all these start type configurations were used with an external utility to overlay them on the geometry visualized by Fulcrum.

- **start type 1**, samples neutrons initial starting points with a cosine distribution (in each dimension) within a user-defined box given in start data input. All points except the ones in four fissile cylinders inside the global unit are discarded. Start type 1 produces initial neutron distributions concentrated in the middle of the problem as depicted in Fig. 8.1.13.

```

END START
```

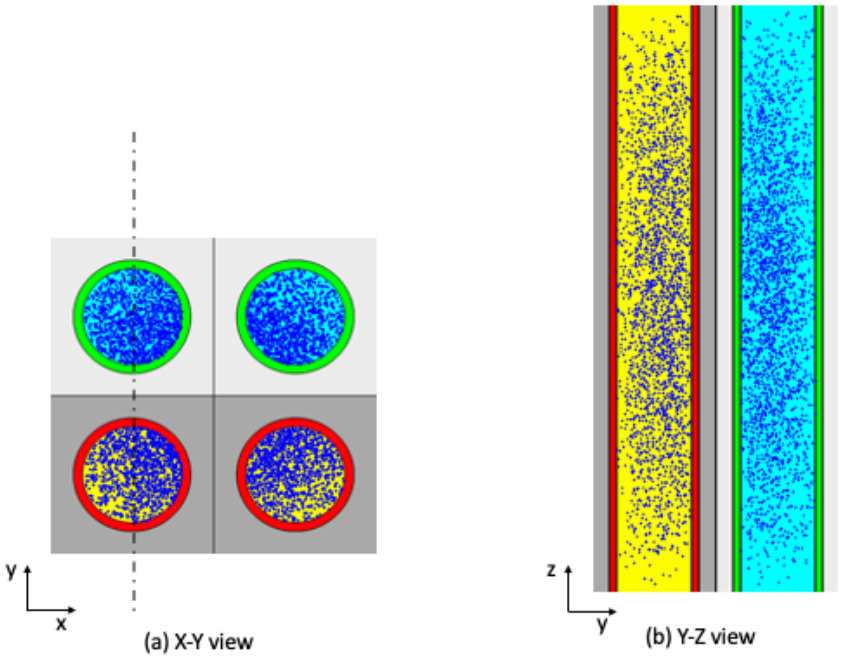

Fig. 8.1.13: Starting point distribution obtained with start type 1 overlayed on the geometry

- **start type 2** is used with the array problems. With the following start data definition, an arbitrary fraction (FCT=0.5 in this case) of neutrons is started uniformly in the unit (unit=1) located at position NXS=1 NYS=1 and NZS=1 in the global array. The remainder of the neutrons are started in fissile material, from points chosen from a cosine distribution throughout the volume of a cuboid defined by +x=1.275 -x=-1.275 +y=1.275 -y=-1.275 +z=6.0 -z=0.0. All points except the ones in four fissile cylinders inside the user-defined cuboid are discarded. Start type 2 produces initial neutron distributions concentrated both in the middle of the problem and in the unit=1 located at the specified global array element. Fig. 8.1.14 shows both vertical and horizontal spatial distributions of the initial neutrons sampled with this start type.

```

ASCII Start Data File Format

A sample ASCII start data file is shown below. In a typical ASCII start data file, each line defines a data set. The first three columns are `TFX`, `TFY`, and `TFZ` values, the next four columns are `NXS`, `NYS`, `NZS`, and `KFS`, and the last column is always `LNU`. The file must be ended with a termination line with `LNU` =0. The file format is given with `(3es20.9,5i12)`.

8.1.3.9 Extra 1-D XSECS IDs data

Extra 1-D cross section IDs are not required. They are allowed as input in order to simplify future modifications to calculate reaction rates, etc., as well as for compatibility with other SCALE codes. The syntax for the extra 1-D cross section data block is:

`READ X1DS NEUTRON` *i1* ... *ix1d* `END X1DS`

`NEUTRON` is a keyword to indicate that the following ID identifies a neutron interaction.

***i*₁ ... *i*_{x1d}** `X1D` 1-D identification numbers or keyword identifiers for the 1-D cross section to be used. These cross sections must be available on the mixture cross section library. `X1D` entries are expected to be read (see integer PARAMETER data).

8.1.3.10 Mixing table data

A cross section mixing table must be entered if KENO is being run stand alone and a Monte Carlo cross section format library is not being used in the multigroup mode, or KENO is being run stand alone in the continuous energy mode. If the parameter `LIB=` (Sect. 8.1.3.3) is entered, then mixing table data must be entered. A cross section mixing table is entered using the following syntax:

`READ MIXT` p_1 ... p_N `END MIXT`

***p*₁ ... *p*_N** are *N* parameters that might or might not be keyworded.

The possible parameters that can be used in a `MIXT` block are described below.

`SCT` **= *nsct*** is used to input the number of scattering angles and only applies in multigroup mode. *nsct* is the number of discrete scattering angles, default = 1. The number of scattering angles specifies the number of discrete scattering angles to be used for the cross sections. If SCT is not set (i.e., SCT= -1), then the number of scattering angles is determined from the cross section library specified. The number of scattering angles defaults to (ncoef+1)/2, where ncoef is the largest Legendre polynomial order used in the problem. It needs to be entered only once for a problem. If more than one value is entered, the last one is used for the problem. For assistance in determining the number of discrete scattering angles for the cross sections, see Sect. 8.1.4.4.3.

`EPS` **= *pbxs*** is used to enter the cross section message cutoff value, and it only applies in multigroup mode. *pbxs* is the value of the P_0 cross section for each transfer, above which generated warning messages will be printed, default = 3×10^{-5}. The primary purpose of entering this cutoff value is to suppress printing these messages when they are generated during cross section processing. For assistance in determining a value for EPS, see Sect. 8.1.4.4.4.

`MIX` **= *mix*** is used to input the identification number of the mixture being described. *mix* defines the mixture being described.

`NCM` **= *ncmx*** is used to input the nuclide mixture IDs to be used for this mixture. *ncmx* defines the nuclide mixture ID. When `MIX`=*mix* is read, *ncmx* is defaulted to *mix* also. Then, as long as all the nuclides that need to be mixed into *mix* already have *mix* specified as their nuclide mixture (frequently the case when using SCALE), the user does not need to specify `NCM`. The most usual case where `NCM` must be specified is when the mixtures were specified as a different mixture number when they were created in SCALE as compared to the mixture number used for them in KENO. Cell homogenized mixtures also need `NCM` specified.

`TMP|TEM` **= *temperature*** is used to input the desired temperature of the CE cross section data.

`nucl` is the nuclide ID number from the AMPX working format cross section library.

XS=*fname* is used to input the optional continuous energy cross section filename to override the default cross sections. *fname* is the name of the file.

dens is the number density (atoms/b-cm) associated with nuclide ID number *nucl*.

The sequence "*nucl* NCM=*ncmx* [XS=*fname*] *dens*" may be repeated until the mixture defined by MIX=*mix* has been completely described.

The sequence "MIX = *mix* NCM = *ncmx* TMP|TEM = *temperature nucl* NCM=*ncmx* [XS=*fname*] *dens*" may be repeated until all the mixtures have been described.

Note: If a given nuclide ID is entered more than once in the same mixture, then the number densities for that nuclide are summed.

If a mixture number is used as a nuclide ID, then it is treated as a nuclide and the number density associated with it is used as a density modifier. (If the density is entered as 1, then the mixture is mixed in at full density. If it is entered as 0.5, the mixture is mixed in at one half of its full density.) A Monte Carlo formatted cross section library is generated on the unit defined by the parameter XSC=. If this data set is saved, subsequent cases can utilize these mixtures without remixing.

The entry XS=*fname* is optional. If a nuclide is entered more than once in a mixture and this entry is specified, then they must be the same (i.e., cannot use more than one continuous energy cross section sets for a nuclide in a given mixture). Different mixtures may have the same nuclide with different continuous energy cross section sets.

8.1.3.11 Plot data

Plots of slices specified through the geometry can be generated and displayed (1) as character plots using alphanumeric characters to represent mixture numbers, unit numbers or bias ID numbers or (2) as color plots which generate a PNG file using colors to represent mixture numbers, unit numbers or bias ID numbers. Color plots require an independent program to display the PNG file to a PC or workstation monitor or to convert the file to be displayed using a plotting device. The keyword SCR= is used to control the plot display method. SCR=YES, the default value, uses the color plot display method. SCR=NO uses the character plot display method. The value of SCR determines the plot display method for all the plots specified in a problem. If SCR= is entered more than once, the last entry determines the plot display method. In other words, all plots generated by a problem will be either character plots or color plots.

The plot data can include the data for any or all types of plots. A plot by mixture number is the default. The kind of plot is defined by the parameter PIC=. Character plots are printed after the volumes are printed and before the final preparations for tracking are completed. Plot data are not required for a problem, but theyb can be used to verify the problem description. The actual plotting of the picture can be suppressed by entering PLT= NO in the parameter data or plot data. This allows plot data to be kept in the problem input for reference purposes without actually plotting the picture(s). Entering a value for PLT in the plot data will override any value entered in the parameter data. However, if a problem is restarted, the value of PLT from the parameter data is used. The upper left and lower right coordinates of the plot must be specified relative to the origin of the problem. See Sect. 8.1.4.10 for a discussion of plot origins and plot data.

Enter the plot data using the following syntax:

READ PLOT p_1 ... p_N END PLOT

***p*$_1$ ... *p*$_N$** are *N* parameters entered using keywords followed by the appropriate data. The plot title and the plot character string must be contained within delimiters. Enter as many picture parameters as necessary to describe the plot. Multiple sets of plot data can be entered. The parameter input for each plot is terminated by a labeled or unlabeled END. The labeled END cannot use the word PLOT as the first four characters of the label. For example, END PLT1 is a valid label, but END PLOT1 is not. If an unlabeled END is used, it cannot start in column 1.

The possible parameters that can be used in a PLOT block are described below.

TTL=*delim ptitl delim* Enter a one-character delimiter *delim* to signal the beginning of the title (132 characters maximum). The title is terminated when *delim* is encountered the second time. Acceptable delimiters include ” , ` , * , ^ , or !. Default = title of the KENO case.

PIC= *wrd* The plot type, *wrd*, is followed by one or more blanks and must be one of the keywords listed below. The plot type is initialized to MAT; the default is the value from the previous plot.

MAT MIX[T[URE]] MEDI[A]	These keywords will cause the plot to represent the mixture numbers used in the specified geometry slice.
UNT UNIT[TYPE]	These keywords will cause the plot to represent the units used in the specified geometry slice. In the legend of the color plot, the material number actually refers to the units.
IMP BIAS[ID] WTS WEIG[HTS] WGT[S]	These keywords will cause the plot to represent the bias ID numbers used in the specified geometry slice. In the legend of the color plot, the material number actually refers to the bias ID numbers.

TYP = Enter the type desired. XY for an X-Y plot XZ for an X-Z plot YZ for a Y-Z plot Direction cosines do not need to be entered if TYP is entered.

Plot coordinates Enter values for the upper left and lower right coordinates of the plot as described below. **Data must be entered for all nonzero coordinates unless all six values from the previous plot are to be used.**

Upper left coordinates Enter the X, Y, and Z coordinates of the upper left-hand corner of the plot.

XUL=*xul* is used to enter the X coordinate of the upper left-hand corner of the plot. Default = value from previous plot; initialized to zero if any other coordinates are entered.

YUL=*yul* is used to enter the Y coordinate of the upper left-hand corner of the plot. Default = value from previous plot; initialized to zero if any other coordinates are entered.

ZUL=*zul* is used to enter the Z coordinate of the upper left-hand corner of the plot. Default = value from previous plot; initialized to zero if any other coordinates are entered.

Lower right coordinates Enter the X, Y, and Z coordinates of the lower right-hand corner of the plot.

XLR=*xlr* is used to enter the X coordinate of the lower right-hand corner of the plot. Default = value from previous plot; initialized to zero if any other coordinates are entered.

YLR=*ylr* is used to enter the Y coordinate of the lower right-hand corner of the plot. Default = value from previous plot; initialized to zero if any other coordinates are entered.

ZLR=*zlr* is used to enter the Z coordinate of the lower right-hand corner of the plot. Default = value from previous plot; initialized to zero if any other coordinates are entered.

Direction cosines across the plot Enter direction numbers proportional to the direction cosines for the AX axis of the plot. The AX axis is from left to right across the plot. If any one of the AX direction cosines is entered, the other two are set to zero. The direction cosines are normalized by the code.

UAX=*uax* is used to enter the X component of the direction cosines for the AX axis of the plot. Default = value from previous plot; initialized to zero if any other direction cosines are entered.

VAX=*vax* is used to enter the Y component of the direction cosines for the AX axis of the plot. Default = value from previous plot; initialized to zero if any other direction cosines are entered.

WAX=*wax* is used to enter the Z component of the direction cosines for the AX axis of the plot. Default = value from previous plot; initialized to zero if any other direction cosines are entered.

Direction cosines down the plot Enter direction numbers proportional to the direction cosines for the DN axis of the plot. The DN axis is from top to bottom down the plot. If any one of the DN direction cosines is entered, the other two are set to zero. The direction cosines are normalized by the code.

UDN=*udn* is used to enter the X component of the direction cosines for the DN axis of the plot. Default = value from previous plot; initialized to zero if any other direction cosines are entered.

VDN=*vdn* is used to enter the Y component of the direction cosines for the DN axis of the plot. Default = value from previous plot; initialized to zero if any other direction cosines are entered.

WDN=*wdn* is used to enter the Z component of the direction cosines for the DN axis of the plot. Default = value from previous plot; initialized to zero if any other direction cosines are entered.

Scaling parameters Enter one or more scaling parameters to define the size of the plot.

Note: If any of the scaling parameters are entered for a plot, the value of those that were not entered is recalculated. If none of the scaling parameters are specified for a plot, the values from the previous plot are used.

DLX=*dlx* is used to input the horizontal spacing between points on the plot. Default = value from previous plot; initialized to zero if NAX or NDN is entered.

DLD=*dld* is used to input the vertical spacing between points on the plot. Default = value from previous plot; initialized to zero if NAX or NDN is entered.

Note: If either DLX or DLD is entered, the code will calculate the value of the other. If both are entered, the plot may be distorted.

NAX=*nax* is used to input the number of intervals to be printed across the plot. Default = value from previous plot; initialized to zero if DLX or DLD is entered.

NDN=*ndn* is used to input the number of intervals to be printed down the plot. Default = value from previous plot; initialized to zero if DLX or DLD is entered.

Global scaling parameter

LPI=*lpi* is used to input a scaling factor used to control the horizontal to vertical proportionality of a plot or plots. SCALE 4.3 and later versions allow *lpi* to be input as a floating point number. For an undistorted character plot, *lpi* should be specified as the number of characters down the page that occupy the same distance as ten characters across the page. For an undistorted color plot, *lpi* should be entered as ten times the ratio of the vertical pixel dimension to the horizontal pixel dimension. The default value of *lpi* is 8.0 for a character plot and 10.0 for a color plot. *lpi*=10 will usually display an undistorted color plot.

The value entered for *lpi* applies to all plot data following it until a new value of *lpi* is specified.

Note: Plot data must include the specification of the upper left corner of the plot and the direction cosines across and down the plot.

Additional data required to generate a plot are one of the following combinations:

1. the lower right corner of the plot, the global scaling parameter, LPI, and one of the scaling parameters (DLX, DLD, NAX, NDN).

2. the lower right corner of the plot, one of the scaling parameters related to the horizontal specifications of the plot (DLX or NAX), and one of the scaling parameters related to the vertical specification of the plot (DLD or NDN). LPI, even if specified will not be used.

3. NAX and NDN and any two of LPI, DLX, and DLD. If LPI, DLX, and DLD are all specified, LPI is not used.

The data required to generate a plot may be supplied from (1) defaulted values, (2) data from the previous plot, or (3) data that are specifically entered for the current plot.

Miscellaneous parameters Enter miscellaneous parameters

RUN=*run* is used to determine if the problem is executed or is terminated after data checking. A value of YES for *run* means the problem will be executed if all the data were acceptable. A value of NO specifies the problem will be terminated after data checking is completed. The default value of RUN is YES.

PLT=*plt* is used to specify if a plot is to be made. A value of YES for *plt* specifies that a plot is to be made. If plot data are entered, PLT is defaulted to YES.

Note: The parameters RUN and PLT can also be entered in the PARAMETER data. See Sect. 8.1.3.3. It is recommended that these parameters be entered only in the parameter data block in order to ensure that the data printed in the "Logical Parameters" table are what is actually performed.

SCR= *src* This is used to determine the plot display method. The plot display method is specified by entering either YES or NO for *src*. The default value is YES. SCR=YES uses the color plot display method. SCR=NO uses the character plot display method. If SCR is entered more than once in a problem, the last value entered is the one that is used.

NCH= *delim char delim* Enter only if plots are to be made utilizing the character plot display method (SCR=NO). Enter a delimiter (i.e., " , ` , * , ^ , or !) to signal the beginning of character string *char*. The character string is terminated when the *delim* character is encountered the second time. Do

not use the initial delimiter in the *char* string, as it will be read as terminating the string. *char* is a character string with each entry representing a plottable quantity (i.e., media {mixture} number, unit number, or bias ID). These are the characters that will be used in the plot. The first entry represents media, unit, or bias ID zero; the second entry represents the smallest media, unit, or bias ID used in the problem; the third entry represents the next larger media, unit, or bias ID used in the problem; etc. For example, assume PIC=MAT is specified, and 15 mixtures are defined in the mixing table, and the geometry data use only mixtures 3 and 7. By default, a blank will be printed for mixture zero, a 1 will be printed for mixture 3, and a 2 will be printed for mixture 7. If you wish to print a zero for a void (mixture 0), a 3 for mixture 3, and a 7 for mixture 7, enter NCH=`037'.

The default values of CHAR are the following:

Quantity	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
SYMBOL		1	2	3	4	5	6	7	8	9	A	B	C	D	E	F
Quantity	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
SYMBOL	G	H	I	J	K	L	M	N	O	P	Q	R	S	T	U	V
Quantity	32	33	34	35	36	37	38	39	40	41	42	43	44	45	46	
SYMBOL	W	X	Y	Z	#	,	$	-	+	)		&	>	:	;	
Quantity	47	48	49	50	51	52	53	54	55	56	57	58				
SYMBOL	·	-	"%"	"*"	""“	"="	"!"	"("	"@"	"<"	"/"	0				

CLR= ***n*₁ *r*(*n*₁) *g*(*n*₁) *b*(*n*₁) … *n*N *r*(*n*N) *g*(*n*N) *b*(*n*N)** **END COLOR** this entry is used to define the colors to be used by the color plot. It may be entered only if plots are to be made utilizing the color plot display method (SCR=YES). After entering the keyword CLR=, 4 numbers are entered *N* times. The first number, n_1, represents a media (mixture) number, unit number, or bias ID. The next three numbers, whose values can range from 0 through 255, define the *red, green, and blue* components of the color that will represent this n_1 in the plot. The sequence of 4 numbers is repeated until the colors associated with all of the media (mixture) numbers, unit numbers, or bias IDs used in the problem have been defined. The smallest number that can be entered for n_i is -1, representing undefined regions in the plot. An *ni* of 0 represents void regions; n_i of 1 represents the smallest media, unit, or bias ID used in the problem; n_i of 2 represents the next larger media, unit, or bias ID used in the problem, etc. The color plot definition data are terminated by entering the keywords END COLOR. A total of 256 default colors are provided in Table 8.1.28 Two of those colors represent undefined regions, n_i=-1*, as black and void regions, and n_i=0 as gray. The remaining 254 colors represent the default values for mixtures, bias IDs, or unit numbers used in the problem. If **num** is entered as **-1**, the next three numbers define the color that will be used to represent undefined regions of the plot. The default color

for undefined regions is black, represented as 0 0 0. If n_i is entered as 0, the next three numbers define the color that will represent void regions in the plot. The default color for void is gray, represented as 200 200 200. For example, assume a color plot is to be made for a problem that uses void regions and mixture numbers 1, 3, and 5. By default, the undefined regions (Index -1) will be black; void regions (Index 0) will be gray; the first mixture, mixture 1 (Index 1), will be medium blue; the next larger mixture, mixture 3 (Index 2), will be turquoise2; and the last mixture, mixture 5 (Index 3), will be green2. If these values are acceptable, data do not need to be entered for `CLR=`. If the user decides to define void to be white (255 255 255), mixture 1 to be red (255 0 0), mixture 3 to be bright blue (0 0 255), and mixture 5 to be green (0 255 0), then the following data could be entered:

`CLR=0 255 255 255 1 255 0 0 2 0 0 255 3 0 255 0 END COLOR`

In this example, the first number (0) defines the void, and the next three numbers are the *red, green, and blue* components that combine as the color white. The fifth number (1) represents the smallest mixture number (mixture 1), and the next three numbers are the *red, green, and blue* components of red. The ninth number (2) represents the next larger mixture number (mixture 3), and the next three numbers are the *red, green, and blue* components of bright blue. The thirteenth number (3) represents the next larger mixture number (mixture 5), and the next three numbers are the red, green, and blue components of green. The `END COLOR` terminates the color definition data. Because color data were not entered for *ni* of -1, undefined regions will be represented by the color black, the default specification from Table 8.1.28. The *red, green, and blue* components of some bright colors are listed below.

Display Color	**red**	**green**	**blue**
black	0	0	0
white	255	255	255
“default void gray”	200	200	200
red	255	0	0
green	0	255	0
brightest blue	0	0	255
yellow	255	255	0
brightest cyan	0	255	255
magenta	255	0	255

The 256 default colors are listed in Table 8.1.28.

Table 8.1.28: Default color specifications for the color plot display method

Mixture number	Red	Green	Blue	Color
-1	0	0	0	
0	200	200	200	
1	0	0	205	
2	0	229	238	
3	0	238	0	
4	205	205	0	
5	238	0	0	
6	145	44	238	
7	150	150	150	
8	240	200	220	
9	0	191	255	
10	224	255	255	
11	0	255	127	
12	255	255	224	
13	255	0	0	
14	255	0	255

8.1.3.12 Energy group boundary data

Upper energy group boundary data in eV are entered to determine the groups into which the tallies will be collected in the continuous energy mode. For G groups G+1 entries are entered. The last entry is the lower energy boundary of the last group. The values must be in descending order. The parameter NGP is set equal to the number of entries-1. The syntax is:

READ ENERGY u_1 ... uG u_{G+1} END ENERGY

$u_1 \ldots u_G$ are the upper energy limits of energy groups 1 ... G, respectively.

u_{G+1} is the lower energy limit of energy group G.

Example:

```
READ ENERGY

2e7 1e5 1 1e-5

END ENERGY
```

Defines a 3-group structure with group 1 (2e+7 eV to 1e+5 eV), group 2 (1e+5 eV to 1 eV), and group 3 (1 eV to 1e-5 eV) and sets NGP=3.

Energy group boundary data are optional. Default values for the energy group boundaries in the calculations are determined as in the following order:

i. Use energy group boundaries from ENERGY block if specified in the input. The number of entries in the ENERGY block is NGP+1.

ii. If only NGP is specified (in PARAMETER block) in the input and NGP is equal to the number of energy groups in one of the SCALE neutron cross section libraries, the energy group structure from that library will be used.

iii. If only NGP is specified (in PARAMETER block) in the input and NGP is not equal to the number of energy groups in one of the SCALE neutron cross section libraries, NGP equal lethargy bins will be used.

iv. Use SCALE 252-group structure as default, NGP=252.

8.1.3.13 Volume data

If volumes are needed (for calculating fission densities, fluxes, etc.), then the data necessary to determine them are entered. The syntax for this block is:

READ VOLUME p_1 ... p_N END VOLUME

$p_1 \ldots p_N$ are N parameters entered using keywords followed by the appropriate data.

The possible parameters that can be used in a VOLUME block are described below.

READVOL=*vol* used to input the file name (up to 256 characters) of the file from which user-specified volumes are read. This is an optional parameter and only works for KENO-VI. The data are read in sections for each UNIT contained in the problem. First the keyword "UNIT" is read, followed by the UNIT number. For that UNIT the data for each region containing material in the order shown in the input is read as follows: the keyword "MEDIA" is read, followed by the mixture number, followed by the keyword "VOL=", followed by the total volume for that region. Regions containing ARRAYs and HOLEs are skipped. An example of the data contained in a volume file is given later in this section.

TYPE=*vcalc* used to determine the type of volume calculation. *vcalc* can have the values:

NONE: (only works in KENO-VI, where it is also the default) No volume calculation, volumes are set to -1.0 (only in KENO-VI).

TRACE: A trapezoidal integration will be performed (only in KENO-VI).

RANDOM: A Monte Carlo integration will be performed.

NRAYS=*ntotal* the number of intervals used in the trapezoidal integration (default 100,000). Used only with TYPE=TRACE (KENO-VI).

BATCHES=*nloop* the number of batches to be used in the Monte Carlo integration (default 500). Used only with TYPE=RANDOM.

POINTS=*nplp* the number of points per batch used in the Monte Carlo integration (default 1000). Used only with TYPE=RANDOM.

XP= *xp* the pls X face of the encompassing cuboid.

XM=*xm* the minus X face of the encompassing cuboid.

YP=*yp* the plus Y face of the encompassing cuboid.

YM=*ym* the minus Y face of the encompassing cuboid.

ZP=*zp* the plus Z face of the encompassing cuboid.

ZM*zm* the minus Z face of the encompassing cuboid.

SAMPLE_DEN=*sampleden* the density of sampling points per cm^3 per batch. Used only with TYPE=RANDOM.

IFACE =*fname* the face of the enclosing cuboid where the trapezoidal integration will be performed. Enter either `XFACE`, `YFACE`, or `ZFACE`. KENO-VI will integrate over the face with the smallest area by default. This allows specifying a different face. Used only for `TYPE=TRACE` (KENO-VI).

The volume parameters include specifying the type of calculation to determine the volumes and additional parameters needed for the selected type. In KENO-VI the default type is NONE (i.e., no volume calculation will be performed), and the volumes for regions not containing `HOLE`s or `ARRAY`s will be set to -1.0. No other data are needed for this type.

In KENO-VI the volume data may be entered for any or all regions within the geometry data by placing the keyword `VOL=` followed by the total volume of that region in the problem at the end of the `MEDIA` card. See Sect. 8.1.3.4 (Geometry Data) for more details.

For KENO-VI, in the same problem, volumes may be entered using a combination of three methods: (1) in the geometry data using `VOL=`, (2) read from a volume file, and (3) calculated. The calculated volumes (method 3) are obtained for both the regions, and the meshes are defined by a grid (such as in TSUNAMI runs). As for KENO V.a, the mesh volumes must always be calculated (i.e., there is no method to input the mesh volumes). If volumes are entered or calculated using more than one method, the following hierarchy is used to determine which volume is used for the regions.

1. Volumes entered as part of a `MEDIA` card using `VOL=` are always used.
2. Volumes read from the volume file are used if that volume for the region was not specified using VOL= following a `MEDIA` card.

3. Calculated volumes are used if they are not specified using VOL= and if there is no volume file or data for that region on the volume file.
4. Volumes that have not been set or calculated will be set to -1.0. This may result in negative fluxes and fission densities for these regions.
5. Volumes are only calculated for regions containing material. Regions containing ARRAYs or HOLEs have no volume. Those volumes are associated with the UNIT contained in the ARRAY or HOLE.

In KENO V.a, the region volumes are always calculated by the code without the user's intervention. This is possible because KENO V.a has no region intersections, so calculation of the volumes is always possible using analytical methods. The use of the (RANDOM) calculated volumes using the VOLUME block is then only justified when the user needs to calculate the volumes defined by a grid, such as for TSUNAMI calculations.

When volumes are calculated using either RANDOM or TRACE, then a file containing volumes and named _volxxxx (where xxxx is an 18-digit number with the leftmost unused digits padded with zeros) is created in the temporary directory. The program searches the temporary directory for a file name beginning with _vol. If it is not found, the volume file that is created is named _vol000000000000000000. If a file exists, then a new file will be created where the file number is the largest number associated with a previous volume file incremented by 1. The file is automatically copied to the user directory with the input file base name prepended to it, such as inputfile.volxxxx.volumes.

Below is an example of the VOLUME data block associated with a case in which volumes are being calculated using ray tracing. The number of rays used is set to one million, and if the outer unit volume is not a cuboid, then a cuboid will be placed around the global region prior to calculating volumes.

```
read volume
type=trace nrays=1000000
XP=10  XM=-15 YP=15  YM=-15  ZP=15  ZM=-15
end volume
```

Below is an example of the VOLUME data block associated with a case where volumes are being calculated using random sampling. The number of particles per batch is set to 100,000, and the number of batches used is set to 500. After being calculated, the volume data will be written to a file in the temporary directory as discussed above.

```
read volume
type=random points=100000 batches=500
XP=10  XM=-10  YP=15  YM=-15  ZP=25  ZM=15
end volume
```

Below is an example of the VOLUME data block associated with a case where volumes are both read in from the file VOLUME_DATA and calculated using random sampling. The number of particles per generation is set to 1,000,000, and the number of generations used is set to 500. The file VOLUME_DATA must be formatted as shown below. The calculated volume data are written in the temporary working directory to a file as discussed above. Calculating volume data for some volume regions and providing input volume data for others may be useful if only part of the volume data is known and the remaining data need to be calculated.

```
read volume
type=random points=1000000 batches=500
readvol=volume_DAta
end volume
```

Example volume file VOLUME_DATA:

```
UNIT 1
   MEDIA 1 VOL=110.0
   MEDIA 2 VOL=2435.8
   MEDIA 2 VOL=3242.9
UNIT 2
   MEDIA 2 VOL=342.8
   MEDIA 0 VOL=4235.0
```

Below is an example of a sample problem in which volumes are being calculated using random sampling. The number of particles per generation is set to 100,000, and the number of generations used is set to 500. After being calculated, the VOLUME data will be written as described above.

8.1.3.14 Grid geometry data

This data block is used to input the data needed to define a Cartesian grid for tallying purposes.

READ GRID N $p_1 \ldots p_L$ END GRID

N mesh grid identifier, always entered.

$p_1 \ldots p_L$ are L parameters chosen from the list below. The parameters are entered using keywords followed by the appropriate data, except for the grid identifier, which is always entered first as an integer.

N[UM]XCELLS=*numx* number of cells in the x direction, default = 1.

N[UM]YCELLS=*numy* number of cells in the y direction, default = 1.

N[UM]ZCELLS=*numz* number of cells in the z direction, default = 1.

XMIN=*xmin* minimum cell boundary in the x direction, default = 0.

XMAX=*xmax* maximum cell boundary in the x direction, default = 1.

YMIN=*ymin* minimum cell boundary in the y direction, default = 0.

YMAX=*ymax* maximum cell boundary on the y direction, default = 1.

ZMIN=*zmin* minimum cell boundary in the z direction, default = 0.

ZMAX=*zmax* maximum cell boundary in the z direction, default = 1.

XPLANES*xplanes* the cell boundaries in the x direction followed by end, default = 0, 1 end.

YPLANES*yplanes* the cell boundaries in the y direction followed by end, default = 0, 1 end.

ZPLANES=*zplanes* the cell boundaries in the z direction followed by end, default = 0, 1 end.

XLINEAR=*numcellsx* *x_{min} x_{max} generate y-z planes from x_{min} to x_{max} creating *numcellsx* intervals.

YLINEAR=*numcellsy* *y_{min} y_{max} generate x-z planes from y_{min} to y_{max}, creating *numcellsy* intervals.

ZLINEAR=*numcellsz* *z_{min} z_{max} generate x-y planes from z_{min} to z_{max}, creating *numcellsz* intervals.

TITLE=*title* optional title for this mesh grid. Only used in KENO if an error in the grid causes a debug print.

If *numx, xmin, xmax* are entered, then the code will calculate *numx* equally spaced cells in the x direction between *xmin* and *xmax*.

If *xplanes* is entered, then the code will count the number of unique *xplanes*, and order them from minimum to maximum, deleting any duplicates.

If the user inputs both sets of data, then the code will use the *xplanes* data.

If *xplanes* and *xlinear* are both entered, then the code will retain all unique planes from *xplanes* and all *xlinear* entries provided. The above also applies to Y and Z.

NOTE: The user **MUST** set the minimum and maximum values in each direction so that the actual geometry is totally covered by the mesh for mesh flux tally that is used in TSUNAMI sensitivity calculations.

KENO checks for and eliminates duplicate or nearly duplicate planes.

The user may specify multiple mesh grids; each must be defined in separate READ GRID blocks. In this case, each grid should have different *N* (grid ID number). See Sect. 8.1.4.11 for details and samples.

8.1.3.15 Reaction data

The reaction data block is used to specify the type of tally (e.g., reaction rates, flux, and few group reaction cross sections) and the reaction/nuclide pairs in any mixture used in the problem for reaction tally calculations. This block is operational only with the continuous energy mode, and it provides the specifications for reaction rate, neutron flux, and reaction cross section tallies. See Sect. 8.1.7.6 for more details. For multigroup KENO calculations, use KMART5 or KMART6, which are described in the KMART section of the SCALE manual.

A reaction data block consists of *REACTION FILTERS*, *TALLY TYPE*, *ENERGY GROUP BOUNDARIES*, and *OUTPUT EDITS*. These data types can be entered in any order. A combination of parameters for describing the *REACTION FILTERS* and *TALLY TYPE* must be entered for any reaction or cross section tally calculation. *ENERGY GROUP BOUNDARIES* and *OUTPUT EDITS* data are optional. Tally calculations can be performed for multiple reactions specified by the *REACTION FILTERS*. Only one energy grid, either specified with the data in *ENERGY GROUP BOUNDARIES* or from the READ ENERGY block or from the code defaults, is used for all reaction tally calculations. To provide data for the continuous energy depletion calculations, another energy grid can be specified and used for tallying only the mixture flux.

Enter *REACTION DATA* in the form:

READ REACTION *REACTION FILTERS [TALLY TYPE] [ENERGY GROUP BOUNDARIES][OUTPUT EDITS]* END REACTION

REACTION FILTERS define a reaction map that is used in reaction tally calculations. The *REACTION FILTERS* must be entered in the following order; mixture data (MIX or MIXLIST) followed by nuclide data (NUC or NUCLIST) followed by reaction IDs (MT or MTLIST). Each filter is defined using a combination of the following keywords:

MIX=*mixnum* Mixture number, no default value. Specified mixture number must exist in the mixing table and be used in the problem for a valid filter generation. A wildcard * can be used to define a filter applicable for all mixtures in the problem.

MIXLIST ***mixnum*$_1$ *mixnum*$_2$ ... *mixnum*$_N$** **END** A list of mixture numbers followed by *end,* no default values. Specified mixture numbers must exist in the mixing table and be used in the problem for a valid reaction tally calculation. Within each filter, use either MIX or MIXLIST, but not both.

NUC=*nucid* Nuclide identifier, no default value. Specified nuclide must be a constituent of the mixtures used in this filter definition (specified with MIX or MIXLIST). A wildcard "*" can be used to define a filter applicable for all nuclides in each mixture in this filter definition. Nuclide identifiers are listed for all isotopes in the Standard Composition Library section of the SCALE manual.

NUCLIST ***nucid*$_1$ *nucid*$_2$ ... *nucid*$_N$** **END** A list of nuclide identifiers followed by *end,* no default values. Specified nuclides must be the constituents of the mixtures used in this filter definition (specified by MIX or MIXLIST). Within each filter, use either NUC or NUCLIST, but not both.

MT=*mt* Reaction MT number, no default value. Specified reaction MT number should be available for the nuclides defined in this filter definition (specified by NUC or NUCLIST). Otherwise, the code skips the filter definition with this given reaction MT. A wildcard "*" can be used to define a filter with all reaction MTs. Valid SCALE library MT values are listed in the MT Reaction Types on SCALE Cross-Section Libraries.

MTLIST ***mt*$_1$ *mt*$_2$ ... *mt*$_N$** **END** A list of reaction MT numbers followed by *end,* no default values. Specified MT numbers should be available for the nuclides defined in this filter definition (specified by MIX or MIXLIST). Otherwise, KENO skips that reaction specified in the filter for the reaction tally calculations. Within each filter, use either MT or MTLIST, but not both.

A reaction filter consists of either single or multiple mixture, nuclide and reaction definitions. A valid reaction filter starts with mixture specification, followed by nuclide specification, and ends with reaction specification. Mixture(s) must be specified with either MIX or MIXLIST keywords. Nuclide(s) in these mixtures must be entered with either NUC or NUCLIST, and reactions for each nuclide must be specified with either MT or MTLIST.

Mixture, nuclide, and reaction number are required for mixture average fluxes, even though the nuclide and reaction numbers are not used for the neutron flux tallies.

Multiple reaction filter definitions are allowed. KENO processes all the definitions and creates a reaction map based on them. The following examples demonstrate the reaction filter specifications for different problems. In these examples, reaction filters are specified based on the following composition data used in the problem:

compositions in the example problem

mixture	nuclides
10	92235, 92238, 8016
20	92238, 94239, 8016
30	92235, 92238, 8016
40	1001, 8016
100	1001, 8016, 5010, 5011

Example 8.1.1: Defines a reaction filter used to tally only fission reaction (MT=18) of ^{235}U in mixture 10.

```
READ REACTION
   MIX=10 NUC=92235  MT=18
   ...
END REACTION
```

Example 8.1.2: Defines a reaction filter used to tally all available reactions of ^{235}U in mixture 10

```
READ REACTION
   MIX=10 NUC=92235  MT=*
   ...
END REACTION
```

Example 8.1.3: Defines a reaction filter used to tally the elastic scattering (mt=2), fission (mt=18), and capture (mt=102) reactions of ^{235}U in mixture 10

```
READ REACTION
   MIX=10 NUC=92235  MTLIST 2 18 102 END
   ...
END REACTION
```

Example 8.1.4: Defines a reaction filter used to tally the elastic scattering (`MT=2`), fission (`MT=18`), and capture (`MT=102`) reactions of ^{235}U in mixture 10. Reaction filter definition in this example is identical to the filter definition given in Example 8.1.3.

```
READ REACTION
   MIX=10 NUC=92235  MT=2
   MIX=10 NUC=92235  MT=18
   MIX=10 NUC=92235  MT=102
   ...
END REACTION
```

Example 8.1.5: Defines a reaction filter used to tally the fission reaction (`MT=18`) of ^{235}U and ^{238}U in mixture 10. Code skips the reaction tally request for ^{16}O since the requested reaction is not available for this nuclide in the data library.

```
READ REACTION
   MIX=10 NUC=*  MT=18
   ...
END REACTION
```

Example 8.1.6: Defines a reaction filter used to tally the fission reaction (`MT=18`) of ^{235}U and ^{238}U in mixture 10. Reaction filter definition in this example is identical to the filter definition given in Example 8.1.5.

```
READ REACTION
   MIX=10 NUC=92235  MT=18
   MIX=10 NUC=92238  MT=18
   ...
END REACTION
```

Example 8.1.7: A reaction filter used to tally the capture reaction (`MT=102`) of ^{16}O in all mixtures.

```
READ REACTION
   MIX=* NUC=8016  MT=102
   ...
END REACTION
```

Example 8.1.8: Areaction filter used to tally the capture reaction (MT=102) of ^{16}O in mixtures 10, 20, 30, 40, and 100 respectively. Reaction filter definition in this example is identical to the filter definition given in Example 8.1.7.

```
READ REACTION
     MIX=10  NUC=8016  MT=102
     MIX=20  NUC=8016  MT=102
     MIX=30  NUC=8016  MT=102
     MIX=40  NUC=8016  MT=102
     MIX=100 NUC=8016  MT=102
      ...
END REACTION
```

Example 8.1.9: A reaction filter used to tally the capture reaction (MT=102) of ^{16}O in mixtures 10, 20, 30, 40, and 100 respectively. Reaction filter definition in this example is identical to the filter definition given in Example 8.1.7 and Example 8.1.8.

```
READ REACTION
   MIXLIST 10 20 30 40 100 END NUC=8016  MT=102
   ...
END REACTION
```

Example 8.1.10: Complex reaction tally for U-238, Pu-239, H-1, and O-16 across several mixtures.

```
READ REACTION
     MIXLIST 10 20 30 END NUC=92238  MT=102
     MIX=20  NUC=94239 MT=18
     MIX=40  NUC=1001  MT=*
     MIX=*   NUC=8016  MT=2
     MIX=*   NUC=*     MT=27
      ...
END REACTION
```

Example 8.1.10 defines a complex reaction filter used to tally:

a) Capture reaction (**MT**=102) of ^{238}U in mixtures 10, 20 and 30 respectively,

b) Fission reaction (**MT**=18) of ^{239}Pu in mixture 20,

c) All reactions of ^{1}H in mixture 40,

d) Elastic scattering reaction of ^{16}O in all mixtures,

e) Total absorption reaction of all nuclides in all mixtures.

Parameters of TALLY TYPE are logical parameters used to select quantities (reaction cross section, reaction rate, and mixture flux) that are tallied for the given problem. The user specifies any combination of these TALLY TYPEs once for all filters:

XSTALLY=*lCEXSTally* Enter YES or NO. A value of YES specifies that reaction cross sections be tallied for the reactions listed in *REACTION FILTERS*. The default value of XSTALLY is NO. Computed reaction cross sections are saved in a file named *BASENAME_keno_micro_xs.0* in RTNDIR, which is a SCALE environment variable for the directory from where the calculation was started. BASENAME is a SCALE environment variable that is the base name of the input file. (BASENAME is equal to *"mytest"* if the SCALE input name is *"mytest.inp."*)

RRTALLY=*lCERRTally* Enter YES or NO. A value of YES specifies that reaction rates be tallied for the reactions listed in *REACTION FILTERS*. The default value of RRTALLY is NO. Computed reaction rates are saved in a file named *BASENAME_keno_micro_rr.0* in RTNDIR.

Note: KENO combines and saves reaction rate and reaction cross section tallies to the same file, named *BASENAME_keno_micro_xs_rr.0* in RTNDIR, if both `XSTALLY` and `RRTALLY` are set to YES.

MIXFLX=*lCEMixFlux* Enter YES or NO. A value of YES specifies that mixture fluxes are to be tallied for the mixtures listed in *REACTION FILTERS*. The default value of `MIXFLX` is NO. Computed mixture fluxes are saved in a file named *BASENAME_keno_mixture_flux.0* in RTNDIR.

Mixture, nuclide, and reaction number are required for mixture average fluxes, even though the nuclide and reaction numbers are not used for the neutron flux tallies.

Example 8.1.11: Defines a reaction filter, which uses fission reaction (`MT=18`) of ^{235}U in mixture 10, for tallying reaction cross sections.

```
READ REACTION
   MIX=10 NUC=92235  MT=18
   XSTALLY=YES
   ...
END REACTION
```

Note: Computed data are saved in a file named *BASENAME_keno_micro_xs.0*

Example 8.1.12: Defines a reaction filter, which uses fission reaction (`MT=18`) of ^{235}U in mixture 10, for tallying reaction rates as well as the reaction cross sections.

```
READ REACTION
   MIX=10 NUC=92235  MT=18
   XSTALLY=YES RRTALLY=YES
   ...
END REACTION
```

Note: Computed data are saved in files named *BASENAME_keno_micro_xs_rr.0*

Example 8.1.13: Defines a reaction filter, which uses fission reaction (`MT=18`) of ^{235}U in mixture 10, for tallying reaction cross sections. In addition, mixture flux is tallied for mixture 10 given in this reaction filter.

```
READ REACTION
   MIX=10 NUC=92235  MT=18
   XSTALLY=YES MIXFLX=YES
   ...
END REACTION
```

Note: Computed data are saved in files named *BASENAME_keno_micro_xs.0*, and *BASENAME_keno_mixture_flux.0*, respectively.

ENERGY GROUP BOUNDARIES data define energy group structure other than the defaults for tallying both reaction cross sections/reaction rates and mixture fluxes.

ENER_XS *e1 e2 e3 . . .* END Upper energy boundary for each group. The last entry is the lower energy boundary of the last group. For N groups, there are N+1 entries. Entries must be in descending order. This may be specified once in the REACTION block and, if used, is applied to all cross section and reaction rate tallies.

ENER_FLX *e1 e2 e3 . . .* END Upper energy boundary for each group, default is NGP-group data. The last entry is the lower energy boundary of the last group. For N groups, there are N +1 entries. Entries must be in descending order. This may be specified once in the REACTION block and, if used, is applied to all mixture flux tallies.

Note: Default values for the energy group boundaries in reaction tally calculations are determined as in the order described in Sect. 8.1.3.12.

Example 8.1.14: No READ ENERGY block, no NGP in READ PARAMETER block, no energy group

```
READ REACTION
   MIX=10 NUCLIST 92235 92238 END
   MTLIST 16 17 18 END
   MIXFLX=YES XSTALLY=YES
   ...
END REACTION
```

Default SCALE 252-group energy structure is used for tallying both mixture flux and reaction cross sections.

Example 8.1.15: Energy group bounds specified in READ ENERGY block. 2-group energy structure given in READ ENERGY block is used for tallying both mixture flux and reaction cross sections.

```
READ ENERGY
   20.E6   0.6 1.E-4
END ENERGY
...
READ REACTION
   MIX=10 NUCLIST 92235 92238 END
   MTLIST 16 17 18 END
   MIXFLX=YES XSTALLY=YES
   ...
END REACTION
```

Example 8.1.16: NGP is set in READ PARAMETER block; 4-group energy group structure (4-equal lethargy bins) is used for tallying both mixture flux and reaction cross sections.

```
READ PARAMETER
   ...
   NGP=4
END PARAMETER
...
READ REACTION
   MIX=10 NUCLIST 92235 92238 END
   MTLIST 16 17 18 END
   MIXFLX=YES XSTALLY=YES
   ...
END REACTION
```

Example 8.1.17: 3-group energy group structure given in `reaction data` block is used for tallying reaction cross sections, and default SCALE 252-group energy structure is used for tallying mixture flux.

```
READ REACTION
     MIX=10 NUCLIST 92235 92238 END
     MTLIST 16 17 18 END
     MIXFLX=YES XSTALLY=YES
     ENER_XS 20.E6 1.E3 1.0 1.E-4 END
      ...
END REACTION
```

Example 8.1.18: 2-group energy group structure given in `reaction data` block is used for tallying reaction cross sections, and 3-group energy group structure given in `reaction data` block is used for tallying mixture flux.

```
READ REACTION
     MIX=10 NUCLIST 92235 92238 END
     MTLIST 16 17 18 END
     MIXFLX=YES XSTALLY=YES
     ENER_FLX 20.E6 1.E3 1.0 1.E-4 END
     ENER_XS 20.E6 1.0 1.E-4 END
      ...
END REACTION
```

Parameters of *OUTPUT EDITS* are logical parameters used to print reaction tallies and mixture fluxes in separate files. These parameters are optional parameters.

`PRNTXS`=*lCEprintXS* Enter YES or NO. A value of YES specifies that reaction cross sections tallies for each mixture be written in separate files in RTNDIR (*BASENAME_keno_micro_xs_mix{mixnum}.0, mixnum* is the mixture numbers specified in the reaction filters). The default value of `PRNTXS` is NO.

`PRNTRR`=*lCEprintRR* Enter YES or NO. A value of YES specifies that reaction rate tallies for each mixture be written in separate files in RTNDIR (*BASENAME_keno_micro_rr_mix{mixnum}.0, mixnum* is the mixture numbers specified in the reaction filters). The default value of `PRNTRR` is NO.

`PRNTFLX`=*lCEprintMixFlux* Enter YES or NO. A value of YES specifies that mixture flux tallies for each mixture be written in separate files in RTNDIR (*BASENAME_keno_mixture_flux_mix{mixnum}.0, mixnum* is the mixture numbers specified in the reaction filters). The default value of `PRNTFLX` is NO.

8.1.4 NOTES FOR KENO USERS

This section provides assorted tips designed to assist the KENO user with problem mockups. Some information concerning methods used by KENO is also included.

8.1.4.1 Data entry

The KENO data is entered in blocks that begin and end with keywords as described in Sect. 8.1.3.1. Only one set of parameter data can be entered for a problem. However, for other data blocks, it is possible to enter more than one block of the same kind of data. When this is done, only the last block of that kind of data is retained for use by the problem, except for the GRID block for which all blocks are retained.

Within data blocks, a number, x, can be repeated n times by specifying nRx, n*x, or n$x.

Numbers in engineering notation may be specified with or without an “E” between the base and the exponent. For example; 0.0011 may be specified as 1.1e-3 or as 1.1-3.

Multiple and scattered entries in the mixing table

In the following examples, assume 1001 is the nuclide ID for hydrogen, 8016 is the nuclide ID for oxygen, 92235 is the nuclide ID for ^{235}U, and 92238 is the nuclide ID for ^{238}U. If a given nuclide ID is used more than once in the same mixture, the result is the summing of all the number densities associated with that nuclide. For example:

```
MIX =1 92235 4.3e-2 92238 2.6e-3 1001 3.7e-2 92235 1.1e-3 8016 1.8e-2
```

would be the same as entering:

```
MIX =1 92235 4.41e-2 92238 2.6e-3 1001 3.7e-2 8016 1.8e-2
```

A belated entry for a mixture can be made as follows:

```
MIX =1 1001 6.6e-2 MIX=2 92235 4.3e-2 92238 2.6e-3 MIX=1 8016 3.3e-2
```

This is the same as entering:

```
MIX =1 1001 6.6e-2 8016 3.3e-2 MIX=2 92235 4.3e-2 92238 2.6e-3
```

Multiple entries in geometry data

Individual geometry regions cannot be replaced by adding an additional description. However, entire unit descriptions can be replaced by adding a new description having the same unit number. The last description entered for a unit is used in the calculation. For example, the following geometry descriptions are equivalent in KENO V.a and KENO-VI, respectively:

In KENO V.a:

```
READ GEOM  UNIT 1 SPHERE 1 1 5.0 CUBE 0 1 10.0 -10.0
UNIT 2 CYLINDER 1 1 2.0 5.0 -5.0  CUBE  0 1 10.0 -10.0

```

The order of entry for UNIT descriptions is not important because the UNIT number is assigned as the value following the word UNIT. They do not need to be entered sequentially, and they do not need to be numbered sequentially. It is perfectly acceptable to enter UNITs 2, 3, and 5, omitting Units 1 and 4 as long as UNITs 1 and 4 are not referenced in the problem. It is also acceptable to scramble the order of entry as in entering UNITs 3, 2, and 5.

8.1.4.2 Default logical unit numbers for KENO

The logical unit numbers for data used by KENO are listed in Table 8.1.29.

Table 8.1.29: KENO logical unit numbers

Function	Parameter name	Unit number	Variable name

continues on next page

Table 8.1.29 – continued from previous page

Problem input data (ASCII)		5	INPT
Problem input data (binary)		95	BIN
Program output (ASCII)		6	OUTPT
Albedo data	ALB=	79	ALBDO
Scratch unit	SKT=	16	SKRT
Read restart data	RST=	0[a]	RSTRT
		34[b]	RSTRT
Write restart data	WRS=	0[a]	WSTRT
		35[c]	WSTRT
Direct access storage for input data		8	DIRECT(1)
Direct access storage for super-grouped data		9	DIRECT(2)
Direct access storage for cross section mixing		10	DIRECT(3)
Mixed cross section data set	XSC=	14[d]	ICEXS
Group-dependent weights	WTS=	80	WTS
AMPX working format cross sections	LIB=	0[a]	AMPXS
Group boundary Library (KENO-VI)	GRP=	77	GRPBS
[a] Defaulted to zero [b] Defaulted to 34 if BEG= a number greater than 1 and RSTRT=0. c Defaulted to 35 if ``RES=` a number greater than zero and WSTRT=0. [d] Defaulted to 0; if LIB= a number greater than zero, ICEXS is defaulted to 14.			

8.1.4.3 Parameter input

When the parameter data block is entered for a problem, the same keyword may be entered several times. The last value that is entered is used in the problem. Data may be entered as follows:

```
READ PARAM  FLX=YES NPG=1000 TME=0.5 TME=1.0
NPG=50 TME=10.0 FLX=NO
NPG=500
END PARA
```

This will result in the problem having FLX=NO, TME=10.0, and NPG=500. It may be more convenient for the user to insert a new value than to change the existing data.

Certain parameter default values should not be overridden unless the user has a very good reason to do so. These parameters are as follows:

1. X1D= which defines the number of extra 1-D cross sections. The use of extra 1-D cross sections-other than the use of the fission cross section for calculating the average number of neutrons per fission-requires programming changes to the code;

2. NFB= which defines the number of neutrons that can be entered in the fission bank (the fission bank is where the information related to a fission is stored);

3. XFB= which defines the number of extra positions in the fission bank;

4. NBK= which defines the number of neutrons that can be entered in the neutron bank (the neutron bank contains information about each history);

5. XNB= which defines the number of extra positions in the neutron bank;

6. WTH= which defines the factor that determines when splitting occurs;

7. WTA= which defines the default average weight given to a neutron that survives Russian roulette;

8. WTL= which defines the factor that determines when Russian roulette is played; and

9. LNG= which sets the maximum words of storage available to the program.

It is recommended that BUG=, the flag for printing debug information, never be set to YES. The user would have to look at the FORTRAN coding to determine what information is printed. BUG=YES prints massive amounts of sparsely labeled information. The user should only rarely consider using TRK=YES. This generates thousands of lines of well-labeled output that provides information about each history at key locations during the tracking procedure. All other parameters can be changed at will to provide features the user wishes to activate.

8.1.4.4 Cross sections

In multi-energy group mode, KENO always uses cross sections from a mixed cross section data file. The format of this file is the Monte Carlo processed cross section file. A mixed cross section file can be created by previous KENO run, or by using an AMPX working format library and entering mixing table data in KENO.

Use a mixed cross section Monte Carlo format library

A mixed cross section Monte Carlo format library (premixed cross section data file) from a previous KENO case may be used. This file is specified using the parameter XSC=. If a mixing table data block is entered, the premixed cross section data file will be rewritten. Therefore, a mixing table should not be entered if a premixed cross section data file is used. The user should verify that the mixtures created by a previous KENO case are consistent with those used in the geometry data of the problem.

Use an AMPX working format library

When an AMPX working format library is used, it must be specified using the parameter LIB=, and mixing table data must always be entered. IDs used in the mixing table must match the IDs on the AMPX working format library. The user must provide a file with the correct cross sections with a name that matches the pattern ftNNf001, with NN being the number of the logical unit.

Number of scattering angles

The number of scattering angles is defaulted to 1 (defaulted to 2 when KENO-VI is run as part of the CSAS6 sequence). This stand alone default is not adequate for many applications. The user should specify the scattering angle to be consistent with the cross sections being used. The number of scattering angles is entered in the cross section mixing table by using the keyword SCT=. See Sect. 8.1.3.10.

The order of the last Legendre coefficient to be preserved in the scattering distribution is equal to ($2 \times$ SCT - 1). SCT=1 could be used with a P_1 cross section set such as the 16-group Hansen-Roach cross section library, and SCT=2, for a P_3 cross section set such as the SCALE 27-group cross section library. ENDF/B-VII cross section libraries such as the 44-group or 252-group libraries contain many nuclides having P_5 cross section sets. Isotropic scattering is achieved by entering SCT=0.

Cross section message cutoff

The cross section message cutoff value, *pbxs*, is defaulted to 3×10^{-5}. Warning messages generated when errors are encountered in the P_L expansion of the group-to-group transfers will be suppressed if the P_0 cross section for that particular energy transfer is less than *pbxs*. The value of *pbxs* is specified in the cross section mixing table by using the keyword EPS=. See Sect. 8.1.3.10.

The default value of *pbxs* is sufficient to assure that warning messages will not be printed for most of the SCALE P_1 and P_3 cross section libraries. However, the v7.0-n library may print a few errors if P_5 cross sections are specified.

The error messages below were printed for a problem using the 238-group cross section library and *pbxs* = 3.0×10^{-5}. If the default value of *pbxs* allows too many warning messages to be printed, a value can be determined which does not print the error messages from the printed messages by choosing a number larger than the P_0 component on the first line, as shown below.

THE LEGENDRE EXPANSION OF THE CROSS SECTION (P_0-P_N) IS P_0 P_1 P_2 ... P_n

THE MOMENTS CORRESPONDING TO THIS DISTRIBUTION ARE M_1 M_2 ... M_n

THE MOMENTS CORRESPONDING TO THE GENERATED DISTRIBUTION ARE M_1 M_2 ... M_n

THE LEGENDRE EXPANSION CORRESPONDING TO THESE MOMENTS IS P_0 P_1 P_2 ... P_n

___ MOMENTS WERE ACCEPTED

For the following messages, EPS=6.9e-5 would cause all three messages to be suppressed. A value less than 5.615159e-5 and greater than 4.767635e-5 would suppress the second message, and a value less than 6.855362e-5 and greater than 5.615159e-5 would suppress the first two messages.

```

The user does not need to attempt to suppress all these messages. They are printed to inform the user of the fact that the moments of the angular distribution are not moments of a valid probability distribution. The original P_n coefficients and their moments are listed in lines 3–6 of the message. Lines 7–10 list the new corrected moments and their corresponding P_n coefficients.

The weights and angles printed in lines 11–13 were generated from the corrected moments. The last two lines of the message list the moments generated from those weights and angles. They should match line 8, which lists the moments corresponding to the generated distribution.

For most criticality problems, the first moment contributions are much more significant than the contributions of the higher order moments. Thus, the higher order moments may not affect the results significantly. The user may compare the original moments and corrected moments to make a judgment as to the significance of the change in the moments.

8.1.4.5 Mixing table

Mixtures can be used in defining other mixtures. When defining mixture numbers, care should be taken to avoid using a mixture number that is identical to a nuclide ID number if the mixture is to be used in defining another mixture. If a mixture number is defined more than once, it results in a summing effect.

The nuclide mixing loop is done before the mixture mixing loop, which performs mixing in the order of data entry. Thus, the order of mixing mixtures into other mixtures is important because a mixture must be defined before it can be used in another mixture. Some examples of correct and incorrect mixing are shown below, using 1001 as the nuclide ID for hydrogen, 8016 as the nuclide ID for oxygen, 92235 as the nuclide ID for ^{235}U, and 92238 as the nuclide ID for ^{238}U.

EXAMPLES OF CORRECT USAGE

```
READ MIXT
  MIX=1 1001 6.6e-2  8016 3.3e-2
  MIX=2 1 0.5
END MIXT
```

This results in mixture 1 being full-density water and mixture 2 being half-density water.

```
READ MIXT
  MIX=1  2  0.5
  MIX=3  1  0.5
  MIX=2  1001  6.6e-2  8016  3.3e-2
END MIXT
```

This results in mixture 1 being half-density water, mixture 2 being full-density water, and mixture 3 being quarter-density water. Because the nuclide mixing loop is done first, mixture 2 is created first and is available to create mixture 1, which is then available to create mixture 3.

```
READ MIXT
   MIX=1   1001   6.6e-2   8016   3.3e-2
   MIX=2   92235   7.5e-4   92238   2.3e-2  8016   4.6e-2  1 .01
END MIXT
```

This results in mixture 1 being full-density water and mixture 2 being uranium oxide containing 0.01 density water.

```
READ MIXT
   MIX=1    1001  6.6e-2    8016  3.3e-2
   MIX=2  92235  4.4e-2  92238  2.6e-3
   MIX=1  1  0.5
END MIXT
```

This results in mixture 1 being water at 1.5 density (1001 9.9e-2 and 8016 4.95e-2) and mixture 2 is highly enriched uranium metal.

EXAMPLES OF INCORRECT USAGE

```
READ MIXT
  MIX=3  1  0.75
  MIX=1  2  0.5
  MIX=2  1001  6.6e-2  8016  3.3e-2
END MIXT
```

Here the intent is for mixture 2 to be full-density water, mixture 1 to be half-density water, and mixture 3 to be 3/8 (0.75×0.5) density water. Instead, the result for mixture 3 is a void, mixture 1 is half-density water, and mixture 2 is full-density water. This is because the nuclide mixing loop is done first, thus defining mixture 2. The mixture mixing loop is done next. Mixture 3 is defined to be mixture 1 multiplied by 0.75, but since mixture 1 has not been defined yet, 0.75 of zero is zero. Mixture 1 is then defined to be mixture 2 multiplied by 0.5. If the definition of mixture 1 preceded the definition of mixture 3, as in item (2) under examples of correct usage, it would work correctly.

```
READ MIXT
    MIX=1         1001   6.6e-2     8016     3.3e-2
    MIX=1001 92235   4.4e-2   92238   2.6e-3
    MIX=2   1001   0.5
END MIXT
```

This results in mixture 1 being full-density water, mixture 1001 being uranium metal, and mixture 2 being hydrogen with a number density of 0.5 because 1001 is the nuclide ID number for hydrogen. When a mixture number is identical to a nuclide ID and is used in mixing, that number is assumed to be a nuclide ID rather than a mixture number. The intent was for mixture 1 to be full-density water, mixture 1001 to be uranium metal, and mixture 2 to be half-density uranium metal.

8.1.4.6 Geometry Considerations

In general, KENO geometry descriptions consist of (1) geometry data (Sect. 8.1.3.4) defining the geometrical shapes present in the problem, and (2) array data (Sect. 8.1.3.5) defining the placement of the units that were defined in the geometry data. The geometry data block is prefaced by READ GEOM, and the array data block is prefaced by READ ARRAY.

When a 3-D geometrical configuration is described as KENO geometry data, it may be necessary to describe portions of the configuration individually. These individual partial descriptions of the configuration are called UNITs. KENO geometry modeling is subject to the following restrictions:

1. **Units are composed of regions. These regions are created using** geometric bodies and surfaces (shapes) that are previously defined.
    1. In KENO-VI the geometric bodies and surfaces may intersect. Regions are defined relative to the geometric bodies and surfaces in a UNIT. HOLEs provide a means of creating complex geometries in a UNIT and then inserting the UNIT into existing UNITs. For complex geometries the use of HOLEs may decrease the CPU time required for the problem.
    2. In KENO V.a, each geometry region in a UNIT must completely enclose all geometry regions which precede it. Boundaries of the surfaces of the regions may be shared or tangent, but they must not intersect. The use of HOLEs in KENO V.a provides an exception to this complete enclosure rule. The use of HOLEs in KENO V.a will increase the CPU time required for the problem.
2. **All geometrical surfaces must be describable in KENO V.a as spheres,** hemispheres, cylinders, hemicylinders, cubes, cuboids, or as a set of quadratic equations in KENO-VI.
3. **When specifying an ARRAY, each UNIT used in a cuboidal** ARRAY must have a CUBE or CUBOID as its outer region (this is the only option in KENO V.a); a hexprism as the outer boundary if it is a hexagonal, triangular, or shexagonal ARRAY; a rhexprism as the outer boundary if it is a rhexagonal ARRAY; and a dodecahedron as the outer boundary if it is a dodecahedral ARRAY. In addition, the outer boundary of a UNIT cannot be rotated or translated in KENO V.a.
4. **When several UNITs are used to describe an ARRAY, the** adjacent faces of the UNITs in contact with each other must be the same size and shape.
5. **UNITs are placed directly into regions using HOLEs. As** many HOLEs as will fit without intersecting other HOLEs, nested ARRAYs or HOLEs, or the UNIT BOUNDARY can be placed in a UNIT without intersecting each other. In KENO V.a, HOLEs cannot intersect any of the regions within the UNIT in which they are placed. HOLEs are described in more detail in Sect. 8.1.4.6.1, and nested HOLEs are described in Sect. 8.1.4.6.2.
6. **Multiple ARRAYs may be required to describe a complicated** system. In KENO V.a, only one ARRAY may be placed directly into a UNIT. However, multiple ARRAYs may be placed in a UNIT by placing the ARRAYs in other UNITs and placing those UNITs in the original UNIT using HOLEs. Multiple ARRAYs may be placed directly into a UNIT in KENO-VI. These UNITs may then be used to create other ARRAYs, or they may be placed in other UNITs using HOLEs. UNITs placed in ARRAYs or HOLEs that are contained in other HOLEs or ARRAYs are said to be nested. The nesting level of a UNIT is the number of ARRAYs and HOLEs between the ARRAY or HOLE in the GLOBAL UNIT or ARRAY and the UNIT. Multiple ARRAYs are described in more detail in Sect. 8.1.4.6.3.

The KENO V.a geometry package allows any applicable shape to be enclosed by any other applicable shape, subject only to the complete enclosure restriction. The KENO-VI geometry package allows any shape describable using quadratic equations to be enclosed or intersected by any other allowable shape. The implication of this type of description is that the entire volume between two adjacent geometrical surfaces contains only one mixture, HOLE, or ARRAY. A void is specified by a mixture ID of zero. If HOLEs are present in the volume between two surfaces, the volume of that region is reduced by the HOLE's volume(s).

In KENO V.a geometry, if the problem requires several UNITs to describe its geometrical characteristics, each UNIT that is used in an ARRAY must have a rectangular parallelepiped as its outer surface. This restriction is relaxed in KENO-VI, where the outer surface may be a rectangular parallelepiped, a hexagonal prism, a 90° rotated hexagonal prism, or a dodecahedron, but all units placed in an array must use the same shape as their outer BOUNDARY. In order to describe the composite overall geometrical characteristics of the problem, these UNITs may be arranged in a rectangular ARRAY for KENO V.a geometry, or in either a rectangular, hexagonal, shexagaonal, rhexagonal, or dodecahedral ARRAY for KENO-VI geometry. This is done by specifying the number of units in the X, Y, and Z directions. If more than one UNIT is involved, data must be entered to define the number assigned to the ARRAY and the placement of the individual UNITs in the ARRAY. The ARRAY number, the number of UNITs in the X, Y, and Z directions, and the placement data are called *array data* (Sect. 8.1.3.5).

In the KENO V.a geometry description, the surrounding regions of any shape may be placed around an ARRAY, and they may consist of any number of regions in any order subject to the complete enclosure restriction. ARRAYs are positioned relative to the UNIT ORIGIN by specifying the location of the most negative point in the array, i.e. the most negative X, most negative Y, and most negative Z corner of the ARRAY. In KENO-VI geometry, an ARRAY may be placed in a region of any shape if the region boundary is contained within the ARRAY or shares the ARRAY boundary and does not cut across nested ARRAYs or HOLEs. In this case, only the section of the ARRAY contained within the region is recognized by the problem. ARRAYs are positioned relative to the UNIT ORIGIN by placing the ORIGIN of a specified UNIT in the ARRAY at a specified location in the UNIT.

To create a geometry mockup from a physical configuration, the user should keep the restrictions mentioned earlier in mind. There may be several ways of correctly describing the same physical configuration. Careful analysis of the system can result in a simpler mockup and shorter computer running time. A mockup with fewer geometry regions may run faster than the same mockup with extraneous regions. The number of UNITs used can affect the running time, because a transformation of coordinates must be made every time a history moves from one UNIT into another. Thus, if the size of a UNIT is small relative to the mean free path, a larger percentage of time is spent processing the transformation of coordinates. Because all boundaries in a UNIT must be checked for crossings, it may be more efficient to break up complex UNITs into several smaller, simpler UNITs. The trade-off involves the time required to process more boundary crossings vs the time required to transform coordinate systems when UNIT boundaries are crossed.

Geometry dimensions: The use of FIDO syntax may help simplify the description of the geometry. For example, a $20 \times 20 \times 2.5$ cm rectangular parallelepiped would have been described as CUBOID 1 1 10.0 -10.0 10.0 -10.0 1.25 -1.25 in KENO V.a and CUBOID 1 10.0 10.0 10.0 10.0 1.25 1.25 in KENO-VI. By using the P option (see Table 8.1.19), the same rectangular parallelepiped could be described as CUBOID 1 1 4P10.0 2P1.25 in KENO V.a and or CUBOID 1 4P10.0 2P1.25 in KENO-VI, where the last 6 entries describe the geometry. The P option simply repeats the dimension following the P for the number of times stated before the P, and it reverses the sign every time. Therefore, 6P8.0 is equivalent to 8.0 -8.0 8.0 -8.0 8.0 -8.0.

Geometry comments: One comment can be entered for each UNIT in the *geometry region data*. Similarly, one comment can be entered for each ARRAY in the *array definition data*. A comment can be entered using the keyword COM=. This is followed by a comment with a maximum length of 132 characters. The comment

must be preceded and terminated by a delimiter character. Acceptable delimiters include ” , ` , * , ^ , or !. One comment is allowed for each UNIT in the *geometry region data*. If multiple comments are entered for a UNIT, the last comment is used. The comment can be entered anywhere after the UNIT number where a keyword is expected (Sect. 8.1.3.4). See the following example.

KENO V.a:

```
READ GEOM

```

Some of the basics of KENO geometry are illustrated in the following examples:

EXAMPLE 1. Assume a stack of six cylindrical disks each measuring 5 cm in radius and 2 cm thick. The bottom disk is composed of material 1, and the next disk is composed of material 2, etc., alternating throughout the stack. A square plate of material 3 that is 20 cm on a side and 2.5 cm thick is centered on top of the stack. This configuration is shown in Fig. 8.1.18.

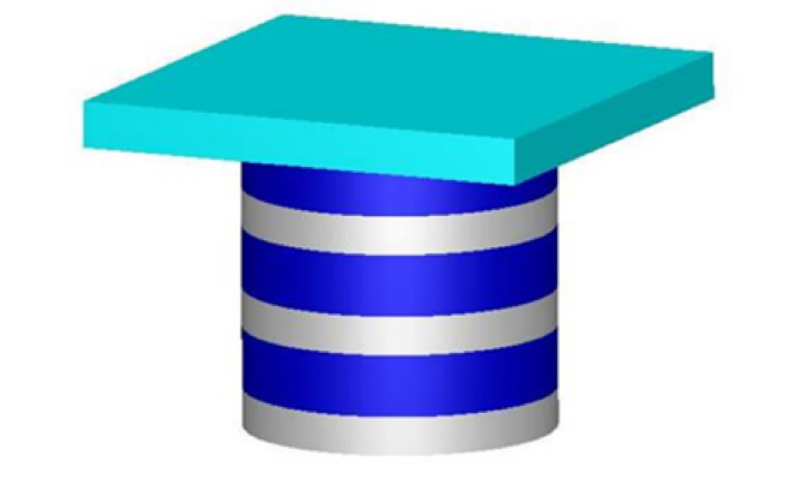

Fig. 8.1.18: Stack of disks with a square top.

This problem can be described as a single UNIT problem, describing the cylindrical portion first. In this instance, the origin has been chosen at the center bottom of the bottom disk. The bottom disk is defined by the first cylinder description, and the next disk is defined by the difference between the first and second cylinder descriptions. Since both disks have a radius of 5.0 and a -Z length of 0.0, the first cylinder containing material 1 exists from Z = 0.0 to Z = 2.0, and the second cylinder containing material 2 exists from Z = 2.0 to Z = 4.0. When all the disks have been described, a void cuboid having the same X and Y dimensions as the square plate and the same Z dimensions as the stack of disks is defined. The square plate of material 3 is then defined on top of the stack. Omission of the first cuboid description would result in the stack of disks being encased in a solid cuboid of material 3 instead of having a flat plate on top of the stack. The geometry input is shown below.

Data description 1, Example 1.

KENO V.a:

An alternative description of the same example is given below. The origin has been chosen at the center of the disk of material 1 nearest the center of the stack. This disk of material 1 is defined by the first cylinder description, and the disks of material 2 on either side of it are defined by the second cylinder description. The top and bottom disks of material 1 are defined by the third cylinder, and the top disk of material 2 is defined by the last cylinder. The square plate is defined by the two cuboids. This description is more efficient than the previous one because there are fewer surfaces to check for crossings.

Data description 2, Example 1.

KENO V.a:

```
READ GEOM

```

Example 1 can also be described as an ARRAY. Define three different UNIT types. UNIT 1 will define a disk of material 1, UNIT 2 will define a disk of material 2, and UNIT 3 will define the square plate of material 3. The origin of each UNIT is defined at the center bottom of the disk or plate being described. As mentioned earlier, only UNITs with a CUBE or CUBOID as their outer boundary can be placed in a cuboidal ARRAY. The geometry input for this arrangement is shown below.

Data description 3, Example 1.

KENO V.a:

```
READ GEOM
UNIT 1
CYLINDER  1 1  5.0   2.0  0.0
CUBOID    0 1 10.0 -10.0 10.0 -10.0 2.0 0.0
UNIT 2
CYLINDER  2 1  5.0   2.0  0.0
CUBOID    0 1 10.0 -10.0 10.0 -10.0 2.0 0.0
UNIT 3

```

Be aware that each UNIT in a geometry description can have its origin defined independent of the other UNITs. It would be correct to use UNITs 1 and 3 from data descriptions 3, and UNIT 2 from data description 4. The *array data* would remain the same as data description 3, Example 1. The user should define the origin of each unit to be as convenient as possible for the chosen description. Care should be taken when assigning coordinates to the UNIT used to PLACE the ARRAY in its surrounding region.

Another method of describing Example 1 as a bare array is to define UNIT 1 to be a disk of material 1 topped by a disk of material 2. The origin has been chosen at the center bottom of the disk of material 1. UNIT 2 is the square plate of material 3 with the origin at the center of the UNIT. The ARRAY consists of three UNIT 1s, topped by a UNIT 2, as shown below.

Data description 5, Example 1.

KENO V.a:

```
READ GEOM
UNIT 1
CYLINDER  1 1  5.0   2.0  0.0
CYLINDER  2 1  5.0   4.0  0.0

```

Example 1 can be described as a reflected ARRAY by treating the square plate as a reflector in the positive Z direction. One means of describing this situation is to define UNITs 1 and 2 as in data description 3, Example 1. The origin of the GLOBAL UNIT is defined to be at the center of the ARRAY. The corresponding input geometry is shown below.

Data description 6, Example 1.

KENO V.a:

```
READ GEOM
UNIT 1
CYLINDER  1 1   5.0   2.0  0.0
CUBOID    0 1  10.0  -10.0  10.0  -10.0  2.0  0.0
UNIT 2

END GEOM
READ ARRAY  NUX=1 NUY=1 NUZ=6 FILL 1 2 1 2 1 2 END ARRAY
```

KENO-VI:

```
READ GEOM
UNIT 1
CYLINDER  1  5.0   2.0  0.0
CUBOID  2   10.0 -10.0 10.0 -10.0 2.0  0.0
MEDIA 1 1 1
MEDIA 0 1 -1 2
BOUNDARY  2
UNIT 2
CYLINDER  1  5.0   2.0  0.0
CUBOID  2  10.0 -10.0 10.0 -10.0 2.0  0.0
MEDIA 2 1 1
MEDIA 0 1 -1 2
BOUNDARY  2
GLOBAL UNIT 3
CUBOID 1  10.0 -10.0 10.0 -10.0 6.0 -6.0
CUBOID 2  10.0 -10.0 10.0 -10.0 8.5 -6.0
ARRAY 1 1 PLACE 1 1 1 0.0 0.0 -6.0
MEDIA 3 1 -1 2
BOUNDARY  2
END GEOM
READ ARRAY ARA=1 NUX=1 NUY=1 NUZ=6 FILL 1 2 1 2 1 2 END ARRAY
```

The user could have chosen the origin of the ARRAY boundary to be at the center bottom of the ARRAY, in which case the geometry description for the GLOBAL UNIT would be:

KENO V.a:

```
ARRAY       1 -10.0  -10.0  0.0
CUBOID   3 1 10.0  -10.0  10.0  -10.0  14.5  0.0
```

or

```
ARRAY    1  -10.0  -10.0 0.0
REPLICATE  3  4*0.0  2.5  0 1
```

The reflector region at the top of the array can be added by using a CUBOID or by using a REPLICATE description in KENO V.a. Recall that there is no REPLICATE function in KENO-VI.

A simpler method of describing Example 1 as a reflected array is to define only one unit as in data description 5, Example 1. The square plate is treated as a reflector, as in data description 6, Example 1. The input for this arrangement is given below.

Data description 7, Example 1.

KENO V.a:

```
READ GEOM

```

EXAMPLE 2. Assume that the stack of six disks in Example 1 is placed at the center bottom of a cylindrical container composed of material 6 whose inside diameter is 16.0 cm. The bottom and sides of the container are 0.25 cm thick, the top is open, and the total height of the container is 18.25 cm. Assume the square plate of Example 1 is centered on top of the container.

The geometry input can be described utilizing most of the data description methods associated with Example 1. One method of describing Example 2 as a single UNIT is given below.

Data description 1, Example 2.

KENO V.a:

```
READ GEOM
UNIT 1

MEDIA 0 1 -6 7
MEDIA 3 1 -7 8
BOUNDARY  8
END GEOM
```

In the above description, the origin is defined to be at the center of the disk of material 1 nearest the center of the stack. This disk is defined by the first cylinder description. The disks of material 2 above and below it are defined by the second cylinder description. The disks of material 1 above and below them are defined by the third cylinder description. The top disk of material 2 is defined by the fourth cylinder description. The void interior of the container is defined by the fifth cylinder description. The container is defined by the last cylinder description. The first cuboid description is used to define a void whose X and Y dimensions are the same as the square plate and whose Z dimensions are the same as the container. The last cuboid description defines the square plate. Omission of the first cuboid description would result in the container being encased in a solid cuboid of material 3. Thus, both cuboids are necessary to properly define the square plate.

Example 2 can be described as a reflected **ARRAY**. One of the descriptions uses only one **UNIT** and is similar to data description 7, Example 1. This description is shown below.

Data description 2, Example 2.

KENO V.a:

```

In the above data description, the first two cylinder descriptions define a disk of material 1 with a disk of material 2 directly on top of it. A tight fitting void cuboid is placed around them so they can be stacked three high to achieve the stack of disks shown in Example 1, Fig. 8.1.18. This array comprises the array portion of the geometry region description. The origin of the array boundary, a tight fitting cube or cuboid that encompasses the array, is defined by the **ARRAY** description. Everything after the **ARRAY** record is considered part of the reflector. The first cylinder after the **ARRAY** record defines the void interior of the cylindrical container. The next cylinder defines the walls of the container. The second-to-last cuboid defines a void volume outside the container from its bottom to its top and having the same X and Y dimensions as the square plate. The last cuboid defines the square plate of material 3 that is sitting on top of the container.

Another method to describe Example 2 is as an array composed of units that contain both the stack and container. This description requires a minimum of four units to describe the problem. This configuration is given below in data description 3, Example 2.

Data description 3, Example 2.

KENO V.a:

In the above description, UNIT 1 is the bottom of the cylindrical container. The void CUBOID is only as tall as the bottom of the container, and its X and Y dimensions are the same as the square plate on top of the container. If all the UNITs in the ARRAY use these same dimensions in the X and Y directions, the requirement that adjacent faces of units in contact with each other must be the same size and shape is satisfied. This ARRAY is stacked in the Z direction, so all UNITs must have the same overall dimensions in the X direction and in the Y direction. UNIT 2 will be used in the ARRAY three times to create the stack of disks. It contains a disk of material 1 topped by a disk of material 2. The portion of the container that contains the disks and the cuboid that defines the outer boundaries of the unit are included in UNIT 2. UNIT 3 describes the empty top portion of the container and the square plate on top of it. The Z dimensions of UNIT 3 were determined by subtracting three times the total Z dimension of UNIT 2 from the inside height of the container [18.0 - (3 × 4.0) = 6.0]. This can also be determined from the overall height of the container by subtracting off the bottom thickness of the container and three times the height of UNIT 2 [18.25 - 0.25 - (3 × 4.0) = 6.0]. The origin of UNIT 3 is located at the center of this distance. For the KENO-VI input, a GLOBAL UNIT is also provided,

UNIT 4, containing the ARRAY built with UNITs 1, 2, 3.

EXAMPLE 3. Refer to Example 1, Fig. 8.1.18, and imagine a HOLE 1.5 cm in diameter is drilled along the centerline of the stack through the disks and the square plate. In KENO V.a this HOLE would eliminate the possibility of describing the system as a single unit because the HOLE in the center of the alternating materials of the stack cannot be described in a manner that allows each successive geometry region to encompass the regions interior to it. Therefore, it must be described as an ARRAY. The square plate on the top of the disks is defined as a UNIT in the ARRAY. In the geometry description given below, the square plate is defined in UNIT 3. KENO-VI can easily describe this configuration as a single UNIT.

Data description 1, Example 3.

In data description 1, Example 3 above, KENO V.a input, UNIT 1 describes a disk of material 1 with a HOLE through its centerline. The first CYLINDER defines the HOLE, the second defines the rest of the disk, and the CUBOID defines the size of the UNIT to be consistent with the square plate so they can be stacked together in an ARRAY. UNIT 2 describes a disk of material 2 in similar fashion. UNIT 3 describes the square plate of material 3 with a HOLE through its center. The CYLINDER defines the HOLE and the CUBOID defines the square plate. These three UNITs are stacked in the Z direction to achieve the composite system. This is represented by FILL 1 2 2Q2 3. The 2Q2 repeats the two entries preceding the 2Q2 twice. Alternatively, this can be

achieved by entering FILL 1 2 1 2 1 2 3 END FILL. The same ARRAY can also be achieved using the LOOP option. An example of the data for this option is:

LOOP 1 6R1 1 5 2 2 6R1 2 6 2 3 6R1 7 7 1 END LOOP.

UNIT 1 is placed at the X = 1, Y = 1, and Z = 1,3,5 positions of the ARRAY by entering 1 6R1 1 5 2. UNIT 2 is positioned at the X = 1, Y = 1 and Z = 2,4,6 positions in the ARRAY by entering 2 6R1 2 6 2. UNIT 3 is placed at the X = 1, Y = 1, Z = 7 position of the ARRAY by entering 3 6R1 7 7 1. See Sect. 8.1.3.5 for additional information regarding ARRAY specifications.

For the KENO-VI input, UNIT 1 contains the entire problem description. The first CYLINDER describes the 1.5 cm diameter hole through the stack. The next four CYLINDERs define the stack. The sixth and seventh CYLINDERs describe the void and container. The two CUBOIDs describe the top plate and surrounding global region of void. The MEDIA cards are used to place the materials in the appropriate regions.

EXAMPLE 4. Assume two large cylinders that are 2.5 cm in radius and 5 cm long are connected by a smaller cylinder that is 0.5 cm in radius and 10 cm long, as shown in Fig. 8.1.19. All three cylinders are composed of material 1. By starting the geometry description in the small cylinder, this system can be described as a single unit.

Fig. 8.1.19: Two large cylinders joined axially by a small cylinder.

```

The origin is at the center of the small cylinder, which is described by the first cylinder description. The second cylinder description defines a void cylinder surrounding the small cylinder. Its radius is the same as the large cylinders, and its height (length) coincides with that of the small cylinder. The last cylinder description defines the large cylinders on either end of the small cylinder. In KENO V.a, because this problem does not specify otherwise, the length of the CYLINDERs is assumed to coincide with the Z axis. In KENO-VI,

because the problem was created using XCYLINDERs, the long axes of the CYLINDERs coincide with the X axis.

EXAMPLE 5. Assume two large cylinders with a center-to-center spacing of 15 cm, each having a radius of 2.5 cm and length of 5 cm, are connected radially by a small cylinder having a radius of 1.5 cm, as shown in Fig. 8.1.20.

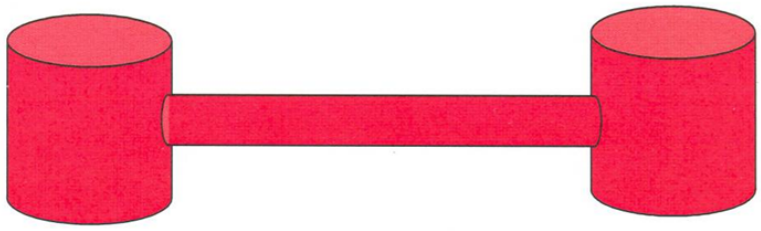

Fig. 8.1.20: Two large cylinders radially connected by a small cylinder.

This system cannot be described rigorously in KENO V.a geometry because the intersection of the cylinders cannot be described. However, it can be approximated two ways, as shown in Fig. 8.1.21. The top approximation is described in data description 1, Example 5. The bottom approximation is described in data description 2, Example 5, and data description 3, Example 5. These may be poor approximations for criticality safety calculations.

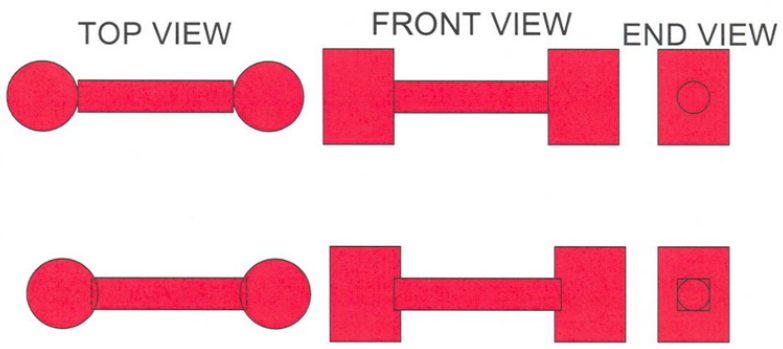

Fig. 8.1.21: KENO V.a approximations of cylindrical intersections.

UNIT 1 defines a large CYLINDER, and UNIT 2 describes the small CYLINDER. In both UNITs the origin is at the center of the CYLINDER. The large CYLINDERs have their centerlines along the Z axis and the small CYLINDER has its length along the X axis.

```

The above geometry description uses ARRAYs of ARRAYs (see Sect. 8.1.4.6.3) to describe the bottom approximation of Fig. 8.1.21. UNIT 1 defines a large CYLINDER that has a radius of 2.5 cm and a height of 10 cm inside a close-fitting CUBOID. This is used in both large CYLINDERs as the portion of the large CYLINDER that exists above and below the region where the small CYLINDER joins it. UNIT 5 is the spacing between the tops of the two large CYLINDERs and the spacing between the bottoms of the two large CYLINDERs. ARRAY 1 thus defines the bottom of the system: two short CYLINDERs (UNIT 1s) separated by 10 cm (UNIT 5 is the separation). UNIT 6 contains ARRAY 1.

UNIT 2 is the left hemicylinder that adjoins the horizontal CYLINDER, and UNIT 3 is the right hemicylinder that adjoins the horizontal CYLINDER. UNIT 4 defines the horizontal CYLINDER. ARRAY 2 contains UNITs 2, 4, and 3 from left to right. This defines the central portion of the system where the horizontal CYLINDER adjoins the two hemicylinders. These hemicylinders are larger than half CYLINDERs. UNIT 7 contains ARRAY 2. The entire system is achieved by stacking a UNIT 6 above and below the UNIT 7 as defined in ARRAY 3, the GLOBAL ARRAY.

READ ARRAY
ARA=1 NUX=1 NUY=1 NUZ=3 FILL 2 5 2 END FILL
END ARRAY
```

The above geometry description uses HOLEs (see Sect. 8.1.4.6.1) to describe the bottom approximation of Fig. 8.1.21. UNIT 1 defines a large CYLINDER with a radius of 2.5 cm and a height of 1.0 cm. UNIT 2 defines the same CYLINDER within a CUBOID that extends from X = -2.5 to X = 17.5, from Y = -2.5 to Y = 2.5, and Z = 0.0 to Z = 1.0. The origin of the CYLINDER is at (0.0,0.0,0.0). Thus UNIT 2 describes the top and bottom of the CYLINDER on the left. UNIT 1 is positioned within this CUBOID as a HOLE with its origin at (15.0,0.0,0.0) to describe the top and bottom of the CYLINDER on the right. UNIT 3 is the left hemicylinder that adjoins the horizontal CYLINDER, and UNIT 4 is the right hemicylinder that adjoins the horizontal CYLINDER. UNIT 5 defines the horizontal CYLINDER with its origin at the center within a CUBOID that extends from X = -10.0 to X = +10.0, Y = -2.5 to Y = 2.5, and Z = -1.5 to Z = 1.5. UNIT 3 is positioned to the left of the horizontal CYLINDER, and UNIT 4 is positioned to the right of the horizontal CYLINDER by using HOLEs. The entire system is achieved by stacking a UNIT 2 above and below UNIT 5 as shown in the ARRAY data.

This same geometry description can be used with UNIT 2 redefined, having its origin defined so that it extends from X = -10 to X = 10, Y = -2.5 to Y = 2.5, and Z = 0.0 to Z = 1. In this instance, the geometry data would be identical except for UNIT 2. This alternative description of UNIT 2 is

KENO V.a:

```
UNIT 2
CYLINDER 1 1 2.5 1.0 0.0 ORIGIN -7.5 0.0
CUBOID 0 1 2P10.0 2P2.5 1.0 0.0
HOLE 1 7.5 0.0 0.0
```

This system can be easily described in KENO-VI geometry because intersections are allowed. The small CYLINDER is rotated in data description 1, Example 5.

Data description 1, Example 5.

KENO-VI:

```
READ GEOM

BOUNDARY  4
END GEOM
```

The first and second CYLINDERs define the two large CYLINDERs, and the third CYLINDER describes the small connecting CYLINDER. The two large CYLINDERs are oriented along the Z axis. The second large cylinder is translated so its origin is at position (0.0, 15.0, 0.0). The small CYLINDER is oriented along the Y axis. Region 1 consists of the material in the first large CYLINDER. Region 2 consists of the material in the second large CYLINDER. Region 3 consists of the material in the small CYLINDER but not in either of the large CYLINDERs. Region 4 is the BOUNDARY region.

EXAMPLE 6. Assume 2 small cylinders 1.0 cm in radius and 10 cm long are connected by a large cylinder 2.5 cm in radius and 5 cm long as shown in Fig. 8.1.22.

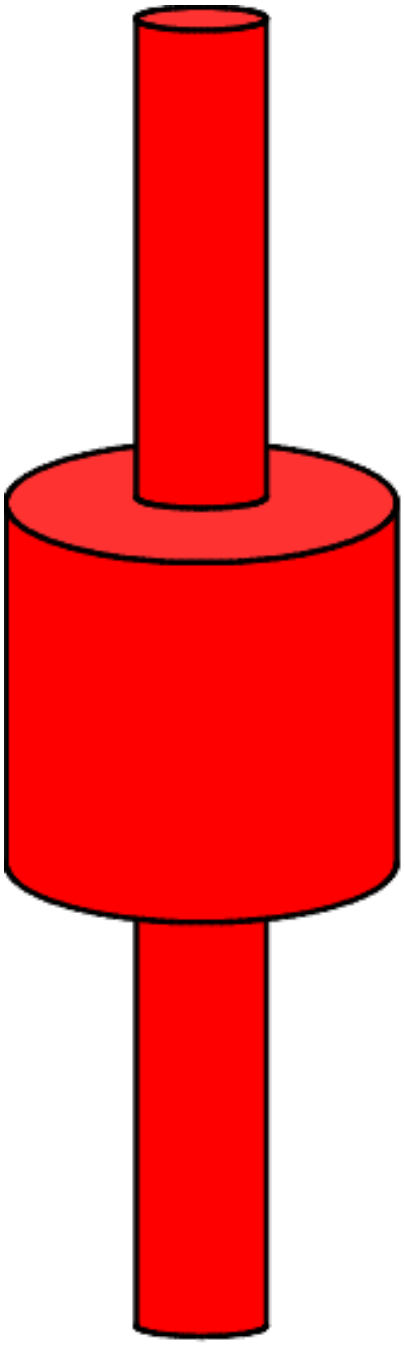

Fig. 8.1.22: Two small cylinders joined axially by a large cylinder.

This problem is very similar to Example 4. It can be described as a single `UNIT` in KENO-VI, but not in KENO V.a where it must be described as an array. In KENO V.a, `UNIT` 1 defines the large cylinder, and `UNIT` 2 defines the small cylinder. The origin of each `UNIT` is at its center. The composite system consists of two `UNIT` 2s and one `UNIT` 1 as shown below. In KENO-VI, `CYLINDER` 1 defines the long thin cylinder, and

CYLINDER 2 defines the short thick cylinder. The origin of each cylinder is at its center. In both KENO V.a and KENO-VI, the centerline of the cylinders lies along the Z axis.

In the KENO V.a input, the ARRAY boundary defines the origin of the REFLECTOR to be at the center of the ARRAY. The 6*3.0 in the REFLECTOR description repeats the 3.0 six times. The REFLECTOR record is used to generate ten REFLECTOR regions, each of which is 3.0 cm thick, on all six faces of the ARRAY.

In the KENO-VI input, the basic UNIT used to construct the ARRAY is defined in UNIT 1. The ARRAY is positioned in UNIT 2 (the GLOBAL UNIT) using the ARRAY card and the PLACE option. The ARRAY is then surrounded by ten REFLECTOR regions, each 3.0 cm thick, on all sides.

The first bias ID is 2, so the last bias ID will be 11 if 10 regions are created. The biasing data block is necessary to apply the desired weighting or biasing function to the reflector. The biasing material ID is obtained from Table 8.1.25. IDs, group structure and incremental thickness for weighting data available on the KENO weighting library. If the biasing data block is omitted from the problem description, the 10 reflector regions will not have a biasing function applied to them, and the default value of the average weight will be used. This may cause the problem to execute more slowly, and therefore require the use of more computer time.

EXAMPLE 10. Assume the reflector in Example 9 is present only on both X faces, both Y faces, and the negative Z face. The reflector is only 15.24 cm thick on these faces. The top of the array (positive Z face) is unreflected.

Data description 1, Example 10.

In the KENO V.a input, the first REFLECTOR description generates five regions around the ARRAY, each region being 3.0 cm thick in the +X, -X, +Y, -Y, and -Z directions, and of zero thickness in the +Z direction. This defines a total thickness of 15 cm of reflector material on the appropriate faces. The second REFLECTOR description generates the last 0.24 cm of material 2 on those faces. Thus, the total reflector thickness is 15.24 cm on each face of the array, except the top which has no reflector. Five reflector regions were generated by the first REFLECTOR description, and one was generated by the second REFLECTOR description; so, six biasing regions must be defined in the biasing data. Thus, the beginning bias ID is 2, and the ending bias ID is 7.

In the KENO-VI input, the first CUBOID in Unit 2 represents the boundary for the ARRAY. The next four CUBOIDs represent the first four regions around the ARRAY, each region being 3.0 cm thick in the +X, X, +Y, -Y, and -Z directions, and of zero thickness in the +Z direction. A total thickness of 12 cm of reflector material is on the appropriate faces. The last CUBOID represents the last 3.24 cm of material 2 on those faces. Thus, the total reflector thickness is 15.24 cm on each face of the array, except the top which has no reflector. The beginning bias ID is 2, and the ending bias ID is 6. The last region could either be larger or smaller than the recommended thickness to complete the reflector.

The biasing material ID and thickness per region are obtained from Table 8.1.25. The thickness per region should be very nearly the thickness per region from the table to avoid over biasing in the reflector. Partial increments at the outer region of a reflector are exempt from this recommendation. If a biasing function is not to be applied to a region generated by the REFLECTOR record, the thickness per region can be any desired thickness and the biasing data block is omitted.

EXAMPLE 11. Assume the array of Example 7 has the central unit of the array replaced by a cylinder of material 4, 5 cm in radius and 10 cm tall. Assume a 20 cm thick spherical reflector of material 3 (concrete) is positioned so its inner radius is 65 cm from the center of the array. The minimum inner radius of a spherical reflector for this array is 62.25 cm ($\sqrt{55^2 + 25^2 + 15^2}$). If the inner radius is smaller than this, the problem cannot be described using KENO V.a geometry.

UNIT 1 describes the SPHERE and spacing used in the ARRAY. UNIT 2 defines the CYLINDER located at the center of the ARRAY. In KENO V.a, the ARRAY record defines the origin of the reflector to be at the center of the ARRAY, while in KENO-VI it defines the origin of the ARRAY to be at the center of the GLOBAL UNIT. The first SPHERE in the GLOBAL UNIT defines the inner radius of the reflector. The next four SPHERE and four MEDIA records of the KENO-VI input and the REPLICATE record of the KENO V.a input will generate four spherical regions of material 3, each 5.0 cm thick. The data for the BIAS block is generated in a similar manner to previous examples, except that concrete (ID=301) is used. The recommended reflector thickness is 5 cm; this thickness is incorporated explicitly in the KENO-VI model and with 4 repetitions of the 5 cm thick reflector via REPLICATE in the KENO V.a model. The first 10 entries following the word LOOP fills the 11 ×

5 × 3 ARRAY with UNITs 1. The next 10 entries position UNIT 2 at the center of the ARRAY (X = 6, Y = 3, and Z = 2), replacing the UNIT 1 that had been placed there by the first 10 entries.

EXAMPLE 12. Assume a data profile such as fission densities is desired in a cylinder at 0.5 cm intervals in the radial direction and 1.5 cm intervals axially. The cylinder is composed of material 1 and has a radius of 5 cm and a height of 15 cm. The REPLICATE or REFLECTOR description can be used to generate these regions in KENO V.a. A biasing data block is not entered because default biasing is desired throughout the cylinder.

EXAMPLE 13. (KENO-VI due to pipe junctions) Assume a cross composed of two Plexiglas cylinders (material 3) having an inner diameter of 13.335 cm and an outer diameter of 16.19 cm. The bottom and side legs of the cross are closed by a 3.17 cm thick piece of Plexiglas. From the center of the intersection, the bottom and side legs are 91.44 cm long and the top leg is 121.92 cm long. The cross is filled with a UO_2F_2 solution (material 1) to a height of 28.93 cm above the center of the cylinder intersection. The cross is then surrounded by a water reflector (material 2) that extends from the center of the intersection: 111.74 cm in the ±X directions, 20.64 cm in the ±Y directions, 29.03 cm in the +Z direction, and -118.428 cm in the -Z direction. A schematic of the assembly is shown in Fig. 8.1.23.

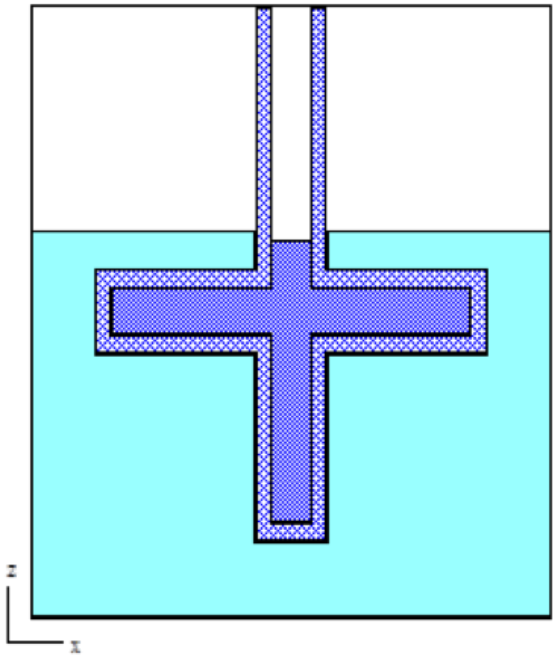

Fig. 8.1.23: Plexiglas UO_2F_2-filled cross.

Use of holes in the geometry

Sect. 8.1.4.6 tells how each KENO V.a geometry region in a UNIT must completely enclose all previously described regions in that UNIT and how KENO-VI geometry allows regions in a UNIT to intersect, thus eliminating the need for HOLEs. HOLEs can be used to circumvent the complete enclosure restriction in KENO V.a to some degree. In KENO-VI, they can be useful in simplifying the input of a problem and decreasing the total CPU time needed for a problem. A HOLE is a means of placing an entire UNIT within a geometry region. A separate HOLE description is required for every location in a geometry region where a UNIT is to be placed. The information contained in a HOLE description is (1) the keyword HOLE, (2) the UNIT number of the UNIT to be placed, and (3) any modification data needed to correctly position and rotate (in KENO-VI) the specified UNIT within the containing UNIT. In KENO V.a, a HOLE is placed inside the geometry region that precedes it. This excludes HOLEs ... (i.e., if a CUBE geometry region is followed by four HOLE descriptions, all four HOLEs are located within the CUBE). In KENO V.a, HOLEs are subject to the restriction that they cannot intersect any other geometry region. HOLEs can be nested to any depth (see Sect. 8.1.4.6.2). It is

not advisable to use HOLEs tangent to other HOLEs or geometry, because round-off error may cause them to overlap. It is not uncommon for a problem that runs on one type of computer to fail on another type using the same data. Therefore, it is recommended that tangency and boundaries shared with HOLEs be avoided. This may be accomplished by separating the otherwise collocated or tangent surfaces by a very small (i.e., 10^{-6} cm) distance.

In KENO V.a, tracking in regions that contain holes is less efficient than tracking in regions that do not contain holes. Therefore, holes should be used only when the system cannot be easily described by conventional methods. One example of the use of holes is shown in Fig. 8.1.25, representing nine close-packed rods in an annulus.

In KENO-VI, tracking in regions that contain HOLEs can be more efficient than tracking in regions that do not contain HOLEs because every region boundary in a UNIT must be checked for a crossing whenever a crossing is possible. Putting small but complex geometries in a hole will lessen the number of boundaries that need to be checked for possible crossings. However, the indiscriminate use of holes is not advised since the particle must change coordinate systems every time a hole is entered or exited. Therefore, holes should be used carefully and only when the system can be simplified significantly by their use.

EXAMPLE 15. One example of a unit that requires holes in KENO V.a is better described not using holes in KENO-VI as shown in Fig. 8.1.25, representing nine close-packed rods in an annulus. The large rods are 1.4 cm in radius and composed of mixture 3. The small rods are 0.6 cm in radius and composed of mixture 1. The inside radius of the annulus is 3.6 cm, and the outside radius is 3.8 cm. The annulus is made of mixture 2. The rods and annulus are both 30 cm long. The annulus is centered in a cuboid having an 8 cm^2 cross section and a length of 32 cm. The black and gray areas in Fig. 8.1.25 are void.

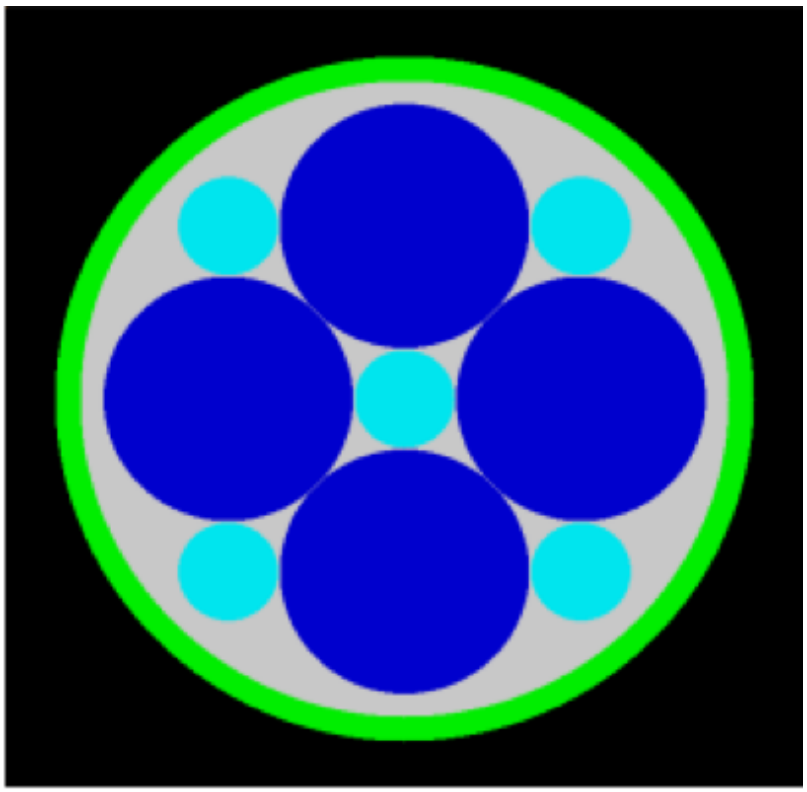

Fig. 8.1.25: Close-packed cylinders in an annulus.

The first HOLE description in the KENO V.a input represents the bottom large rod. It takes UNIT 2 and places its ORIGIN at (0.0,-2.0,0.0) relative to the ORIGIN of UNIT 3. The second HOLE description represents the small rod to the right of the large rod just discussed. It places the origin of UNIT 1 at (2.0,-2.0,0.0) in UNIT 3. The third HOLE description represents the large rod to the right. It places the origin of UNIT 2 at (2.0,0.0,0.0) in UNIT 3. This procedure is repeated in a counterclockwise direction until all eight rods have been placed within the region that defines the inner surface of the annulus. The CYLINDER that defines the outer surface of the annulus is described after all the HOLEs for the previous region have been placed. Then the outer CUBOID is described. This example illustrates that a UNIT that is to be placed using a HOLE description need not have

a CUBE or CUBOID as its last region. Note that including the central rod directly in UNIT 3 reduces the CPU time required for transport compared to the case of all 9 rods being inserted as HOLEs. It is also important that the 9 HOLEs are inserted *after* the void cylinder into which they are inserted. Entering the HOLEs in any other position in the input would generated region intersection errors. The order of the HOLE records in any given region is not important, as they can be interchanged with each other randomly. However, they must always appear immediately after the region in which they are placed.

The KENO-VI input does not need to use HOLEs. The first CYLINDER description in this case represents the middle small rod. The next four CYLINDER records describe the four remaining small rods surrounding the middle rod. The ORIGIN attribute is used to shift the origin of each CYLINDER to the appropriate location. The following four CYLINDER records represent the four large rods. Again, the ORIGIN attribute is used to shift the ORIGIN of each CYLINDER to the appropriate location. Only the nonzero dimensions need to be entered in the ORIGIN data. The tenth CYLINDER record is the void in the annulus that contains the rods. The last CYLINDER record defines the outer surface of the annulus. Finally, the CUBOID record describes the surrounding UNIT boundary.

In KENO-VI, holes may not extend across any array outer boundary, may not intersect with other holes, and may not cross the host UNIT outer boundary. Thus a hole may be placed so that it crosses several regions within an array. The hole description replaces the unit description within the hole domain. Since the holes are placed using the host UNIT coordinate system, the location of the hole record in the unit definition is not relevant.

An array of the arrangement shown in Fig. 8.1.25 can be easily described by altering the array description data. For example, a $5 \times 3 \times 2$ array of these shapes with a center-to-center spacing of 8 cm in X and Y and 32 cm in Z can be achieved by using the following array data:

```
READ ARRAY  NUX=5 NUY=3 NUZ=2  FILL F3  END FILL  END ARRAY
```

or

```
READ ARRAY  NUX=5 NUY=3 NUZ=2  FILL 30*3  END FILL  END ARRAY
```

or

```
READ ARRAY  NUX=5 NUY=3 NUZ=2  LOOP  3 1 5 1 1 3 1 1 2 1  END LOOP END ARRAY
```

Nesting holes

This section illustrates how holes are nested. Holes can be nested to any level. Consider the configuration illustrated in Fig. 8.1.25 and replace the large rods with a complicated geometric arrangement. The resulting Fig. is shown in Fig. 8.1.26. Fig. 8.1.27 shows the complicated geometric arrangement that replaced the large rods of Fig. 8.1.25. Fig. 8.1.28 shows a component of the arrangement shown in Fig. 8.1.26.

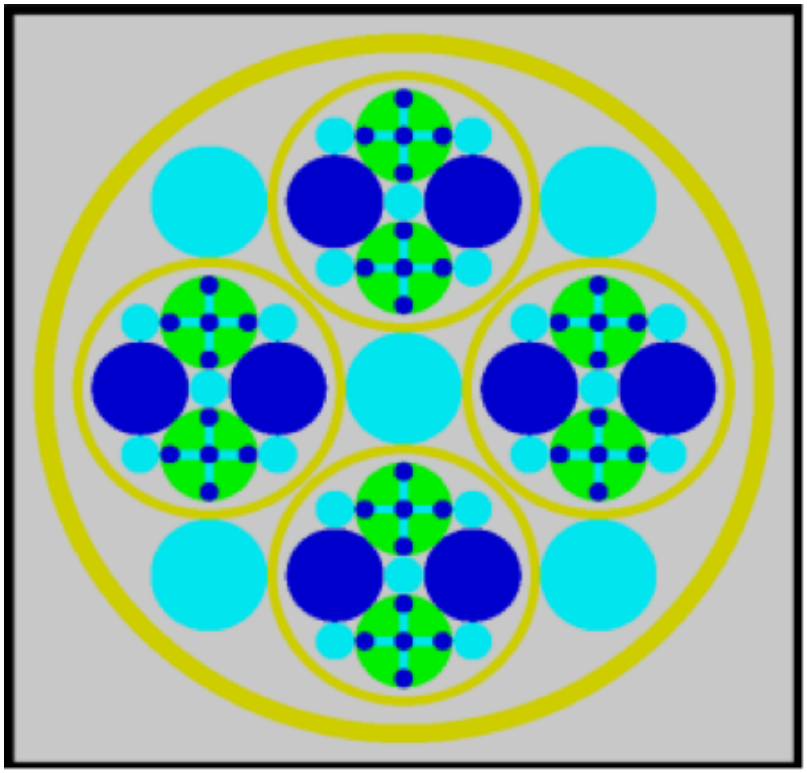

Fig. 8.1.26: Configuration using nested holes.

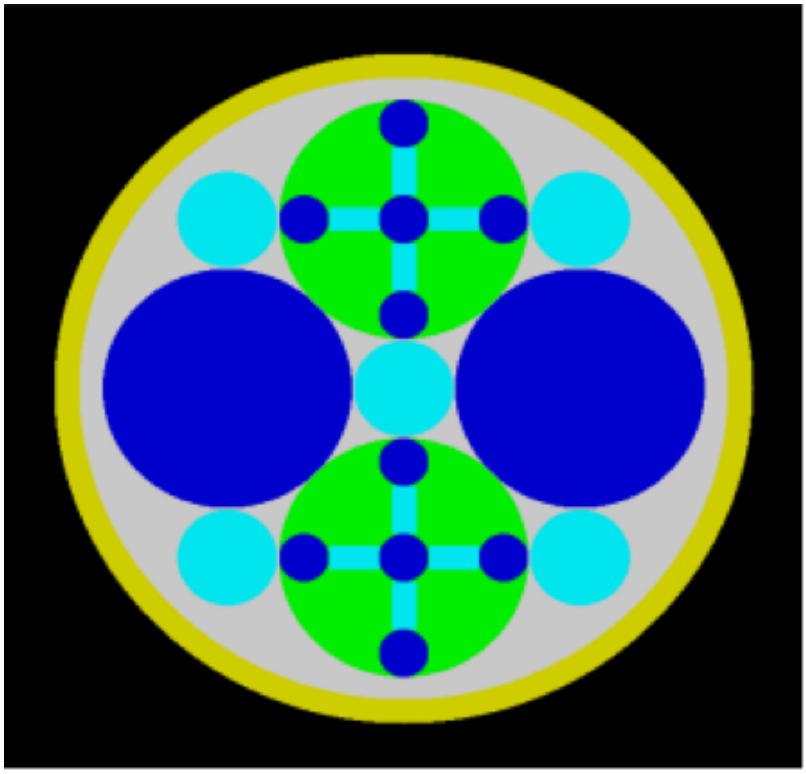

Fig. 8.1.27: Complicated geometric arrangement by Unit 7.

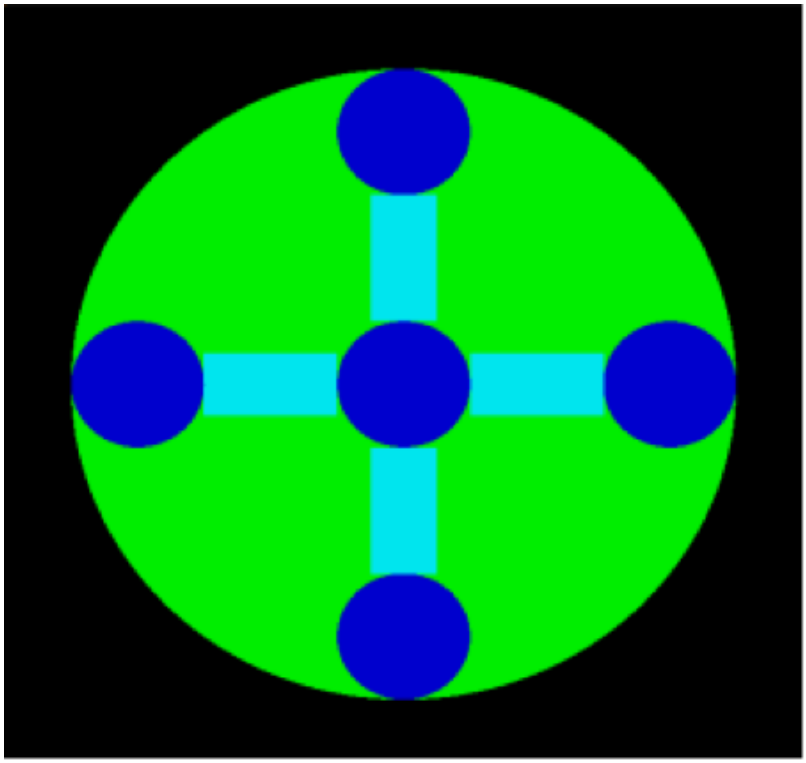

Fig. 8.1.28: Geometric component represented by Unit 4.

EXAMPLE 16. There is no predetermined preferred method to create a geometry mockup for a given physical system. The user should determine the most convenient order. To describe the configuration shown in Fig. 8.1.26 using nested HOLEs, it is likely most convenient to start the geometry mockup at the deepest nesting level, as shown in Fig. 8.1.27. The small CYLINDERs are composed of mixture 1, and they are each 0.1 cm in radius and 30 cm long. There are five small CYLINDERs used in Fig. 8.1.28. Their centers are located at (0,0,0) for the central one, at (0,-0.4,0) for the bottom one, at (0.4,0,0) for the right one, at (0,0.4,0) for the top one, and at (-0.4,0,0) for the left one. The rectangular parallelepipeds (CUBOIDs) are composed of mixture 2. Each one is 30 cm long and 0.1 cm by 0.2 cm in cross section. The large CYLINDER containing the configuration is composed of mixture 3, is 30 cm long and has a radius of 0.5 cm.

A possible geometry mockup for this system is described as follows in KENO V.a:

(1) define a small cylinder to be UNIT 1,

(2) define a small CUBOID with its length in the X direction to be UNIT 2,

(3) define a small CUBOID with its length in the Y direction to be UNIT 3,

(4) define UNIT 4 to be the large cylinder and place the CYLINDERs and CUBOIDs in it using HOLEs.

```
UNIT 1
CYLINDER 1 1 0.1 2P15.0
UNIT 2
CUBOID 2 1 2P0.1 2P0.05 2P15.0
UNIT 3
CUBOID 2 1 2P0.05 2P0.1 2P15.0

CYLINDER  1 1 0.1 2P15.0
CYLINDER  3 1 0.5 2P15.0
HOLE 1 0.0 -0.4 0.0
HOLE 1 0.4 0.0 0.0
HOLE 1 0.0 0.4 0.0
HOLE 1 -0.4 0.0 0.0
HOLE 2 -0.2 0.0 0.0
HOLE 2 0.2 0.0 0.0
HOLE 3 0.0 -0.2 0.0
HOLE 3 0.0 0.2 0.0
```

The first cylinder description in UNIT 4 places the central rod,

the second cylinder description in UNIT 4 places the outer cylinder,

the *first* HOLE places the bottom CYLINDER,

the *second* HOLE places the CYLINDER at the right,

the *third* HOLE places the top CYLINDER,

the *fourth* HOLE places the CYLINDER at the left,

the *fifth* HOLE places the left CUBOID whose length is in X,

the *sixth* HOLE places the right CUBOID whose length is in X,

the *seventh* HOLE places the bottom CUBOID whose length is in Y, and

the *eighth* HOLE places the top CUBOID whose length is in Y.

A possible geometry mockup for this system is described as follows in KENO-VI:

1. define UNIT 1 to contain the five small cylinders and four blocks,

2. define UNIT 2 to contain the next two larger-sized cylinders and UNIT 1 as HOLEs, and
3. define GLOBAL UNIT 3 to contain the large cylinders and UNIT 2 as HOLEs.

geometry record *1* places the central rod,

geometry record *2* places the bottom CYLINDER,

geometry record *3* places the CYLINDER at the right,

geometry record *4* places the top CYLINDER,

geometry record *5* places the CYLINDER at the left,

geometry record *6* places the left CUBOID whose length is in X,

geometry record *7* places the right CUBOID whose length is in X,

geometry record *8* places the bottom CUBOID whose length is in Y,

geometry record *9* places the top CUBOID whose length is in Y, and

geometry record *10* is the surrounding CYLINDER that defines the unit boundary.

In Fig. 8.1.27, the large plain cylinders are composed of mixture 1 and are 0.5 cm in radius and 30 cm long. The cylindrical component of UNIT 4 for KENO V.a or UNIT 1 for KENO-VI is the same size: an outer radius of 0.5 cm and a length of 30 cm. The small cylinders located in the interstices between the large cylinders are composed of mixture 2, are 0.2 cm in radius, and are 30 cm long. The annulus is composed of mixture 4, has a 1.3 cm inside radius and a 1.4 cm outer radius. The volume between the inner cylinders is void. The large cylinders each have a radius of 0.5 cm and are tangent. Therefore, their origins are offset from the origin of the UNIT by 0.707107. This is from $X^2 + Y^2 = 1.0$, where X and Y are equal.

For KENO V.a, define UNIT 5 to be the large plain cylinder, UNIT 6 to be the small cylinder, and UNIT 7 as the annulus that contains the cylinders. Its origin is at its center. The geometry mockup for this portion of the problem follows:

KENO V.a:

```
UNIT 5
CYLINDER  1 1 0.5 2P15.0
UNIT 6
CYLINDER  2 1 0.2 2P15.0
UNIT 7
CYLINDER  2 1 0.2 2P15.0
CYLINDER  0 1 1.3 2P15.0
HOLE      5 0.707107 0.0 0.0
HOLE      6 0.707107 0.707107 0.0
HOLE      4 0.0 0.707107 0.0
HOLE      6 -0.707107 0.707107 0.0
HOLE      5 -0.707107 0.0 0.0
HOLE      6 -0.707107 -0.707107 0.0
HOLE      4 0.0 -0.707107 0.0
HOLE      6 0.707107 -0.707107 0.0
CYLINDER  4 1 1.4 2P15.0
```

The *first* HOLE places the larger CYLINDER of mixture 1 at the right with its origin at (0.707107,0.0,0.0),

the *second* HOLE places the small CYLINDER in the upper right quadrant,

the *third* HOLE places the top CYLINDER that contains the geometric component defined in UNIT 4,

the *fourth* HOLE places the small CYLINDER in the upper left quadrant,

the *fifth* HOLE places the larger CYLINDER of mixture 1 at the left,

the *sixth* HOLE places the small CYLINDER in the lower lower left quadrant,

the *seventh* HOLE places the bottom CYLINDER that contains the geometric component defined in UNIT 4, and

the *eighth* HOLE places the small CYLINDER in the lower right quadrant.

The last CYLINDER defines the outer surface of the annulus.

For KENO-VI, UNIT 2 is the annulus that contains the cylinders.

KENO-VI:

In Unit 2 of the above KENO-VI geometry,

CYLINDER *1* places a small CYLINDER of mixture 2 at the origin,

CYLINDER *2* places the small CYLINDER of mixture 2 in the upper right quadrant,

CYLINDER *3* places the small CYLINDER of mixture 2 in the upper left quadrant,

CYLINDER *4* places the small CYLINDER of mixture 2 in the lower left quadrant,

CYLINDER *5* places the small CYLINDER of mixture 2 in the lower right quadrant,

CYLINDER *6* places the larger CYLINDER of mixture 1 at the right with its origin at (0.707107,0.0,0.0),

CYLINDER *7* places the larger CYLINDER of mixture 1 at the left with its origin at (0.0,0.707107.0.0),

CYLINDER *10* defines the inner surface of the annulus,

CYLINDER *11* defines the outer surface of the annulus and the UNIT boundary,

the first HOLE places the top CYLINDER that contains the geometric component defined in UNIT 1, and

the second HOLE places the bottom CYLINDER that contains the geometric component defined in UNIT 1.

To complete the geometry mockup, consider Fig. 8.1.26.

For KENO V.a geometry, define UNIT 8 to be a cylinder of mixture 2 having a radius of 0.6 cm and a length of 30 cm. Define UNIT 9 to be the central rod and the large annulus of 3.6 cm inner radius, 3.8 cm outer radius, and 30 cm length centered in a CUBOID having an 8 cm^2 cross section and being 32 cm long.

KENO V.a:

```
UNIT 8
CYLINDER  2 1 0.6 2P15.0

HOLE   8 2*-2.0 0.0
HOLE   7 0.0 -2.0 0.0
HOLE   8 2P2.0 0.0
CYLINDER  4 1 3.8 2P15.0
CUBOID    0 1 4P4.0 2P16.0
```

In UNIT 9 of the KENO V.a description, the first CYLINDER defines the rod of mixture 2, centered in the annulus. The second CYLINDER defines the void volume between the central rod and the annulus.

The *first* HOLE places the composite annulus of UNIT 7 to the right of the central rod,

the *second* HOLE places a rod defined by UNIT 8 in the upper right quadrant of the annulus,

the *third* HOLE places the composite annulus of UNIT 7 above the central rod,

the *fourth* HOLE places a rod defined by UNIT 8 in the upper left quadrant of the annulus,

the *fifth* HOLE places the composite annulus of UNIT 7 to the left of the central rod,

the *sixth* HOLE places a rod defined by UNIT 8 in the lower left quadrant,

the *seventh* HOLE places the composite annulus of UNIT 7 below the central rod, and

the *eighth* HOLE places a rod defined by UNIT 8 in the lower right quadrant.

The last CYLINDER defines the outer surface of the annulus. The outer CUBOID is the last region.

For KENO-VI geometry, define UNIT 3 to be the central rod and four outer rods of 0.6 cm radius and 30.0 cm length, and the large annulus of 3.6 cm inner radius, 3.8 cm outer radius, and 30 cm length centered in a cuboid having an 8 cm^2 cross section and a length of 32 cm.

KENO-VI:

In UNIT 3 of the above KENO-VI description,

CYLINDER *1* defines the rod of mixture 2, centered in the annulus,

CYLINDER *2* places a rod of mixture 2 in the upper right quadrant of the annulus,

CYLINDER *3* places a rod of mixture 2 in the upper left quadrant of the annulus,

CYLINDER *4* places a rod of mixture 2 in the lower left quadrant,

CYLINDER *5* places a rod of mixture 2 in the lower right quadrant,

CYLINDER *10* defines the void volume between the central rod and the annulus,

CYLINDER *11* defines the outer surface of the annulus,

CUBOID *12* defines the unit boundary,

the first HOLE places UNIT 2 to the right of the central rod,

the second HOLE places UNIT 2 above the central rod,

the third HOLE places UNIT 2 to the left of the central rod, and

the fourth HOLE places UNIT 2 below the central rod.

This problem illustrates three levels of HOLE nesting. The total input data for the problem is given below. The geometry description accurately recreates the geometry arrangement of Fig. 8.1.26. The 2D color plot output is shown in Fig. 8.1.29.

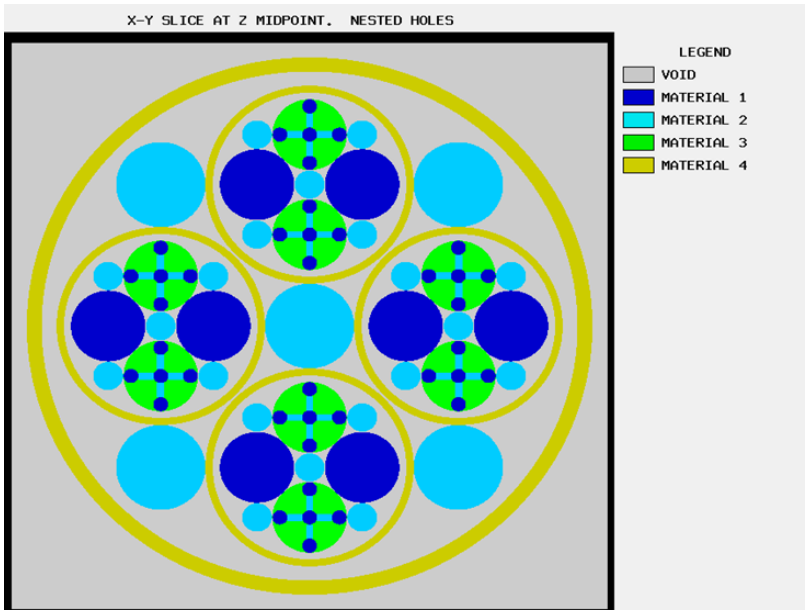

Fig. 8.1.29: Color plot of nested holes example problem.

Multiple arrays

EXAMPLE 17. Sect. 8.1.4.6 demonstrates how UNITs are composed of geometry regions and how these UNITs can be stacked in an ARRAY. This same procedure can be extended to create multiple ARRAYs. Furthermore, ARRAYs can be used as building blocks within other ARRAYs.

Consider Sample Problem 19 from Sect. 8.1.8.3. This problem is a critical experiment consisting of a composite array [Tho64, Tho73] of four highly enriched uranium metal cylinders and four cylindrical Plexiglas containers filled with uranyl nitrate solution. A photograph of the experiment is given in Fig. 8.1.235. The coordinate system is defined to be Z up the page, Y across the page, and X out of the page.

The Plexiglas containers have an inside radius of 9.525 cm and an outside radius of 10.16 cm. The inside height is 17.78 cm, and the outside height is 19.05 cm. Four of these containers are stacked with a center-to-center spacing of 21.75 cm in the Y direction and 20.48 cm in the Z direction (vertical). This arrangement of four Plexiglas containers can be described as follows: mixture 2 is the uranyl nitrate and mixture 3 is Plexiglas, so the Plexiglas container with its appropriate spacing CUBOID can be described as UNIT 1. This considers the ARRAY to be bare and suspended with no supports.

KENO V.a:

```
UNIT 1
CYLINDER  2 1 9.525  2P8.89
CYLINDER  3 1 10.16  2P9.525
CUBOID    0 1 4P10.875  2P10.24
```

KENO-VI:

```
UNIT 1
CYLINDER 1  9.525  2P8.89
CYLINDER 2  10.16  2P9.525
CUBOID  3   4P10.875  2P10.24
MEDIA 2 1 1
MEDIA 3 1 2 -1
MEDIA 0 1 3 -2
BOUNDARY  3
```

The ARRAY of four Plexiglas containers can be described as ARRAY 1 in the array data as follows:

```
ARA=1 NUX=1 NUY=2 NUZ=2 FILL F1 END FILL
```

The four metal cylinders, comprised of mixture 1, each have a radius of 5.748 cm and are 10.765 cm tall. They have a center-to-center spacing of 13.18 cm in the Y direction and 12.45 cm in the Z direction (vertical). Thus, one of the metal cylinders with its appropriate spacing CUBOID can be described as UNIT 2. This ARRAY is also considered to be bare and unsupported.

KENO V.a:

```
UNIT 2
CYLINDER 1 1  5.748 2P5.3825
CUBOID   0 1  4P6.59 2P6.225
```

KENO-VI:

```
UNIT 2
CYLINDER 1 5.748 2P5.3825
CUBOID   2   4P6.59 2P6.225
MEDIA 1 1 1
MEDIA 0 1 2 -1
BOUNDARY  2
```

The array of four metal cylinders can be described as ARRAY 2 in the array data.

```
ARA=2 NUX=1 NUY=2 NUZ=2 FILL F2 END FILL
```

Now two ARRAYs have been described. The overall dimensions of the ARRAY of Plexiglas containers are 21.75 cm in X, 43.5 cm in Y, and 40.96 cm in Z. The overall dimensions of the ARRAY of metal cylinders are 13.18 cm in X, 26.36 cm in Y, and 24.9 cm in Z.

In order to describe the composite ARRAY, these two ARRAYs must be positioned within UNITs and stacked together into one ARRAY. In order for them to be stacked into one ARRAY, the adjacent faces must match. This is accomplished by defining a UNIT 3 which contains ARRAY 1, the ARRAY of Plexiglas solution containers. The overall dimensions of this UNIT are 21.75 cm in X, 43.5 cm in Y, and 40.96 cm in Z. These dimensions are calculated by the code and need not be specified. UNIT 3 is defined as follows:

KENO V.a:

```
UNIT 3
ARRAY 1  3*0.0
```

KENO-VI:

```
UNIT 3
CUBOID  1 2P10.875 2P21.75 2P20.48
ARRAY 1 1 PLACE 1 1 1 0.0 -10.875 -10.24
BOUNDARY  1
```

The ARRAY of metal cylinders will be defined to be UNIT 4. However, this ARRAY is 17.14 cm smaller in the Y and 16.06 cm smaller in the Z dimensions than the ARRAY of Plexiglas UNITs. Therefore, a void region must be placed around the ARRAY in those directions so UNIT 4 and UNIT 3 will be the same size in Y and Z.

KENO V.a:

```
UNIT 4
ARRAY  2  3*0.0
REPLICATE  0 1 2*0.0  2*8.57  2*8.03  1
```

KENO-VI:

Now that UNIT 3 and UNIT 4 have been defined, they must be placed in the global or universe ARRAY to define the physical arrangement of the eight pieces. This procedure is implemented via a GLOBAL ARRAY in KENO V.a, while KENO-VI uses a GLOBAL UNIT 3 as follows:

KENO V.a:

```
GBL=3  ARA=3  NUX=2  NUY=1  NUZ=1  FILL  4 3  END FILL
```

KENO-VI:

```
GLOBAL UNIT 5
CUBOID 1 34.93 0.0 43.5 0.0 40.96 0.0
ARRAY 3 1 PLACE 1 1 1 6.59 21.75 20.48
BOUNDARY  1
```

The description of ARRAY 3 in KENO-VI is identical to that shown for KENO V.a.

This completes the geometry description for the problem. The complete geometry input description for the problem is given below.

A plot of an X-Y slice taken through the bottom layer of the array is shown in Fig. 8.1.30. A plot of an X-Z slice taken through the +Y half of the array is shown in Fig. 8.1.31. These plots were used to verify the geometry mockup.

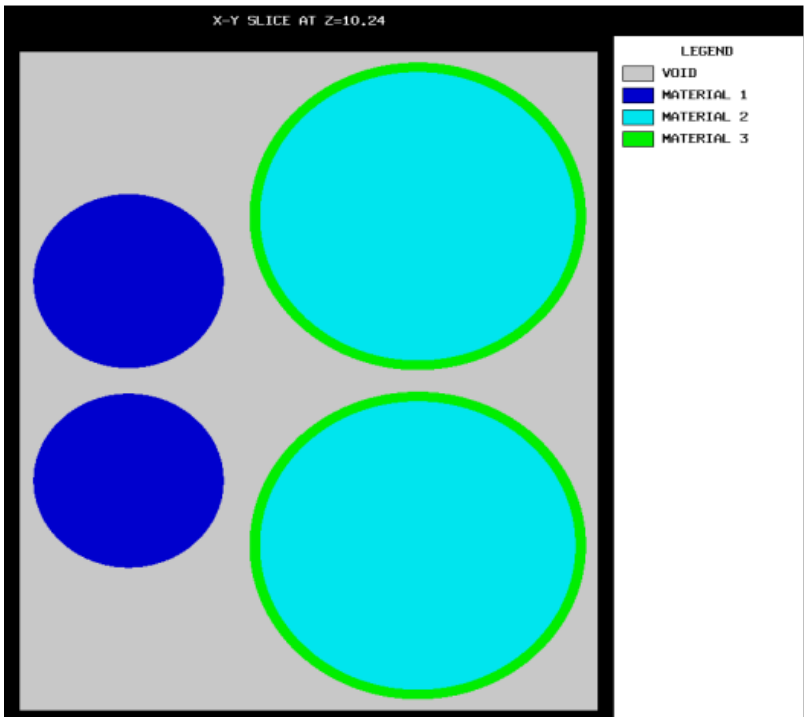

Fig. 8.1.30: X-Y plot of mixed array.

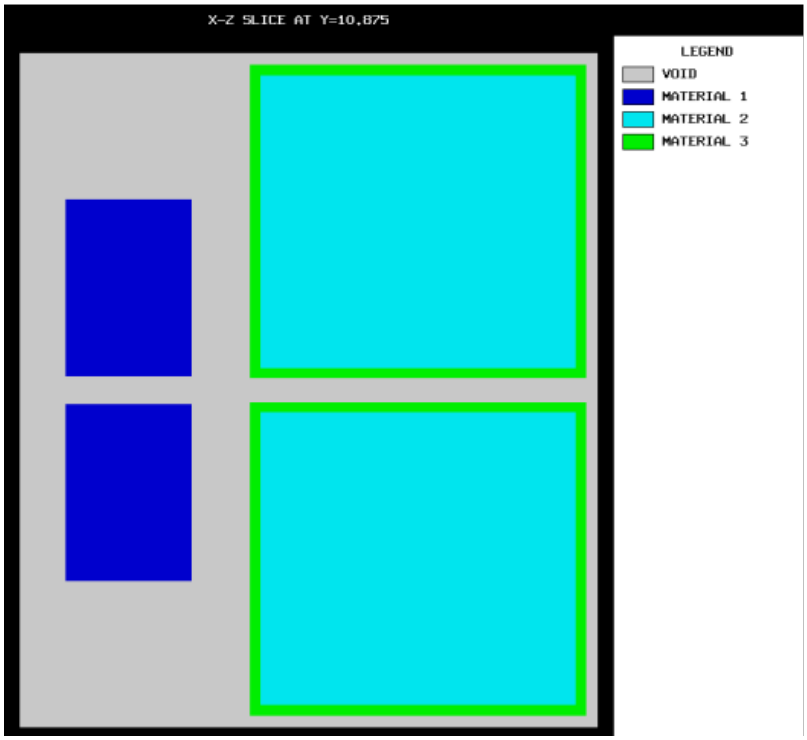

Fig. 8.1.31: X-Z plot of mixed array.

STORAGE ARRAY

EXAMPLE 18. Consider a storage array of highly enriched uranium buttons, each 1 in. tall and 4 in. in diameter. These buttons are stored on stainless steel shelves with a center-to-center spacing of 60.96 cm (2 ft) between them in the Y direction, and only one button on each shelf in the X direction. The shelves are 0.635 cm ($^1/_4$in.) thick (Z dimension), 45.72 cm (18 in.) wide (X dimension), 609.6 cm (20 ft) long (Y dimension), and are 45.72 cm (18 in.) from the top of a shelf to the bottom of the shelf above it. Each rack of storage shelves is four shelves high, with the first shelf being 15.24 cm (6 in.) above the floor. The storage room is 586.56 cm (19.5 ft) in the X direction by 1293.44 cm (43 ft) in the Y direction with 365.76 cm (12 ft.) ceilings in the Z direction. The walls, ceiling, and floor are composed of concrete, 30.48 cm (1 ft) thick. All the aisles between the storage racks are 91.44 cm (3 ft) wide. The racks are arranged with their length in the Y direction and an aisle between them. The arrays of racks are arranged with two in the Y direction and five in the X direction. Mixture 1 is the uranium metal, mixture 2 is the stainless steel, and mixture 3 is the concrete.

The metal button and its center-to-center spacing are described first. The void vertical spacing has arbitrarily been chosen to extend from the bottom of the button to the next shelf above the button. The shelf of stainless steel is described under the button.

BOUNDARY  1
```

Stack UNITs 5 and 6 in the X direction to achieve the array of racks in the room. Then put the 6 in. spacing below the bottom of the racks, the spacing between the top of the top rack and the ceiling, and add the concrete floor, walls, and ceiling around the array. ARRAY 4 describes the array of racks in the room. ARRAY record (first CUBOID description in KENO-VI) encompasses this ARRAY, and the first REFLECTOR (second CUBOID in KENO-VI) descriptions are used to add the spacing between the top rack and the ceiling. The last two REFLECTOR (CUBOIDs 3 through 9 in KENO-VI) descriptions add the ceiling, walls, and floor in 5.0 cm increments to bias the concrete. A perspective of the room is shown in Fig. 8.1.33.

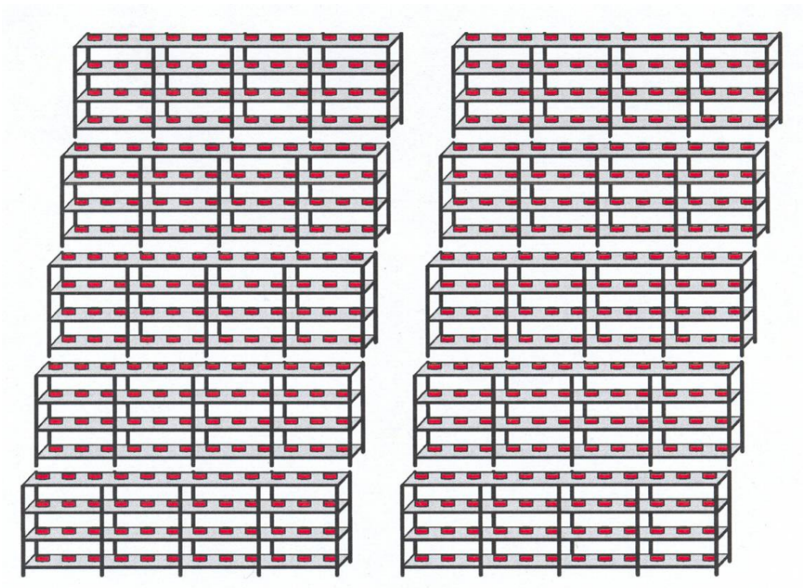

Fig. 8.1.33: Entire storage array in the room.

The complete input for this room is given below: The plots for this problem must be quite large in order to see all the detail because the array is sparse and the shelves are thin. Therefore, the plots for this system are not included as Fig.s. The user can generate the plots if it is desirable to see them. The nuclide IDs used in this problem are for the 16-group Hansen-Roach working format library, which is no longer distributed with SCALE.

Arrays and holes

Sect. 8.1.4.6.1 and Sect. 8.1.4.6.2 describe the use of HOLEs, and Sect. 8.1.4.6.3 describes multiple ARRAYs and ARRAYs of ARRAYs. HOLEs can be used to place ARRAYs at locations in other UNITs. This section contains examples to illustrate the combined use of ARRAYs and HOLEs.

EXAMPLE 19. A SIMPLE CASK

This example consists of cylindrical mild steel container with an inside radius of 4.15 cm and a radial wall thickness of 0.45 cm. The thickness of the ends of the container is 1.27 cm, and the inside height is 10.1 cm. Highly enriched uranium rods 1 cm in diameter and 10 cm long are banded together into square bundles of four. These bundles are then positioned in the mild steel container as shown in Fig. 8.1.34. The rods sit on the floor of the container and have a 0.1 cm gap between their tops and the top of the container.

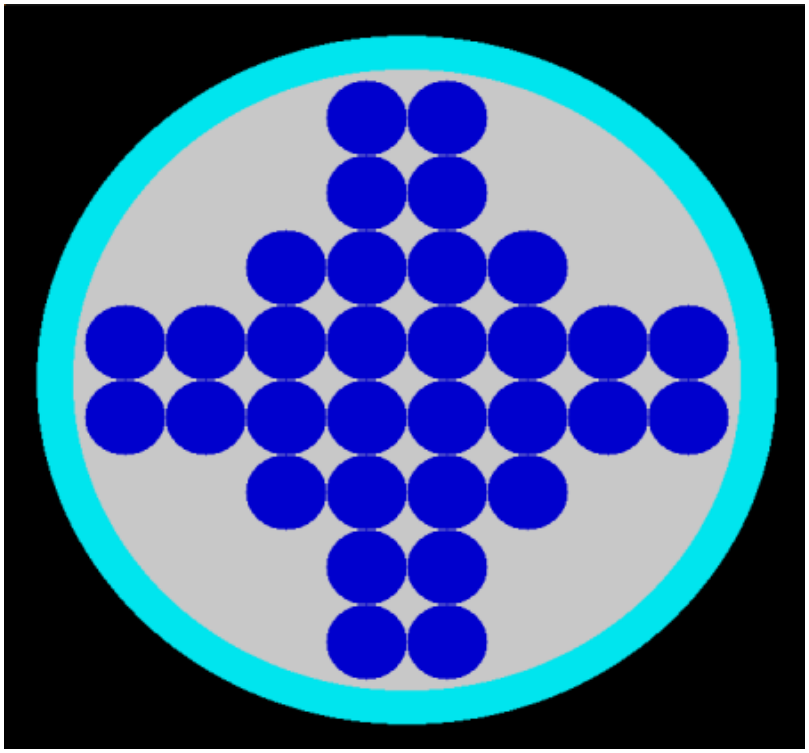

Fig. 8.1.34: Uranium rods in a cylindrical container.

To generate the geometry description for this system, UNIT 1 is defined as one uranium rod and its associated square-pitch close-packed spacing region.

KENO V.a:

```
UNIT 1
CYLINDER  1 1  0.5  2P5.0
CUBOID    0 1  4P0.5  2P5.0
```

KENO-VI:

```
UNIT 1
CYLINDER 1 0.5  2P5.0
CUBOID   2   4P0.5  2P5.0
MEDIA 1 1 1
MEDIA 0 1 2 -1
BOUNDARY  2
```

From here, the geometry description diverges between KENO V.a and KENO-VI.

KENO V.a:

ARRAY 1 is defined to be the central square ARRAY consisting of four bundles of rods.

```
ARA=1 NUX=4 NUY=4 NUZ=1 FILL F1 END FILL
```

ARRAY 2 is defined to be a bundle of four rods.

```
ARA=2 NUX=2 NUY=2 NUZ=1 FILL F1 END FILL
```

ARRAY 2 is placed in UNIT 2. This defines the outer boundaries of an imaginary CUBOID that contains the ARRAY. It is convenient to have the origin of the ARRAY at its center, so the most negative point of the array will be (-1, -1,-5).

```
UNIT 2
ARRAY 2  -1.0 -1.0 -5.0
```

An ARRAY record is used to place ARRAY 1 in the GLOBAL UNIT. Then the cylindrical container is described around it and HOLEs are used to place the four outer bundles around the central ARRAY.

```
GLOBAL UNIT 3
ARRAY   1  -2.0  -2.0  -5.0
CYLINDER   0 1  4.15  5.1  -5.0
HOLE   2    0.0 -3.0  0.0
HOLE   2    3.0  0.0  0.0
HOLE   2    0.0  3.0  0.0
HOLE   2   -3.0  0.0  0.0
CYLINDER   2  1  4.6  6.37 -6.27
```

The first HOLE places the bottom bundle of four rods, the second HOLE places the bundle of four rods at the right, the third HOLE places the top bundle of rods and the fourth HOLE places the left bundle of rods.

KENO-VI:

Define UNIT 2 to be a void CUBOID with the same square pitch as the rod square pitch.

> UNIT 2
>
> CUBOID 1 4P0.5 2P5.0
>
> MEDIA 0 1 1
>
> BOUNDARY 1

ARRAY 1 is defined to be the central square 10×10 ARRAY consisting of 32 rods and 68 void positions that can be used to represent the array shown in Fig. 8.1.34.

```
ARA=1 NUX=10 NUY=10 NUZ=1
FILL 14*2 1 1 8*2 1 1 7*2 4*1 4*2 8*1 2 2 8*1 4*2 4*1 7*2 1 1 8*2 1 1 14*2
END FILL
```

ARRAY 1 is placed in UNIT 3. The first CYLINDER card defines the ARRAY BOUNDARY. Everything external to this boundary is not considered part of the problem. The positions in the ARRAY that do not contain rods are filled with cuboids consisting of void. The ARRAY boundary must either coincide with the outer boundary of the ARRAY or be contained within the ARRAY. An exterior void region is placed around the array boundary to coincide with the size of the interior radius of the container. The 10×10 ARRAY with the ARRAY boundary is shown in Fig. 8.1.35.

```

BOUNDARY  2
```

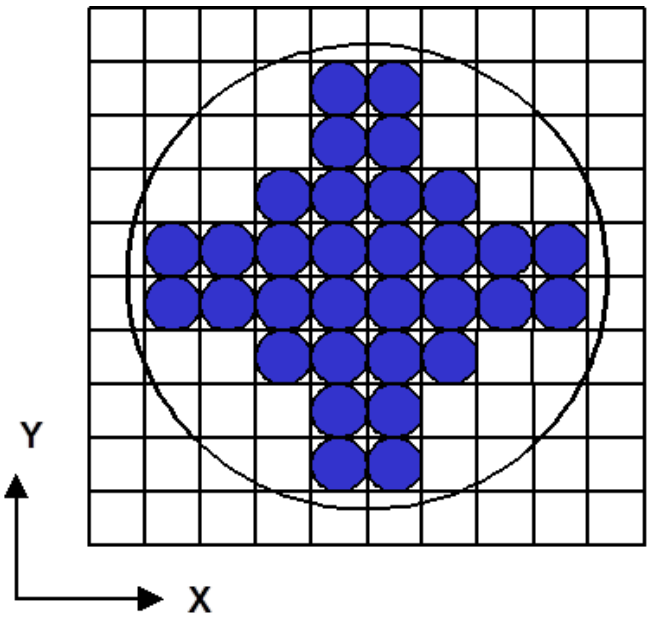

Fig. 8.1.35: The 10 × 10 array of 32 uranium rods and 68 void cuboids with the array boundary.

The UNIT containing the ARRAY is now placed within the global unit using a HOLE content record. The location of the HOLE is determined using ORIGIN data to match the origin of the UNIT in the HOLE with an X, Y, Z position in the surrounding UNIT. In this problem, the origin of the UNIT must be at position (0,0,0). Since only nonzero data must be entered, ORIGIN data are not needed for this problem. The boundary region consists of the steel container.

```

The overall problem description is shown below. Two of the color plots used for verification of this mockup are shown in Fig. 8.1.36 and Fig. 8.1.37. The black outside border of the two color plots indicates volume outside the global unit. The plot can be extended just outside the global unit boundary to ensure that the entire problem is included in the plot. This results in a black area surrounding the actual problem.

EXAMPLE 20. A TYPICAL PRESSURIZED WATER REACTOR (PWR) SHIPPING CASK

A typical PWR shipping cask is illustrated in Fig. 8.1.38. The interior and exterior shell of the cask is carbon steel (mixture 7), and a depleted uranium gamma shield (mixture 6) is present in the annulus between the steel layers. The shipping cask contains seven PWR fuel assemblies. Each assembly is a 17×17 `ARRAY` of

fuel rods with water holes. Each assembly is contained in a stainless steel (mixture 5) box. Each fuel rod is composed of 4% enriched UO_2 (mixture 1) clad with Zircaloy (mixture 2). Rods of B_4C clad (mixture 4) with stainless steel are positioned between the fuel assemblies. The entire cask is filled with water (mixture 3).

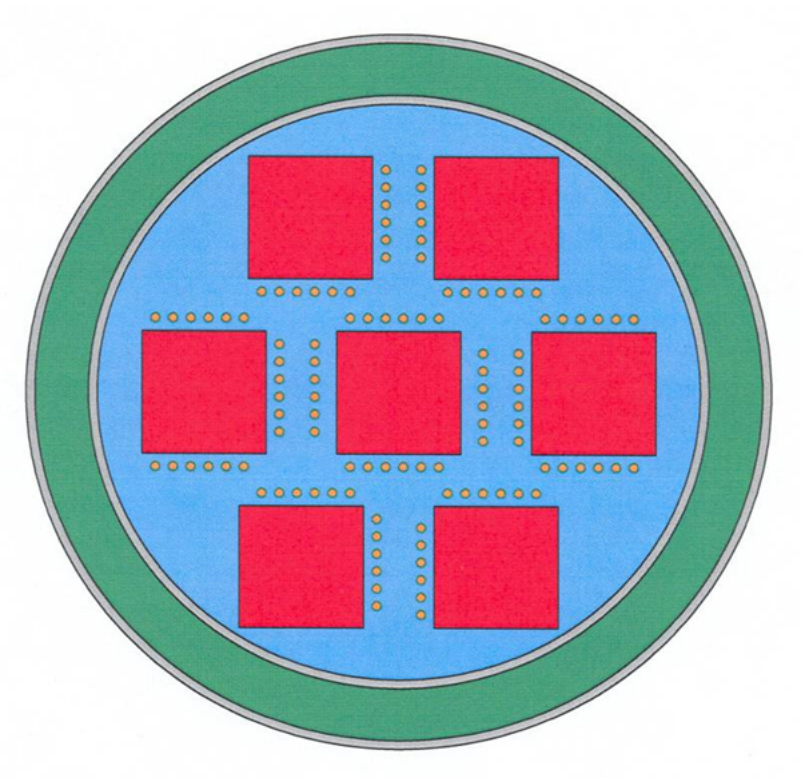

Fig. 8.1.38: Typical PWR shipping cask.

To describe the geometry of the cask, some simple units are defined as shown in Fig. 8.1.39. `UNIT` 1 represents a fuel rod and its associated square pitch spacing region. `UNIT` 2 represents a water hole in a fuel assembly. `UNIT`s 3, 4, and 6 represent the B_4C rods with their various spacings, and `UNIT` 5 is a water hole that is used in association with some of the B_4C rods.

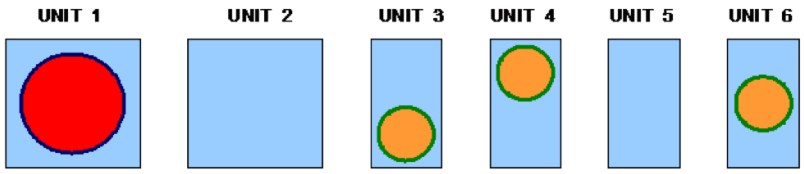

Fig. 8.1.39: Simple units.

UNITs 1 and 2 are stacked together into ARRAY 1 to form the ARRAY of fuel pins and water holes in a fuel assembly as shown in Fig. 8.1.40. This ARRAY is then encompassed with a layer of water and a layer of stainless steel to complete a fuel assembly in a storage cell (UNIT 7) as shown in Fig. 8.1.41.

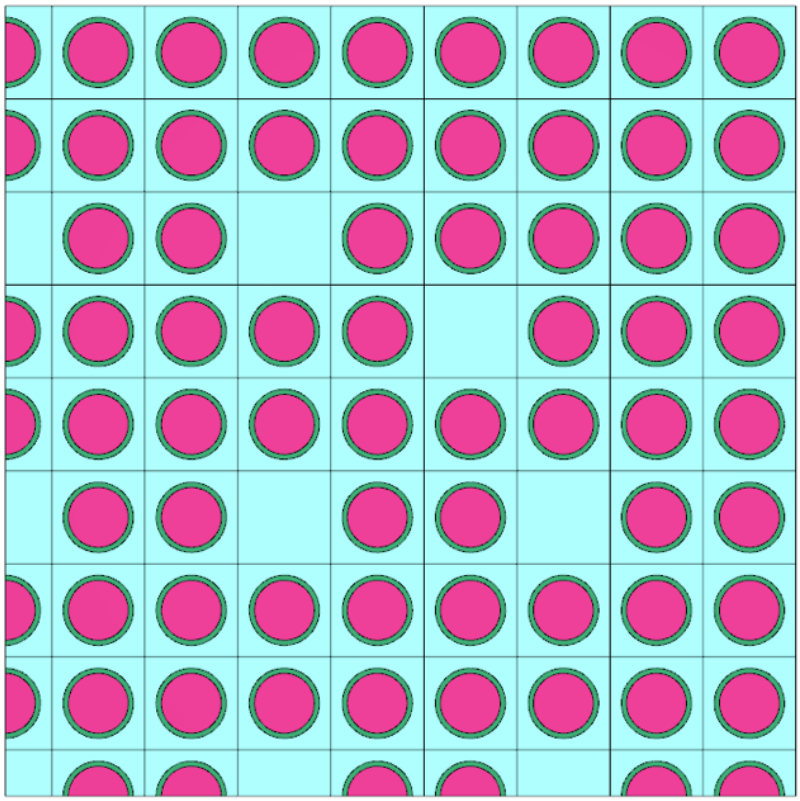

Fig. 8.1.40: Quarter section of fuel pin array.

An array of `UNIT` 6s is created to represent the array of B_4C rods that is positioned between the fuel assemblies. In KENO V.a, the array of B_4C rods shown in Fig. 8.1.42 is contained in `UNIT` 8 for further use. KENO-VI geometry description does not need the placement of `ARRAY` 2 in a separate `UNIT`.

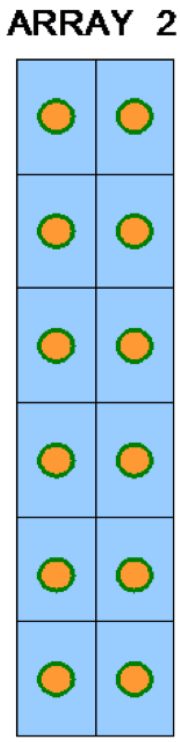

Fig. 8.1.42: 2 × 6 array of B_4C rods.

KENO V.a:

```
ARA=2 NUX=2 NUY=6 NUZ=1    FILL F6        END FILL

UNIT 8
ARRAY 2 0 0 0
```

KENO-VI:

```
ARA=2 NUX=2 NUY=6 NUZ=1    FILL F6        END FILL
```

The next step is to create the central array of three fuel assemblies with B_4C rods between them. In KENO V.a, this is done by stacking fuel assemblies in storage cells (`UNIT` 7) and B_4C rod arrays (`UNIT` 8) into an array (`ARRAY` 3) and placing it in a `UNIT` (`UNIT` 9). In KENO-VI description, `UNIT` 7 (fuel assembly in storage cell) and the array of B_4C rods (`ARRAY` 2) are directly placed into a `UNIT` (`UNIT` 8). The resultant geometry is shown in Fig. 8.1.43.

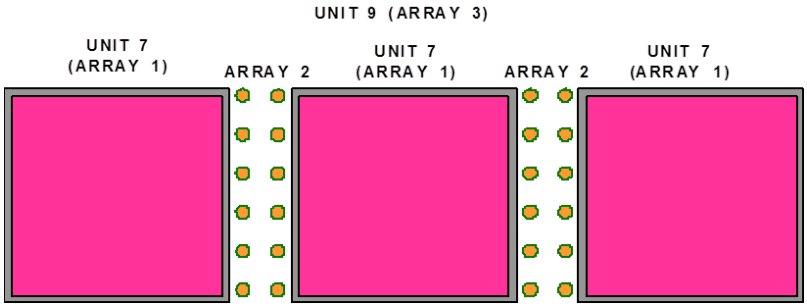

Fig. 8.1.43: Central array.

KENO V.a:

```
ARA=3 NUX=5 NUY=1 NUZ=1    FILL 7 8 7 8 7 END FILL

UNIT 9    ARRAY 3 0 0 0
```

ARRAY 2 5 PLACE 1 1 1  12.4897595  -9.418530 0.0
MEDIA 3 1 6 -5 -4
BOUNDARY  6
```

UNITs 3, 4, and 5 are used to define the arrays of B_4C rods that fit above and below the central array, as shown in Fig. 8.1.44.

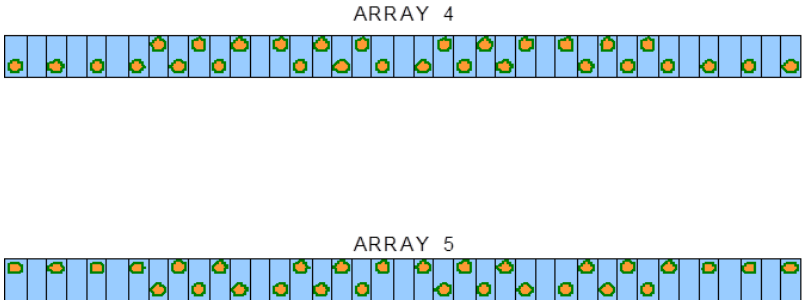

Fig. 8.1.44: Long B_4C rod arrays.

```
ARA=4 NUX=39 NUY=1 NUZ=1   FILL 3 5 2Q2 3 4 2Q2 5 4 3 2Q2 5 3 4 2Q2 5 4 3 2Q2 5 2Q2 3

ARRAY 4 3 PLACE 20 1 1 0.0 13.054836  0.0
```

This completes the three central fuel assemblies and all the B_4C rods associated with them. Next, UNITs 7 and 8 in KENO V.a geometry, UNIT 7 and ARRAY 2 in the KENO-VI geometry, are stacked together to form the array of two fuel assemblies separated by B_4C rods as shown in Fig. 8.1.46. This is designated as ARRAY 7 and UNIT 12 in KENO V.a, and UNIT 9 in KENO-VI. The origin of UNIT 12 for KENO V.a is specified at the center of the array in the X and Y directions and the bottom of the fuel assemblies (Z=27.94 cm). The origin of UNIT 9 in the KENO-VI description is specified at the center of the B_4C array in the X and Y directions and the bottom of the array in the Z direction.

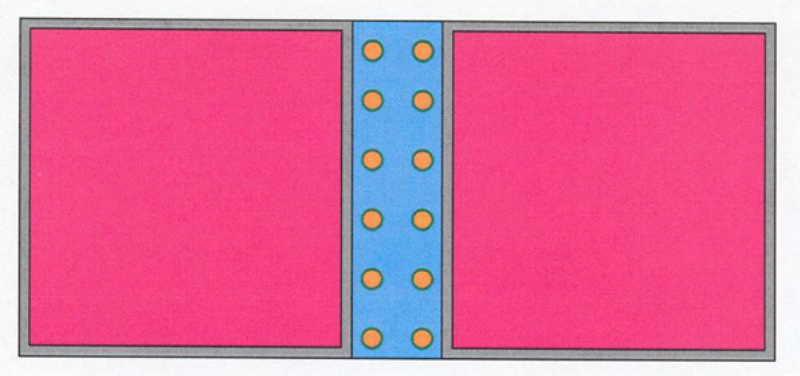

Fig. 8.1.46: Two fuel assemblies and B_4C rods.

In KENO V.a, UNIT 13 is simply a cylindrical lid that fits on top of the shipping cask. It is described relative to the origin of the shipping cask and is made of depleted uranium.

KENO V.a:

```
UNIT 13
CYLINDER  6 1 47.625 457.2 449.58
```

All necessary subassemblies that make up the shipping cask have been built. The shipping cask is completed by specifying the origin of the central section (ARRAY 6 in KENO V.a) (see Fig. 8.1.45) to be at the center of the array in X and Y and the bottom of the array in the Z direction. A cylinder of water defining the interior of the shipping cask is described around the array. In the KENO V.a geometry, a HOLE is used to place UNIT 12 (Fig. 8.1.46) below the array, and a second HOLE is used to place another UNIT 12 above the array. In the KENO-VI geometry, UNIT 9 is placed as a HOLE above and below the central array. Then a cylinder of steel is placed around the water, which is in turn encased by depleted uranium. The depleted uranium is then contained in the outer steel cylinder of the shipping cask. In KENO V.a description, a third HOLE is used to place the depleted uranium lid (UNIT 13) on the shipping cask. This completes the shipping cask description of Fig. 8.1.38

The geometry data for this shipping cask are shown below. The plot data have been included for verification of the geometry description. However, the plot generated by this data is quite large and is therefore not included in this document.

Triangular pitched arrays in KENO-VI

EXAMPLE 21.

Triangular pitched ARRAYs can be described in KENO-VI by defining the UNITs that make up the ARRAY as HEXPRISM and in the array data block setting TYP=TRIANGULAR, HEXAGONAL, SHEXAGONAL, or RHEXAGONAL. This includes close-packed triangular pitched arrays. Since the ARRAYs are constructed by stacking hexprisms, care must be taken to ensure that the ARRAY boundary is completely enclosed within the stacked UNIT. Below is an example of a triangular pitched ARRAY.

The first and second UNITs are the HEXPRISMs that make up the ARRAY. UNIT 1 is the fuel cell stacked in a triangular pitched or hexagonal lattice. UNIT 2 is a dummy UNIT used to fill in the ARRAY so the array boundary is contained within the stacked UNITs. Since the ARRAY is not moderated, UNIT 2 contains void. Fig. 8.1.47 shows an X-Y cross section schematic of UNITs 1 and 2.

```

UNIT 3 is the GLOBAL UNIT that contains the ARRAY and ARRAY BOUNDARY. The ARRAY is an unmoderated triangular pitched assembly of 7 cells. Unrotated triangular or hexagonal pitched arrays can be set up in two array configurations. The first configuration, selected using the TYP= followed by keyword HEXAGONAL or TRIANGULAR, stacks the UNITs so that the faces perpendicular to the X axis meet. Each consecutive row in the Y direction begins 1/2 of the face-to-face dimension farther over in the positive X direction than in the previous row. The second configuration, selected using the TYP= followed by keyword SHEXAGONAL, also stacks the UNITs so that the faces perpendicular to the X axis meet. However, for this type of ARRAY, the odd numbered rows in the Y direction (1, 3, 5, etc.) begin at the left edge of the ARRAY, and the even numbered rows in the Y direction (2, 4, 6, etc.) begin 1/2 of the face-to-face dimension to the right of the left edge of the ARRAY. Fig. 8.1.48 and Fig. 8.1.49 show X-Y cross section schematics of the assembly for the two different unrotated hexagonal ARRAY types.

EXAMPLE 21a.

Another hexagonal ARRAY type involves stacking rotated hexprisms, which are hexprisms rotated 30°/ 90° so that the flat faces perpendicular to the Y axis now meet. Rotated hexagonal arrays are specified by setting TYP=RHEXAGONAL in the array data block. Because the ARRAYs are constructed by stacking hexprisms, care must be taken to ensure the array boundary is completely enclosed within the stacked UNIT. Below is an example of a rotated hexagonal pitched ARRAY.

The first and second UNITs are the rotated hexprisms that make up the ARRAY. They are specified using the geometry keyword RHEXPRISM. UNIT 1 is the fuel cell that is stacked in a rotated hexagonal lattice. UNIT 2 is a dummy UNIT used to fill in the ARRAY so that the ARRAY BOUNDARY is contained within the stacked UNITs. Since the ARRAY is not moderated, UNIT 2 contains void. Fig. 8.1.51 shows an X-Y cross section schematic of UNITs 1 and 2.

UNIT 3 is the GLOBAL UNIT that contains the ARRAY and ARRAY BOUNDARY. The ARRAY is an unmoderated rotated hexagonal pitched assembly of 7 cells. The rotated hexagonal array type is specified in the array data block using TYP= with the keyword RHEXAGONAL. This ARRAY type stacks the UNITs so the faces perpendicular to the Y axis meet. In the odd numbered columns (i.e., 1, 3, 5, etc.), the UNITs are stacked so

the columns begin at the lower edge of the array and in the even numbered columns (i.e., 2, 4, 6, etc.), the UNITs are stacked so the columns begin 1/2 of the face-to-face dimension above the lower edge of the ARRAY. Fig. 8.1.52 shows the X-Y cross section schematic of the assembly for the rotated hexagonal ARRAY type.

Triangular pitched Arrays in KENO V.a

Triangular pitched arrays can be described in KENO V.a geometry by properly defining the basic unit from which the array can be built. This includes close-packed triangular pitched arrays. Two geometry configurations are described below.

EXAMPLE 1. Bare Triangular pitched Array.

Fig. 8.1.54 illustrates a small close-packed triangular pitched **ARRAY**. Each rod in the **ARRAY** has a radius of 2.0 cm, and the pitch of the **ARRAY** is 4 cm. To create this **ARRAY**, describe five units as defined in Fig. 8.1.55.

Assume the rods described in the **ARRAY** are each 2.0 cm in radius and 100 cm tall. The rods are composed of mixture 1. The geometry descriptions for the first four **UNIT**s are given below.

```
UNIT 1
ZHEMICYL-Y 1 1 2.0 50.0 -50.0

UNIT 2
ZHEMICYL+Y 1 1 2.0 50.0 -50.0

UNIT 3
ZHEMICYL-X 1 1 2.0 50.0 -50.0

UNIT 4
ZHEMICYL+X 1 1 2.0 50.0 -50.0
```

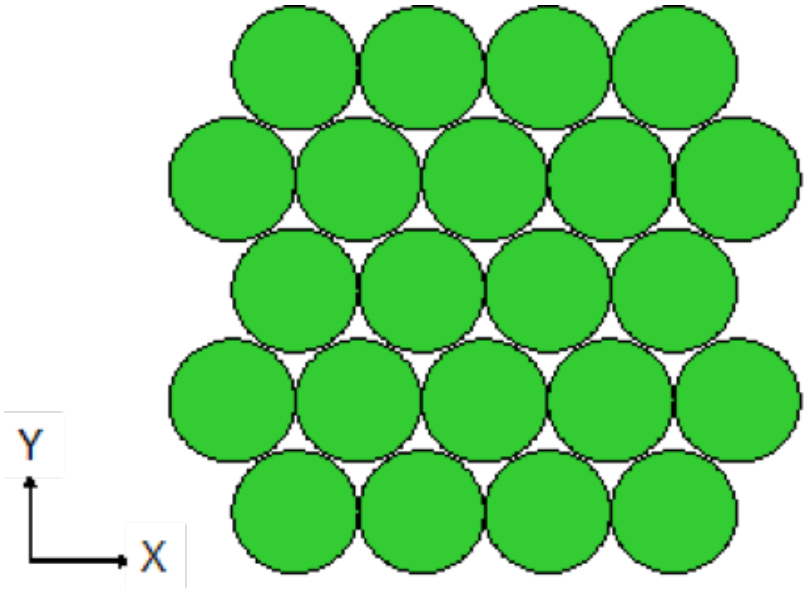

Fig. 8.1.54: Bare triangular pitched ARRAY.

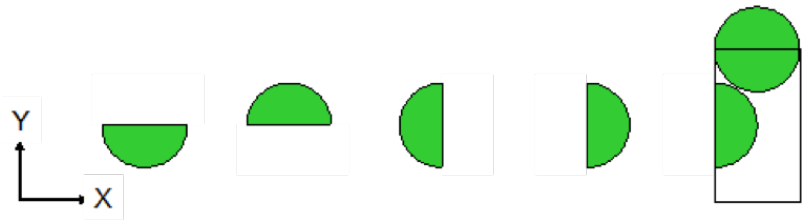

Fig. 8.1.55: Units used to describe a bare triangular pitched ARRAY.

To describe UNIT 5, the origin of the UNIT is defined to be at its center. One of the hemicylinders is built into the box, and the other three are added as holes. In this example, the +X hemicylinder is built into the box, and the other hemicylinders are inserted as holes. (Because the +X hemicylinder is built into UNIT 5, UNIT 4 is not used in the problem.) The half dimension of the box in the X dimension is equal to the radius, 2.0 cm. The half dimension of the box in the Y direction is $\frac{\sqrt{3}}{2}$ times the pitch (0.866025 * 4.0) or 3.46411 cm. UNIT 5 is described below.

```
UNIT 5
ZHEMICYL+X  1 1 2.0 50.0 -50.0 ORIGIN -2.0 0.0
CUBOID   0 1 2P2.0 2P3.46411 2P50.0
HOLE 1 0.0   3.46411    0.0
HOLE 2 0.0 -3.46411    0.0
HOLE 3 2.0             0.0
```

In the description of UNIT 5, the ZHEMICYL+X places the hemicylinder at the left of the box. HOLE 1 places the top hemicylinder, HOLE 2 places the bottom hemicylinder, and HOLE 3 places the hemicylinder at the right of the box.

Next, a UNIT 6 is defined that can be used to complete the lower rod of UNIT 5. A UNIT 7 is defined that can be used to complete the upper rod of UNIT 5. UNIT 8 is defined to complete the left rod of UNIT 5, and UNIT 9 is defined to complete the right rod of UNIT 5. UNIT 10 is defined to complete the corners of the overall ARRAY. The input data for these UNITs are given below and are illustrated in Fig. 8.1.56.

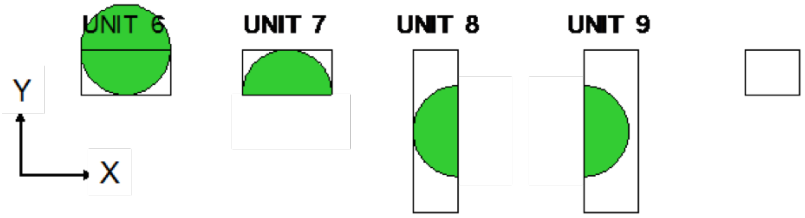

Fig. 8.1.56: UNITs to complete the triangular pitched ARRAY.

```
UNIT 6
ZHEMICYL-Y       1 1 2.0 50.0 -50.0
CUBOID           0 1 2P2.0 0.0 -2.0 50.0 -50.0

UNIT 7

UNIT 8
ZHEMICYL-X       1 1 2.0 50.0 -50.0
CUBOID           0 1 0.0 -2.0 2P3.46411 2P50.0
```

(continues on next page)

(continued from previous page)

```
UNIT 9
ZHEMICYL+X   1 1 2.0 50.0 -50.0
CUBOID           0 1 2.0 0.0 2P3.46411 2P50.0

UNIT 10
CUBOID           0 1 2.0 0.0 2.0 0.0 2P50.0
```

Fig. 8.1.57 shows the arrangement of the UNITs to complete the ARRAY. The data to describe the ARRAY are shown below.

```
ARA=1 NUX=6 NUY=4 NUZ=1
FILL 10 4R6 10 8 4R5 9 1Q6 10 4R7 10 END FILL
```

The bottom row of the ARRAY is described by the data entries 10 4R6 10. The second row of the ARRAY is described by the data entries 8 4R5 9. The third row is filled by repeating the previous six entries (1Q6). It could also have been described by entering 8 4R5 9. The top row of the ARRAY is described by the data entries 10 4R7 10.

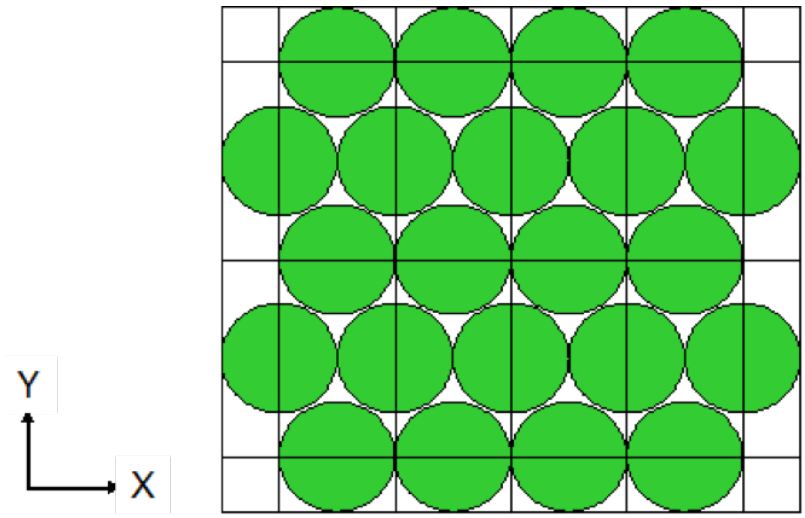

Fig. 8.1.57: Completed ARRAY.

EXAMPLE 2a. Triangular Pitched ARRAY in a Cylinder

Fig. 8.1.58 illustrates a close-packed triangular pitched **ARRAY** in a cylinder. This array may be described by defining five basic units that are the same as those of Example 1 shown in Fig. 8.1.55.

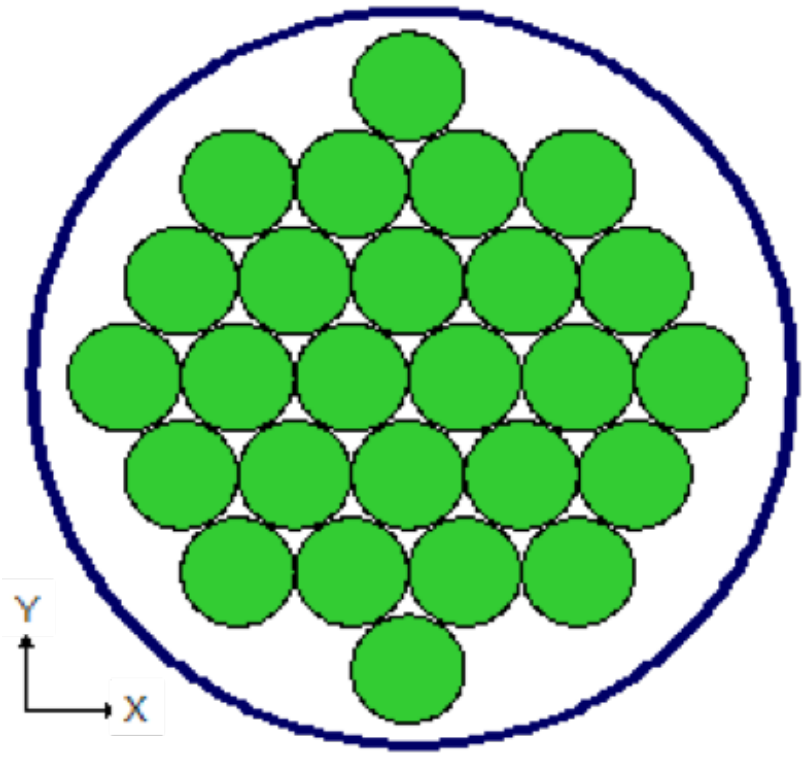

Fig. 8.1.58: Triangular pitched ARRAY within a cylinder.

```
UNIT 1
ZHEMICYL-Y 1 1 2.0 50.0 -50.0

UNIT 2
ZHEMICYL+Y 1 1 2.0 50.0 -50.0

UNIT 3
ZHEMICYL-X 1 1 2.0 50.0 -50.0

UNIT 4
ZHEMICYL+X 1 1 2.0 50.0 -50.0
```

To describe UNIT 5, the origin of the UNIT to be at its center is defined. One of the hemicylinders is built into the box, and the other three are added as HOLEs. In this example, the +X hemicylinder is built into the box, and the other hemicylinders are inserted as HOLEs. The half dimension of the box in the X dimension is equal to the radius, 2.0 cm. The half dimension of the box in the Y direction is $\frac{\sqrt{3}}{2}$ times the pitch (0.866025 * 4.0) or 3.46411 cm. UNIT 5 is described below.

```
UNIT 5
ZHEMICYL+X 1 1 2.0 50.0 -50.0 ORIGIN -2.0 0.0
CUBOID     0 1 2P2.0 2P3.46411 2P50.0
HOLE 1  0.0  3.46411 0.0
HOLE 2  0.0 -3.46411 0.0
HOLE 3  2.0  0.0     0.0
```

In the description of UNIT 5, the ZHEMICYL+X places the hemicylinder at the left of the box. HOLE 1 places the top hemicylinder, HOLE 2 places the bottom hemicylinder, and HOLE 3 places the hemicylinder at the right of the box.

To describe the base ARRAY of the problem, UNITs 5 is stacked in a $4 \times 2 \times 1$ array as shown in Fig. 8.1.59. The input data for the ARRAY are the following:

```
ARA=1 NUX=4 NUY=2 NUZ=1  FILL F5 END FILL
```

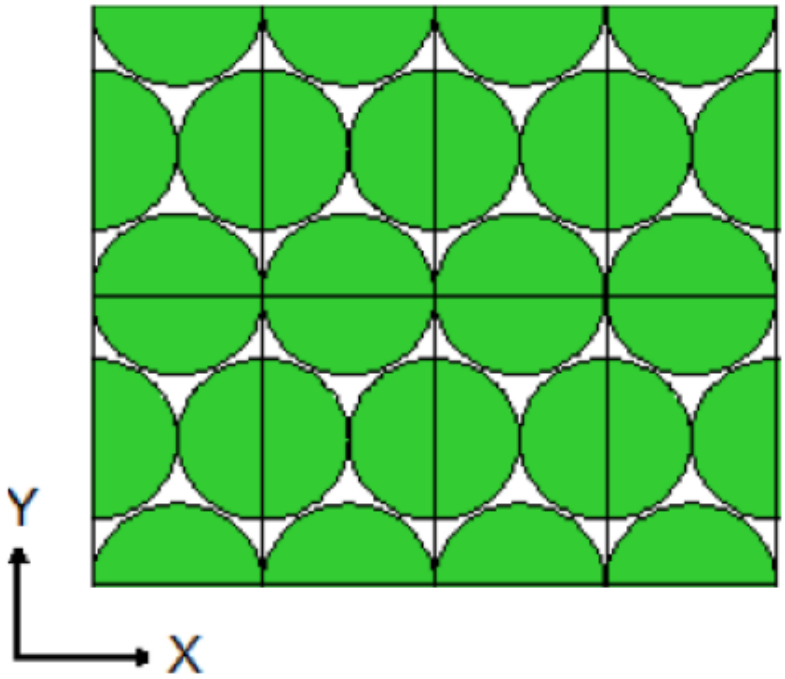

Fig. 8.1.59: $4 \times 2 \times 1$ array to be placed within a cylinder.

Next, the ARRAY is placed within the cylinder. This is done by placing the ARRAY in a UNIT, defined here to be UNIT 6. The origin of the cylinder has been defined to be at the center of the ARRAY. The resulting geometry is shown in Fig. 8.1.60.

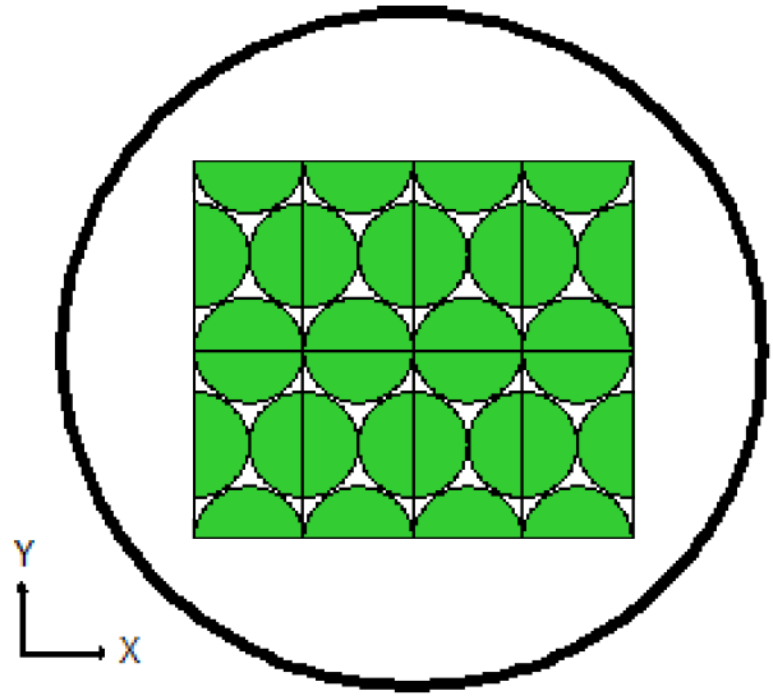

Fig. 8.1.60: $4 \times 2 \times 1$ ARRAY within a cylinder.

```
UNIT 6
ARRAY 1 -8.0 -6.92822 -50.0
CYLINDER 0 1 12.4  2P50.0
CYLINDER 2 1 12.65 2P50.0
```

Next, the hemicylinders necessary to complete all of the half cylinders remaining in Fig. 8.1.60 are added. This is done by placing four UNITs 1 at the appropriate positions along the bottom of the ARRAY, four UNITs 2 at the top of the ARRAY, two UNITs 3 at the left of the ARRAY, and two UNITs 4 at the right of the ARRAY. The input data are shown below, and the resulting configuration is shown in Fig. 8.1.61. In UNIT 6, the first HOLE 1 places a UNIT 1 under the lower left UNIT of the ARRAY. The second HOLE 1 places a UNIT 1 under the next ARRAY UNIT to the right of the first one. This procedure is repeated for the next two lower ARRAY UNITs, thus completing the lower row of cylinders. Similarly, the first HOLE 2 places a UNIT 2 above the upper left UNIT of the ARRAY. The second HOLE 2 places a UNIT 1 to the right of the first one, etc., until the four cylinders at the top of the ARRAY are completed. The first HOLE 3 places a UNIT 3 at the lower left side of the ARRAY to complete that rod. The second HOLE 3 completes the rod above it. The first HOLE 4 completes the lower rod on the right side of the ARRAY. The second HOLE 4 completes the rod above it. The geometry data listed below result in the configuration shown in Fig. 8.1.61.

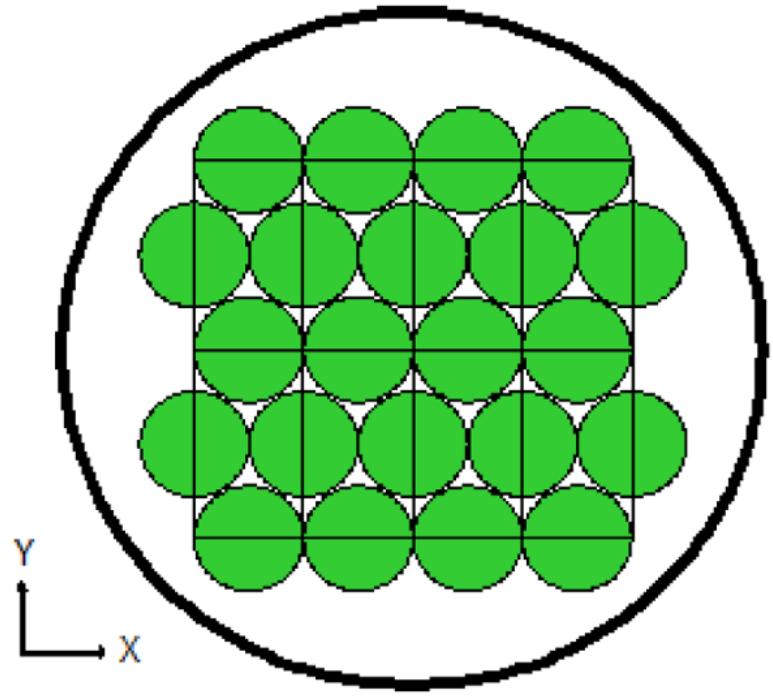

Fig. 8.1.61: Partially completed triangular pitched ARRAY in a cylinder.

```
UNIT 6
ARRAY 1 -8.0 -6.92822 -50.0
CYLINDER 0 1 12.4  2P50.0
HOLE 1  -6.0 -6.92822 0.0
HOLE 1  -2.0 -6.92822 0.0
HOLE 1   2.0 -6.92822 0.0
HOLE 1   6.0 -6.92822 0.0
HOLE 2  -6.0  6.92822 0.0
HOLE 2  -2.0  6.92822 0.0
HOLE 2   2.0  6.92822 0.0
HOLE 2   6.0  6.92822 0.0
HOLE 3  -8.0 -3.46411 0.0
HOLE 3  -8.0  3.46411 0.0
HOLE 4   8.0 -3.46411 0.0
HOLE 4   8.0  3.46411 0.0
CYLINDER 2 1 12.65 2P50.0
```

To complete the desired configuration, a cylinder is defined, UNIT 7, and it is placed at the four appropriate positions as shown below. The first HOLE 7 places the cylinder of UNIT 7 at the left of the ARRAY, the second HOLE 7 places the cylinder at the top of the ARRAY, the third HOLE 7 places the cylinder at the right of the ARRAY, and the fourth HOLE 7 places the cylinder at the bottom of the ARRAY. The completed configuration is shown in Fig. 8.1.62. It is not necessary for UNIT 7 to precede UNIT 6. It is allowable to place UNIT 7 after UNIT 6 in the input data. Because the final configuration is defined in UNIT 6, it must be designated as the GLOBAL UNIT. The total geometry input for this example is listed below.

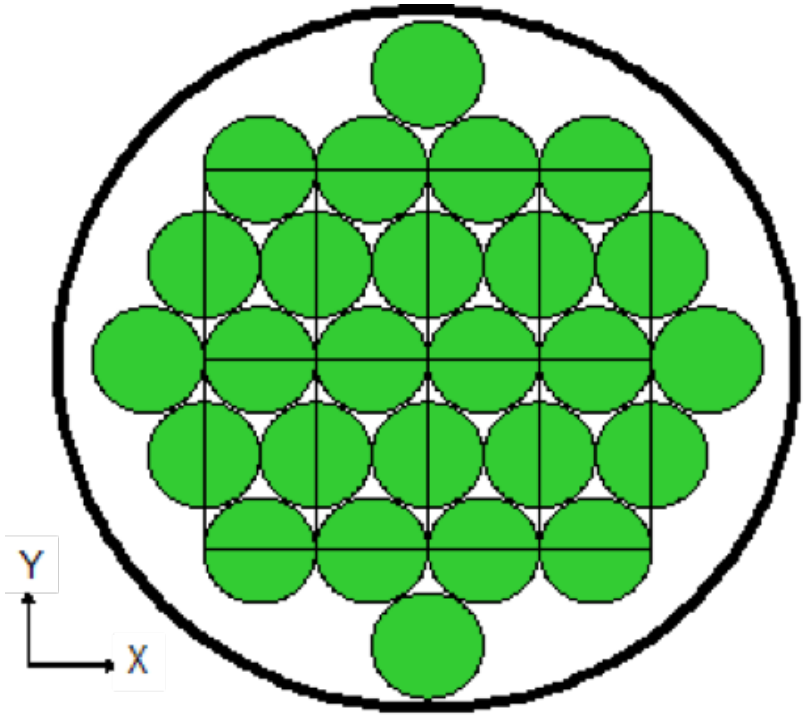

Fig. 8.1.62: Completed triangular pitched array in a cylinder.

EXAMPLE 2b. Alternative Mockup of Triangular Pitched ARRAY in a Cylinder.

Consider the triangular pitched ARRAY shown in Fig. 8.1.58. Another method of describing this configuration is given below. Four basic UNITs are defined, as listed below. These are the same UNITs shown in Fig. 8.1.55.

```
UNIT 1
ZHEMICYL-Y 1 1 2.0 50.0 -50.0

UNIT 2
ZHEMICYL+Y 1 1 2.0 50.0 -50.0

UNIT 3
ZHEMICYL-X 1 1 2.0 50.0 -50.0

UNIT 4
ZHEMICYL+X 1 1 2.0 50.0 -50.0
```

UNIT 5 is the same as previously defined in Example 2a, and pictured in Fig. 8.1.55.

```
UNIT 5
ZHEMICYL+X 1 1 2.0 50.0 -50.0 ORIGIN -2.0 0.0
CUBOID     0 1 2P2.0 2P3.46411 2P50.0
HOLE 1  0.0  3.46411 0.0
HOLE 2  0.0 -3.46411 0.0
HOLE 3  2.0  0.0     0.0
```

To describe the basic array for the problem, UNITs 5 is stacked in a $4 \times 2 \times 1$ as shown in Fig. 8.1.59. The input data for the ARRAY are the following:

```
ARA=1 NUX=4 NUY=2 NUZ=1  FILL F5 END FILL
```

Next, the ARRAY (ARRAY 1) is placed in UNIT 6, and UNITs 7 and 8 are defined to be placed to the left and right of it (see Fig. 8.1.63). UNIT 7 will complete the two rods at the left boundary of the ARRAY and will contain half of the far left rod in the completed configuration. In the description of UNIT 7, the ZHEMICYL+X is half of the far right rod and is located with its cut face at the left boundary of a box that is as tall as the entire ARRAY of Fig. 8.1.59. The first HOLE 3 in UNIT 7 completes the lower left rod of that ARRAY, and the second HOLE 3 completes the upper left rod. UNIT 8 is constructed in similar fashion to complete the two rods at the right of the ARRAY shown in Fig. 8.1.59. UNIT 8 is the mirror image of UNIT 7. UNITs 6, 7, and 8 are stacked in an ARRAY (ARRAY 2) to achieve the configuration shown in Fig. 8.1.63. The data to accomplish this are listed below.

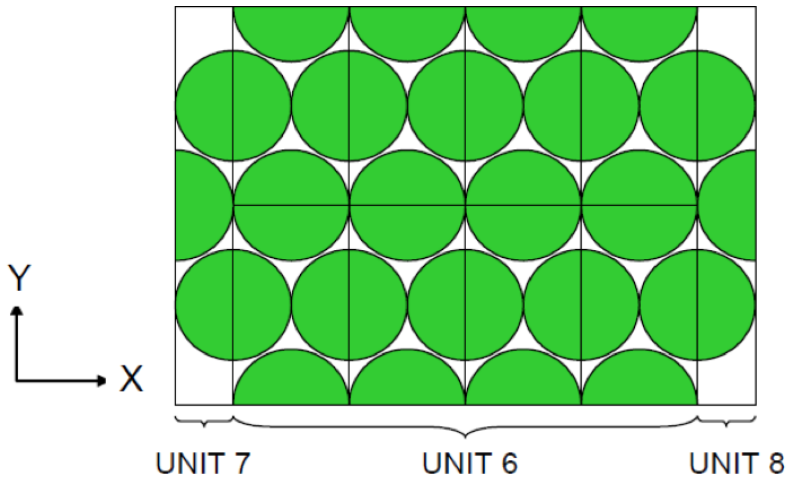

Fig. 8.1.63: Array to be placed in a cylinder.

```
UNIT 6
ARRAY 1 -8.0 -6.92822 -50.0

GLOBAL
UNIT 7
ZHEMICYL+X 1 1 2.0 50.0 -50.0
CUBOID     0 1 2.0 0.0 2P6.92822 2P50.0
HOLE 3 2.0 -3.46411 0.0
HOLE 3 2.0  3.46411 0.0

UNIT 8
ZHEMICYL-X 1 1 2.0 50.0 -50.0
CUBOID     0 1 0.0 -2.0 2P6.92822 2P50.0
HOLE 4 -2.0 -3.46411 0.0
HOLE 4 -2.0  3.46411 0.0

ARA=2 NUX=3 NUY=1 NUZ=1 FILL 7 6 8 END FILL
```

Next, `ARRAY 2` is placed in the cylinder as shown in Fig. 8.1.64. The data are listed below.

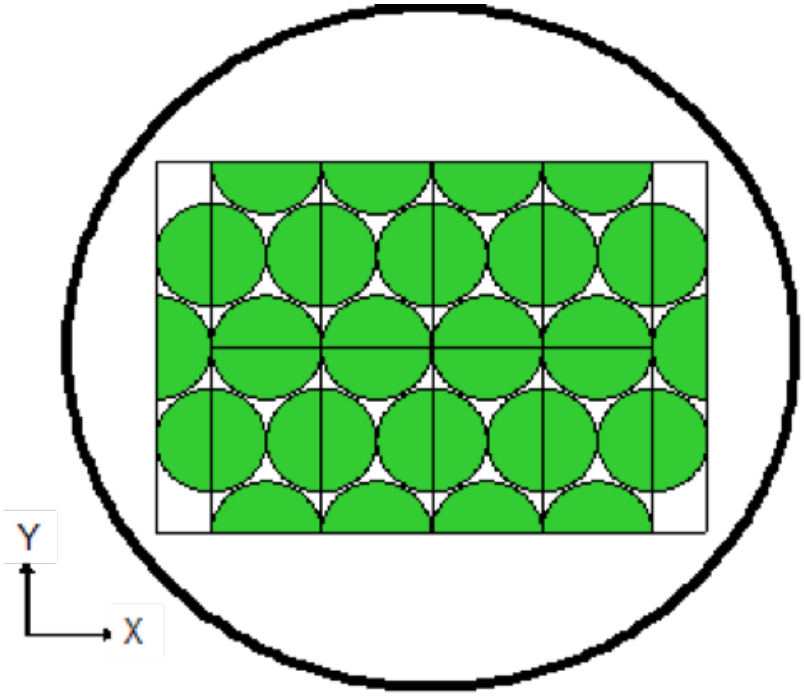

Fig. 8.1.64: Partially completed array in a cylinder.

```
UNIT 9
ARRAY 2 -10.0 -6.92822 -50.0
CYLINDER 0 1 12.4  2P50.0
CYLINDER 2 1 12.65 2P50.0
```

Now UNITs 10 and 11 are described and placed above and below the ARRAY. These UNITs are shown in Fig. 8.1.65. UNIT 10 is described to complete the two central rods at the top of the ARRAY of Fig. 8.1.64. Fig. 8.1.65 and Fig. 8.1.66 illustrate these UNITs. The ZHEMICYL-Y is placed at the top of the UNIT to describe half of the rod at the very top of the ARRAY. The first HOLE 2 completes the left center rod at the top of the ARRAY pictured in Fig. 8.1.64. The second HOLE 2 completes the right center rod at the top of the ARRAY. UNIT 11 is described in similar fashion. It is the mirror image of UNIT 10 and is placed below the ARRAY of Fig. 8.1.64. The resulting configuration is shown in Fig. 8.1.65.

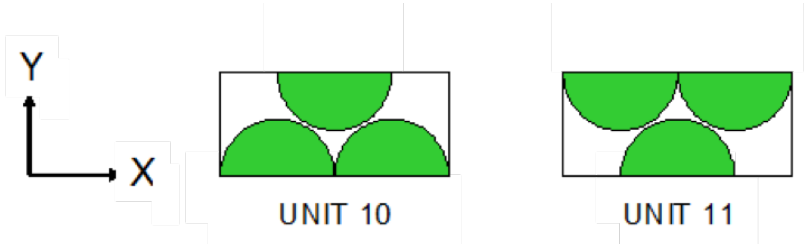

Fig. 8.1.65: Description of UNITs 10 and 11 for Example 2b.

```
UNIT 10
ZHEMICYL-Y 1 1 2.0 2P50.0

```

(continues on next page)

(continued from previous page)

```
HOLE 2 -2.0 -3.46411 0.0 2P50.0
HOLE 2  2.0 -3.46411 0.0

UNIT 11
ZHEMICYL+Y 1 1 2.0 2P50.0
CUBOID  0 1 2P4.0 3.46411 0.0 2P50.0
HOLE 1 -2.0 3.46411 0.0
HOLE 1  2.0 3.46411 0.0
```

Now UNITs 10 and 11 are placed above and below the ARRAY of Fig. 8.1.64 to obtain the configuration shown in Fig. 8.1.66.

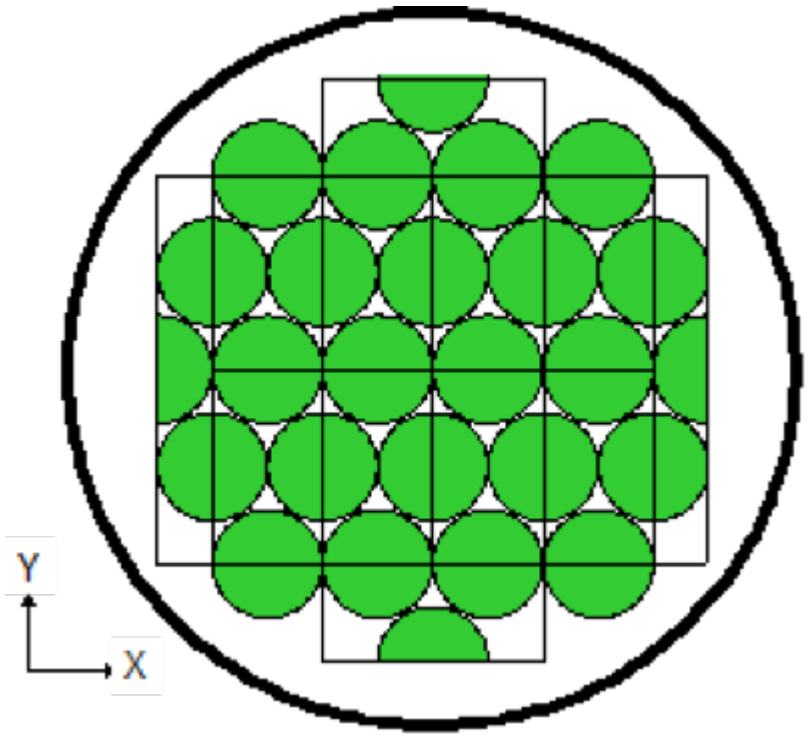

Fig. 8.1.66: Partially completed triangular pitched ARRAY in a cylinder.

```
UNIT 9
ARRAY 2 -10.0 -6.92822 -50.0
CYLINDER 0 1 12.4  2P50.0
HOLE 10 0.0 10.39233 0.0
HOLE 11 0.0 -10.39233 0.0
CYLINDER 2 1 12.65 2P50.0
```

To complete the array, the remaining half cylinders must be entered as HOLEs, as shown below. The first HOLE 1 completes the half rod at the lower left of Fig. 8.1.66. The second HOLE 1 completes the half rod at the lower center, and the third HOLE 1 completes the half rod at the lower right of Fig. 8.1.66. Similarly, the first HOLE 2 completes the half rod at the upper left of Fig. 8.1.66. The second HOLE 2 completes the half rod at the upper center, and the third HOLE 2 completes the half rod at the upper right. HOLE 3 completes the half rod at the left of Fig. 8.1.66, and HOLE 4 completes the half rod at the right. The final geometry configuration is shown in Fig. 8.1.67. UNIT 9 must be specified as the GLOBAL UNIT because it defines the overall configuration.

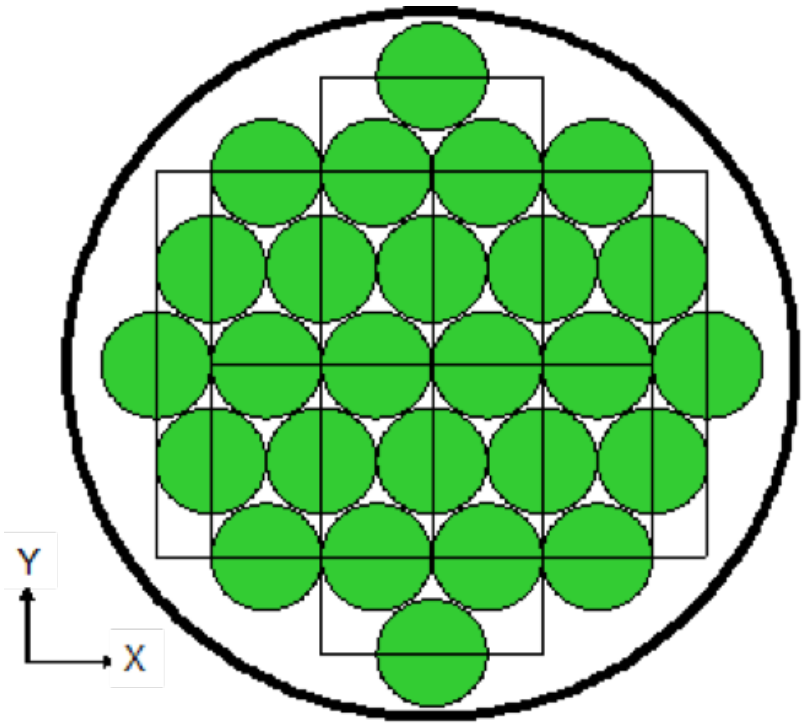

Fig. 8.1.67: Final configuration of triangular pitched ARRAY in a cylinder.

Dodecahedral pitched arrays

EXAMPLE 22.

Dodecahedral pitched **ARRAY**s can be described in KENO-VI by defining the **UNIT**s that make up the **ARRAY** as dodecahedra and in the **ARRAY** data block setting **TYP**=DODECAHEDRAL. Since the **ARRAY**s are constructed by stacking dodecahedra, care must be taken to ensure the **ARRAY** boundary is completely enclosed within the stacked unit. Below is an example of a dodecahedral **ARRAY** that represents a close packed **ARRAY** of spheres.

The first and second **UNIT**s are the dodecahedra that make up the **ARRAY**. **UNIT** 1 is the fuel sphere stacked in a dodecahedral lattice. **UNIT** 2 is a dummy **UNIT** used to fill in the **ARRAY** so the **ARRAY** boundary is contained within the stacked **UNIT**s. Since the **ARRAY** is not moderated, **UNIT** 2 contains void. Fig. 8.1.68 shows an isometric, cross section view of **UNIT**s 1 and 2.

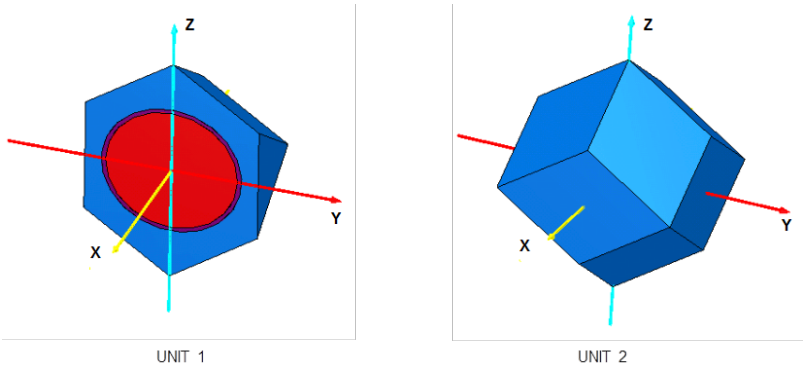

Fig. 8.1.68: Fuel cell and empty cell set up as dodecahedra.

UNIT  2
COM='EMPTY CELL'
DODECAHEDRON 10  10.5
MEDIA  0  1  10
BOUNDARY     10
```

UNIT 3 is the **GLOBAL UNIT** that contains the **ARRAY** and **ARRAY BOUNDARY**. The **ARRAY** is an unmoderated triangular pitched assembly of 17 fuel spheres. Dodecahedral **ARRAY**s are specified by using **TYP**= followed by keyword dodecahedral in the array data block. The X and Y coordinates are stacked together as a square pitched **ARRAY** with the pitch equal to twice the dodecahedron radius. In the Z dimension, the odd Z planes (Z = 1, 3, 5, etc.) have the X and Y **UNIT**s begin at the most negative edge of the **ARRAY**, while the even Z planes (Z = 2, 4, 6, etc.) have the X and Y **UNIT**s begin one dodecahedron inscribed sphere radius in the positive direction from the most negative edge of the **ARRAY**. Also, the Z distance between the centers of the **UNIT**s in successive Z planes is the square root of 2.0 times the dodecahedron radius (or the dodecahedron diameter divided by the square root of 2.0). Fig. 8.1.69 and Fig. 8.1.70 show X-Y cross sectional color plots of the assembly at an odd and even Z plane.

8.1.4.7 Alternative sample problem mockups

The geometry data for KENO can often be described correctly in several ways. Some alternative geometry descriptions are given here for sample problems C.12 and C.13. (See Sect. 8.1.8.3 of the KENO manual.)

Sample Problem C.12, First Alternative

This mockup maintains the same overall unit dimensions that were used in sample problem C.12. In sample problem C.12, the origin of **UNIT** 1, the solution cylinder, is at the center of the unit; the origin of **UNIT**s 2, 3, 4, and 5, the metal cylinders, are at the center of the cylinders. In this mockup, the unit numbers remain the same and the origin of each unit is at the center of the unit. In each unit the cylinder is offset by specifying the position of its centerline relative to the origin of the **UNIT**.

KENO V.a:

Sample Problem C.12, Second Alternative

In this mockup, the outer boundaries of the system are made as close fitting as possible on all six faces. The origin of each **UNIT** is located at the center of the cylinder. **UNIT**s 1, 3, 5, and 7 contain the metal cylinders. **UNIT**s 2, 4, 6, and 8 contain the solution cylinders.

Sample Problem C.13, Alternative

This mockup maintains the same overall **UNIT** dimensions that were used in sample problem C.13, (KENO Manual, Sect. 8.1.8.3). In sample problem C.13, the origin of **UNIT**s 1, 2, and 3 is located at the center of the base of the uranium metal cuboid. In this mockup, the origin of **UNIT**s 1 and 2 is located at the center of the cylinder. In **UNIT** 3, the origin is at the center of the **UNIT**.

8.1.4.8 Initial starting distributions with Start data

Sect. 8.1.3.8 discusses the input directions for entering different starting distributions in the start data input block. The following start type 0 and start type 6 examples demonstrate how KENO codes process the entered start data parameters.

Example-1:

An 8 cm radius fissile sphere without a start data block is modeled with both KENO-VI and KENO V.a geometries. Start type 0, which is the default starting option, is used, and neutrons are started uniformly in the entire volume defined by the outermost geometry (fissile sphere).

KENO-VI:

```
...
 read geometry
    global unit 1
       sphere 1  8
       media 1 1 1
       boundary 1
 end geometry
end data
end
```

KENO V.a:

```
' input without global unit
...
 read geometry
    unit 1
       sphere 1 1 8
 end geometry
end data
end

' input with global unit
...
 read geometry
    global unit 1
       sphere 1 1 8
 end geometry
end data
end
```

Example-2:

This input models a simple $2 \times 2 \times 2$ array of fissile cylinders with the default starting option, which is start type 0. In this array problem, **XSM**, **YSM**, and **ZSM** are defaulted to the minimum X, Y, and Z coordinates of the global array, and **XSP**, **YSP**, and **ZSP** are defaulted to the maximum coordinates of the global array. A

bounding box is constructed with these values, and neutrons are started at the points uniformly sampled inside the fissile cylinders within this cuboid (For KENO V.a model, the cuboid is defined by +x=27.48, -x=0.0, +y=27.48, -y=0.0, +z= 26.02, -z= 0.0, and for KENO-VI model, it is defined by +x=13.74, -x=-13.74, +y=13.74, -y=-13.74, +z= 13.01, -z=-13.01).

```
KENO-VI:

...
 read geometry
    unit 1
       cylinder 1 5.748 2p5.3825
       cuboid   2 4p6.87 2p6.505
       media 1 1 1
       media 0 1 2 -1
       boundary 2
    global unit 2
       cuboid  10 4p13.74 2p13.01
       array 1 +10 place 1 1 1 2r-6.87 -6.505
       boundary 10
 end geometry
 read array
   gbl=1 ara=1 nux=2 nuy=2 nuz=2 fill f1  end fill
 end array
end data
end

KENO V.a:

' input with a global array
...
 read geometry
     unit 1
        cylinder 1 1 5.748 5.3825 -5.3825
        cuboid  0 1 6.87 -6.87 6.87 -6.87 6.505 -6.505
 end geometry
 read array
    gbl=1 ara=1 nux=2 nuy=2 nuz=2 fill f1  end fill
 end array
end data
end
```

Example-3:

Neutrons are started uniformly throughout the fissile materials in a user-defined box that is inside the outermost geometry (+x=3.0 -x=-3.0 +y= 1.0 -y=-1.0 +z= 2.0 -z=-2.0).

```
KENO-VI:

...
 read geometry
    global unit 1
       sphere 1  8
       media 1 1 1
       boundary 1
 end geometry

 READ START
    NST=0
    XSP=3.0 XSM=-3.0 YSP=1.0 YSM=-1.0 ZSP=2.0 ZSM=-2.0
 END START

end data
end
```

Example-4:

This test case is another example of the start type 0 specification with a user-defined cuboid, but whole cuboid is not inside the outermost geometry. KENO V.a immediately terminates the execution with some error messages since some starting points are sampled outside the outermost geometry.

Unlike KENO V.a, KENO-VI continues the sampling process by discarding these points, which are outside the global geometry, until all starting points have been successfully sampled throughout the fissile regions inside the global unit.

```
KENO-VI:
...
 read geometry
    global unit 1
       sphere 1  8
       media 1 1 1
       boundary 1
 end geometry

 READ START
    NST=0
    XSP=10.0 XSM=-10.0 YSP=10.0 YSM=-10.0 ZSP=10.0 ZSM=-10.0
 END START

end data
end
```

Note: Note that the KENO-VI sampling process for such a case will be terminated if

- the first starting point has not been sampled in *tbtch* minutes. *tbtch* is the time per generation in minutes, defaulted to 10 minutes. User can control this with parameter **TBA=** in parameter input; see Sect. 8.1.3.3 for details, or
- all points have not been successfully sampled inside the global units in total *tbtch* $\times$ *9.5* minutes.

Example-5:

This test input demonstrates how KENO-VI performs source sampling with the default starting type (start type 0) if the boundary definition vector of the global unit has the multiple body labels. For such cases, KENO-VI starts neutrons at the points that are uniformly sampled in the first body entered in the boundary definition vector of the global unit if and only if none of translation and transformation operations are performed on this body. For this KENO-VI specific example, all starting points are sampled throughout the fissile materials inside the *cylinder 3*.

```
KENO-VI:

...
 read geometry
    global unit 1
       sphere 1 8.741
       sphere 2 10.0
       cylinder 3 8.0 2p8.0
       media 1 1 1
       media 2 1 2 3 -1
       BOUNDARY  3 2
 end geometry

end data
end
```

Example-6:

Start type 0 specification with one or more missing optional parameters; their default values (0.0) are used to construct a cuboid, and neutrons are started uniformly throughout the fissile materials in this box (+x=3.0 -x=0.0 +y= 1.0 -y=0.0 +z=0.0 -z=-2.0).

```
KENO-VI:

...
 read geometry
    global unit 1
       sphere 1  8
       media 1 1 1
       boundary 1
 end geometry

 READ START
    NST=0
    XSP=3.0 YSP=1.0 ZSM=-2.0
 END START

end data
end
```

Note: In start data input, user-defined cuboid shape is considered as a deformed cuboid shape if the minimum and maximum bounds in any dimension are equal entries (**XSP = XSM** or/and **YSP = YSM** or/and **ZSP = ZSM**). Deformed shape specification is a legitimate input specification across SCALE sequences (i.e., a box is deformed into a plane if minimum and maximum bounds in one dimension are the same, e.g., +x = -x). In such a case, user-defined entries for **XSM**, **XSP**, **YSM**, **YSP**, **ZSM**, and **ZSP** are ignored, and source sampling is performed throughout the volume defined by the outermost geometry card.

The following two examples with start type 0 demonstrate code behavior for the deformed shapes for start types 0, 1, 2, and 7.

Example-7:

Box defined with missing **ZSM**, and **ZSP** is considered as a deformed cuboid since these parameters are identical after defaulting their values to 0.0. Instead of this deformed cuboid box, neutrons are started uniformly throughout the fissile materials in the global unit.

```
KENO-VI:

...
 read geometry
    global unit 1
       sphere 1  8
       media 1 1 1
       boundary 1
 end geometry

 READ START
    NST=0
    XSP=3.0 XSM=-3.0 YSP=1.0 YSM=-1.0
 END START

end data
end
```

Example-8:

A box defined with identical **XSM** and **XSP** entries is considered as a deformed cuboid since these parameters are identical after defaulting their values to 0.0. Instead of this deformed cuboid box, neutrons are started uniformly throughout the fissile materials in the global unit.

```
KENO-VI:

...
 read geometry
    global unit 1
       sphere 1  8
       media 1 1 1
       boundary 1
 end geometry

 READ START
    NST=0
    XSP=3.0 XSM=3.0 YSP=1.1 YSM=-2.1 ZSP=4.0 ZSM=-4.1
 END START

end data
end
```

In the start type 6 capability, the selection process for the initial fission source points depends on the values of the last LNU value and number per generation (parameter NPG= in the parameter input Sect. 8.1.3.3). The following rules are applied when selecting the starting points:

- Start NPG initial fission neutrons at first-NPG starting points defined by start type 6 data if **NPG** < **LNU**. Remaining starting points beyond NPG will be discarded.
- Start NPG initial fission neutrons at LNU starting points defined by start type 6 data if **NPG** = **LNU**.
- Start LNU initial fission neutrons at the starting points defined by start type 6 data, then randomly select the remaining fission source points (NPG-LNU) from these starting points if **NPG** > **LNU**.

Warning: It is the user's responsibility to enter all arbitrary starting points consistent with the geometry specified. Both KENO V.a and KENO-VI terminate the execution with several error messages if any user-specified starting point entered is outside the outermost geometry.

Example-9:

In this example, 120 starting points have been defined by start type 6 data, and NPG=100 starting points are selected from the defined start type 6 data, 25 neutrons are started at the point (2.0, 3.0, 0.0), 20 neutrons are started at the point (3.0, -2.0, -6.0), and the remaining 55 neutrons are started at (3.0, 5.2, 1.0). All selected points are relative to the global coordinate system. Missing **TFX** entry in the last start type 6 data set is set to the last updated **TFX** value which is 3.0.

```
KENO-VI:

...

 READ PARAMETER
    NPG=100
 END PARAMETER

 read geometry
    global unit 1
       sphere 1  8
```

(continues on next page)

(continued from previous page)

```
      media 1 1 1
      boundary 1
 end geometry

 READ START
    NST=6
    TFX=2.0 TFY= 3.0 TFZ=0.0  LNU=25
    TFX=3.0 TFY=-2.0 TFZ=-6.0 LNU=45
            TFY=5.2  TFZ=1.0  LNU=120
 END START

end data
end
```

Example-10:

In this example, only 45 starting points have been defined by start type 6 data. The first 25 neutrons are started at the point (2.0, 0.0, 0.0), and 20 neutrons are started at the point (2.0, 3.0, -6.0). The remaining 55 neutrons are started at the points randomly selected from these starting points. All selected points are relative to the global coordinate system. Missing **TFY** and **TFZ** entries are defaulted to 0.0 in the first start type 6 data set. The missing **TFX** entry in the last start type 6 data set is set to the last updated **TFX** value, which is 2.0 (from the previous start type 6 data set).

```

Start type 6 is capable of reading starting points from an ASCII start data file, which could be created by writing starting points from a previous calculation, defined by RDU in a start type 6 data set. See Sect. 8.1.3.8.1 for the details about a typical ASCII start data file currently supported.

Reading starting data from multiple ASCII start data files is also supported. Similarly, single or multiple start type 6 date sets with RDU specification can be used together with other start type 6 data sets discussed above. The following examples demonstrate this capability.

Example-12:

In this example, all starting points stored in the ASCII start data file *sample.src* are read, and **NPG** neutrons are started at these points. If the number of starting points (last LNU read from the file) is less than **NPG**, **LNU** number of neutrons are started at the points read, and the remaining neutrons (NPG-LNU) are started at the points randomly sampled from the starting points already read. The starting points beyond **NPG** are discarded if **NPG** is less than the number of starting points read.

```
...
READ START
   NST=6
   RDU=sample.src
END START
```

Example-13:

The first 32 starting points stored in the ASCII start data file *sample.src* are read, and **NPG** neutrons are started at these points. If **NPG** > **LNU** = 32, then 32 neutrons are started at these starting points, and the remaining neutrons are started at the points randomly sampled from these 32 starting points. The starting points beyond **NPG** is discarded if **NPG** < 32.

```
...
READ START
   NST=6
   RDU=sample.src LNU=32
END START
```

Note: Reading starting data from multiple ASCII start data files is also supported. Similarly, single or multiple start type 6 date sets with the RDU specification can be used together with other start type 6 data

sets discussed above. The following examples demonstrates this capability.

Example-14:

A total of 30 starting points are read both from the specified ASCII start data files and from the start type 6 data set defined with **TFX**, **TFY**, and **TFZ**. Neutrons are started at these points. If there is a shortage of starting points (NPG >> last LNU), then the required number of starting points is randomly sampled from these 30 starting points.

```
...
READ START
   NST=6
   RDU=sample1.src LNU=10
   RDU=sample2.src LNU=25
       TFX=1.0 TFY=3.0 TFZ=4.0 LNU=30
END START
```

8.1.4.9 Biasing or weighting data for multigroup mode

Sect. 8.1.4.6.3 discusses the basis of weighting or biasing. The use of biasing data in reflected problems has been illustrated in Examples 9, 10, and 11 of Sect. 8.1.4.6. Sect. 8.1.3.7 discusses the input directions for entering biasing data.

Every **shape** card in KENO V.a, or **MEDIA** card in KENO-VI requires a bias ID to associate that geometry region with a biasing or weighting function. A biasing or weighting function is a set of energy-dependent values of the average weight that are applicable in a given region. The default function for all bias IDs is constant through all energy groups and is defined to be the default value of weight average which can be specified in the parameter data. A bias ID can be associated with a biasing function (other than default) by specifying it in the biasing input data. This function can be chosen from the weighting library, or it can be entered from records. Table 8.1.25 lists the materials and energy group structures for biasing functions available from the weighting library.

> **Caution:** In general, the use of biasing should be restricted to external reflectors unless the user has generated correct biasing functions for other applications. Improper use of biasing functions can result in erroneous answers without giving any indication that they are invalid. Caution should be exercised in the generation and use of biasing functions.

Biasing functions are most applicable to thick external reflectors. Their use can significantly reduce the amount of computer time required to obtain answers in KENO. If the user wishes to use a biasing function for a concrete reflector, for example, the following steps must be included in preparing the input data:

1. The geometry region data must define the shape and dimensions of the reflector using the mixture ID for concrete and a sequence of bias IDs that associate the geometry region with the appropriate interval of the concrete weighting function. CAUTION: THE THICKNESS AND SEQUENTIAL LOCATION OF EACH REGION USING BIASING FUNCTIONS MUST MATCH OR VERY NEARLY MATCH THE INCREMENT THICKNESS AND ORDER OF THE WEIGHTING DATA. NO CHECK IS MADE ON THE REQUIREMENT. IT IS THE USER'S RESPONSIBILITY TO ENSURE CONSISTENCY.

2. Biasing data must be entered. This must include the material ID for the reflector material (from Table 8.1.25 or as specified on records) and a beginning and ending bias ID. The beginning bias ID is used to

select the first set of energy-dependent average weights, and the subsequent sets of energy-dependent average weights are assigned consecutive IDs until the ending bias ID is reached.

Small deviations in reflector region thickness are allowed, such as using three generated regions with a thickness per region of 5.08 cm to generate a 15.24 cm thick reflector of concrete, or using five generated regions with a thickness per region of 3.048 cm to generate a 15.24 cm thick reflector of water. See Table 8.1.25 for a list of the increment thicknesses for the materials in the weighting library. It is acceptable for the thickness of the last reflector region to be significantly different than the increment thickness. For example, a reflector record specifying five generated regions with a thickness per region of 3.0 cm could be followed by a reflector record specifying one region with a thickness per region of 0.24 cm. Assuming that material 2 is water and a 15.24 cm thick cuboidal reflector of water is desired, the required reflector description and biasing data could be entered as follows:

KENO V.a:

```
REFLECTOR 2 2 6*3.0  5
REFLECTOR 2 7 6*0.24 1
READ BIAS ID=500 2 7 END BIAS
```

KENO-VI:

```
GLOBAL UNIT 1
CUBOID 1 6P10.0
CUBOID 2 6P13.0
CUBOID 3 6P16.0
CUBOID 4 6P19.0
CUBOID 5 6P22.0
CUBOID 6 6P25.0
CUBOID 7 6P25.24
MEDIA 1 1 1
MEDIA 2 2 2 -1
MEDIA 2 3 3 -2
MEDIA 2 4 4 -3
MEDIA 2 5 5 -4
MEDIA 2 6 6 -5
MEDIA 2 7 7 -6
BOUNDARY  7
READ BIAS ID=500 2 7 END BIAS
```

The same 15.24 cm thick reflector can be described by including the extra 0.24 cm in the last region as shown below:

KENO V.a:

```
REFLECTOR 2 2 6*3.0  4
REFLECTOR 2 6 6*3.24 1
READ BIAS  ID=500 2 6 END BIAS
```

KENO-VI:

```
GLOBAL UNIT 1
CUBOID 1 6P10.0
CUBOID 2 6P13.0
CUBOID 3 6P16.0
CUBOID 4 6P19.0
CUBOID 5 6P22.0
CUBOID 6 6P25.24
MEDIA 1 1 1
MEDIA 2 2 2 -1
```

(continues on next page)

(continued from previous page)

```
MEDIA 2 3 3 -2
MEDIA 2 4 4 -3
MEDIA 2 5 5 -4
MEDIA 2 6 6 -5
BOUNDARY  6
READ BIAS ID=500 2 6 END BIAS
```

Here the weighting functions associated with bias IDs 2, 3, 4, and 5 each have a thickness of 3.0 cm, corresponding exactly to the increment thickness for water in Table 8.1.25 Bias ID 6 is used for the last generated region which is 3.24 cm thick.

The following examples illustrate the use of biasing data. Suppose the user wishes to use the weighting function for water from Table 8.1.25 for bias IDs 2 through 6. The biasing input data would then be:

```
READ BIAS  ID=500 2 6 END BIAS
```

The energy-dependent values of weight average for the first 3 cm interval of water will be used for weighting the geometry regions that specify a bias ID of 2. The energy-dependent values of weight average for the second 3 cm interval of water will be used for geometry regions that specify a bias ID of 3, etc. Thus, the energy-dependent values of weight average for the fifth 3 cm interval of water will be used for geometry regions that specify a bias ID of 6. Geometry regions that use bias IDs other than 2, 3, 4, 5, and 6 will use the default value of weight average that is constant for all energies as a biasing function.

Several sets of biasing data can be entered at once. Assume the user wishes to use the weighting function for concrete from Table 8.1.25 for bias IDs 2 through 4 and the weighting function for water for bias IDs 5 through 7. The appropriate input data block is the following:

```
READ BIAS  ID=301 2 4 ID=500 5 7 END BIAS
```

The energy-dependent values of weight average for the first 5 cm interval of concrete will be used for the geometry regions that specify a bias ID of 2, the energy-dependent values of weight average for the second 5 cm interval of concrete will be used for the geometry regions that specify a bias ID of 3, and the energy-dependent values of weight average for the third 5 cm interval of concrete will be used for the geometry regions that specify a bias ID of 4. The energy-dependent values of weight average for the first 3 cm interval of water will be used for geometry regions that specify a bias ID of 5, the values for the second 3 cm interval of water will be used for geometry regions that specify a bias ID of 6, and the values for the third 3 cm interval of water will be used for geometry regions that specify a bias ID of 7. The default value of weight average will be used for all bias IDs outside the range of 2–7.

If the biasing data block defines the same bias ID more than once, the value that is entered last supersedes previous entries. Assuming that the following data block is entered,

```
READ BIAS  ID=400 2 7 ID=500 5 7 END BIAS
```

the data for paraffin (ID=400) will be used for bias IDs 2, 3, and 4, and the data for water (ID=500) will be used for bias IDs 5, 6, and 7.

EXAMPLE 1. USE OF BIASING DATA

It is assumed that a 5 cm radius sphere of material 2 is reflected by a 20 cm thickness of material 1 (concrete). The concrete reflector is spherical and close fitting upon the sphere of material 2. The mixing table must specify material 1 and material 2. Material 1 must be defined as concrete. The geometry and biasing data should be entered as follows:

KENO V.a:

```
READ GEOM
SPHERE 2 1 5.0
REPLICATE 1 2 5.0 4
END GEOM
READ BIAS ID=301 2 5 END BIAS
```

KENO-VI:

```
READ GEOM
GLOBAL UNIT 1
SPHERE 1 5.0
SPHERE 2 10.0
SPHERE 3 15.0
SPHERE 4 20.0
SPHERE 5 25.0
MEDIA 2 1 1
MEDIA 1 2 2 -1
MEDIA 1 3 3 -2
MEDIA 1 4 4 -3
MEDIA 1 5 5 -4
BOUNDARY  5
END GEOM
READ BIAS ID=301 2 5 END BIAS
```

The bias ID for the first generated region is 2, the second is 3, the third is 4, and the fourth is 5. The biasing data block specifies that the biasing function for material ID 301 (concrete) will be used from the weighting library. The bias ID to which the energy-dependent weighting function for the first 5.0 cm interval of concrete is applied is 2; the energy-dependent weighting function for the fourth 5 cm interval of concrete is applied to the fourth generated geometry region. This generated region has a bias ID of 5.

In KENO V.a, Example 1 can also be described without using a reflector record as shown below. The records that are generated by the reflector record in the previous set of data are identical to the last four spheres in this mockup.

EXAMPLE 1. Use of biasing without a reflector record.

KENO V.a:

```
READ GEOM

SPHERE 1 2 10.0
SPHERE 1 3 15.0
SPHERE 1 4 20.0
SPHERE 1 5 25.0
END GEOM
READ BIAS  ID=301 2 5 END BIAS
```

8.1.4.10 Color plots

Plots are generated only if a plot data block has been entered for the problem and **PLT**=NO has not been entered in the parameter data or the plot data. See Sect. 8.1.3.11 for a description of plot data. When a plot is to be made, the user MUST correctly specify the upper left-hand corner of the plot with respect to the origin of the plot. The origin of a plot is defined as the origin of the **GLOBAL UNIT**.

Plots can represent mixture numbers, unit numbers, or bias ID numbers. A title can be entered for each plot. If plot titles are omitted, the title of the KENO case will be printed for each plot title until a plot title is entered. If a plot title is entered and a subsequent plot title is omitted, the last plot title prior to the omitted one will be used for the omitted one.

The upper left and lower right coordinates define the area (i.e., the slice and its location) for which the plot is to be made. The direction cosines across the plot and the direction cosines down the plot define the direction of the vector across the plot and the vector down the plot with respect to the geometry coordinate system. One of the simplest ways of generating a plot is to specify the desired coordinates of the upper left and lower right corners of the plot. Then one must determine which plot axis is to be across the plot and which is to be down. The sign of the direction cosine should be consistent with the direction of that component when moving from the upper left to lower right corner. For example, to draw a plot of an X-Z slice at Y = 5.0 with X across the plot and Z down the plot for a system whose X coordinates ranges from 0.0 to 10.0 and whose Z coordinates range from 0.0 to 20.0, the upper left coordinate could be **XUL**=0.0 **YUL**=5.0 **ZUL**=20.0 and the lower right coordinates could be **XLR**=10.0 **YLR**=5.0 **ZLR**=0.0. Since X is to be plotted across the plot with X = 0.0 at the left and X = 10.0 at the right, only the X component of the direction cosines across the plot need be entered. It should be positive because going from 0.0 to 10.0 is moving in the positive direction. Thus, **UAX**=1.0 would be entered for the direction cosines across the plot. **VAX** and **WAX** could be omitted. Z is to be plotted down the plot with Z = 20.0 at the top and Z = 0.0 at the bottom. Therefore, only the Z component of the direction cosines down the plot needs to be defined. It should be negative because moving from 20.0 to 0.0 is moving in the negative direction. Thus, **WDN** = -1.0 would be entered for the direction cosines down the plot. **UDN** and **VDN** could be omitted. The sign of the direction cosines should be consistent with the coordinates of the upper left and lower right corners in order to get a plot.

It is not necessary that the plot be made for a slice orthogonal to one of the axes. Plots can be made of slices cut at any desired angle, but the user should exercise caution and be well aware of the distortion of shapes that can be introduced. (Nonorthogonal slices through cylinders plot as ellipses.)

The user can specify the horizontal and vertical spacing between points on the plot. It is usually advisable to enter one or the other. Entering both can cause distortion of the plot. **DLX**= is used to specify the horizontal spacing between points and **DLD**= is used to specify the vertical spacing between points. When only one of them is specified, the code calculates the correct value of the other so the plot will not be distorted. **DLX** or **DLD** can be specified by the user to be small enough to show the desirable detail in the plot. The plot is generated by starting at the upper left corner of the plot and generating a point every **DLX** across the plot; then moving down **DLD** and repeating the generation of the points across the plot.

NAX specifies the number of intervals (pixels) that will be printed across the plot. **NDN** specifies the number of intervals (pixels) that will be printed down the plot. If both **NAX** and **NDN** are entered, the plot may be distorted. If one of them is entered, the value of the other will be calculated so the plot will not be distorted.

When a plot is being made, the first pixel represents the coordinates of the upper left corner. The value of **DELV** is added to the coordinate that is to be printed across the plot, and the next pixel is printed. **DELV** is added to that value to determine the location of the next pixel, that is, a point is determined every **DELV** across the plot and a pixel is printed for each point. When a line has been completed, a new line is begun **DELU** from the first line. This procedure is repeated until the plot is complete.

EXAMPLE 1. SINGLE UNIT WITH CENTERED ORIGIN

Consider two concentric cylinders in a cuboid. The inner cylinder is 5.2 cm in diameter. The outer cylinder has an inside diameter of 7.2 cm and an outside diameter of 7.6 cm. Both cylinders are 30 cm high. They are contained in a tight-fitting box with a wall thickness of 0.5 cm and top and bottom thickness of 1.0 cm. The inner cylinder is composed of mixture 1, the outer cylinder is made of mixture 4, and the box is made of mixture 2. The problem can be described with its origin at the center of the inner cylinder. The problem description for this arrangement is shown below:

KENO V.a:

UAX=1.0  VDN=-1.0  NAX=640  END
PIC=UNIT   END
END PLOT
END DATA
END
```

The plot data blocks included above are set up to draw a mixture map of an X-Y slice taken at the half height (Z=0.0) and a unit map for the same slice. In the above examples, the geometry dimensions extend from X = -4.3 to X = 4.3, from Y = -4.3, to Y = 4.3, and from Z = -16.0 to Z = 16.0. An X-Y slice is be printed at the half height (Z = 0.0). The desired plot data sets the upper left-hand corner of the plot to be X = -4.6 and Y = 4.6. The lower right-hand corner of the plot is specified as X = 4.6 and Y = -4.6. These data are entered

by specifying the upper left-hand corner as **XUL**= -4.6 **YUL**=4.6 **ZUL**=0.0 and the lower right-hand corner as **XLR**=4.6 **YLR**= -4.6 **ZLR**=0.0. It is desired to print X across the plot and Y down the plot. Therefore, the X direction cosine is specified across the plot, in the direction from X = -4.6 to X = 4.6 as **UAX**=1.0. The Y direction cosine is specified down the plot, from Y = 4.6 to Y = -4.6 as **VDN**= -1.0.

A black border will be printed for points outside the range of the problem geometry description. By setting the plot dimension slightly larger than the geometry dimension, a black border will be printed around the specified plot. This verifies that the outer boundaries of the geometry are contained within the plot dimensions. NAX is the number of pixels across for a color plot. An initial recommended range for NAX is between 600 and 800 pixels. The resulting plots are shown in Fig. 8.1.71 and Fig. 8.1.72. The associated data for both plots are shown in Example 8.1.19 and Example 8.1.20.

EXAMPLE 2. SINGLE UNIT WITH OFFSET ORIGIN.

The physical problem is the same as that described in Example 1: two concentric cylinders in a cuboid. The dimensions are exactly the same, and the difference is in the choice of the origin. In this geometry description, the origin was specified as the most negative point of the unit. Thus, the cylinders must have an origin specified to center them in the cuboid, and the cuboid extends from 0.0 to 8.6 in X and Y and from 0.0 to 32 in Z as shown in the problem description below.

The plot data included above will draw a mixture map of an X-Y slice taken at the half height (Z = 16.0). It will also draw a unit map of the same slice. The plot dimensions extend 0.3 cm beyond the problem dimensions to provide a black border around the plot. The associated plot data specification for the mixture map is shown in Example 8.1.21, the mixture map is shown in Fig. 8.1.73, and the associated plot data for the unit map is shown in Example 8.1.22. The unit map is identical to Fig. 8.1.72 and is not included.

Example 8.1.21: Associated data for mixture map of single unit with offset origin.

```
x-y slice at z midpoint. single unit concentric cyls.

EXAMPLE 3. A $2 \times 2 \times 2$ UNREFLECTED ARRAY OF CONCENTRIC CYLINDERS IN CUBOIDS

The physical representation of this example is a $2 \times 2 \times 2$ array of the configuration described in Example 1 of this section. The input data description for this array is given below:

As stated at the beginning of Sect. 8.1.4.10, the origin of a plot is defined as the origin of the **GLOBAL UNIT**. Each individual unit in the array is 8.6 cm wide in X and Y and 32 cm high in Z. Since the array has two units stacked in each direction, the array is 17.2 cm wide in X and Y and is 64 cm high. Therefore, the array exists from X = 0.0 to X = 17.2, from Y = 0.0 to Y = 17.2 and from Z = 0.0 to Z = 64.0.

The first color plot is to generate an X-Y slice through the array at the half height (Z = 16.0 cm) of the first layer as shown in Fig. 8.1.74. It is desirable to create an image with a larger extent than the global unit to ensure that the boundaries are as expected. This is achieved by setting the boundaries of the plot larger than the array. In this case, the boundaries were arbitrarily set 0.3 cm larger than the array, resulting in a black border around the array. If the plot were to exclude everything external to the array, the following coordinates could have been entered: **XUL**=0.0 **YUL**=17.2 **ZUL**=16.0 **XLR**=17.2 **YLR**=0.0 **ZLR**=16.0. This would have eliminated the black border. The existing plot was made using **XUL**= -0.3 **YUL**=17.5 **ZUL**=16.0 **XLR**=17.5 **YLR**= -0.3 **ZLR**=16.0.

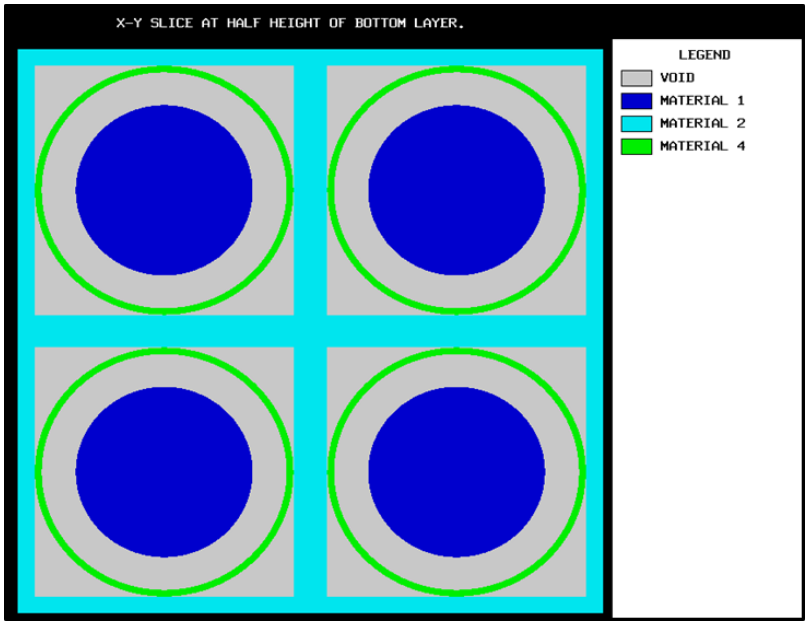

Fig. 8.1.74: X-Y plot of $2 \times 2 \times 2$ bare array.

The second color plot is to generate an X-Z slice through the center of the front row of the array. In order to obtain a black border, the coordinates of X and Z were arbitrarily set 1.0 cm larger than the boundaries of the array. The center of the front row occurs at Y = 12.9. The coordinates of the plot were: **XUL**= -1.0 **ZUL**=65.0 **YUL**=12.9 **XLR**=18.2 **ZLR**= -1.0 **YLR**=12.9. The resulting mixture map is shown in Fig. 8.1.75.

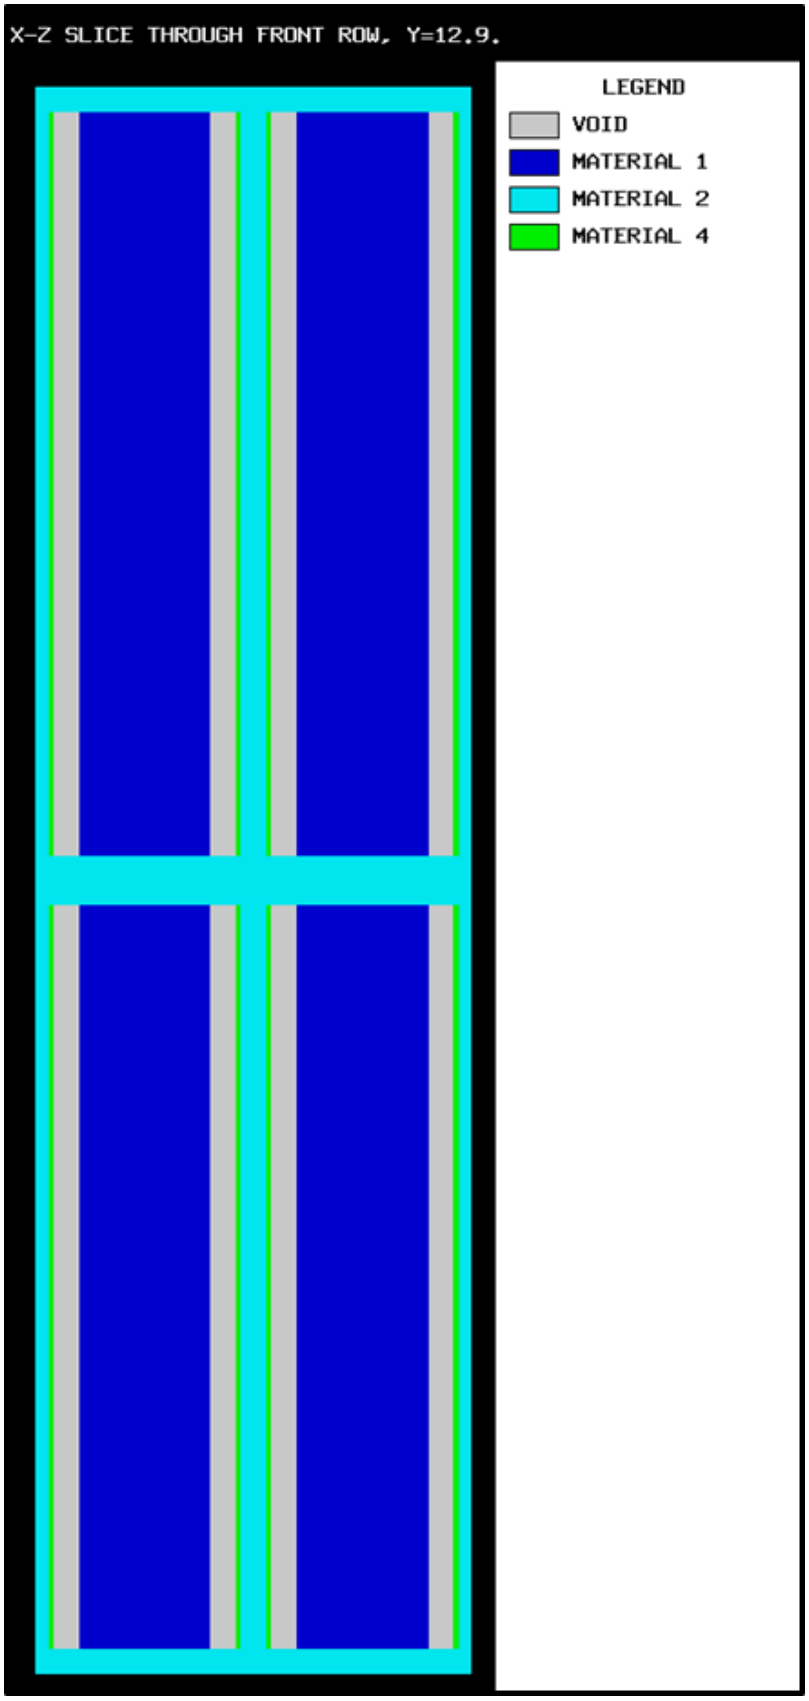

Fig. 8.1.75: X-Z plot of $2 \times 2 \times 2$ bare array.

EXAMPLE 4. A 2 × 2 × 2 REFLECTED ARRAY WITH THE ORIGIN AT THE MOST NEGATIVE POINT OF THE ARRAY

The **ARRAY** is described in Example 3 of this section with a 6 in. concrete reflector on all faces. The input data description for this array is given below.

The **ARRAY** record specifies the array number and the coordinates of the most negative point of the array to be (0.0,0.0,0.0) and the coordinates of the most positive point to be (17.2,17.2,64.0). Thus the reflected array extends from -15.24 cm to +32.44 cm in X and Y and from -15.24 to +79.24 in Z.

The first color plot for this example is to show an X-Y slice through the array and reflector at the half height of the bottom layer. A black border is used to verify that the entire reflector has been shown. This is accomplished by arbitrarily setting the plot boundaries 1 cm beyond the reflector boundaries. The coordinates used for this plot are **XUL** = -16.24 **YUL** = 33.44 **ZUL** = 16.0 **XLR** = 33.44 **YLR** = 16.24 **ZLR** = 16.0. The plot data description is shown in Example 8.1.23, and the plot is shown in Fig. 8.1.76.

Example 8.1.23: Plot data for X-Y slice of Example 4.

```

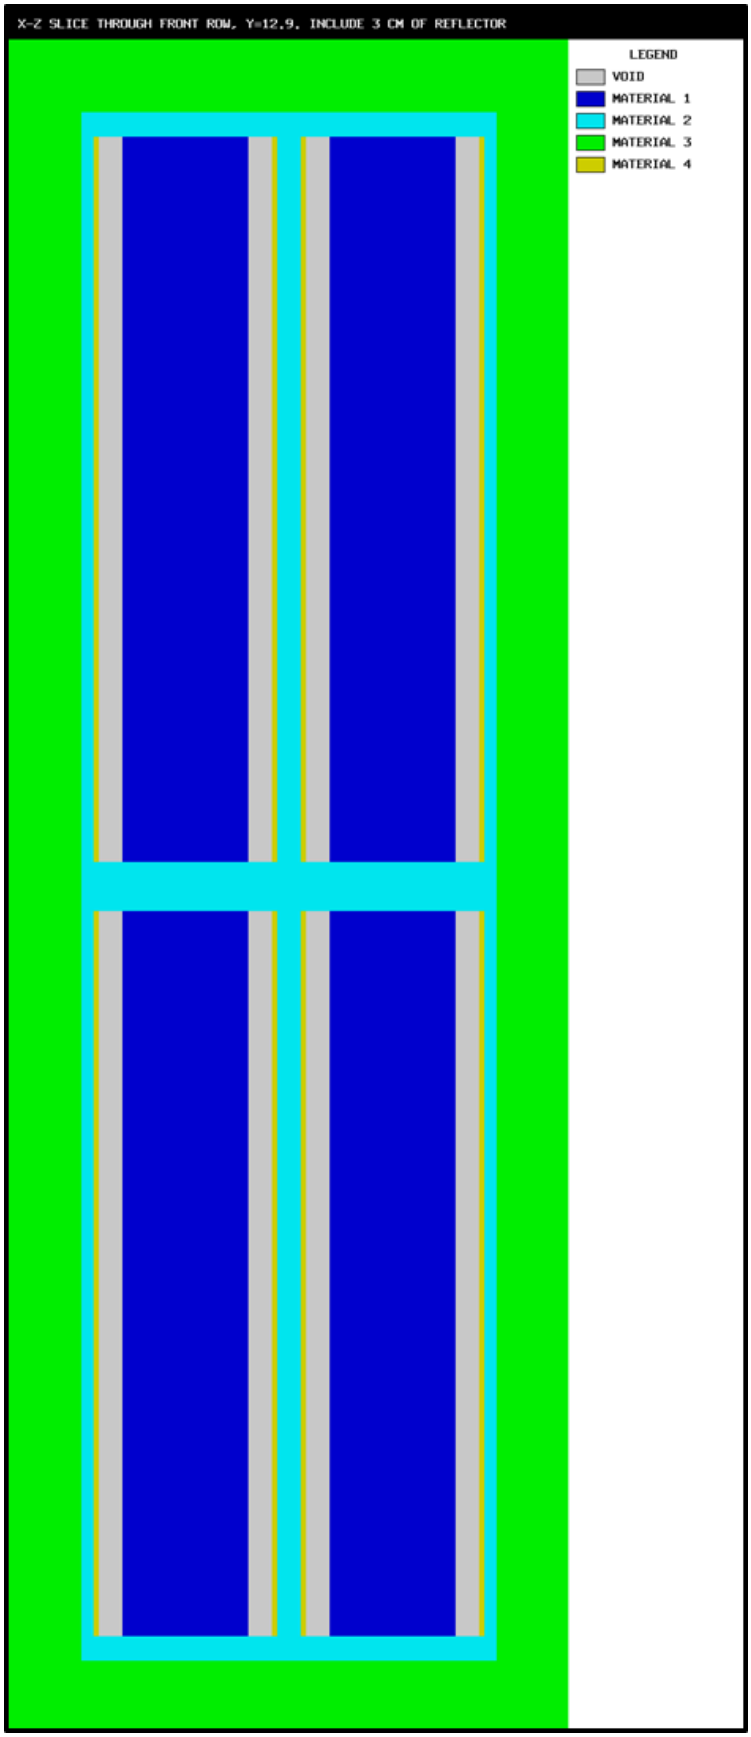

Fig. 8.1.79: Enlarged X-Z plot of $2 \times 2 \times 2$ reflected array.

EXAMPLE 5. A 2 × 2 × 2 REFLECTED ARRAY WITH THE ORIGIN CENTERED IN THE ARRAY

This example is physically identical to Example 4. The difference is in the specification of the origin. The bare array is 17.2 cm wide in X and Y and 64 cm high. The origin (0,0,0) can be placed at the exact center of the array by specifying the most negative point of the array as X = -8.6, Y = -8.6 and Z = -32.0. This is done using the **ARRAY** description in the geometry block. Because the origin is located at a different position, the coordinates of the plots will also be different. The input data description for this example is given below.

EXAMPLE 6. NESTED HOLES.

The nested hole description is provided in Sect. 8.1.4.6.2. Because this example involves a complicated placement of units, it is helpful useful to the user to generate a mixture plot and/or a unit plot for the problem. The resultant mixture plot for this problem is shown in Fig. 8.1.84, and the data description for Example 6 follows.

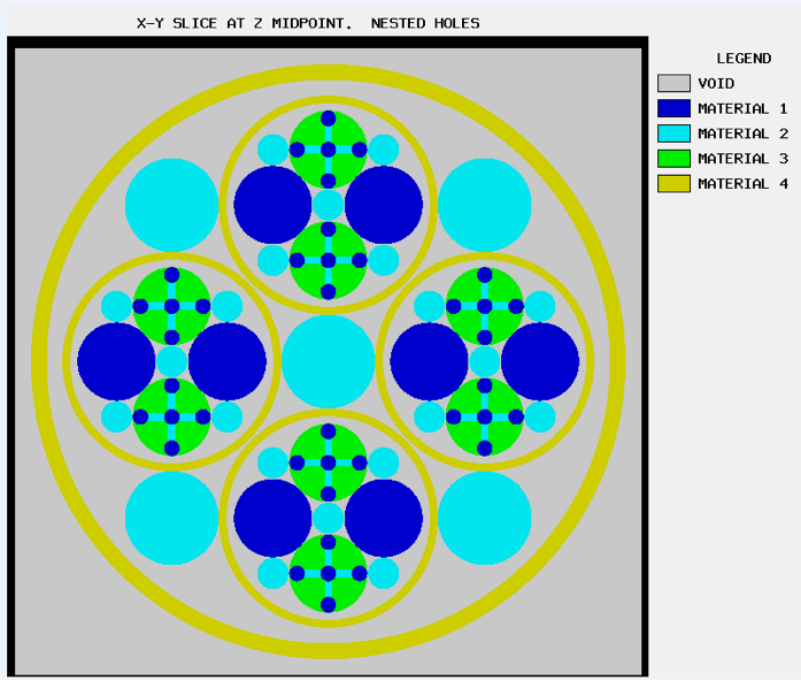

Fig. 8.1.84: Mixture plot of nested holes problem.

Example 8.1.31: Plot data for unit plot of nested holes.

```
x-y slice at z midpoint. nested holes. unit map

```

.he plot data description for the **UNIT** plot of nested holes is shown in Example 8.1.31. The **UNIT** plot is shown in Fig. 8.1.85. The user can reference this map to verify the correct placement of the **UNIT**s. Note that the **UNIT** map plots the **UNIT**s present at the deepest nesting level for the 2-D slice. It does not show any detail within a **UNIT**. The apparent detail within **UNIT** 7 includes **UNIT**s 1–6, which were placed there via the hole option. In the legend of the plot, the material number actually refers to the **UNIT** number.

EXAMPLE 7. LARGE STORAGE ARRAY.

The storage array described Example 18 in Sect. 8.1.4.6.3 and Fig. 8.1.33 is such a sparse array that the mixture map had to be very large in order to show the detail of the shelves and uranium buttons. The mixture maps for this configuration were not presented in Sect. 8.1.4.6.3, but the data description was listed so the user can generate them. It may be useful to generate a **UNIT** map for this kind of problem. The input data for generating unit maps for this storage array is given below.

```
READ PLOT  PIC=UNIT
TTL='X-Z SLICE THROUGH STORAGE ARRAY ROOM AT Y=30.48 WITH Z ACROSS AND X DOWN'
XUL=624.84 YUL=30.48 ZUL=-45.72 XLR=-30.48 YLR=30.48 ZLR=381.0
WAX=1.0 UDN=-1.0 NAX=320  END
TTL='X-Y SLICE THROUGH STORAGE ARRAY ROOM AT Z=0.3175 WITH X ACROSS AND Y DOWN'
XUL=-30.48 YUL=1341.1 ZUL=0.3175 XLR=624.84 YLR=-30.48 ZLR=0.3175
UAX=1.0 VDN=-1.0 NAX=320 END
END PLOT
```

The plot data and **UNIT** map for an X-Z slice through the array at Y=30.48 cm is given in Example 8.1.32 and Fig. 8.1.86. The Z direction, which extends from -45.72 cm to 381.0 cm, is plotted in 320 pixels across the plot. This **UNIT** map was created with Z across the plot and X down the plot.

Example 8.1.32: Plot data for X-Z slice of storage array.

```
x-z slice through storage array room at y=30.48 with z across and x down

unit map

8.1.4.11 KENO Multiple Mesh and Mesh-based Quantity Specifications

KENO constructs a grid object and stores several mesh definitions in this object. The following mesh definitions are supported by KENO:

i. Default mesh grid (grid `ID` =10001):

KENO generates a $5 \times 5 \times 5$ Cartesian mesh grid which overlays the entire geometry. This mesh is used only for fission source convergence diagnostics if the user does not specify any spatial mesh for this quantity.

Note: Currently, users cannot enter grid `ID`s greater than 9999.

---

ii. A cubic mesh grid (grid `ID` = 20001):

KENO generates a cubic mesh with the mesh size specified by `MSH` parameter, which is introduced in Table 8.1.1. This mesh definition can be used by all mesh-based quantities except the Shannon Entropy tallies used for fission source convergence diagnostics.

iii. Mesh with `grid geometry data` input (grid `ID` = NUMBER):

The user can specify either a mesh with a single `grid data` input block or multiple meshes by repeating the `grid data` input block with different mesh definitions. Note that the entire block, including `READ GRID` and `END GRID`, must be repeated each time; this behavior is different from all other blocks of KENO input.

After processing all grid data and constructing all grid meshes, KENO prints the specification of each mesh grid in the Grid Definitions output edit; see Sect. 8.1.5.19 for details.

Before starting the transport process, KENO tries to match the IDs specified in the parameter block with the keywords `SCD`, `MFX`, `CDS`, `CGD`, `FIS`, and `GFX` (See Sect. 8.1.3.3) to the grid `ID` in each grid definition. Each mesh-based quantity requested by the user is associated with a grid if the requested grid `ID` exists.

Note: Parameters `CDS`, `CGD`, `FIS`, `GFX`, and `MFX` with *YES* entry always require a mesh defined by either parameter `MSH` or `grid data` input.

Parameters `CDS`, `CGD`, `FIS`, `GFX`, and `MFX` with *YES* entry always use the mesh defined by the first `grid data` input if there are multiple meshes defined by both `MSH` and `grid data` input block(s).

The following examples demonstrate the mesh features in KENO:

Example: Source Convergence Diagnostics with Default Mesh KENO always generates a default mesh for source convergence diagnostics if the user does not specify any mesh for this quantity. The following example (only KENO-VI version is shown) with some updates in `parameter data` and `grid data` input blocks will be used in all examples in this section to summarize several mesh definition scenarios with several mesh-based quantity requests.

In this sample problem, a bounding box is defined to enclose the entire geometry with xmin=-13.74, xmax=13.74, ymin=-13.74, ymax=13.74, zmin=-13.01, and zmax=13.01. KENO uses this bounding box and creates a $5 \times 5 \times 5$ grid for source convergence diagnostics.

KENO-VI:

```

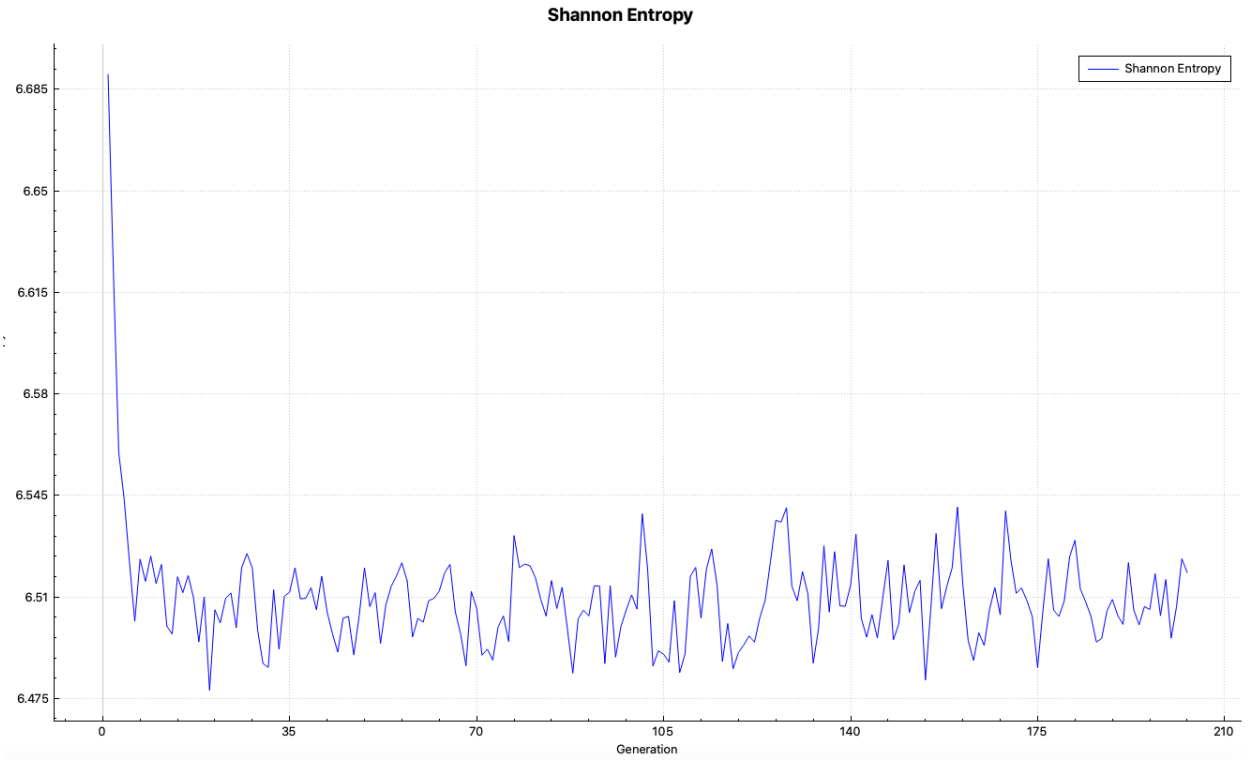

Fig. 8.1.88: Shannon entropy tallied on default mesh.

Example: Source Convergence Diagnostics with User-defined Mesh. The user can request the accumulation of the fission source on a different grid rather than the default grid for source convergence diagnostics. In this example, the sample problem specified in previous example is modified for this purpose. A new $6 \times 6 \times 6$ grid is defined over the entire geometry in a **grid geometry data** input with grid **ID** 12, and source convergence diagnostics are requested by setting **SCD** parameter to *12* in the parameter block that matches the NUMBER specification in the **grid geometry data** input.

```

   YMIN=-13.74 YMAX=13.74
   ZMIN=-13.01 ZMAX=13.01
END GRID
...
```

Note: Starting from this example, only a summary of Grid Definiton output edit will be presented for the remaining examples.

A User-defined grid is printed in Grid Definitons output edit, and Example 8.1.35 presents only a summary of this output section. Fig. 8.1.89 shows the variation of Shannon Entropy (tallied on user-defined mesh) over generations for the same problem given in the previous example.

Example 8.1.35: Grid Definitions output edit

```
...

   Grid Geometry: 12
 title: test scd with this mesh
 Plane Summary
   x:    6 cells from -1.37400E+01 to  1.37400E+01
   y:    6 cells from -1.37400E+01 to  1.37400E+01
   z:    6 cells from -1.30100E+01 to  1.30100E+01
 Total number of cells: 216

   ...
```

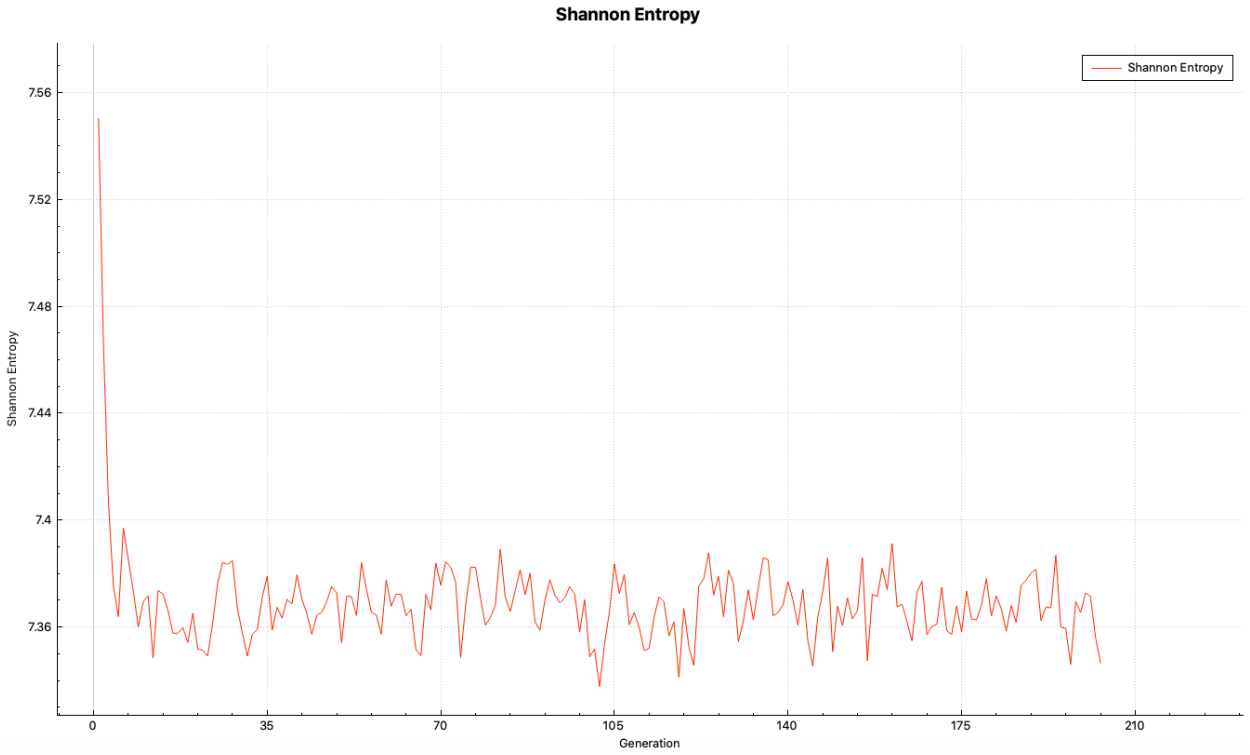

Fig. 8.1.89: Shannon entropy tallied on user-defined mesh.

Example: Source Convergence Diagnostics with Non-Existing Mesh. This example demonstrates the code behavior if there is a mismatch between the NUMBER entry in **grid geometry data** input and the **SCD** parameter in the **parameter data**. The sample input in the first example was modified as (a) a single mesh is defined with grid **ID** = 12, and (b) source convergence diagnostics is intended to use a grid with grid **ID** = 99, which does not exist.

```
=kenovi
mesh test - scd with non-existing grid id

READ PARAMETERS
```

(continues on next page)

(continued from previous page)

```
   CEP=ce_v7.1_endf NPG=10000 SCD=99
END PARAMETERS

...

READ GRID
   12
   TITLE "test scd with this mesh"

   XMIN=-13.74 XMAX=13.74
   YMIN=-13.74 YMAX=13.74
   ZMIN=-13.01 ZMAX=13.01
END GRID
...
```

In this example, calculation is stopped with an error message since the requested grid definition for source convergence diagnostics does not exist in the input.

```
...

***** error ***** keno message number k6-315 follows:
Mesh < 99 > specified for Shannon entropy tally and source convergence diagnostics(SCD) is not found in  input.

...

***** error ***** keno message number k6-100 follows:
this problem will not be run because errors were encountered in the input data.
...
```

Example: Fission Rate Mesh Tally with a Cubic Mesh Definition with MSH Parameter. In this example, the sample problem described in the first example was modified as (a) a cubic mesh defined with the **MSH** parameter, and (b) fission rate mesh tally is requested on this cubic mesh. In this case, a default mesh with grid **ID**=10001 is constructed and used only for source convergence diagnostics. The cubic mesh with grid **ID**=20001 is also constructed with the length of one side as equals to *2.748 cm* and is used for the fission rate mesh tally.

```
=kenovi
mesh test - fis with uniform mesh defined by MSH

READ PARAMETERS
   CEP=ce_v7.1_endf NPG=10000 FIS=yes MSH=2.748
END PARAMETERS

...
```

The output prints the details of mesh grid entries in Grid Definitions edit, as shown in Example 8.1.36. For this sample problem, the cubic mesh grid is constructed in a box that is larger than the bounding box around the global unit (+x=13.74, -x=-13.74, +y=13.74, -y=-13.74, +z=13.01 and -z=-13.01). The extents of the global boundary in each dimension are not equal; therefore, KENO tries to adjust the box size to place the cubic meshes properly inside this box. A grid mesh perfectly overlapping the problem geometry can be defined only by the **grid data** input rather than using the **MSH** parameter.

Example 8.1.36: Grid Definitions output edit

```
                          **** Grid geometries utilized in this problem ****

Grid Geometry: 20001

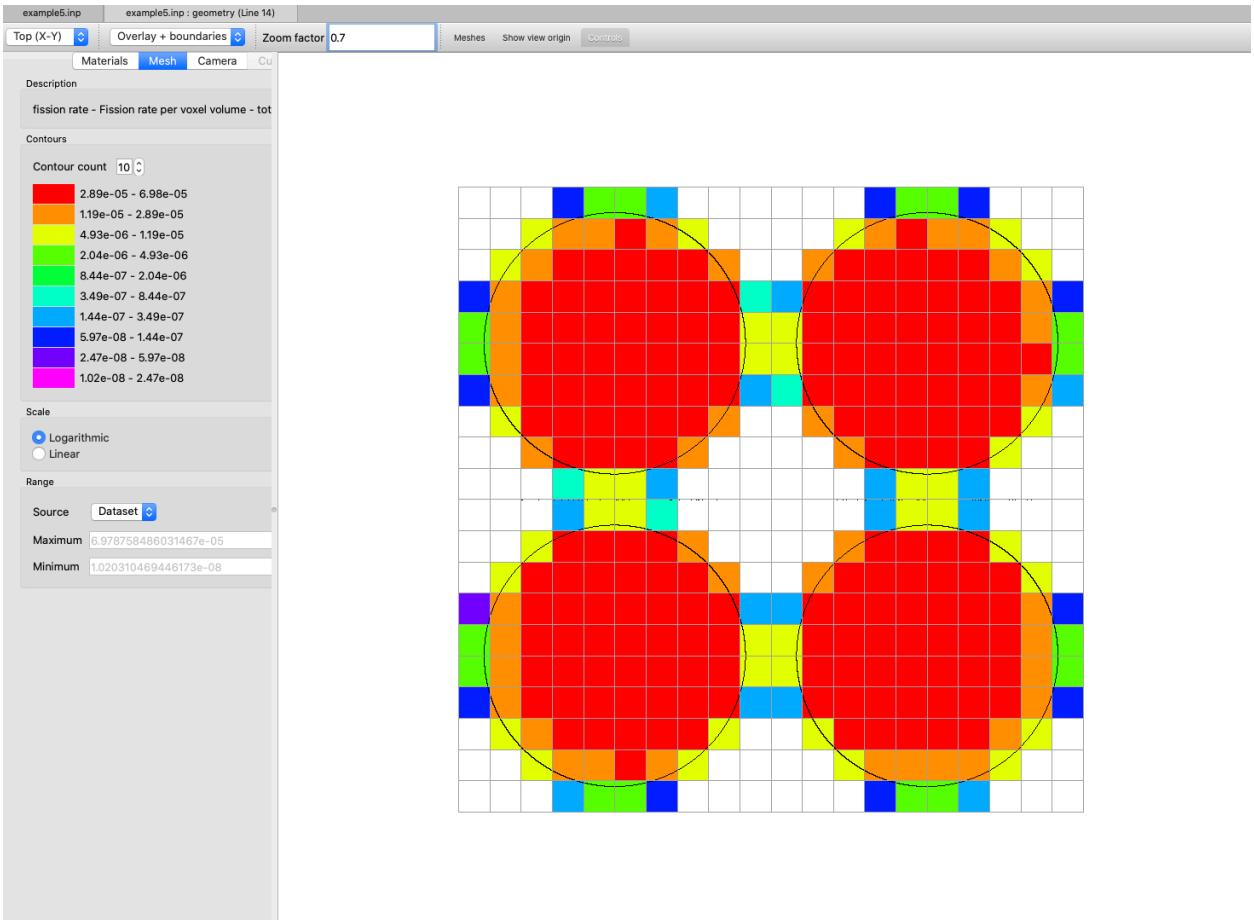

Fig. 8.1.91: Fission rate mesh tally computed on a mesh defined by **grid geometry data** input (X-Y view at z=5.0).

Example: Fission Rate Mesh Tally with Multiple Mesh Definitions. In this example, the sample input from the previous example is used with the old-style definition so that fission rate mesh tally is requested by setting the **FIS** parameter to *YES*.

Additional mesh grids were added to the sample input to demonstrate how KENO assigns a mesh grid to a mesh-based quantity when the value of mesh quantity has been entered as *YES* and multiple mesh grids have already been defined: (a) two mesh grids with grid **IDs** *118* and *113* are defined in **grid geometry data** inputs, and (b) another mesh grid is also defined with the **MSH** parameter.

KENO uses the default mesh grid (grid **ID**=10001) for the source convergence diagnostics, using the mesh with grid **ID**= 118 from the grid data container for the fission rate mesh tally.

```

A summary of Grid Definitions output edit is given in Example 8.1.40. Note that KENO does not print anything for the cubic mesh (requested by setting **MSH=2.5**, grid **ID**= 20001) because this mesh was not constructed. KENO ignores the mesh definition request done with the **MSH** parameter if any mesh grid is defined by **grid data** input.

Example 8.1.40: Grid Definitions output edit

```
                          **** Grid geometries utilized in this problem ****

 Grid Geometry: 118
    title: test fis with this mesh partially covering the geometry
    Plane Summary
      x:   20 cells from -1.74001E+00 to  1.37400E+01
      y:   20 cells from -1.74001E+00 to  1.37400E+01
      z:   18 cells from -1.01001E+00 to  1.30100E+01
    Total number of cells: 7200

...

```

KENO assigns the first grid entry from the grid data container to any mesh quantity whose value is entered as *YES* in the **parameter data** input. Each grid defined in the grid data blocks is stored in the grid data container unit in the order in which it is processed.

In this example, the grid entry *118*, which is processed and stored first, is assigned to the fission rate mesh tally calculation. Mesh Tallies output edit shown in Example 8.1.41 reflects this grid assignment to the fission ate mesh tally.

Example 8.1.41: Mesh tallies output edit

```
                                        **** mesh tallies ****

```

Fig. 8.1.92 illustrates the fission rate mesh tally overlayed on the geometry. Note that the mesh used in the fission rate mesh tally calculation does not cover the entire geometry, and this is not a requirement for this tally.

Note: The fission rate mesh tally capability as well as fission source and grid flux tallies (averaged over mesh volumes) do not require that the mesh grid used in the calculation cover the entire geometry.

However, the mesh flux capability (calculated over the volume of materials in each mesh voxel) activated by the **MFX** parameter always requires that the mesh grid used in its calculations cover the entire geometry.

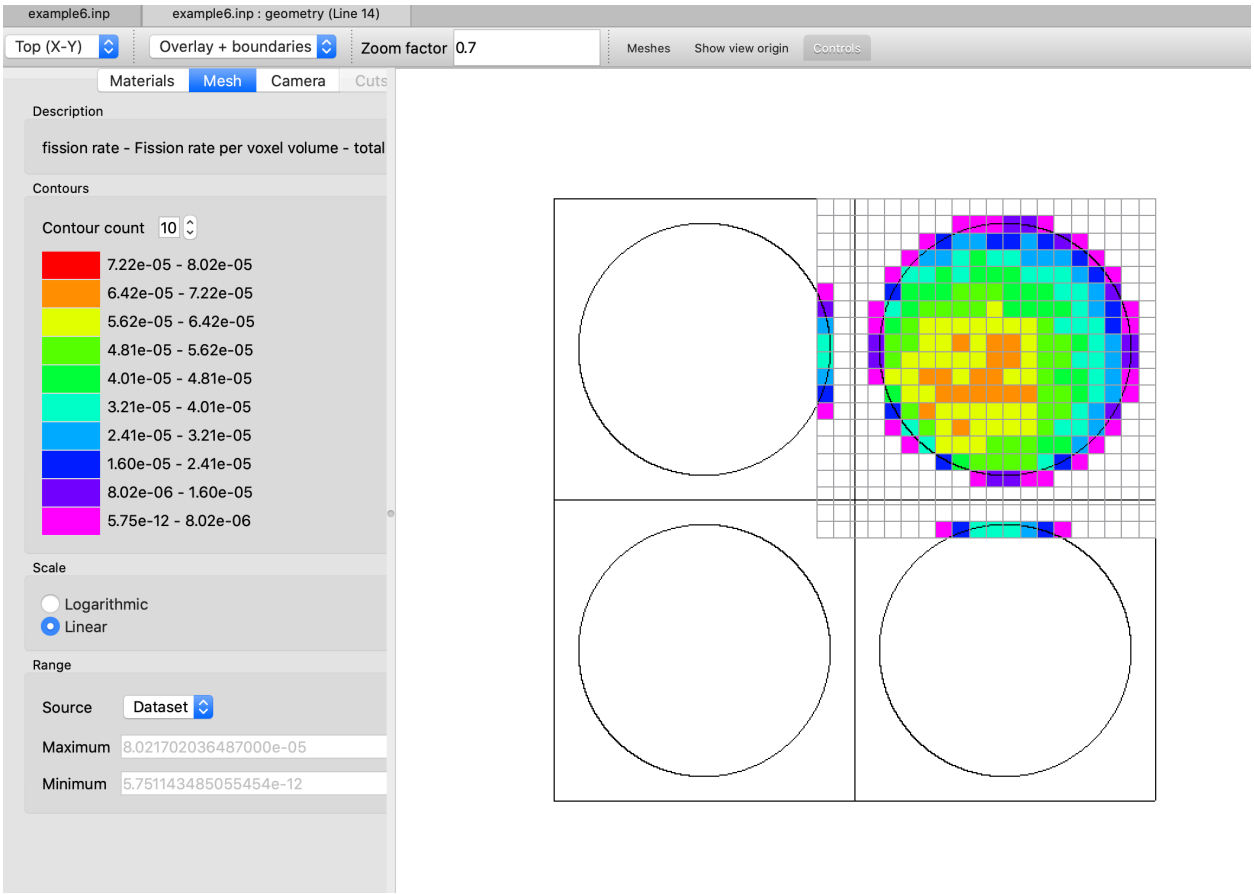

Fig. 8.1.92: Fission rate mesh tally computed over a mesh grid defined by **grid geometry data** input. Defined mesh grid with **ID**= 118 partially covers the geometry (X-Y view at z=6.8).

Example: Mesh Flux Tally with Multiple Mesh Definitions. In this example, the sample problem described in previous example is modified to request a mesh flux calculation (**MFX**) on a mesh grid which partly covers the problem geometry. The mesh volume calculation required by the mesh flux calculation is already requested by adding a volume block to the input.

Note: Calculation of mesh fluxes in all regions enclosed by a mesh voxel requires the volume of each region in this mesh voxel. KENO V.a automatically activates stochastic volume calculation with RANDOM volume estimate for such a case. The user can override the parameters in the **volume data** input block. However, users cannot change the volume calculation method from RANDOM volume estimate to TRACE volume estimate.

In the KENO-VI case, it is the user's responsibility to add a **volume data** input block to activate

the stochastic mesh volume calculation. Like KENO V.a, KENO-VI only allows RANDOM volume estimate for mesh volume calculation. See Sect. 8.1.3.13 and Sect. 8.1.5.17 for more details.

After these updates, KENO with this sample problem uses the default mesh (grid **ID**=10001) for the source convergence diagnostics, and the user-defined mesh with grid **ID**=118 for accumulating the mesh fluxes. Unlike the fission rate mesh tally case discussed in the previous example, execution is terminated for this scenario since the mesh flux capability requested with **MFX** parameter requires a mesh grid covering the entire geometry.

All three user-defined mesh grids and default mesh grids constructed by KENO are printed in the Grid Definitions output edit as shown in Example 8.1.42. In this output edit, a summary of the volume calculation results performed on the mesh grid *17* is also printed as part of the grid geometry 17 output edit. Further details on the mesh volume calculation can be seen in the volume information edit in the output. All mesh volumes can be printed by setting **PMV=YES** in the **parameter data** input (see Table 8.1.1).

Example 8.1.42: Grid Definitions output edit

```

KENO prints the summary of the specifications of the mesh quantities computed in Mesh tallies output edit as shown in Example 8.1.43. The code saves the fission rate mesh tally and grid fluxes in two separate 3dmap files named *example8.fission_density.3dmap* and *example8.flux.3dmap*, respectively. Mesh fluxes are also saved in an ASCII file since the **PMS** parameter is set to *YES*. Fig. 8.1.93 presents the fission rate mesh tally, grid fluxes, and Shannon entropy computed on the meshes defined in **grid geometry data** input.

Example 8.1.43: Mesh tallies output edit

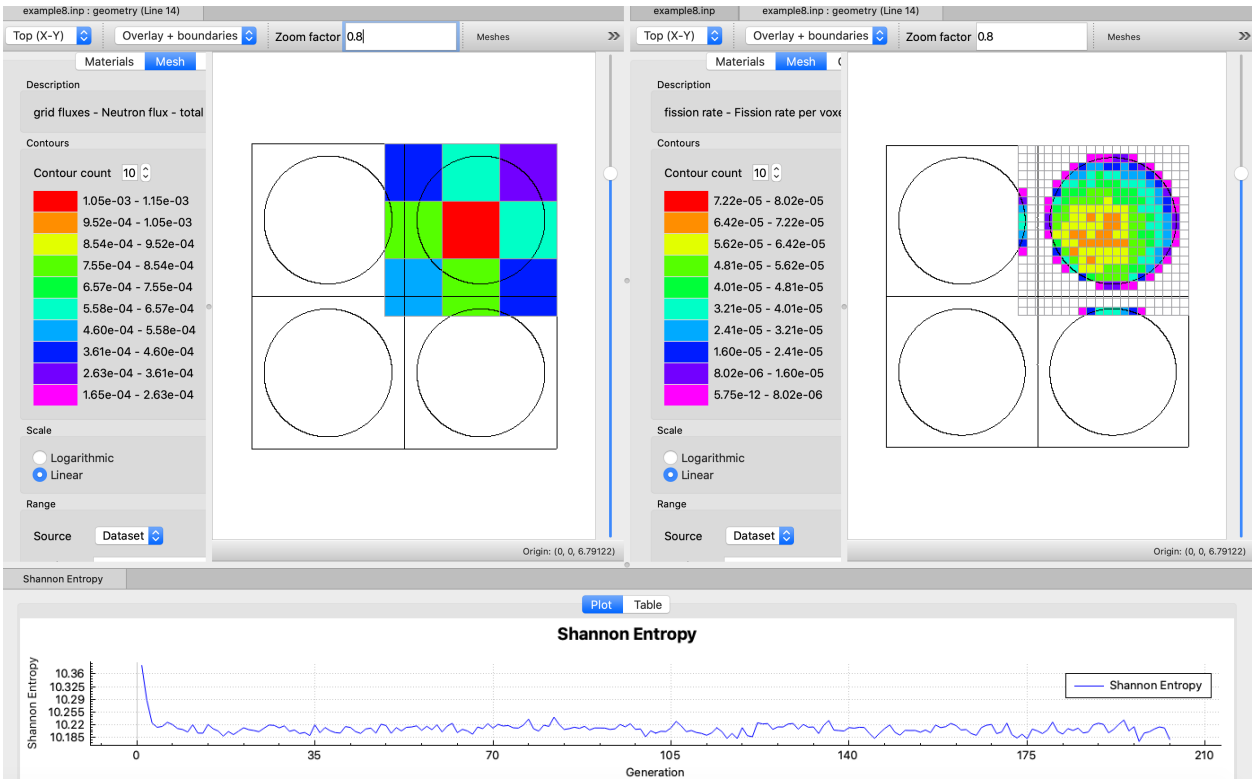

Fig. 8.1.93: Fission rate mesh tally, grid fluxes, and Shannon entropy computed over the different meshes defined by **grid geometry data** input.

8.1.4.12 Random sequence

The random-number package used by KENO always starts with the same seed and thus always reproduces the same sequence of random numbers. Any random number except the one printed as the starting random number in the parameter table can be used to activate a different random sequence. The user can rerun a problem with a different random sequence by simply entering a hexadecimal random number other than the starting random number in the parameter data. For example, by entering RND=A10C1893E6D5 in the parameter data, the problem will be run with a different random sequence.

8.1.4.13 Matrix k-effective

Matrix k-effective calculations provide an alternative method of calculating the k-effective of the system. Cofactor k-effectives and source vectors are additional information that can be provided when the matrix k-effective is calculated. The necessary source and fission weight data are collected during the neutron tracking procedure. This information is converted to a FISSION PRODUCTION MATRIX, which is the number of next generation neutrons produced at J by a neutron born at I. The principal eigenvalue of the fission probability matrix is the matrix k-effective. KENO offers four alternatives when calculating matrix k-effective as discussed below:

(1) If MKP=YES is specified in the parameter data, the fission production matrix is collected by array position or position index in the GLOBAL ARRAY. The position index is used to reference a given location in a 3-D lattice. For a $2 \times 2 \times 2$ array, there are nine unique position indices as shown below. Position zero contains everything outside the GLOBAL ARRAY.

Table 8.1.30: Array index guide for a sample $2 \times 2 \times 2$ array

	POSITION		
	X	Y	Z
0	0	0	0
1	1	1	1
2	2	1	1
3	1	2	1
4	2	2	1
5	1	1	2
6	2	1	2
7	1	2	2
8	2	2	2

The fission production matrix is the number of next generation neutrons produced at index J by a neutron born at index I. This matrix is used to calculate the matrix k-effective, cofactor k-effectives and the source vector by position index. Because the size of the fission probability matrix is the square of the array size (for a $4 \times 4 \times 4$ array there are 4,096 entries), it can use vast amounts of computer memory.

(2) If MKU=YES is specified in the parameter data, the fission production matrix is collected by UNIT. It is the number of next generation neutrons produced in UNIT J by a neutron born in UNIT I. This matrix is used to calculate the matrix k-effective, cofactor k-effectives and source vector by UNIT.

(3) If MKH=YES is specified in the parameter data, the fission production matrix is collected by the HOLE number. Matrix information can be collected at either the highest HOLE nesting level (first level of nesting) or the deepest HOLE nesting level. HHL=YES specifies that the matrix information will be collected at the first nesting level. By default, the matrix information is collected at the deepest nesting level. The fission production matrix is the number of next generation neutrons produced in HOLE J by a neutron born in HOLE I. This matrix is used to calculate the matrix k-effective, cofactor k-effectives and the source vector by HOLE.

(4) If MKA=YES is specified in the parameter data, the fission production matrix is collected by ARRAY number. It can be collected at the highest ARRAY level (first level of nesting) or at the deepest ARRAY level. HAL=YES specifies that the matrix information will be collected at the first nesting level. By default, the matrix information is collected at the deepest nesting level. The fission production matrix is the number of next generation neutrons produced in ARRAY J by a neutron born in ARRAY I. This matrix is used to calculate the matrix k-effective, cofactor k-effectives and the source vector by ARRAY.

The user can simultaneously implement all methods of calculating the matrix k-effective. The results are labeled in the printout. Matrix k-effectives cannot be calculated for a single unit problem. If the user wishes to do so, the geometry description must have a cube or cuboid as its outer region, and the problem description should include `READ ARRAY END ARRAY`. These two actions convert the single unit problem into a $1 \times 1 \times 1$ array.

A cofactor k-effective is the eigenvalue of the fission production matrix reduced by the row and column that references the specified `UNIT` or position index. The difference between the k-effective for the system and the cofactor k-effective for a `UNIT` or position index is an indication of the *in situ* k-effective of that `UNIT` or the contribution that `UNIT` makes to the k-effective of the system. The cofactor k-effective of a `UNIT` devoid of fissile material should approximate the k-effective of the system.

8.1.4.14 Deviations

When a deviation is calculated by KENO, it is the standard deviation of the mean. This assumes a large sample having a normal distribution. KENO calculates the real variance using an iterative approach and lag covariance data between generations as follows [BDL09, Dem99a]

1. The sample variance and covariance estimates are calculated.
2. The apparent variance is set equal to the sample variance and the apparent covariance is set equal to the sample covariance.
3. The real covariance is set equal to the apparent covariance and the real variance is calculated.
4. Using the real variance and apparent covariance calculate the real covariance.
5. The real variance is recalculated.
6. Steps 4 and 5 are repeated until the real variance converges within a preset tolerance.

The covariance estimates are only calculated for the previous 20 generations. A maximum of 50 iterations are allowed for the real variance to converge.

8.1.4.15 Generation time and lifetime

The generation time and lifetime calculations use the average velocity. The validity of these calculations is determined by how accurately the average velocity represents the spectrum over the range of the energy group. The lifetime and generation time calculated by KENO are not kinetics parameters. The lifetime is the average life span of a neutron (in seconds) from the time it is born until it is absorbed or leaks from the system. The generation time is the average time (in seconds) between successive neutron generations.

8.1.4.16 Energy of the Average Lethargy of Fission

The energy of the average lethargy of neutrons causing fission (*EALF*) is a parameter calculated in KENO to characterize the neutron energy spectrum or fastness of a system. The *EALF* is given in units of eV in the KENO output. An *EALF* value that is high (> 100 keV) indicates that most fissions in the system are being caused by fast neutrons, and an *EALF* value that is low (< 1 eV) indicates that most fissions are induced by thermal neutrons.

The *EALF* is calculated by determining the lethargy, u, a measure of how much neutron energy changes from its initial or birth energy:

$$u = ln\left(\frac{E_0}{E}\right), \tag{8.1.1}$$

where E is the energy of the neutron colliding with a nucleus and E_0 is the maximum possible energy of fission neutrons (assumed in KENO to be 10 MeV). The average lethargy of all fission events is calculated by weighting the lethargy for each collision by the probability that the collision will create a fission event, and averaging this quantity. Using a log-scale parameter like lethargy to represent the fastness of systems is more convenient than directly averaging the energy of neutrons causing fission both because of the wide range of neutrons in a problem (potentially more than seven orders of magnitude), and because fast neutrons that are slowing down lose about the same fraction of their energy during each collision.

$$EALF = E_o e^{-u_{\text{avg}}} \tag{8.1.2}$$

Equation Eq. (8.1.2) is then applied again to transform the average lethargy of neutrons causing fission into a neutron energy that corresponds to the average lethargy of neutrons causing fission (this is the *EALF*); this transformation back to units of energy is done because energy has a much more intuitive meaning than units of lethargy.

8.1.5 DESCRIPTION OF OUTPUT

This section contains a brief description and explanation of the KENO output. Portions of the printout will not be printed for every problem. Some printout is optional, as noted in this section. This section provides representative samples of the output format. The actual data contained in this section are not necessarily consistent with results computed by the current version of KENO.

KENO offers an HTML output format including a series of files that can be viewed in a standard web browser. The HTML formatted output offers interactive output that is easy to read and navigate. Many of the tables of data can be sorted in ascending or descending order by clicking on the heading of the column for which sorting is desired. In this section, the standard text output description is followed by a description of the optional HTML formatted output. The HTML formatted output can be deactivated by entering HTM=NO in the parameter data section.

Warning: The HTML-formatted output is no longer actively developed, and the output files created with it may therefore not include recently added capabilities or changes. For example, the fission rate mesh tally and some CE TSUNAMI edits are not included in the HTML output.

8.1.5.1 Program verification information

Program verification information Fig. 8.1.94 is printed after the header page. It lists the name of the program, the date the load module was created, the library that contains the load module, the computer code name from the configuration control table, and the revision number. The job name, date, and time of execution are also printed. This information may be used for quality assurance purposes.

Fig. 8.1.94: Sample program verification table.

The program verification information is the first page shown in the KENO HTML output, after selecting KENO from the SCALE HTML index page. This page can also be displayed by selecting the *Program Verification Information* link under the *General Information* submenu and is shown in Fig. 8.1.94.

8.1.5.2 Tables of parameter data

The first two tables printed by KENO list the numeric parameters and logical parameters used in the problem. The user should always verify that the parameter data block was entered as desired. An example of numeric parameters table is shown in Fig. 8.1.95. An example of the logical parameters table is shown in Fig. 8.1.96.

```

Fig. 8.1.96: Sample table of logical parameter data.

For the logical parameter data table, messages concerning the parameter data may be printed at the bottom of the table. If the problem is being restarted, the title of the parent case is printed at the bottom of the table. If

the restart title or messages are not printed, the bottom section of the table is omitted.

8.1.5.3 Unprocessed geometry input data

This printout is optional and is usually used to locate code difficulties, to show all the geometry input data when only part of it is used in the problem, or to show the order in which units were entered. It is considered debug information and is printed only if **PGM**=YES is specified in the parameter input data. Standard KENO use does not require printing these data because the processed geometry that is used in the problem is always printed. See Sect. 8.1.5.56.9 and Sect. 8.1.5.15 for examples of the standard printed KENO geometry data.

When the unprocessed geometry input is printed, the problem title is located at the top of the page, followed by the heading "GEOMETRY DESCRIPTION INPUT." The region-dependent geometry information is then printed. If the problem contains a unit orientation array, the problem title is printed again, followed by the unit orientation. This is followed by a statement affirming the completion of the data input.

8.1.5.4 Table of data sets used in the problem

This table is the third table of data printed by KENO. It should be carefully scrutinized to verify the desired data set name is associated with the proper unit number and volume. An example of this table is shown in Fig. 8.1.97.

Fig. 8.1.97: Sample table of data sets used in the problem.

This table lists unit numbers specified in the parameter data or that are defaulted in the code, along with the information pertinent to them. This information is given in the following order, left to right: (1) the keyword used in the parameter data to define the unit number, (2) the unit number, (3) the data set name, (4) the name of the volume on which the data set resides, and (5) the type of data contained on the data set. This table can be useful for quality assurance purposes. Information for units for which default values have not been overridden is printed even though they may not be used in the problem. Information for every unit specified in the parameter data is also printed. Units 8 and 10 are the direct-access devices, and their unit numbers are fixed within the code. When this table is printed, Unit 10 has not yet been defined. This causes its data set names to be listed as FT10F001 or as "UNKNOWN" on some systems. If KENO is run as part of a CSAS sequence, this table will include two entries for Unit 35: one for binary input data, and one for read restart data.

8.1.5.5 Table of additional information

The fourth table of data printed by KENO contains additional information determined from the input data. An example of this table is shown in Fig. 8.1.98.

This table should be used to verify the problem input. The NUMBER OF ENERGY GROUPS for a multigroup problem is read either from the Monte Carlo formatted library, identified by the keyword **XSC** and the unit function name MIXED CROSS SECTIONS from the Table of Data Sets in Sect. 8.1.5.4, or from the restart unit, identified by the keyword **RST** and the unit function name, READ RESTART DATA. The NO. OF FISSION SPECTRUM SOURCE GROUP is the number of different energy groups for which a fission spectrum is defined. In the present version, this number should always be 1. The NO. OF SCATTERING ANGLES IN XSECS is the number of scattering angles to be used in processing the cross sections. The default value is 3, and it may be overridden by specifying the parameter **SCT=** in the mixing table input. One scattering angle yields P_1 cross sections, two scattering angles yield P_3 cross sections, three scattering angles yield P_5 cross sections, etc.

```

Fig. 8.1.98: Sample table of additional information.

The NUMBER OF MIXTURES USED is the number of different mixtures (media) used in the geometry data used by the problem. This may be less than the total number of different mixtures specified in the geometry data if portions of the geometry data are not used in the problem.

The NUMBER OF BIAS IDS USED is the number of different biasing regions used in the problem. This will always be one unless a biasing data block is entered.

The NUMBER OF DIFFERENTIAL ALBEDOS USED is the number of different differential albedo reflectors used in the problem. This will always be zero unless the boundary condition data specify the use of differential albedo reflection on one or more faces of the system as described in Sect. 8.1.5.8. The BOUNDARY CONDITION data printed in this table should also be checked. The number of different differential albedos specified on the faces should be consistent with the NUMBER OF DIFFERENTIAL ALBEDOS USED. Specular, mirror, vacuum, and periodic are not differential albedos. Several different keywords may be used to specify the same differential albedo.

The TOTAL INPUT GEOMETRY REGIONS is the number of geometry regions specified in the problem input. This excludes UNIT label and comments provided using COM=, but it includes the array boundary description. It excludes the automatic reflector description, but it includes the geometry regions generated by it. The NUMBER OF GEOMETRY REGIONS USED is the number of geometry regions used in the problem. It may be less than or equal to the TOTAL INPUT GEOMETRY REGIONS. The LARGEST GEOMETRY UNIT NUMBER is the largest unit number defined in the geometry data, including unused units and implicitly defined units. Implicitly defined unit numbers are created when a core boundary specification is not immediately preceded by a specification. The unit number is assigned by the code by adding one to the largest unit number encountered in the geometry region data. For example, if two such core boundary specifications are contained in a problem whose largest explicitly defined unit number is 7, then a unit number of 8 is assigned to the first one, and a unit number of 9 is assigned to the second one. A value of 9 would be printed for the LARGEST GEOMETRY UNIT NUMBER. The LARGEST ARRAY NUMBER is the largest array number specified in the array data.

USE LATTICE GEOMETRY is determined by the logical flag that indicates whether or not the problem is a single unit problem. This should be YES for any problem that is not a single unit problem and NO for a single unit problem. By definition, a single unit problem does not use array data in any form. Sect. 8.1.5.14 describes array data. The GLOBAL ARRAY NUMBER is the number of the array designated as the global, overall, or universal array. The global array can be thought of as the array that defines the overall system.

The NUMBER OF UNITS IN THE GLOBAL X/Y/Z DIR. defines the size of the global array in terms of the number of units that are located along the edge of the array boundaries in the X/Y/Z directions. For a single unit, all three of these should be zero. For a simple $1 \times 1 \times 1$ array consisting of one unit type, all three of these numbers should be 1.

USE NESTED HOLES is set YES if holes are nested deeper than one level.

NUMBER OF HOLES is the number of HOLES that are entered in the geometry region data.

The MAXIMUM HOLE NESTING LEVEL is the deepest level of hole nesting.

USE NESTED ARRAYS is set YES if arrays are nested deeper than one level.

The NUMBER OF ARRAYS USED is the number of array descriptions actually used in the problem description.

MAXIMUM ARRAY NESTING LEVEL is the deepest level of array nesting.

BOUNDARY CONDITIONs are printed near the bottom of the table. They show the type of boundary condition that is applied to each surface of the system. These should all be VACUUM unless albedo boundary conditions are applied to one or more faces of the system. One should refer to the NUMBER OF DIFFERENTIAL ALBEDOS USED, as discussed previously in the description of this table of information.

The outer boundary of the global unit can consist of multiple shapes in KENO-VI geometry. For such a case, BOUNDARY CONDITIONS are printed for all shapes enclosing the global unit as shown in Fig. 8.1.99.

Fig. 8.1.99: Boundary conditions of a KENO-VI model in which combination of multiple shapes encloses the global unit.

Note: Boundary condition edit in Table of additional information does not list the surfaces added to each boundary body by CHORD operations.

8.1.5.6 Cross section data edits for the continuous energy mode

Unlike with the multigroup mode, KENO with continuous-energy mode loads each nuclide data directly from libraries. When loading data, Doppler broadening temperature correction (controlled by **DBX** parameter, see Sect. 8.1.7.2.19 for further details) is performed by default, on all nuclide cross sections, if the requested temperature is more than 4 K from the library temperature. If the Doppler broadening temperature correction is not enabled, then the nuclides' data are loaded from libraries with the closest temperature. When running KENO standalone, material temperatures can be entered by the **TEMP** parameter in the *MIXT data block*. When running KENO as part of a SCALE sequence, all material temperatures can be entered by each composition data definition in the *COMPOSITION data block*.

Cross sections data edits in KENO output summarize the data setup in the continuous-energy calculations. Examples of this summary are given in Fig. 8.1.100 and Fig. 8.1.101 for a sample continuous-energy calculation with and without Doppler broadening temperature correction.

This edit starts with printing the thermal energy cutoff utilized in the problem that, followed by a diagnostic edit, notifies that inverse velocity calculations have completed. In the next section, nuclide id, temperature at which data are being processed, and name of temperature-independent and -dependent cross section data files loaded are printed. When Doppler broadening temperature correction has been enabled (**DBX=** 2), one of the temperature-dependent data files used in this correction is printed as shown in Fig. 8.1.100. This is one of the caveats of this edit since full details of broadening are not listed here. Some messages from the cross section data loader related to broadening can be shown in the message file. After this section, nuclides

for which DBRC data loaded are listed if DBRC has been enabled in the calculations. Finally, elapsed time required for data processing (loading + broadening) is reported.

Fig. 8.1.100: Example of cross section data summary for continuous-energy mode (with DBX=2, DBRC=2)

When Doppler broadening temperature correction is turned off (**DBX=** 0), KENO loads the temperature-dependent data from libraries with the closest temperature and prints their names as shown in Fig. 8.1.101. KENO always notifies the user with a warning message as shown in Fig. 8.1.101 if there is a difference between the temperature at which data would be loaded and the closest temperature for which data has been loaded.

Fig. 8.1.101: Example of cross section data summary for continuous-energy mode (with DBX=0, DBRC=2)

Note: Mixture temperatures printed in the mixing table output edit discussed in the next section are the user-defined temperatures at which cross section data processing has been requested. On the contrary, **nuclide**

temperatures printed in the mixing table output edit show the exact temperatures utilized at which nuclide data are processed for the current calculation.

8.1.5.7 Mixing table data edits

If **LIB=** is entered in the KENO parameter data and a mixing table data block is provided to KENO, mixing table data will be printed. This output edit is not considered optional because it cannot be suppressed if the necessary data are present. There are some differences between the mixing table data edits for both multigroup and continuous-energy modes.

Multigroup mode mixing table data edit

Sample mixing table data for multigroup mode are shown in Fig. 8.1.102. In the HTML output, the mixing table data can be accessed with the *Mixing Table* link in the *Input Data* section.

The data printed in this table include the problem title, the number of scattering angles, and the cross section message threshold. Data are then printed for each mixture. First the mixture number, density, and temperature are printed, followed by a table of the nuclides which make up the mixture. This table contains the following data: nuclide ID number, nuclide mixture ID number, atom density, weight fraction of nuclide in mixture, ZA number, atomic weight, temperature, and nuclide title. Mixture temperature is the same as the nuclides' temperatures for the multigroup calculations. After all mixture data have been printed, a table of nuclides and descriptive titles is printed for all nuclides included in the mixtures. If extra 1-D cross sections were specified in the problem (see **X1D**=, Sect. 8.1.3.3), the extra 1-D cross section IDs will be printed under the heading "1-D CROSS SECTION ARRAY ID NUMBERS." If $\bar{\nu}$ is to be calculated (parameter **NUB**=YES), six MT numbers will be printed. The MT number for the total cross section (Σ_T) is 1; the MT number for the sum of the transfer array normalized by Σ_T is 2002; the MT number for the normalized fission-product cross section ($\nu\Sigma_f/\Sigma_t$) is 1452; the MT number for the normalized absorption cross section ($\sum_{abs}/\Sigma_T$) is 27; the MT number for the normalized fission cross section (Σ_f/Σ_T) is 18; and the MT number for the fission spectrum (χ) is 1018. χ is summed and normalized to 1.0. Other MT numbers in this list have been specified by the user. If the number of blocks on the direct access data set are insufficient to hold the cross section data, a message is printed stating THE NUMBER OF DIRECT ACCESS BLOCKS ON UNIT_____ HAS BEEN INCREASED TO ____. If the problem is to write a restart data set (parameter **RES**=), a message is printed stating that restart information was written, and the restart I/O unit number is specified. This is followed by a statement of the number of I/Os used in preparing the cross sections. The user should examine the mixing table carefully to verify that the proper nuclides are specified for the proper mixtures and that all the data are correct. The mixing table is printed in subroutine PRTMIX.

Note: See Sect. 8.1.4.4.4 for the details for the warning message printed in mixing table edit.

Continuous-energy mode mixing table data edit

In continuous energy mode, each mixture data is printed immediately after the problem title. For a mixture, first the mixture number, density, and temperature are printed, followed by a table of the nuclides which make up this mixture. Format of the nuclide edits in this table is same as the one used for multigroup mode, it contains the following data: nuclide ID number, nuclide mixture ID number, atom density, weight fraction of nuclide in mixture, ZA number, atomic weight, temperature, and nuclide title.

Sample mixing table data for continuous-energy mode are shown in Fig. 8.1.103. The nuclides' titles are relatively short compared to those for the multigroup mode since these data are not provided by AMPX, and KENO creates a short title while loading each nuclide data from the continuous-energy libraries.

```

Fig. 8.1.103: Example of mixing table data for continuous energy mode with **DBX=2**.

Unlike the multigroup calculations, mixture temperature may be different from the nuclides' temperatures for the continuous-energy calculations if Doppler broadening temperature correction is not enabled (setting **DBX=** to 0 disables the temperature correction) because the nuclides are loaded from libraries with the closest temperature. Fig. 8.1.104 is a sample mixing table data edits for such a case.

8.1.5.8 Albedo cross section correspondence

Printing the albedo cross section correspondence tables is optional. The headings for the tables are printed in subroutine CORRE, and then subroutine RATIO prints the data. These tables are printed only if **PAX**=YES is specified in the parameter data as described in Sect. 8.1.3.3. Examples of these tables are shown in Fig. 8.1.105 and Fig. 8.1.106.

The table shown in Fig. 8.1.105 contains, left to right, the cross section energy group, the lower and upper lethargy bounds, the corresponding albedo energy groups, and the cumulative probability associated with each albedo energy group for choosing the albedo energy group corresponding to the cross section energy group. The table shown in Fig. 8.1.106 is the inverse of the table shown in Fig. 8.1.105. It provides the cumulative probabilities for choosing the cross section energy group corresponding to the albedo energy group. The information in these tables is automatically generated by KENO.

xsec energy group	cross section group lethargy boundaries		cumulative probabilities for choosing the corresponding albedo group for each xsec group

Fig. 8.1.106: Cumulative probabilities for correlating the cross section energy group to the albedo energy group.

8.1.5.9 1-D macroscopic cross sections

The decision to print the 1-D mixture cross sections is optional. They are printed only if **XS1**=YES is specified in the parameter data. When the 1-D cross sections are to be printed, they are printed a group at a time for each mixture. The 1-D mixture cross sections for a mixture are shown in Fig. 8.1.107.

Fig. 8.1.107: Example of macroscopic 1-D cross sections.

When the 1-D mixture cross sections are printed, the problem title is printed at the top of the page. The mixture ID, mixture index, and mixture number are then printed. ID is the mixture number from the mixing

table, and mixture index is the index used to reference it and mixture number is its identifier. This step is followed by a heading to identify the different 1-D cross sections. *GROUP* is the energy group, *sigt* is the total cross section for the mixture, *sigs* is the nonabsorption probability, *siga* is the absorption probability, *signu* is the production probability, *chi* is the fission spectrum, *mwa1* is the pointer for the first position of the cross sections for the energy group, *mwa2* is the pointer for the last position of the cross sections for the energy group, and *mwa3* contains the group for the transfer corresponding to the first position. *SUM* is the sum of the absorption probability and the nonabsorption probability. The absorption probability is defined as the absorption cross section divided by the total cross section. The nonabsorption probability is the sum of the group-to-group transfers for this group, divided by the total cross section. The production probability is defined as the fission production cross section divided by the total cross section $\left(\nu\Sigma_f/\Sigma_T\right)$. The nonabsorption probability and the production probability are not true probabilities in that they may be greater than 1. This is because the nonabsorption probability has the (n,2n) transfer array summed into the total transfer array twice, and the (n,3n) is summed three times, etc.

8.1.5.10 Extra 1-d cross sections

Printing the extra 1-D cross sections is optional. They are printed if **P1D**=YES is specified in the parameter data. Extra 1-D cross sections are not used in KENO unless **NUB**=YES is specified in the parameter data or the user has altered the code to access and utilize other 1-D cross sections. If **NUB**=YES is specified, the extra 1-D cross section is the fission cross section, which is used to calculate the average number of neutrons per fission. This is printed only for fissile mixtures as shown in Fig. 8.1.107. The fission cross section heading follows the table of 1D cross sections. The fission cross section heading is XSEC ID 18, and it follows the table of 1-D cross sections.

8.1.5.11 2-D macroscopic cross sections

The decision to print the 2-D mixture cross sections is optional. They are printed only if **XS2**=YES is specified in the parameter data. They are printed after the 1-D cross sections for the mixture. A heading is printed, followed by the transfer data. An example of the 2-D mixture cross sections is given in Fig. 8.1.108.

Fig. 8.1.108: Example of 2-D macroscopic cross sections.

8.1.5.12 Probabilities and angles

Printing the probabilities and angles is optional. They are printed if the number of scattering angles is greater than zero and **XAP**=YES is specified in the parameter data. Examples of the probabilities are shown in Fig. 8.1.109. Examples of the angles are shown in Fig. 8.1.110. If the group-to-group transfer for a mixture is isotropic, the first angle for that transfer will be set to -2.0 as a flag to the code.

Fig. 8.1.110: Example of macroscopic angles.

8.1.5.13 Energy boundaries

KENO codes in the previous SCALE versions supported only single energy group boundaries used in all tally calculations. The energy group boundaries were obtained from the multigroup library used by transport process if the calculation mode is multigroup. These energy bounds may not be overridden by users in multigroup mode. In continuous-energy mode, energy group boundaries were defaulted to the library structure read from the SCALE 252-group multigroup library. The user could override the default energy boundaries either by defining the number of energy groups with **NGP** parameter, or by entering the energy points in **energy data** input block.

In SCALE 6.3, KENO codes can store multiple energy group boundaries; each may be used for different tallies. However, this capability is not enabled for standalone KENO calculations. If KENO is run as part of a CSAS or a TRITON sequence, then multiple energy boundaries can be entered in the **definitions data** input block available for these sequences (see Sect. 2.1.4.2.1).

Energy boundaries output edit always prints **DEFAULT** energy boundaries that are used in all tally calculations if it has not been otherwise requested. In multigroup mode, **DEFAULT** energy boundaries are always read from the multigroup library used by transport, and it cannot be overridden by the users. An example of energy boundaries output edit printed by a standalone multigroup KENO calculation is given in Fig. 8.1.111.

```
***** warning ***** keno message number k5-378 follows:
in multi group mode, DEFAULT energy boundaries used for tallying are always obtained from the multi group library used by
transport.

***** warning ***** keno message number k5-410 follows:
energy boundaries marked as DEFAULT will be used in all tally calculations if otherwise not requested.
```

Fig. 8.1.111: Example of energy boundaries output edit for multi group mode.

In continuous-energy mode, **DEFAULT** energy boundaries are defaulted to the library group structure of the SCALE 252-group library and can be overridden by (1) setting the number of energy groups with **NGP** parameter as shown in Example 8.1.44 and Example 8.1.45, (2) entering all energy points in **energy data** block Example 8.1.46, or (3) entering energy boundaries in the **definitions data** block (valid when running KENO codes as part of a sequence, see Sect. 2.1.4.2.1 for more details).

Example 8.1.44: Energy boundaries are set by NGP=11

```
...

read parameter
   ...
   NGP=11
end parameter

...
```

Example 8.1.45: Energy boundaries are set by NGP=8

```
...

read parameter
   ...
       NGP=8
end parameter

...
```

Example 8.1.46: Energy boundaries are read from energy data block

```
...

read energy
   2.e7 1.e5 1.e1 0.65 1.e-4
end energy

...
```

Three examples of energy boundaries output edits for continuous-energy KENO calculations are given in the Fig. 8.1.112, Fig. 8.1.113, and Fig. 8.1.114. In the first example, the energy boundaries constructed with having 11 equal lethargy intervals by setting **NGP=11** overwrites the **DEFAULT** energy boundaries. Fig. 8.1.113 shows the energy group output edits for a case in which the **DEFAULT** energy boundaries are overridden by the energy boundaries read from the SCALE 8 group test library that was provided by setting **NGP=8**. And the **DEFAULT** energy boundaries are overridden in the last example whose output edit shown in Fig. 8.1.114 by reading the energy boundaries from the **energy data** input block.

Fig. 8.1.115: Example of array summary.

The ARRAY NUMBER is the number by which the array is designated in the input data. The number of units in the X, Y, and Z directions is listed for each array. The NESTING LEVEL indicates the level of nesting for each array. The global, overall, or universe array is flagged by the word GLOBAL. The global array should always appear at the first nesting level. Arrays that have been placed in the global reflector by using holes should also appear at the first nesting level. A nesting level of one is the highest or first nesting levels. The larger the number in the nesting level column, the deeper the nesting level will be.

8.1.5.15 Geometry data edits

KENO V.a geometry edit

The geometry region data used by the problem are always printed and cannot be suppressed. They should be carefully examined by the user to verify the mixture number, bias ID, and geometry specifications used in the problem. If geometry region data are entered but are not referenced in the unit orientation array data, they will not be printed here. An example would be to enter geometry region data describing Units 1, 2, 3, and 4 and to use only Units 1, 3, and 4 in the unit orientation array. Then the geometry region data for Unit 2 will not be printed. An example of the KENO V.a geometry region printout for a problem is given in Fig. 8.1.116.

The problem title and a heading are printed at the top of each page. REGION is the region number within a unit. Each unit has its regions numbered sequentially, beginning with one. MEDIA NUM is the mixture number or mixture ID that occupies the volume defined by the region. BIAS ID is the bias ID that corresponds to the desired set of weight average for biasing the region. The unit number is printed at the top of each unit's geometry region description near the center of the page. The data printed for each geometry region include (1) the region number relative to the unit (numbered sequentially within the unit), (2) the shape of the geometry region, (3) the mixture ID of the material within the volume defined by the region, (4) the bias ID to define the average weight of a neutron in the region, and (5) the dimensions defining the outer boundaries of the geometry region. If additional geometry surrounds an array, a heading is printed stating: UNIT ____ EXTERNAL TO LATTICE ____. The lattice number is the number of the array that is surrounded by the specified geometry. The unit number is the unit that contains the specified geometry. In the case of an external reflector for the global array, the unit number is assigned by the code.

```

Fig. 8.1.116: Example of KENO V.a geometry region data

KENO-VI geometry edit

The geometry region data utilized by the problem are printed and cannot be suppressed. They should be carefully examined by the user to verify the mixture number, bias ID, and geometry specifications used in the problem. If geometry region data are input but are not referenced in the unit orientation array data, they will not be printed here. An example would be to input geometry region data describing Units 1, 2, 3, and 4 and to utilize only Units 1, 3, and 4 in the unit orientation array. Then the geometry region data for Unit 2 will not be printed. An example of the geometry region printout for a problem is given in Fig. 8.1.117 and Fig. 8.1.118.

First, a table of geometry parameters for the problem is printed. This specifies the overall size of the problem, number of components in the problem, and the size of the array needed to store the geometry. Next, the quadratic equations by unit are printed. The problem title and a heading are printed at the top of each page. The unit number followed by the GEOMETRY data for that unit is then printed. Each geometry record type used in the unit, numbered in the order they appear in the unit, is printed out. Following each geometry record type is the set of quadratic equations that describe the input geometry for that geometry record. The CONTENTS data, consisting of four columns, are then listed in the order they appear in the problem. The first column contains the content keyword. The second column contains the media/hole/array number. The third column labeled IMP contains the bias ID number if the content keyword is MEDIA. Otherwise, this column is blank. The fourth column contains the sector definition array, which describes the region location relative to the GEOMETRY records listed above for that unit.

The data consisting of the unit number, GEOMETRY data, and CONTENT data are repeated for each unit used in the problem. The global unit has a heading printed before the unit number to identify it as the global unit.

8.1.5.16 Unit orientation description

Each unit orientation description defines the location of units in the 3-D lattice that represent the specified array. The array described is identified in the heading UNIT ORIENTATION DESCRIPTION FOR ARRAY ____. The arrays used in the problem are stacked together to represent the physical problem being analyzed. The unit orientation description is not printed if only Unit 1 is described in the problem. The user should carefully examine the unit orientation descriptions to ensure proper placement of the units in each lattice. A sample unit orientation description is shown in Fig. 8.1.119 .

Fig. 8.1.119: Example of unit orientation description.

If a very large array is used by the problem, its unit orientation description may be spread over several pages. When checking the printout, the user should pay careful attention to the headings that indicate the portion of each lattice being printed. The detailed printout of an array may be suppressed using the ARRAY parameter **PRT=no**.

8.1.5.17 Volume information

The volume information printout differs between KENO V.a and KENO-VI. Because it does not allow intersections of bodies, KENO V.a is always able to calculate analytically the volume of any region in the geometry. KENO-VI, on the other hand, never calculates volumes analytically. In fact, KENO-VI never calculates volumes unless it is directed to do so, but it can read volumes off the **MEDIA** cards or off a **VOLUME** file (Sect. 8.1.3.13).

KENO V.a volume edit

Three tables of volumes are always printed and cannot be suppressed. The problem title is printed at the top of the page, followed by the heading "VOLUMES FOR THOSE UNITS UTILIZED IN THIS PROBLEM." An example of the volume printout is given in Fig. 8.1.120.

The first table is arranged by ascending unit number. It includes (1) the unit number, (2) the region number within the unit, (3) the overall geometry region number, (4) the net volume of each individual region, and (5) the cumulative volume through each region in the unit. The cumulative volume of the last region in a unit is the total volume of the unit. The unit number is printed under the heading UNIT. Data listed under the heading REGION refer to the number of the geometry region within the unit. The geometry regions within a unit are numbered sequentially starting with 1. Data entered under the heading GEOMETRY REGION refer to the entry number of the individual geometry region. These are numbered sequentially, starting with 1, through the TOTAL INPUT GEOMETRY REGIONS defined in Fig. 8.1.120. The net volume of each individual region is calculated by subtracting the volume of the interior region from the volume of the region and is listed under the heading VOLUME. The data listed under the heading CUMULATIVE VOLUME are calculated from the dimensions of the region. A simple example demonstrating how volumes are calculated can be given by assuming a unit that is composed of three concentric cubes. Region 1 is a cube 3 cm on a side, region 2 is a cube 4 cm on a side, and region 3 is a cube 5 cm on a side. The cumulative volume of region 1 is 27 cm^3 (3^3); the cumulative volume of region 2 is 64 cm^3 (4^3); the cumulative volume of region 3 is 125 cm^3 (5^3). The volume of region 1 is 27 cm^3 (3^3), the volume of region 2 is 37 cm^3 (64 - 27), and the volume of region 3 is 61 cm^3 (125 - 64).

```

Fig. 8.1.120: Sample volume information.

The second table contains (1) the unit number, (2) the number of times the unit is used in the problem, (3) the region number within the unit, (4) the mixture number present in the region, and (5) the total volume associated with the region in the whole problem. The unit number is printed under the heading UNIT, data printed under the heading USES indicates the number of times the unit is used in the problem. Data printed under the heading MIXTURE indicates the mixture number used in the region. The total volume of each region is printed under the heading TOTAL VOLUME and is determined by multiplying the VOLUME of the region listed in the first table by the number of times the unit containing that region is used in the problem.

The third table is printed following the heading “TOTAL MIXTURE VOLUMES.” In this table, the mixtures

used in the problem are listed with their associated total volume and total mass. The mixture numbers are printed under the heading MIXTURE, the total volume of each mixture is printed under the heading TOTAL VOLUME, and the mass of each mixture is printed under the heading MASS(G). All masses will be printed as zero if the working format cross section library does not contain the data required to calculate the densities of the mixtures used in the problem.

KENO-VI volume edit

Two tables of volumes are printed by subroutine VOLUME and cannot be suppressed. The first table will list the number of times each unit is used in the problem and the total volume of each region throughout the entire problem description. The second table will list the total volume and mass of each mixture used in the problem.

If a volume calculation type of NONE is specified and no volumes are read in for the regions, then the volumes will be set to -1.0, which will result in negative fluxes and fission densities. A sample volume output edit for such a case is given in Fig. 8.1.121. Calculations with zero volumes always provide a notification with a warning message as shown in Fig. 8.1.121.

 ***** warning ***** keno message number k6-239 follows:
 The volumes for all regions are not set.
 Some region volumes are not set by input, not in the space for which volumes are calculated,
 missed by the volume calculation, or actually 0.0. For these regions, volumes are set to -1.0
 and the fluxes and fission densities are divided by -1.0 instead of the real volume.
```

Fig. 8.1.121: Sample volume information (volumes are neither defined nor calculated).

For the calculated volumes, an error estimate is printed after the volumes. A summary of the parameters used in both **TRACE** and **RANDOM** volume estimates and some diagnostic information is always printed before the first table if any region volume is calculated by one of these methods. Two examples of the KENO-VI volume output edits with these volume calculation methods are given in Fig. 8.1.122 and Fig. 8.1.123, respectively.

```

Fig. 8.1.123: Sample volume information, undefined volumes are calculated by TRACE estimate.

The unit number is printed under the heading **UNIT**. The REGION refers to the number of the geometry region within the unit determined by the order of the CONTENT records in the unit. USES indicates the number of times the unit is used in the problem. MIXTURE is the mixture number used in the region. A blank indicates an array or unit, placed in a hole, in that region. TOTAL VOLUME is the total volume of that region followed by +/- and an error estimate if the volume for the region was calculated.

If mesh volumes are used, there will be a table listing the cumulative volumes generated by summing the mesh volumes, the deviations, and the deltas between the summed volumes and the overall volumes for the regions. If the overall volume has been calculated, then the delta should be zero, but if it was entered, then the delta will show the difference.

In the last table, the mixtures used in the problem are listed along with their total volumes and masses. Along with the total volumes and masses, an error estimate is printed for any mixtures having regions that were calculated using either the **RANDOM** or **TRACE** volume estimates..

8.1.5.18 Mesh volumes output edit

With the mesh flux accumulator, fluxes are tabulated for each region of each unit in the defined mesh grid. KENO computes the volume of each region in each mesh interval so that fluxes per unit volume can be determined. For KENO V.a models where the mesh flux accumulator is activated by setting **MFX**=YES and either (a) the mesh size set to a positive value with **MSH**=, or (b) mesh grid defined by **grid geometry data** input, a mesh volume sampling summary and the cumulative volume of all mesh intervals for a given region are printed as shown in Fig. 8.1.124. Details of mesh grid 20001 on which a mesh volume calculation was performed are printed in the *grid definitions* output edit. An example of grid definitions output edit can be shown in Sect. 8.1.5.19.

Note that KENO V.a allows users to alter the default settings for the mesh volume calculation. However, **TRACE** volume estimate is not available for mesh volume; therefore, the **RANDOM** volume estimate is always enforced when *type=trace* is entered in **volume data**. A corresponding warning message (message number k?=370) is printed in the output to notify the user about this change.

Fig. 8.1.124: Sample sum of mesh volumes edit (KENO V.a with cubic mesh, MSH=20.0).

Note: Unlike the KENO V.a implementation, mesh flux accumulation with KENO-VI always needs a **volume data** input block to activate the mesh volume calculation; otherwise, calculation is terminated with an error message. KENO-VI does not support mesh volume calculation with **TRACE** volume estimation. Just as KENO V.a does, KENO-VI continues by using the **RANDOM** volume estimation for the mesh volume calculation.

An optional edit of volumes for each mesh interval for each region can be activated by entering **PMV**=YES

in the parameter input. This edit can be very large, especially if a small mesh size is used with a large model. A sample of the volume by mesh for each region is shown in Fig. 8.1.125.

8.1.5.19 Grid definitions

This table specifies the mesh grids to be used in the problem. Each mesh grid is either defined by the **MSH** parameter and/or **grid geometry data** input, or constructed internally. An example of grid information is given in Fig. 8.1.126.

```

                              **** Grid geometries utilized in this problem ****

Grid geometries specified with Ids = (12 and 15) have identical grid definitions.
Only below specification is stored and all grid geometries with Ids listed above will point to this:

Grid Geometry: 12
    title: test fission rate mesh tally

```

Fig. 8.1.126: Sample of grid definitions.

Grid definitions output edit lists all user-defined and internally constructed mesh grids, even some that are not used for any mesh tally. Only one of the grids is stored in the grid data container if the multiple grids are defined with identical grid data. This can be easily seen in the diagnostic messages followed by *grid definitions* header as well as the messages printed just before each stored grid entry. The sample grid definitions shown in Fig. 8.1.126 specify that two mesh grids with grid **IDs=** 12 and 15 were defined by two **grid geometry data** inputs, but only one of them was stored since their definitions were identical. A default mesh grid was also shown in Fig. 8.1.126 that was constructed for Shannon entropy tallies.

8.1.5.20 Biasing information

This table specifies the weighting or biasing data to be used in the problem. An example of biasing information is given in Fig. 8.1.127.

```

```

Fig. 8.1.127: Biasing information.

The user is responsible for determining from the input data whether the group-dependent weights (wtavg) for the specified material(s) were obtained from the weighting library or were entered by the user. The group-dependent weights can be printed for verification purposes as shown in Sect. 8.1.5.21.

8.1.5.21 Group-dependent weights

Printing the group-dependent weights is optional. They are printed if **PWT**=YES is entered in the parameter data. An example of the printed group-dependent weights is shown in Fig. 8.1.128.

Fig. 8.1.128: Example of biasing data.

The title is printed at the top of the table. The average weight (wtavg) is printed for each energy group and each BIAS ID. The BIAS ID number printed at the top of the column corresponds to the BIAS ID used in the geometry region description or MEDIA record and printed in the biasing information.

8.1.5.22 Plot representation

Plots representing 2-D slices through the geometrical description of the problem are optional. They are created if plot data are entered unless **PLT**=NO is specified either in the plot data or the parameter data. Plots can be generated and displayed as (1) character plots with alphanumeric characters representing mixture numbers, unit numbers, or bias ID numbers or (2) color plots with colors representing mixture numbers, unit numbers, or bias ID numbers. Color plots generate a PNG file and require an independent program to be displayed.

An example of the output generated using the character plot method is given in Fig. 8.1.129 and Fig. 8.1.130. An example of the output generated using the color plot method is given in Fig. 8.1.131 and Fig. 8.1.132.

Fig. 8.1.129: Summary of character plot symbols, coordinates, and data.

Fig. 8.1.129 summarizes the data used to generate the character plot. Fig. 8.1.130 is an example of a character plot of the 2-D slice specified through the geometrical description of the problem. In Fig. 8.1.129, the plot title is printed at the top of the page, followed by a statement that "THE FOLLOWING WILL BE A CHARACTER PLOT." If a plot title was not entered in the plot data, the plot title is defaulted to the problem title. The title is followed by a heading specifying the type of plot (MIXTURE MAP, BIAS ID MAP, or UNIT MAP). This is followed by a table that correlates the symbols to be used in the character plot with the mixture numbers, bias ID numbers, or unit numbers that were used in the problem. If the problem is a bare array, the overall system coordinates are printed. Then the coordinates of the upper left corner and lower right corner of the plot are printed. This is followed by the direction cosines down and across the plot. The remaining plot parameters (including both input data and calculated values) are then printed. NU is the number of characters printed in the U (down) direction, NV is the number of characters printed in the V (across) direction, DELU is the incremental distance, in cm, represented by each character in the U (down) direction, DELV is the incremental distance, in cm, represented by each character in the V (across) direction, and LPI is the vertical to horizontal scaling factor for plot proportionality.

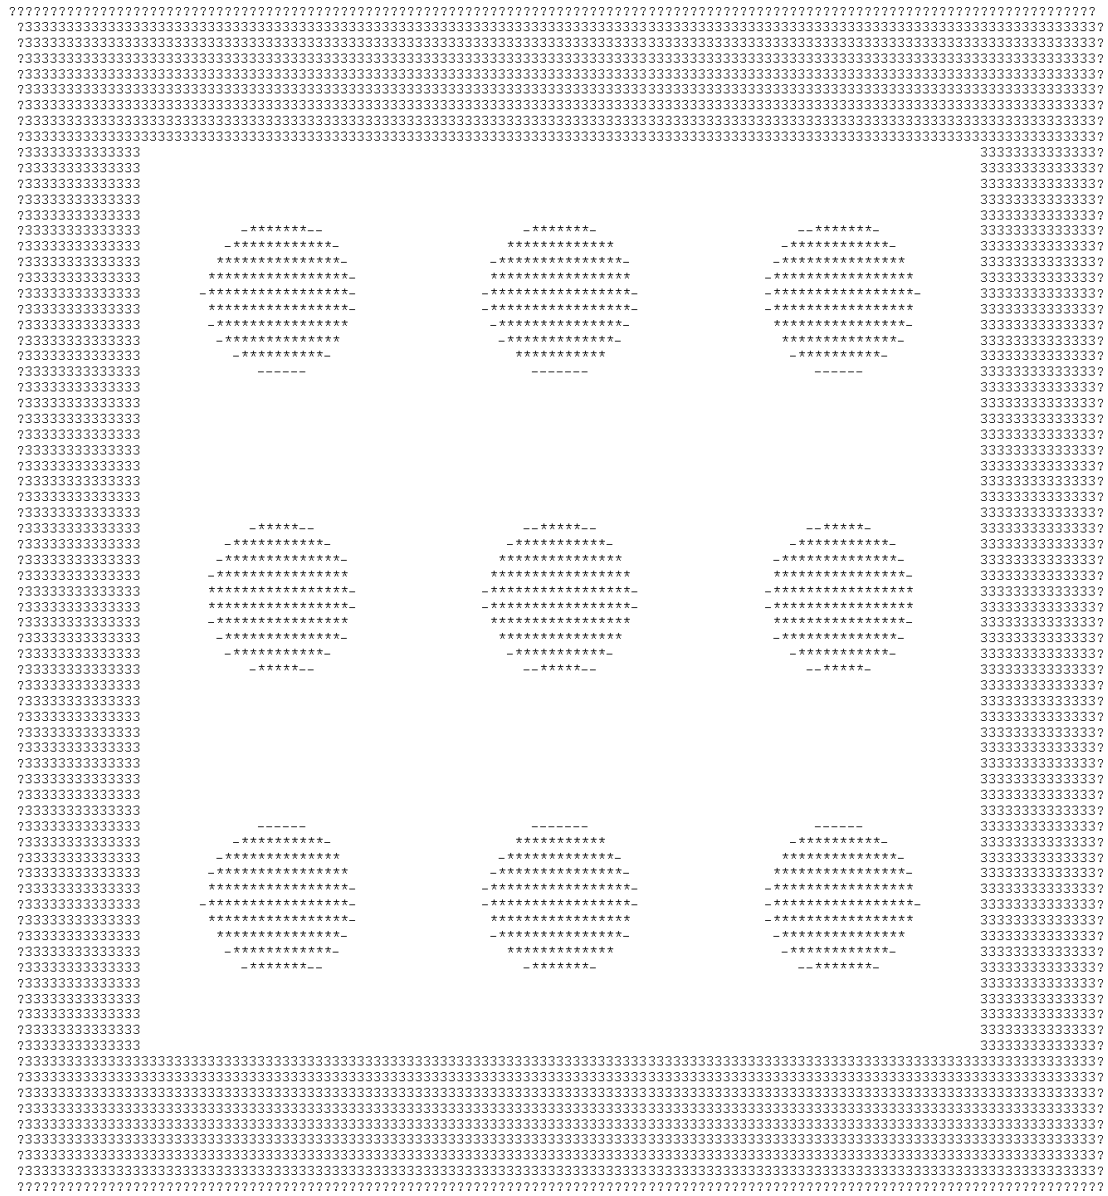

Fig. 8.1.130: Sample character plot representation.

Fig. 8.1.130 shows a character plot of a 2-D slice specified through the geometrical description of the problem. These plots aid the user in verifying that the problem is described correctly. Any number of plots can be made in one problem.

Fig. 8.1.131 summarizes the data used to generate the color plot. Fig. 8.1.132 is an example of a color plot of the 2-D slice specified through the geometrical description of the problem. This plot does not appear in the KENO printout. It is generated from a PNG file that is created when a color plot has been specified in the KENO input data and requires special processing by the user.

In Fig. 8.1.131, the plot title is printed at the top of the page, followed by a statement that "THE FOLLOWING WILL BE A COLOR PLOT." If a plot title was not entered in the plot data, the plot title is defaulted to the

problem title. The title is followed by a heading specifying the type of plot (MIXTURE MAP, BIAS ID MAP, or UNIT MAP). If the problem is a bare array, the overall system coordinates are printed. Then the coordinates of the upper left corner and lower right corner of the plot are printed. This is followed by the direction cosines down and across the plot. The remaining plot parameters (including both input data and calculated values) are then printed. NU is the number of characters printed in the U (down) direction, NV is the number of characters printed in the V (across) direction, DELU is the incremental distance, in cm, represented by each character in the U (down) direction, DELV is the incremental distance, in cm, represented by each character in the V (across) direction, and LPI is the vertical to horizontal scaling factor for plot proportionality.

Fig. 8.1.131: Summary of color plot symbols, coordinates, and data.

Fig. 8.1.132 shows an example of a color plot of a 2-D slice specified through the geometrical description of the problem. Any number of plots can be made in one problem. The color plots can be valuable tools to assist the user in verifying that a problem is described correctly.

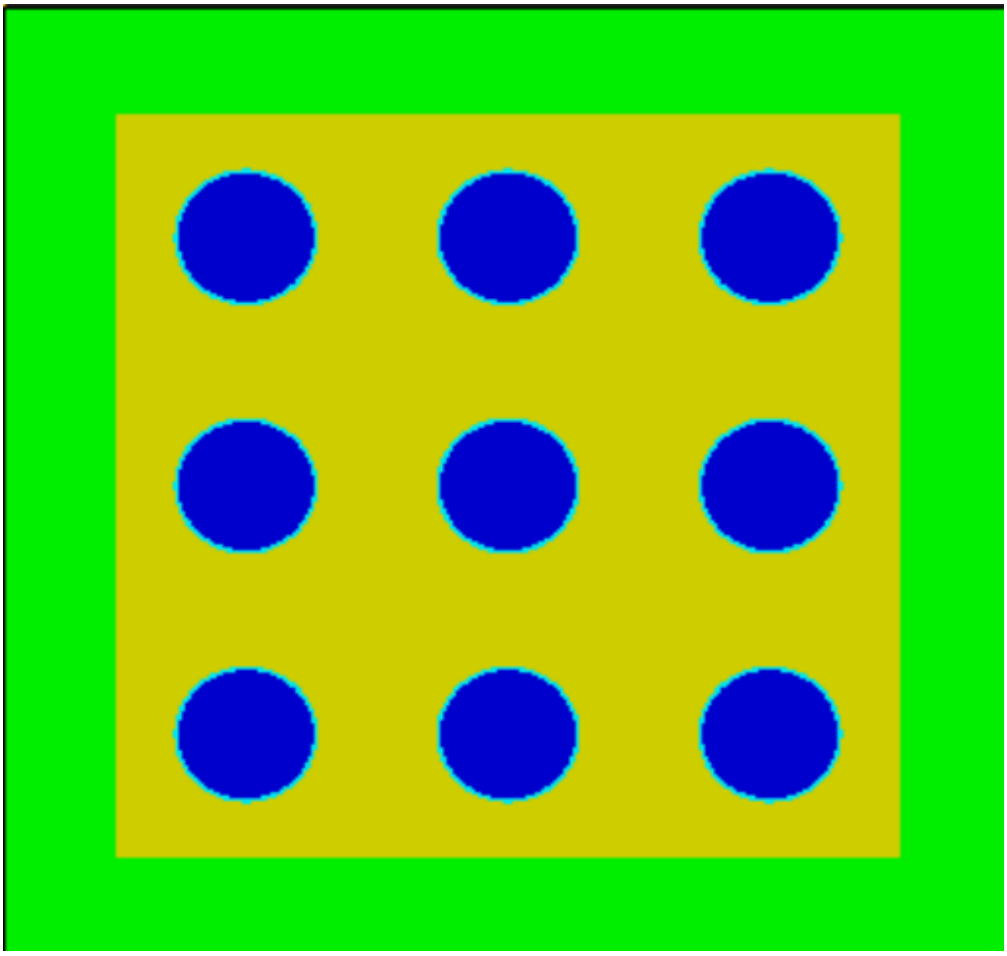

Fig. 8.1.132: Sample color plot representation.

8.1.5.23 Initial source and final pretracking edits

Prior to calculating the *keff* values for each generation, KENO prints the number of I/Os used before tracking and the number of minutes used processing the data. If the problem is not a restart problem, initial source information follows those two lines as shown in both Fig. 8.1.133 (KENO V.a example) and Fig. 8.1.134 (KENO-VI example).

The VOLUME FRACTION OF FISSILE MATERIAL IN THE SYSTEM is the first line of data printed for KENO V.a case. This is followed by the start type, other data used to generate the initial source distribution, and finally, the amount of time used to generate the initial source distribution and the total elapsed time. Fig. 8.1.133 illustrates starting information printed for start type 0. The cuboid for choosing starting points is (1) the bounding box around the global array (either bare or reflected) (2) the overall system if the outermost region is a cuboid, or (2) a cuboid specified by the user via the keywords **XSM**=, **XSP**=, **YSM**=, **YSP**=, **ZSM**=, and **ZSP**=.

Fig. 8.1.133 illustrates typical starting data for start type 0 (a flat start in fissile material). The parameter used in this example was **NST**=0.

```
                              ........ finished in KENO-V.a before tracking       ........

                              ........     0.00017 minutes were used processing data.        ........

volume fraction of fissile material in the system= 1.00000E+00

start type 0 was used.

the neutrons were started with a flat distribution in a cuboid defined by:
                      +x= 3.00000E+00  -x=-3.00000E+00  +y= 1.00000E+00  -y=-1.00000E+00  +z= 2.00000E+00  -z=-2.00000E+00

  0.00017 minutes were required for starting.   total elapsed time is   0.00033 minutes.
```

Fig. 8.1.133: Example of initial source information for start type 0 (KENO V.a).

In KENO-VI case, the first line is a warning message followed by the VOLUME FRACTION OF FISSILE MATERIAL IN THE SYSTEM line. This warning message notifies users about the potential issues that might be encountered when the volume fraction of fissile material in the system is calculated, especially for the cases in which volumes are partially defined or computed. In such cases, the volume fraction of fissile could be a negative values since KENO-VI resets the undefined volumes to -1.0.

This message is followed by the start type, other data used to generate the initial source distribution, and finally, the amount of time used to generate the initial source distribution and the total elapsed time. Fig. 8.1.134 illustrates the starting information printed for start type 0.

```
                              ........ finished in KENO-VI before tracking       ........

                              ........     0.00017 minutes were used processing data.        ........

 ***** warning ***** keno message number k6-380 follows:
 Calculated volume fraction of fissile material in the system reported below may not reflect
 the actual value since some region volumes were neither specified nor calculated. Even negative
 volume fraction for fissile material may be reported since all undefined volumes were set to -1.0.

volume fraction of fissile material in the system= 1.00000E+00

start type 0 was used.

the neutrons were started with a flat distribution in a cuboid defined by:
                      +x= 3.00000E+00  -x=-3.00000E+00  +y= 1.00000E+00  -y=-1.00000E+00  +z= 2.00000E+00  -z=-2.00000E+00

  0.00000 minutes were required for starting.   total elapsed time is   0.00017 minutes.
```

Fig. 8.1.134: Example of initial source information for start type 0 (KENO-VI).

8.1.5.24 Reference center for flux moment/angular flux transform

When **TFM**=YES is entered, the flux moments and angular fluxes are computed in a transformed coordinate system, relative to a "reference center" point. The default position for the reference center is the center of all fueled regions in the model. However, the center can be specified by the user for each region defined in the system model using the "center" modifier on a region input card. Edits of the fuel center and the position of the reference center for each region are shown when **TFM**=YES as shown in Fig. 8.1.135.

```
Fuel Center is x= 6.5307E+01, y= 1.7801E+01, z= 4.8576E+01 Relative to the Global Unit

                                reference center for flux moment/angular flux transform

8.1.5.25 Print starting points

This printout is optional and is used to verify the initial source starting points. This option is activated by specifying the parameter **PSP**=YES in **start data** block, and it is valid with all start types available. Examples of this information are given in Fig. 8.1.136.

The information pertinent to the initial source distribution is printed three lines at a time and appears under the designated headings. For example, the coordinates X, Y, and Z are printed on one line, the direction cosines U, V, and W are printed directly under them, and the global coordinates XGBL, YGBL, and ZGBL on the last line. The data printed for each source neutron include the following:

NEUTRON is the ID number of the neutron.

X, Y, and Z are the coordinates of the starting point relative to the coordinate system of the unit.

WT is the starting weight (WT is always 1.0 for a neutron when it is started).

K is the region number that contains the point X, Y, Z.

NOW is the array number.

NBX, NBY, NBZ are the coordinates of the unit within the array.

LL is the unit number located at NBX, NBY, NBZ.

KR is the mixture number present at the starting point.

KI is the bias ID number or importance region at the starting point.

KCOR is the region in the unit that contains the array where the neutron is located.

U, V, and W are the direction cosines defining the direction the history is traveling.

IG is the energy group.

K1 is the region number of the first region in unit LL.

K2 is the region number of the last region in unit LL.

IGEO is an integer that defines the geometry shape of the region.

KCOL is the region number in which the last collision occurred.

RANDOM NUMBER is the current random number.

XGBL, YGBL, ZGBL are the coordinates of the starting point relative to the coordinate system of the **global unit**.

UGBL, VGBL, WGBL are the direction cosines defining the direction the history is traveling in the global coordinate system.

Note: When starting points are printed, **many of the above named variables have not been initialized**. For example, RANDOM NUMBER does not reflect the random number used to sample the starting point whose details are printed.

For starting, the variables of interest are X, Y, Z, NBX, NBY, NBZ, LL, XGBL, YGBL, and, ZGBL.

```
  starting points will be printed using the debug tracking format because start parameter psp= was entered as yes.
  neutron is the id number of the neutron.
  x, y and z are the coordinates of the starting point.
  wt is the starting weight.
  k is the region number.
  now is the array number.
  nbx, nby and nbz define a location in the now array.
  ll is the unit number at location nbx, nby, nbz.
  kr is the media or mixture number in region k.
  ki is the importance region.
  kcor is the region number surrounding the now array.
  u, v and w are the direction cosines defining the direction.
  ig is the energy group.
  k1 is the region number of the first region in unit ll.
  k2 is the region number of the last region in unit ll.
  igeo defines the geometry of region k.
  kcol is the region number of the last collision.
  random number is the current random number.
  xgbl, ygbl, and zgbl are the global coordinates of starting point.
  ugbl, vgbl, and wgbl are the direction cosines in the global coordinate system.

 1where    neutron            x             y             z             wt          k  now  nbx  nby  nbz   ll   kr   ki kcor

 keno message number k5-123          execution terminated due to completion of the specified number of generations.

 the matrix k-effective is the largest eigenvalue of the fission production by unit number matrix.
```

Fig. 8.1.137: Example of k-effectives and source entropy by generation.

The data printed include (1) the generation number, (2) the k-effective calculated for the generation, (3) the average value of k-effective through the current generation (excluding the *nskip-1* generations), (4) the deviation associated with the average k-effective, (5) Shannon entropy for the generation, (6) the matrix k-effective for the generation, and (7) the deviation associated with the matrix k-effective. Column 5 is omitted if the user disabled source convergence diagnostics. The last two columns are filled with zeros if the user did not specify matrix k-effective calculations. The matrix k-effective is the largest eigenvalue of the fission production matrix. Matrix information can be calculated based on (1) position index, (2) unit number, (3) hole number, and (4) array number. The matrix k-effective printed in the sixth column is based on this order. If the matrix k-effective is calculated by position index, it is the one printed in the sixth column. The matrix k-effective by unit number is given second preference, followed by hole number and then array number.

After the last generation, a message is printed to indicate why execution was terminated. If matrix k-effectives were calculated, this is followed by a message stating the method used to determine the matrix k-effective.

The user should examine this portion of the printed results to ensure that the two methods of calculating k-effective are in acceptable agreement and to verify that the average value of k-effective has become relatively stable. If the k-effectives appear to be oscillating or drifting significantly, then the user should consider rerunning the problem with a larger number of histories per generation.

If a problem is restarted, then the generation numbers and k-effectives are printed and the words FROM RESTART UNIT are printed in the elapsed time column. All other columns are blank. When the generation at which the problem is to be restarted is reached, the print reverts to the normal format as shown in Fig. 8.1.137.

8.1.5.27 Problem characterization edit

The problem characterization edit follows the k-effective by generation edit. The title is printed at the top of the page, followed by the lifetime and the generation time and their associated deviations. The lifetime is the average lifespan of a neutron (in seconds) from the time it is born until it is absorbed or leaks from the system. The generation time is the average time (in seconds) between successive neutron generations. If **NUB**=YES is specified in the parameter data, (Sect. 8.1.3.3) the average number of neutrons per fission, NU BAR, and its associated deviation are printed and the AVERAGE FISSION GROUP (the average energy group at which fission occurs) and its associated deviation are printed. Then the ENERGY(EV) OF THE AVERAGE LETHARGY OF NEUTRONS CAUSING FISSION and its associated deviation are printed, followed by the system mean free path. If **SMU**=YES is specified in the parameter data, the average self-multiplication of a unit and its associated deviation is printed. This self-multiplication results from fissions caused by neutrons born in the unit. Fissions caused by neutrons that exit the unit and return are not included. The problem characterization edit is shown in Fig. 8.1.138.

8.1.5.28 Final k-effective edit

The final k-effective edit prints the average k-effective and its associated deviation and the limits of k-effective for the 67, 95, and 99% confidence intervals. The number of histories used in calculating the average k-effective is also printed. This is done skipping various numbers of generations. The user should carefully examine the final k-effective edit to determine if the average k-effective is relatively stable. If a noticeable drift is apparent as the number of initial generations skipped increases, it may indicate a problem in converging the source. If this appears to be the case, the problem should be rerun with a better initial source distribution and should be run for a sufficient number of generations that the average k-effective becomes stable. The final k-effective edit is printed as shown in Fig. 8.1.139.

no. of initial generations skipped	average k-effective	deviation	67 per cent confidence interval	95 per cent confidence interval	99 per cent confidence interval	number of histories	deviation of variance (per cent)

Fig. 8.1.139: Example of the final k-effective edit.

8.1.5.29 Plot of average k-effective by generation run

This plot consists of average k-effectives plotted versus the number of generations run. The limits of one standard deviation are plotted on either side of each average k-effective. These average k-effectives are not necessarily the same as the average k-effectives described in Sect. 8.1.5.26. The code omits the k-effectives of the first *nskip* generations when the average k-effectives for this plot are calculated. Although the k-effective of the *nskip* generation is summed into the average k-effective, it is not plotted because standard deviations cannot be calculated for a single point. Thus, if *nskip* is 3 (i.e., the first three generations are skipped), the first value plotted is the average k-effective corresponding to the fifth generation. The dotted line represents the value of the average k-effective corresponding to the smallest deviation when the average k-effective and its deviation are computed for each generation over the range of *nskip* through the total number of generations.

Fig. 8.1.140 is an example of this type of plot in the text output. The primary use for this plot is to determine if the problem has source convergence difficulties.

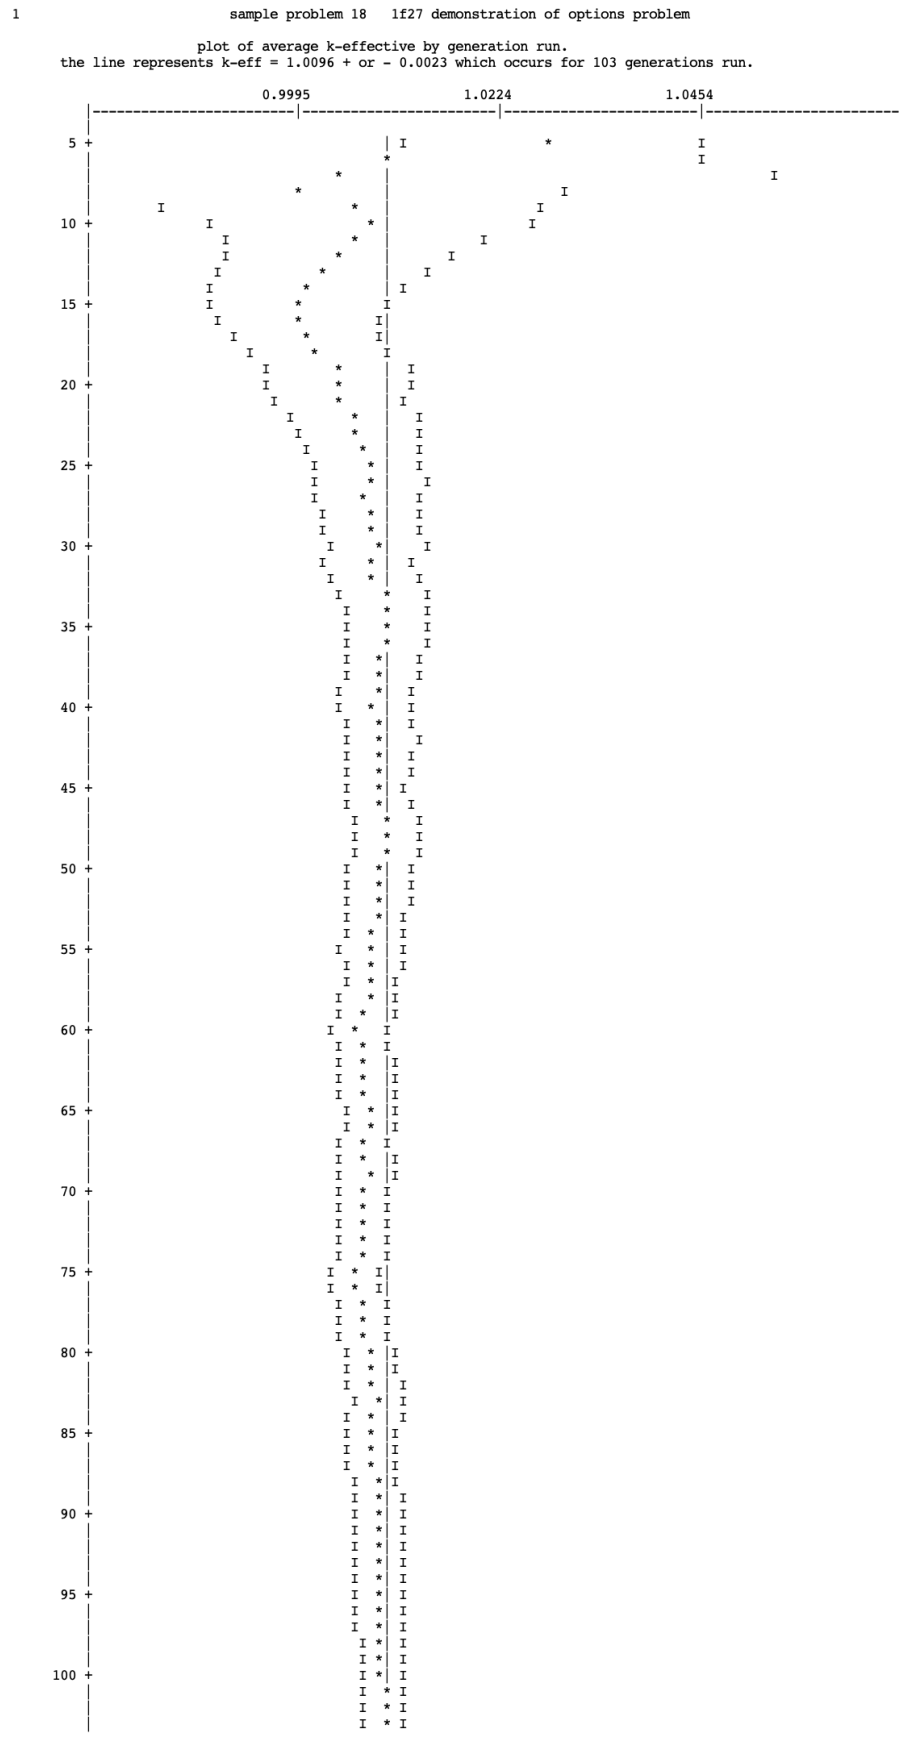

Fig. 8.1.140: Sample plot of average k-effective by generation run.

8.1.5.30 Plot of average k-effective by generations skipped

This plot illustrates the average k-effective versus the number of generations skipped as shown in Fig. 8.1.141. The limits of one standard deviation are plotted on either side of the average k-effective. The dotted line represents the value of the average k-effective corresponding to the smallest deviation when the average k-effective and its deviation are computed for the number of generations skipped over the range of *nskip*+1 through $^2/_3$ the total number of generations calculated. The plot is essentially a plot of the data described in Sect. 8.1.5.28. It is useful for determining if source convergence has been achieved.

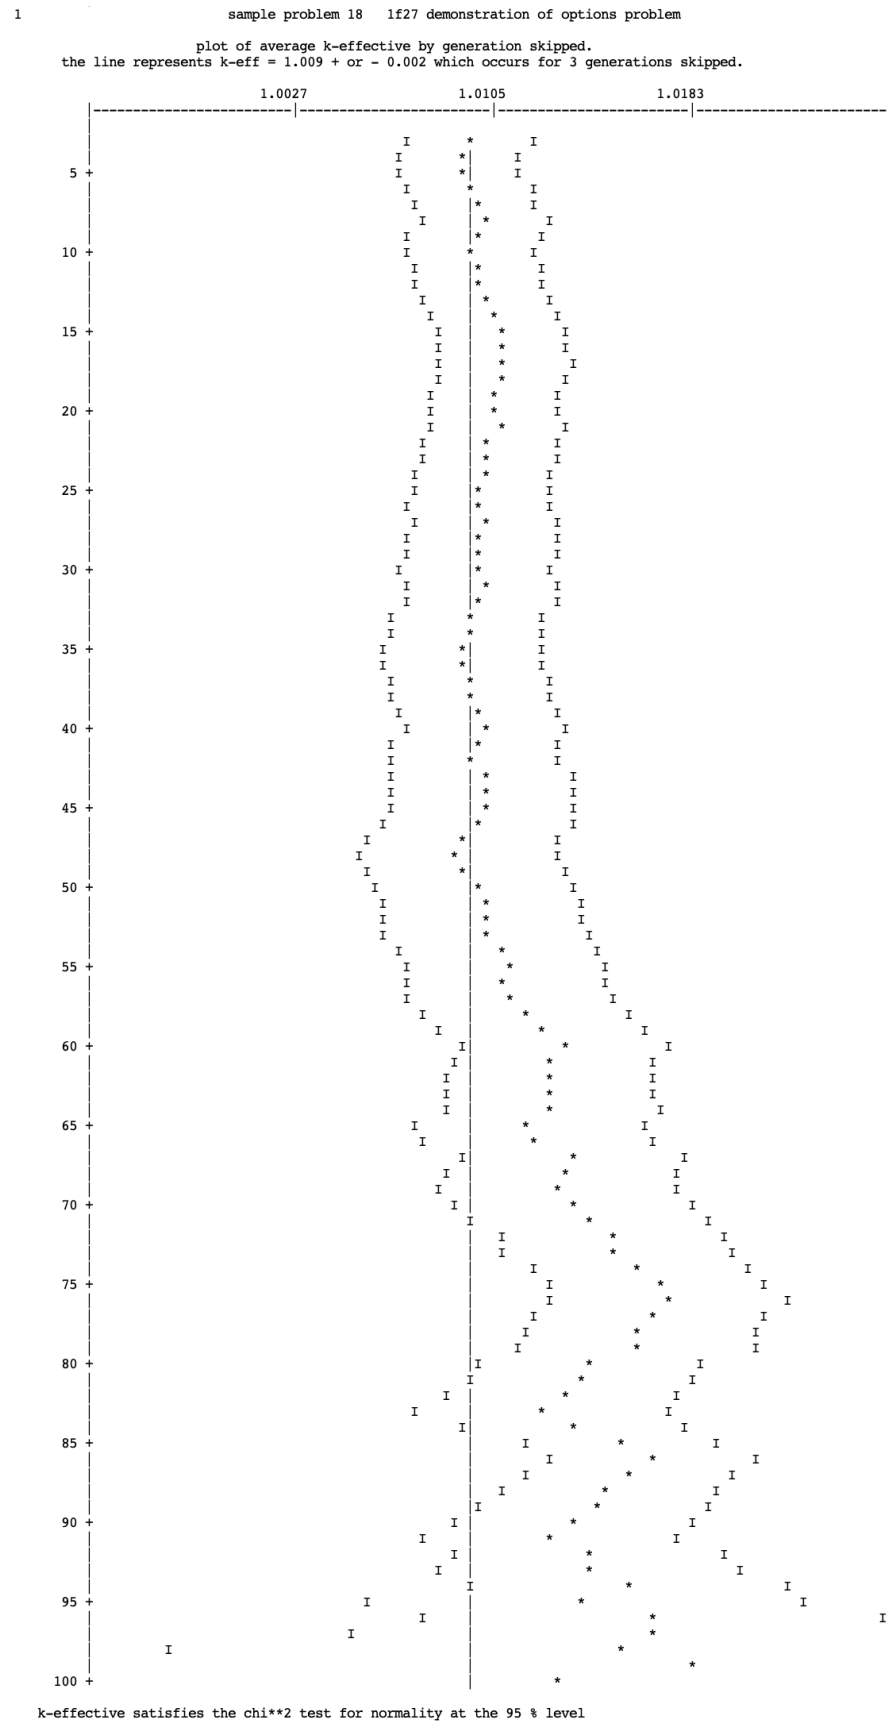

Fig. 8.1.141: Sample plot of average k-effective by generations skipped.

8.1.5.31 Final edit of fissions, absorptions, and leakage

The final edit of fissions, absorptions, and leakage follows the final k-effective edit and includes the fission fraction for each group and the fission production, absorptions, and leakage, each with its associated percent deviation. Examples of the final edits of fissions, absorptions, and leakage are shown in Fig. 8.1.142-Fig. 8.1.144.

If **FAR**=NO is specified, region-dependent fissions and absorptions are not printed. Fig. 8.1.142 demonstrates the printout if **FAR**=NO.

Fig. 8.1.144: Sample of the final edit of fissions, absorptions, and leakage and the region-dependent totals with print by region suppressed (**FAR**=YES **GAS**=NO).

If **FAR**=YES is specified in the parameter data, the fissions and absorptions for each geometry region used in the problem are calculated for each energy group. Leakage is not collected by geometry region, but rather it represents the leakage from the system. GROUP is the energy group number; FISSION FRACTION is the fraction of the fissions that occur in that energy group. The percent deviation for the fission fraction is the same as that of the fissions in the same group. The heading **UNIT** refers to the unit, and REGION is the

region number within the specified unit. The geometry regions are numbered sequentially within each unit, starting with 1. The sum of the fissions for every region for a given energy group is the total printed for that energy group. The same is true of absorptions. The fissions, absorptions, and leakages are given in units of per source neutron. The SYSTEM TOTAL is the sum over all the energy groups of the fissions, absorptions, and leakage. The associated percent deviation is printed for each.

The parameter **GAS** is used to control printing of fission productions and absorptions for each geometry region by energy group as shown in Fig. 8.1.143. **GAS**=YES causes this data to be printed, provided **FAR**=YES is also specified. **GAS**=NO turns off this print by group as shown in Fig. 8.1.144.

The sum of the leakage and absorptions printed for the system total should be close to 1. The fissions printed for the system total should be the same as the first k-effective printed in the final k-effective edit described in Sect. 8.1.5.28. If differential albedos are used, the leakage does not include the weight lost in the albedo reflection. A message stating the weight lost in the albedo is printed. This is the weight lost due to absorptions in the albedo reflector and leakage from the albedo reflector. No leakage is associated with faces having specular, mirror image, or periodic reflection. Thus there is no leakage associated with an infinite problem. The total elapsed time and final random number are printed at the end of this edit.

8.1.5.32 Matrix k-effective by position index

The matrix k-effective by unit location (also referred to as array position or position index) is calculated if **MKP**=YES is specified in the parameter data and a global array is present in the model. It is the largest eigenvalue of the fission production matrix collected by position index. Sect. 8.1.4.13 provides a complete discussion of matrix k-effective. The POSITION INDEX is a number referencing a position in a 3-D lattice. POSITION is the X, Y, and Z location within the lattice. **UNIT** is the unit located at the specified location in the lattice. Thus, in Fig. 8.1.148 , **UNIT** 1 is located at the lower left-hand front corner of the array or 3-D lattice representing the problem (X=1, Y=1, Z=1) and the corresponding POSITION INDEX is 1. POSITION INDEX 8 is the top right-hand back corner of the lattice, POSITION X=2, Y=2, Z=2 and the unit located at that position is **UNIT** 8. An example of the matrix k-effective by position is given in Fig. 8.1.145 . The text output is contained within two rows of asterisks to draw attention to it.

8.1.5.33 Fission production by position index matrix

To obtain fission production by position information, the user must specify **MKP**=YES and **FMP**=YES in the parameter data. The number of entries in the fission production matrix by position index is the square of the array size. Thus for a $2 \times 2 \times 2$ array there are 64 entries, and for a $4 \times 4 \times 4$ array there are 4,096 entries in the fission production matrix by position index. An example of the fission production matrix by position index for a $2 \times 2 \times 2$ array is shown in Fig. 8.1.146.

fission production by global array position index matrix
production is the number of next generation neutrons produced at the sink position by a neutron born at the source position.

Fig. 8.1.146: Sample fission production matrix by position index.

For each position index in the array, the number of next-generation neutrons produced at position index J per neutron born at position index I is determined. The fission production matrix by position index is used to determine the matrix k-effective, cofactor k-effective and source vector by position index.

8.1.5.34 Source vector by position index

Source vector by position index information is printed if **MKP**=YES is specified in the parameter data. The source vector by position index is the eigenvector of the fission production matrix by position index and should sum to 1.0. It represents the fission source for the specified locations in the 3-D lattice representing the physical problem being analyzed. Position zero contains all material outside the global array. An example of the source vector by position index is shown in Fig. 8.1.147. The average self-multiplication by array position is the overall average of the self-multiplication of all units used in the problem.

8.1.5.35 Cofactor k-effective by position index

The cofactor k-effective by position index edit is printed if **MKP**=YES is specified in the parameter data. This means that the fission production matrix is collected by position index. Calculating and printing cofactor k-effectives by position index can be avoided by specifying **CKP**=NO in the parameter data. An example of the cofactor k-effective by position index is shown in Fig. 8.1.148. See KENO Sect. 8.1.8.3 for a description of the problem used for the example.

8	2	2	2	8	9.61290E-01	3.34370E-03

elapsed time   0.05783 minutes

Fig. 8.1.148: Example of cofactor k-effective by position index.

The cofactor k-effective for a given position index is the largest eigenvalue of the fission production matrix collected by position index, reduced by the row and column associated with that position index. Thus the cofactor k-effective is the value of k-effective for the system calculated without the fission source of the unit located at the specified position index.

8.1.5.36 Matrix k-effective by unit number

The matrix k-effective by unit number (unit k-effective) is the largest eigenvalue of the fission production by unit matrix. It is calculated only if **MKU**=YES is specified in the parameter data. An example of the matrix k-effective by unit is given in Fig. 8.1.149.

lsample problem 2 2c8 bare with 8 unit types matrix calculation

Fig. 8.1.149: Example of matrix k-effective by unit number.

8.1.5.37 Fission production by unit number matrix

The fission production by unit number matrix is computed and printed if **MKU**=YES and **FMU**=YES are specified in the parameter data. Thus, for each unit in the array, the number of next-generation neutrons produced in Unit J per neutron born in Unit I is determined. This is the fission production matrix by unit, and it is used to determine the matrix k-effective by unit, the cofactor k-effective by unit, and the source vector by unit. An example of the fission production matrix by unit is shown in Fig. 8.1.150 for text output.

fission production by unit number matrix
production is the number of next generation neutrons produced in the sink unit by a neutron born in the source unit.

Fig. 8.1.150: An example of the fission probability matrix by unit.

8.1.5.38 Source vector by unit number

The source vector by unit is the eigenvector of the fission production matrix by unit and is printed if **MKU**=YES is specified in the parameter data. It represents the fission source for the units used in the problem. The components of the source vector should sum to 1.0. An example of the source vector by unit is given in Fig. 8.1.151. The average self-multiplication by unit is printed following the source vector. This value of self-multiplication includes those histories born in the unit which cause fissions in the same unit regardless of whether or not it exited and then returned. Therefore, this value will not agree with the value printed for the self-multiplication of the unit as described in Sect. Sect. 8.1.5.34 if the problem uses multiple units, if the system is reflected, or if a differential albedo is used in the problem.

Fig. 8.1.151: Example of the source vector by unit.

8.1.5.39 Cofactor k-effective by unit number

The cofactor k-effective for a given unit is the k-effective of the system calculated without the fission source of that unit. Cofactor k-effectives are printed if **MKU**=YES is specified in the parameter data. Calculating and printing cofactor k-effectives by unit can be avoided by specifying **CKU**=NO in the parameter data. This step is accomplished by determining the eigenvalue of the fission production matrix by unit after it has been reduced by the row and column associated with that unit. An example of the cofactor k-effective by unit is given in Fig. 8.1.152.

1sample problem 2 2c8 bare with 8 unit types matrix calculation

8.1.5.40 Matrix k-effective by hole number

The matrix k-effective by hole number is the largest eigenvalue of the fission production matrix collected by hole number and is calculated if **MKH**=YES was specified in the parameter data. An example of the matrix k-effective by hole number is given in Fig. 8.1.153.

1sample problem 18 1f27 demonstration of options problem

hole k-effective= 1.00946E+00 + or - 3.93611E-03
the hole k-effective is the largest eigenvalue of the fission production by hole number matrix.

elapsed time 0.30217 minutes

Fig. 8.1.153: Example of matrix k-effective by hole number.

8.1.5.41 Fission production by hole number matrix

This is the fission production matrix collected by hole number. It is printed only if **MKH**=YES and **FMH**=YES were specified in the parameter data. An example of this fission production matrix is given in Fig. 8.1.154. This matrix indicates the number of next generation neutrons produced in **HOLE** number J by a neutron born in **HOLE** number I.

8.1.5.48 Mesh tallies

The mesh tallies edit is optional. KENO prints the specification of each mesh tally defined by **CDS=**, **FIS=**, and **GFX=** parameters. A sample mesh tallies edit is given in Fig. 8.1.161. This edit does not print any details for both the mesh flux tally activated by **MFX=** and the $F^*(r)$ mesh tally controlled by **CGD=** parameters.

At the top of this output edit, the number of tallies computed for the given problem is printed. Then, a summary section including the tally response, spatial and energy grid identifiers, approximate memory required to compute and write this tally data, and tally 3dmap output filename is provided. The grid identifier points to the spatial mesh grid defined either with **MSH=** parameter or **grid geometry data** input block. Similarly, the energy identifier points to the DEFAULT energy boundaries (see Sect. 8.1.5.13). A summary of the energy and spatial grids is presented after this section. Details of both energy boundaries and grid definitions used for these mesh tallies can be seen in Sect. 8.1.5.13 and Sect. 8.1.5.19.

```

 Now writing mixture flux to the file(s): keno_mixture_flux*

 elapsed time   0.82800 minutes
```

Fig. 8.1.162: Example of reaction tally summary table.

8.1.5.50 Source convergence diagnostics edit

KENO calculates the Shannon entropy of the fission source distribution at each generation and reports this in the problem output (Sect. 8.1.5.26). At the end of calculation, KENO performs three tests to check the fission source convergence and reports these test results in the output. (See Sect. 8.1.7.7 for the definition of these tests.) An example of the fission source convergence diagnostics is given in Fig. 8.1.163. The last entry in this output edit is the plot of Shannon entropy by generations run, and a sample Shannon entropy plot is shown in Fig. 8.1.164.

```

-------------------------------------------------------------------------------------|----------------
 Test 2: Are all the active generations within epsilon of the average?              | Test 2: passed
-------------------------------------------------------------------------------------|----------------

Test 2 details:

Does the Shannon entropy of each active generation vary from the average Shannon entropy of the system?

 ( |D(S||T)-[H(T-H(S))]| < 0.1 )

  0 active generations failed the test.

 The maximum value for the test is 9.67646E-02 which occurred for active generation 167.

-------------------------------------------------------------------------------------|----------------
 Test 3: Are there adequate active generations after the source is converged?       | Test 3: passed
-------------------------------------------------------------------------------------|----------------

Test 3 details:

Does the Shannon entropy for the last half of the active generations vary from the Shannon entropy of all active generations?

 ( |H(T) - Hb| < 0.1 )

   |H(T) - Hb| =  3.42598E-02
```

8.1.5.51 Fission density edit

The fission density edit is optional. Subroutine KEDIT prints the neutron production density and the fission density for each geometry region if **FDN**=YES and **NUB**=YES is specified in the parameter data (these are the default values). If **NUB**=NO is specified, but **FDN**=YES, then only the production density will be given. An example of the fission density edit is shown in Fig. 8.1.165.

Fig. 8.1.165: Example of the fission density edit.

The UNIT is the unit number from the geometry data, the REGION is the region number relative to the unit, the PRODUCTION DENSITY is the neutrons produced per cm^3 per source-neutron, and the FISSION DENSITY is the fissions per cm^3 per source-neutron for that geometry region, the PERCENT DEVIATION is 100 times the fractional standard deviation associated with the production density and/or the fission density, the TOTAL PRODUCTIONS is the total number of neutrons produced per source neutron, and the TOTAL FISSIONS is the total number of fissions per source neutron in the geometry region.

8.1.5.52 Flux edit

Printing the region fluxes is optional; they are only printed if **FLX**=YES is specified in the parameter data. The fluxes are printed for each unit and each geometry region in the unit for every energy group. A sample of a flux edit is given in Fig. 8.1.166.

The title of the problem is printed at the top of the page. The heading FLUXES FOR UNIT____ indicates the geometry unit for which fluxes are being printed. The region numbers relative to the unit are identified by the heading REGION____. The geometry regions within each unit are numbered sequentially, beginning with 1. Then, the volume of each region is printed. Note that if the region volume is printed as -1.0, it indicates that either volume is not defined for this region, or that volume is not calculated, or it is calculated as 0.0. GROUP is the heading for the energy groups. The headings FLUX and PERCENT DEVIATION are printed for each geometry region in the unit. The flux and its associated percent deviation are printed for every energy group and every geometry region. The last entry printed for the flux edit is the TOTL which is the total flux integrated over all energy groups for each region. The flux is in units of neutrons/cm^2 /source neutron.

8.1.5.53 Frequency distributions

A frequency distribution consists of a bar graph indicating the number of generations having k-effective in a specified interval. The intervals are determined by the code, based on the upper and lower limits of the k-effectives calculated for the generations. In this example, one asterisk is printed for each generation k-effective. Four frequency distributions are printed as shown in Fig. 8.1.167. These four plots are: (1) all active generations, (2) the last 3/4 of active generations, (3) the last half of active generations, and (4) the last quarter of active generations. Note that departures from normal distributions in these plots and radical shifts among them may be indications of source convergence issues in the calculation.

8.1.5.54 Summary of parallel performance

KENO summarizes parallel performance in the output if parallel execution is requested by the user. The performance table, shown in Fig. 8.1.168, can be used to evaluate the code parallel performance with the given problem parameters. The quantities like speedup, parallel efficiency, and wall-clock time for each section (serial section, parallel section, and communication time among the processors) can be used to estimate resource requirement for similar problems to accomplish a faster execution.

Fig. 8.1.168: Example of performance analysis table.

8.1.5.55 Final results table

The final results table contains a summary of the most important physics parameters of the system and the number of error and warning messages generated during execution. The table contains the best-estimate system k-effective with one standard deviation, the energy of the average lethargy of fission, the average system nu-bar, the average mean free path of a neutron throughout the system, the number of warning and error messages generated during code execution, and a final statement on the convergence of the χ^2 test results. A summary of the Shannon entropy source convergence diagnostics is printed here. See the details of tests in Sect. 8.1.5.50 and Sect. 8.1.7.7. An example of this table is shown in Fig. 8.1.169. Also shown is the terminal edit of KENO, detailing the time required to traverse the “perilous path” through KENO.

          Congratulations!  You have successfully traversed the perilous path through KENO-V.a in     0.89800 minutes

 ************************************************************************************************************************************
```

Fig. 8.1.169: An example of the final results table.

8.1.5.56 HTML output

The HTML-formatted output is no longer actively developed, and the output files created with it may therefore not include recently added capabilities or changes. For example, the fission rate mesh tally and some CE TSUNAMI edits are not included in the HTML output.

HTML output: Program verification information

The program verification information is the first page shown in the KENO HTML output, after selecting KENO from the SCALE HTML index page. This page can also be displayed by selecting the *Program Verification Information* link under the *General Information* submenu and is shown in Fig. 8.1.170.

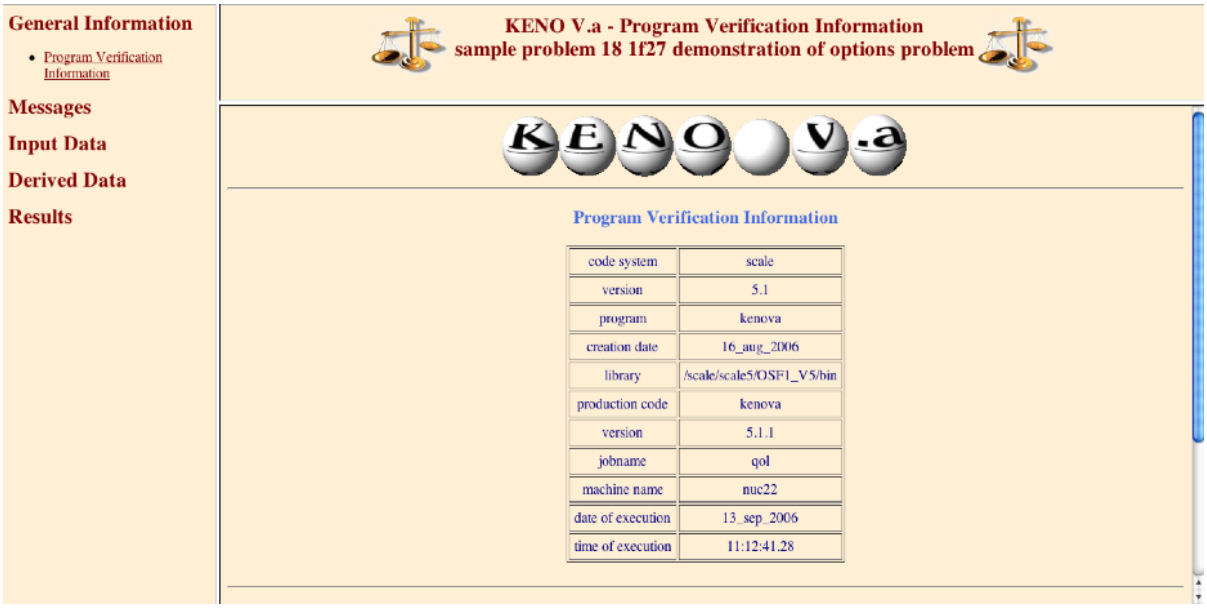

Fig. 8.1.170: Sample program verification information in HTML output.

HTML output: Messages

In the HTML output, all error and warning messages are consolidated into the *Messages* section of the output. *Error Messages* and *Warning Messages* links are available to the user as needed. An example edit with warning messages is shown in Fig. 8.1.171.

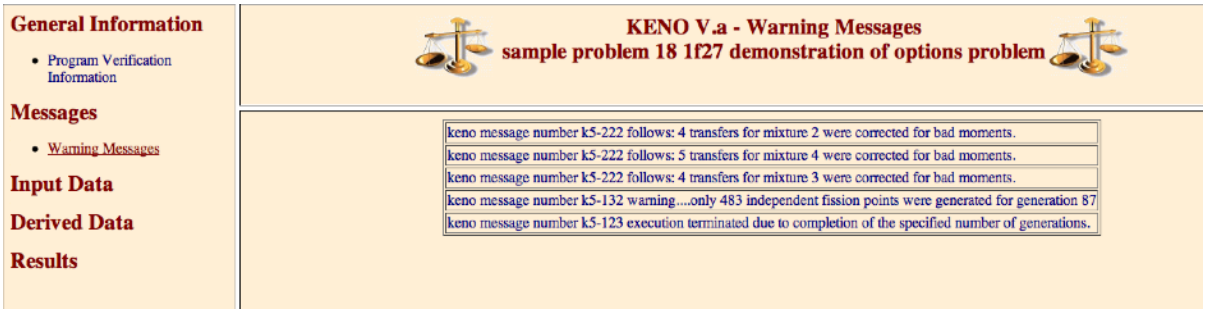

Fig. 8.1.171: Example messages edit in HTML output.

HTML output: Tables of parameter data

The first two tables generated by KENO HTML output list the numeric parameters and logical parameters that are used in the problem. The user should always verify that the parameter data block was input as desired. An example of numeric parameters table is shown in Fig. 8.1.172. An example of the logical parameters table is shown in Fig. 8.1.173. The HTML output is accessed with the *Numeric Parameters* and *Logical Parameters* links in the *Input Data* section.

Keno-V.a - Numeric Parameters
sample problem 18 1f27 demonstration of options problem

Parameter	Description	Value
tme	maximum problem time (min)	0.00
tba	time per generation (min)	10.00
gen	number of generations	103
npg	number per generation	500
nsk	number of generations to be skipped	3
beg	beginning generation number	1
res	generations between checkpoints	0
x1d	number of extra 1-d cross sections	1
nbk	neutron bank size	525
xnb	extra positions in neutron bank	0
nfb	fission bank size	500
xfb	extra positions in fission bank	0
sig	cut off standard deviation	0.0000
wta	default value of weight average	0.5000
wth	weight high for splitting	3.0000
wtl	weight low for russian roulette	0.3333
rnd	starting random number	0000F12C09ED2195
nb8	number of d.a. blocks on unit 8	1000
nl8	length of d.a. blocks on unit 8	512
nqd	quadrature order for angular fluxes	0
pnm	highest order of flux moments	0
msh	mesh size for mesh flux tally	0.0000
adj	mode of calculation	forward
tps	sampling sites per track length	5
cgs	number of secondary groups to sampl	0
cas	number of secondary angles to sampl	0

Fig. 8.1.172: Sample numeric parameters in HTML output.

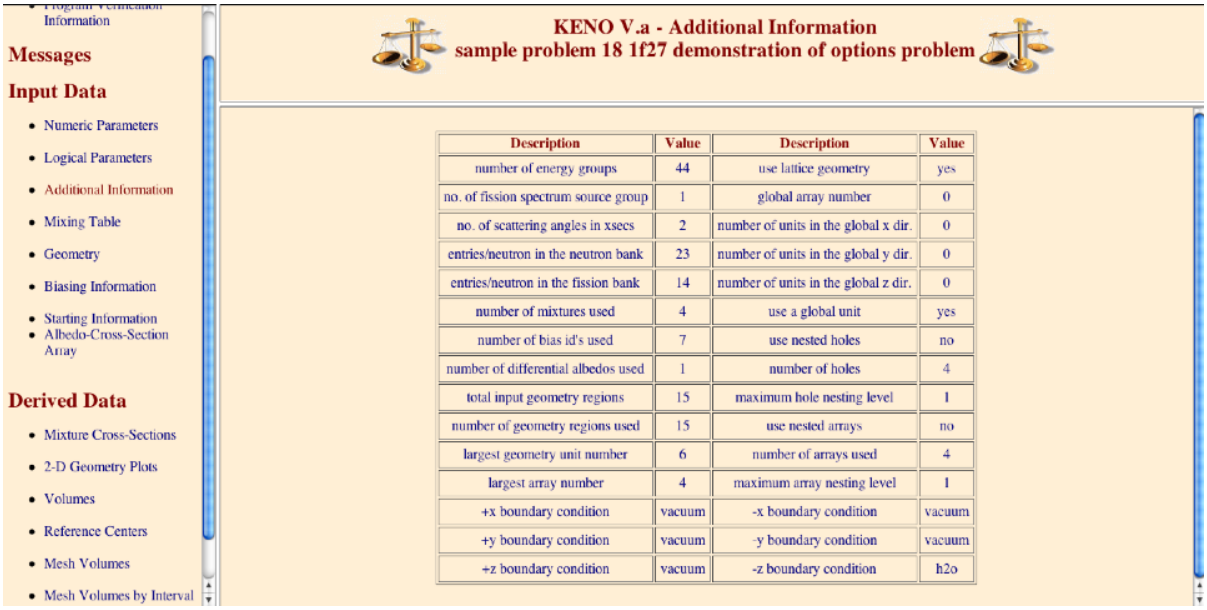
Keno-V.a - Logical Parameters
sample problem 18 1f27 demonstration of options problem

Parameter	Description	Value
run	execute problem after checking data	yes
plt	plot picture map(s)	yes
	compute fluxes (cfx, flx, cfe or mfp)	yes
fdn	compute fission densities	yes
smu	compute avg unit self-multiplication	no
nub	compute nu-bar & avg fission group	yes
mku	compute matrix k-eff by unit number	yes
cku	compute cofactor k-eff by unit number	no
fmu	print fiss prod matrix by unit number	yes
mkp	compute matrix k-eff by unit location	no
ckp	compute cofactor k-eff by unit location	no
fmp	print fiss prod matrix by unit location	no
mkh	compute matrix k-eff by hole number	yes
ckh	compute cofactor k-eff by hole number	no
fmh	print fiss prod matrix by hole number	yes
hhl	collect matrix by highest hole level	no
mka	compute matrix k-eff by array number	yes
cka	compute cofactor k-eff by array number	no
fma	print fiss prod matrix by array number	yes
hal	collect matrix by highest array level	no
amx	print all mixed cross sections	yes
xs1	print 1-d mixture x-sections	yes
xs2	print 2-d mixture x-sections	yes
xsl	print 2-d mixture Pl arrays	yes
xap	print mixture angles & probabilities	yes
pki	print fission spectrum	yes

Fig. 8.1.173: Sample logical parameters in HTML output.

HTML output: Table of additional information

The fourth table of data printed by KENO contains additional information determined from the input data. An example of this table is shown in Fig. 8.1.174. The HTML output is accessed with the *Additional Information* link in the *Input Data* section.



Description	Value	Description	Value
number of energy groups	44	use lattice geometry	yes
no. of fission spectrum source group	1	global array number	0
no. of scattering angles in xsecs	2	number of units in the global x dir.	0
entries/neutron in the neutron bank	23	number of units in the global y dir.	0
entries/neutron in the fission bank	14	number of units in the global z dir.	0
number of mixtures used	4	use a global unit	yes
number of bias id's used	7	use nested holes	no
number of differential albedos used	1	number of holes	4
total input geometry regions	15	maximum hole nesting level	1
number of geometry regions used	15	use nested arrays	no
largest geometry unit number	6	number of arrays used	4
largest array number	4	maximum array nesting level	1
+x boundary condition	vacuum	-x boundary condition	vacuum
+y boundary condition	vacuum	-y boundary condition	vacuum
+z boundary condition	vacuum	-z boundary condition	h2o

Fig. 8.1.174: Sample table of additional information in HTML output.

HTML output: Mixing table data

If **LIB=** is entered in the KENO parameter data and a mixing table data block is provided to KENO, then mixing table data will be printed. Sample mixing table data are shown in Fig. 8.1.175. In the HTML output, the mixing table data can be accessed with the *Mixing Table* link in the *Input Data* section.

Fig. 8.1.175: Example of mixing table data in HTML output.

HTML output: 1D macroscopic cross sections

The decision to print the 1-D mixture cross sections is optional. They are printed only if **XS1**=YES is specified in the parameter data. The 1-D mixture cross sections for a mixture are shown in Fig. 8.1.176. The HTML output is accessed with the *Mixture Cross Sections* link in the *Derived Data* section. The top menu on the right side of the window is used to set the mixture displayed in the bottom menu on the right side of the window. The bottom menu contains hyperlinks to all available edits for mixture cross sections. The 1-D cross sections are accessed with the *Neutron Cross Sections* link in the bottom menu for the desired mixture.

Fig. 8.1.176: Example 1-D macroscopic cross section in HTML output.

When the 1-D mixture cross sections are printed, the problem title is printed at the top of the page. The mixture ID, mixture index and mixture number are then printed. ID is the mixture number from the mixing table and mixture index is the index used to reference it and mixture number is its identifier. This step is followed by a heading to identify the different 1-D cross sections. *GROUP* is the energy group, *sigt* is the total cross section for the mixture, *sigs* is the nonabsorption probability, *siga* is the absorption probability, *signu* is the production probability, *chi* is the fission spectrum, *mwa1* is the pointer for the first position of the cross sections for the energy group, *mwa2* is the pointer for the last position of the cross sections for the energy group, and *mwa3* contains the group for the transfer corresponding to the first position. *SUM* is the sum of the absorption probability and the nonabsorption probability. The nonabsorption probability and the production probability are not true probabilities in that they may be greater than 1. This is because the nonabsorption probability has the (n,2n) transfer array summed into the total transfer array twice, and the (n,3n) is summed three times, etc. The absorption probability is defined as the absorption cross section divided by the total cross section. The nonabsorption probability is the sum of the group-to-group transfers for this group divided by the total cross section. The production probability is defined as the fission production cross section divided by the total cross section $\left(\nu\Sigma_f/\Sigma_T\right)$.

HTML output: 2-D macroscopic cross sections

The decision to print the 2-D mixture cross sections is optional. An example of the 2-D mixture cross sections is given in Fig. 8.1.177. The HTML output is accessed with the *Mixture Cross Sections* link in the *Derived Data* section. The top menu on the right side of the window is used to set the mixture displayed in the bottom menu on the right side of the window. The bottom menu contains hyperlinks to all available edits for mixture cross sections. The 1-D macroscopic cross sections are accessed with the *primary-to-primary scattering transfer array* link in the bottom menu for the desired mixture.

Fig. 8.1.177: Example of 2-D macroscopic cross sections in HTML output.

HTML output: Probabilities and angles

Printing the probabilities and angles is optional. The HTML output, Fig. 8.1.178, is accessed with the *Mixture Cross Sections* link in the *Derived Data* section. The top menu on the right side of the window is used to set the mixture displayed in the bottom menu on the right side of the window. The bottom menu contains hyperlinks to all available edits for mixture cross sections. The probabilities and angles edits, shown in Fig. 8.1.179, are accessed with the *primary-to-primary probability* link in the bottom menu for the desired mixture.

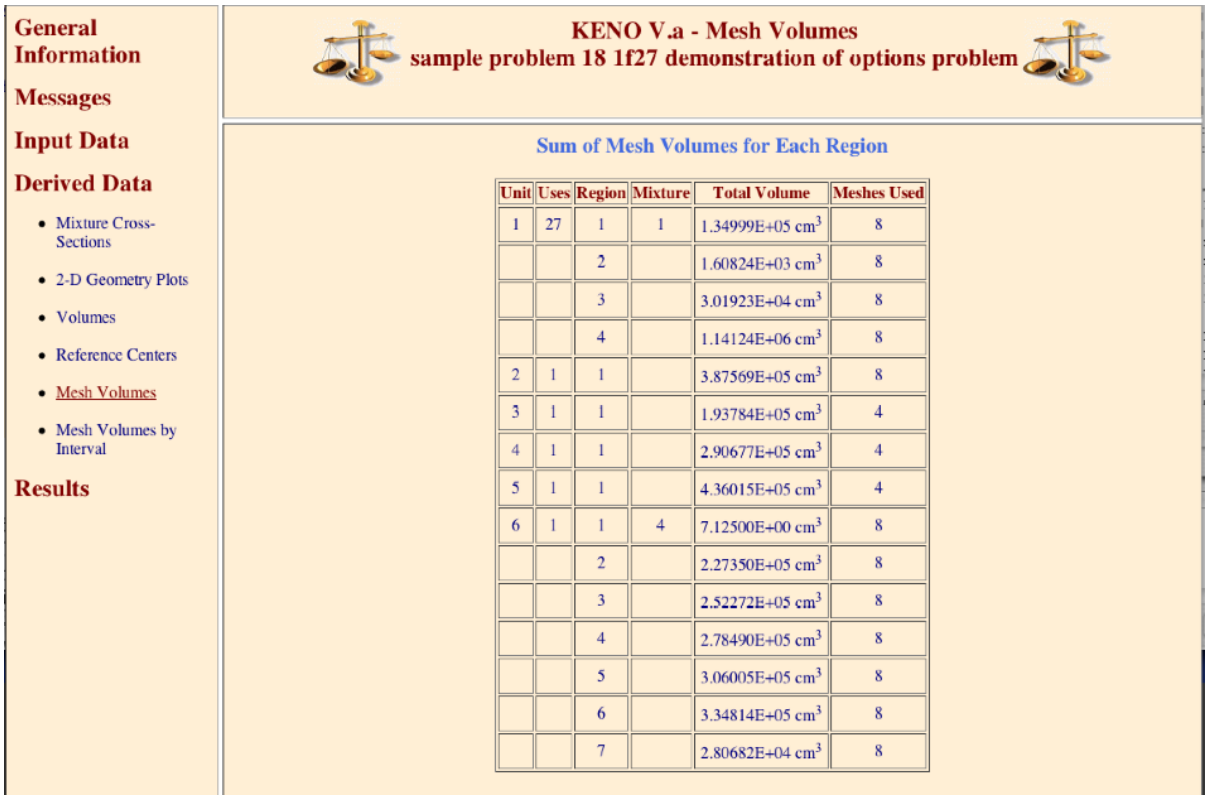
Fig. 8.1.181: Sample volume information in HTML output.

KENO-VI

Two tables of volumes are always printed. The first table will list the number of times each unit is used in the problem and the total volume of each region throughout the entire problem description. The second table will list the total volume and mass of each mixture used in the problem.

Mesh volumes

With the mesh flux accumulator, fluxes are tabulated for each region of each unit in a cubic mesh. For models in which the mesh flux accumulator is activated by setting **MFX**=YES and the mesh size set to a positive value with **MSH**=, the cumulative volume of all mesh intervals for a given region and the number of meshes used in each region are printed as shown in Fig. 8.1.182. The HTML edit is accessed with the *Mesh Volumes* link in the *Derived Data* section.



Unit	Uses	Region	Mixture	Total Volume	Meshes Used
1	27	1	1	1.34999E+05 cm^3	8
		2		1.60824E+03 cm^3	8
		3		3.01923E+04 cm^3	8
		4		1.14124E+06 cm^3	8
2	1	1		3.87569E+05 cm^3	8

		7		2.80682E+04 cm^3	8

Fig. 8.1.182: Sample sum of mesh volumes in HTML output.

An optional edit of volumes for each mesh interval for each region can be activated by entering **PMV**=YES in the parameter input. This edit can be very large, especially if a small mesh size is used with a large model. A sample of the volume by mesh for each region is shown in Fig. 8.1.183. This edit is found under *Derived Data* with the *Mesh Volumes by Interval* link. For the HTML output, the links on the right side of the screen control what data are displayed in the center pane. Clicking on the unit number in the pane labeled **UNIT** places the pane labeled Region at that unit. Clicking on a region number in the region pane places the volume by mesh for the selected unit in the center pane.

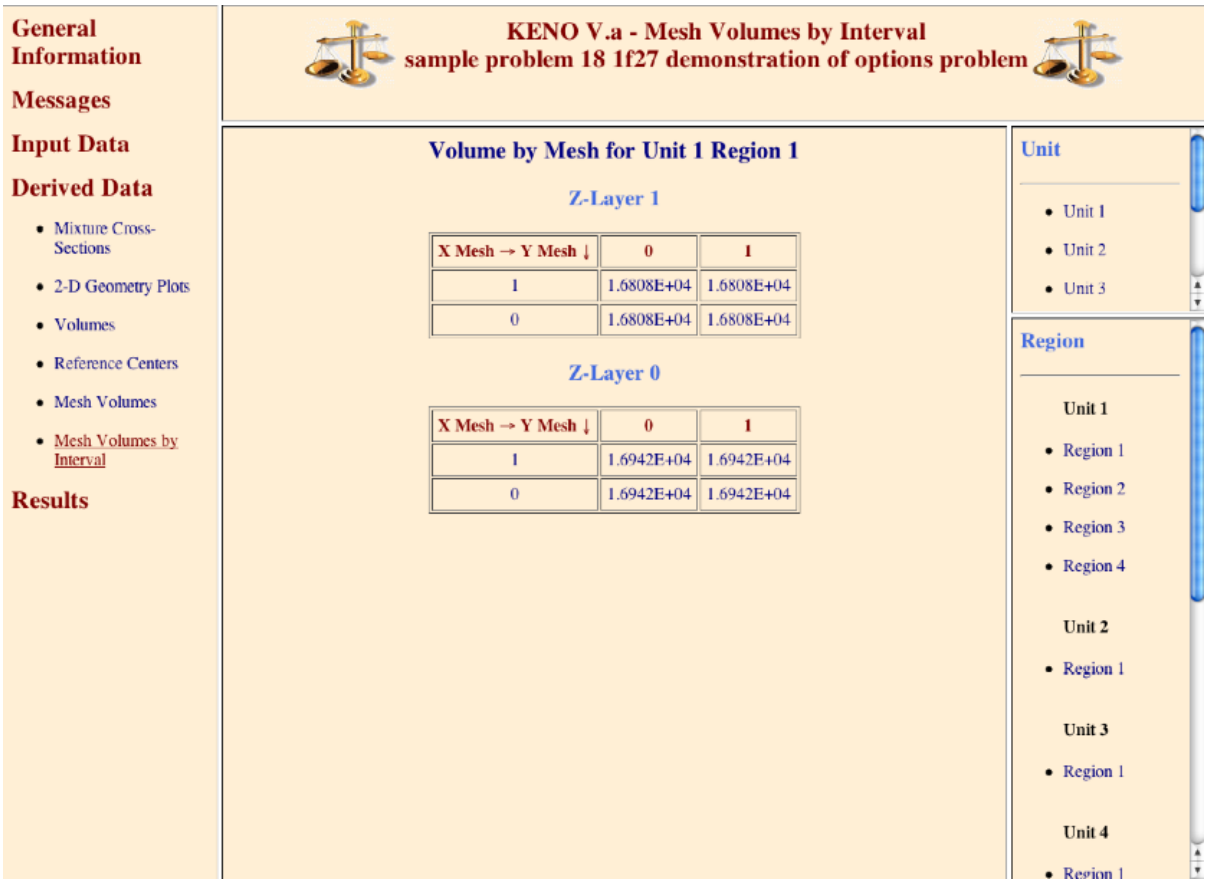

Fig. 8.1.183: Sample of volume by mesh for each region in HTML output.

HTML output: Biasing information

This table specifies the weighting or biasing data to be used in the problem. An example of biasing information is given in Fig. 8.1.184.

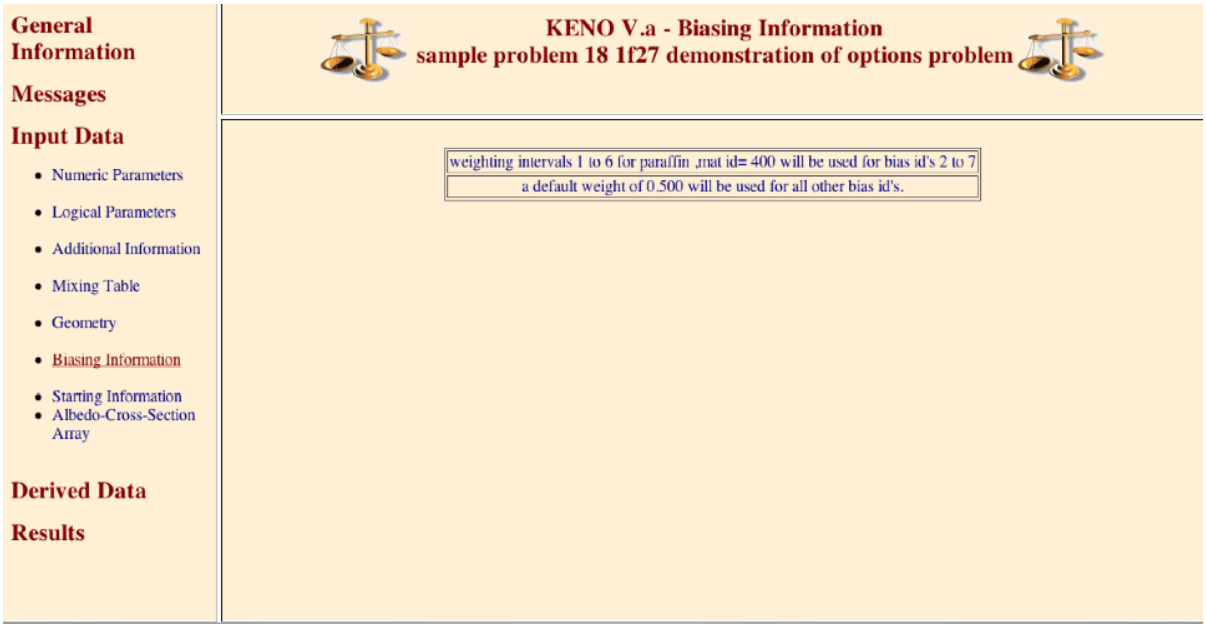

Fig. 8.1.184: Biasing information in HTML output.

HTML output: Group-dependent weights

Printing the group-dependent weights is optional. They are printed if **PWT**=YES is entered in the parameter data. This edit is available in the HTML output under *Results* in the *Average Weight* link, as shown in Fig. 8.1.185.

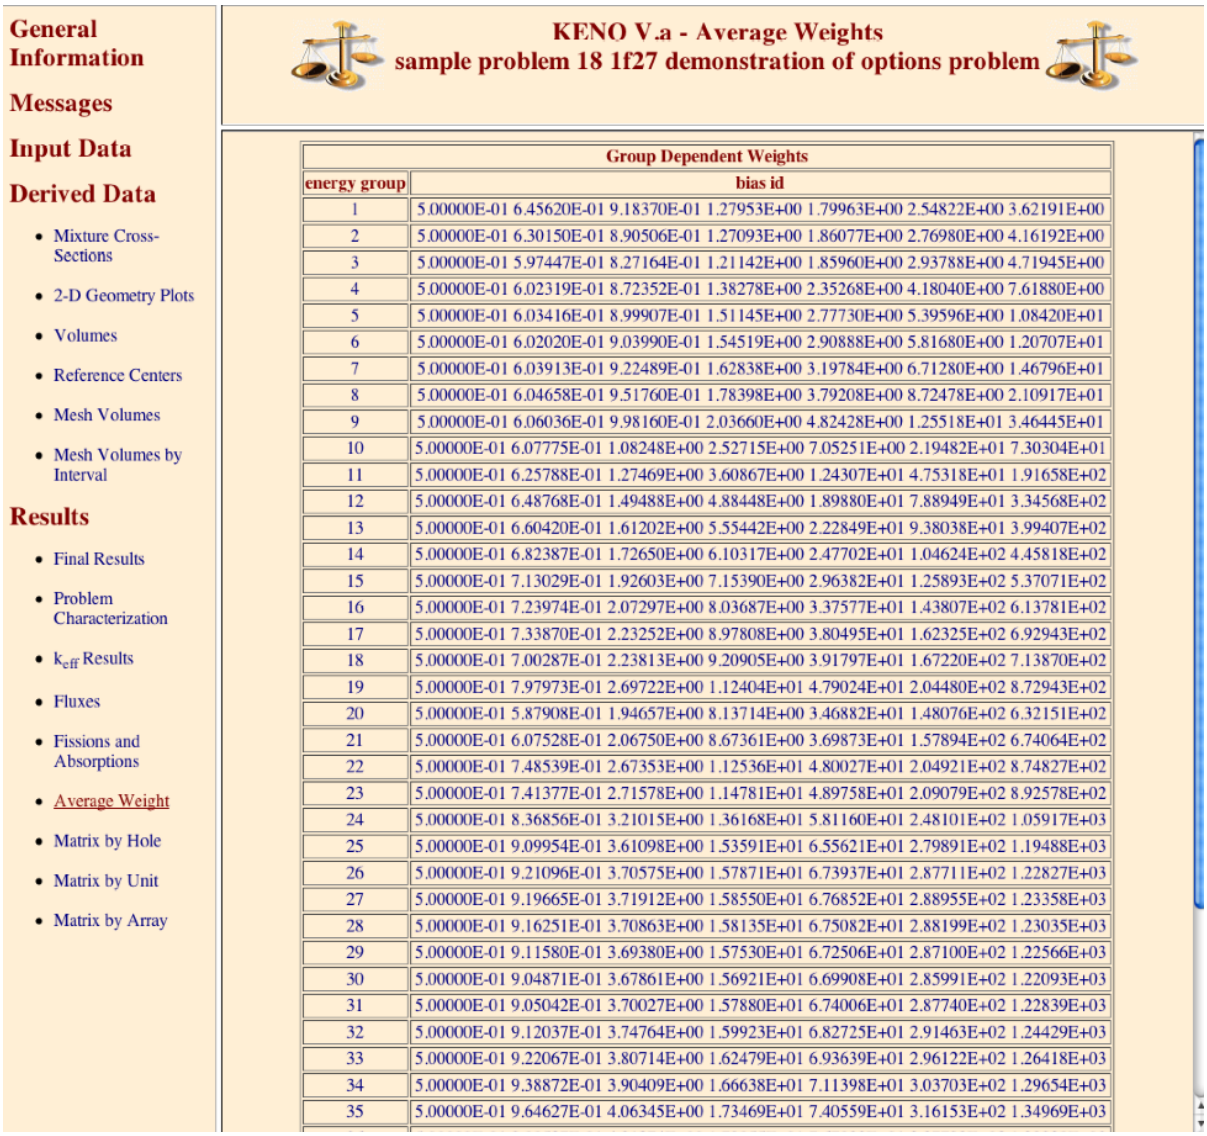

Fig. 8.1.185: Example of biasing data in HTML output.

HTML output: Plot representation

Plots representing 2-D slices through the geometrical description of the problem are optional. They are created if plot data are entered unless **PLT**=NO is specified either in the plot data or the parameter data. Character plots are not available in the HTML output, but the color plots are easily viewed as shown in Fig. 8.1.186. The user-requested plots can be viewed under *Derived Data* in the *2-D Geometry Plots* link.

Fig. 8.1.186 shows two color plots in a single HTML page. The color plots do not appear in the KENO text printout, but they are an integral part of the HTML output. They are generated from PNG files created when a color plot has been specified in the KENO input data. Any number of plots can be made in one problem. The color plots can be valuable tools to assist the user in verifying that a problem is described correctly.

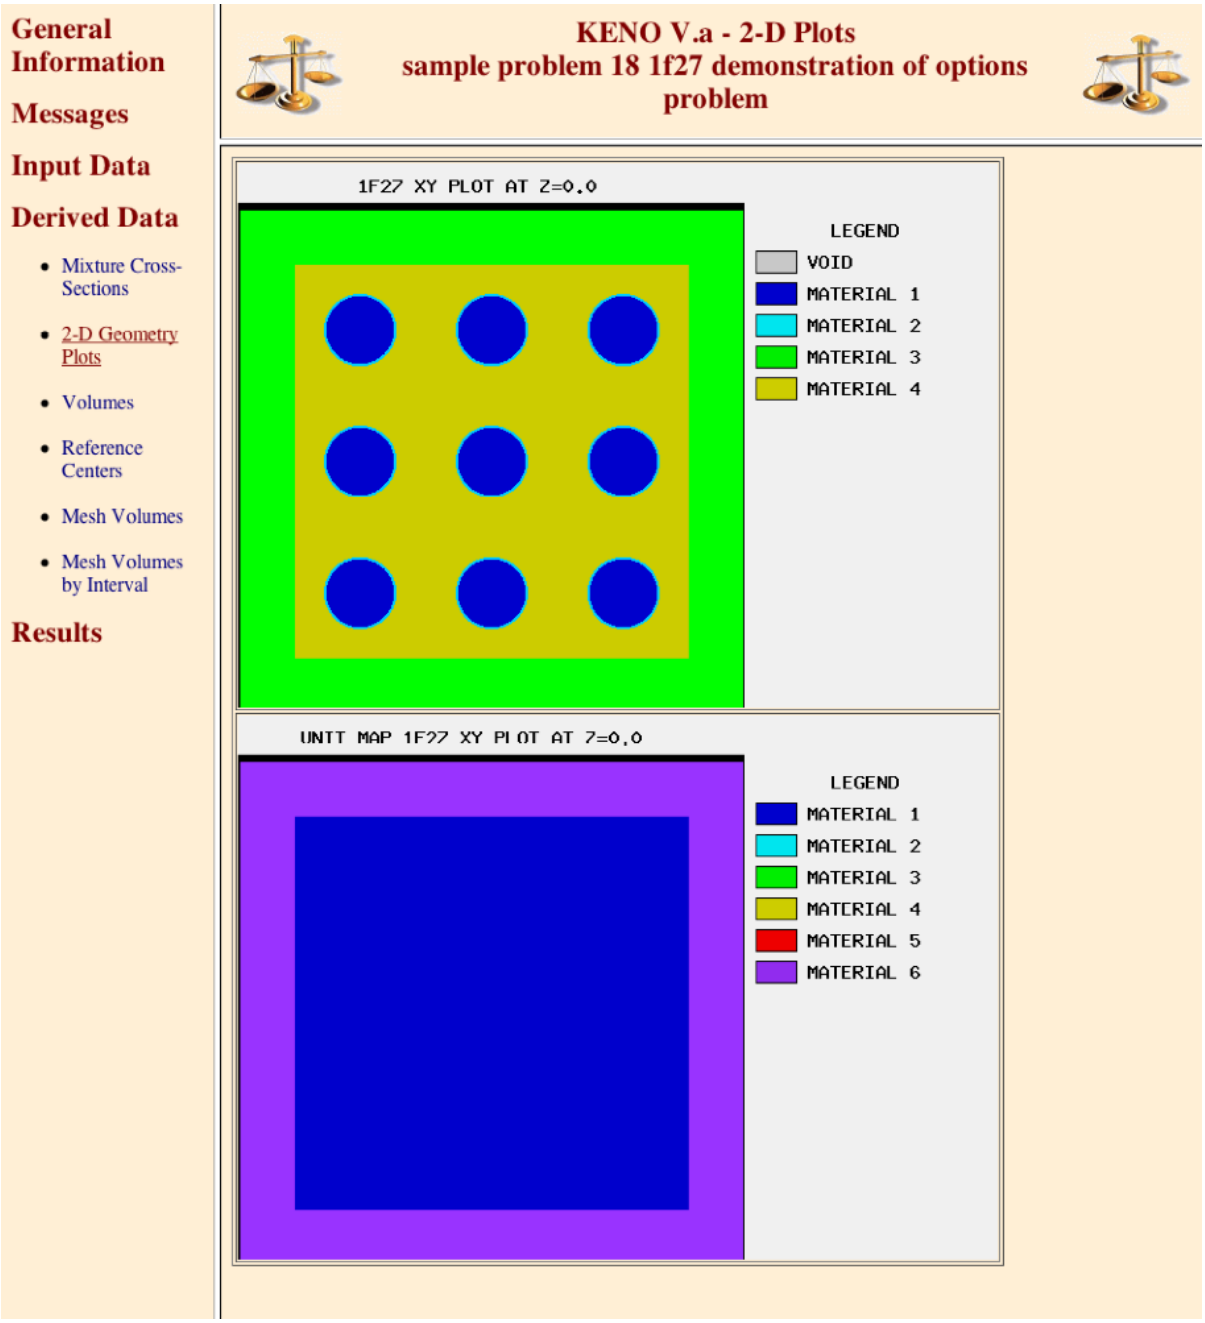

Fig. 8.1.186: Sample color plots in HTML output.

HTML output: Initial source and final pretracking edits

Prior to calculating the k-effs for each generation, KENO prints the final input data edit. The starting information is available in the HTML output under *Input Data* with the *Starting Information* link. An example of the HTML edit is shown in Fig. 8.1.187.

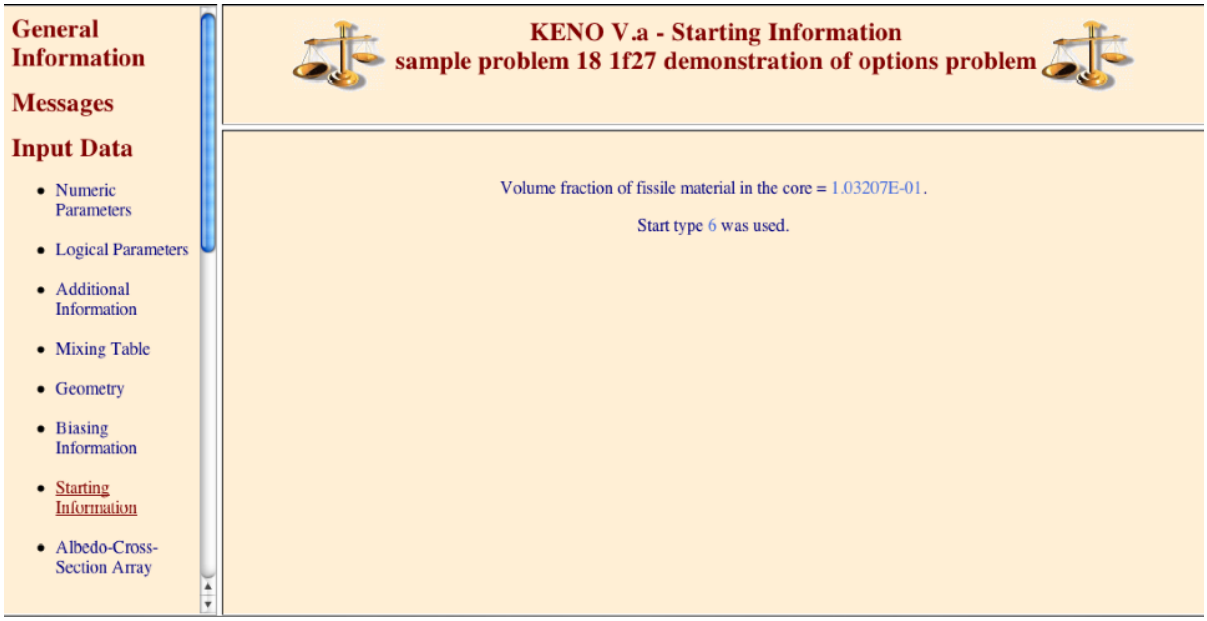

Fig. 8.1.187: Example of initial source information for start type 6 in HTML output.

HTML output: Reference center for flux moment/angular flux tranform

When **TFM**=YES is entered, the flux moments and angular fluxes are computed in a transformed coordinate system relative to a reference center point. Edits of the fuel center and the position of the reference center for each region are shown in Fig. 8.1.188. The HTML output edit is available under *Derived Data* in the *Reference Centers* link.

Fig. 8.1.188: Example of fuel center and reference center edits in HTML output.

HTML output: K-effectives by generation

At the completion of each generation, KENO prints the k-effective for that generation and associated information. An example of this printout is given in Fig. 8.1.188 for HTML output. This HTML output edit is available under *Results* in the section of *keff Results* in the *keff by Generations Run* link.

Example fuel center and reference center edits in HTML output.

Fig. 8.1.189: Example of k-effective by generation in HTML output.

The problem title is printed at the top of the page. A descriptive heading is printed at the top of each column of data. The data printed include (1) the generation number, (2) the k-effective calculated for the generation, (3) the average value of k-effective through the current generation (excluding the first two generations), (4) the deviation associated with the average k-effective, and (5) the matrix k-effective for the generation and the deviation associated with the matrix k-effective. The last two columns are filled with zeros if the user did not specify matrix k-effective calculations. The matrix k-effective is the largest eigenvalue of the fission production matrix. Matrix information can be calculated based on (1) position index, (2) unit number, (3) hole number, and (4) array number. The matrix k-effective printed in the sixth column is based on this order. If the matrix k-effective is calculated by position index, it is the one printed in the sixth column. The matrix k-effective by unit number is given second preference, followed by hole number and then array number. After the last generation, a message is printed to indicate why execution was terminated. If matrix k-effectives were calculated, this is followed by a message stating the method used to determine the matrix k-effective.

The user should examine this portion of the results to ensure that the two methods of calculating k-effective are in acceptable agreement and to verify that the average value of k-effective has become relatively stable. If the k-effectives appear to be oscillating or drifting significantly, the user should consider rerunning the problem with a larger number of histories per generation.

If a problem is restarted, the generation numbers and k-effectives are printed and the words FROM RESTART UNIT are printed in the elapsed time column. All other columns are blank. When the generation at which the problem is to be restarted is reached, the print reverts to the normal format as shown in Fig. 8.1.137.

HTML output: Problem characterization edit

The problem characterization edit is shown in Fig. 8.1.190 for HTML output.

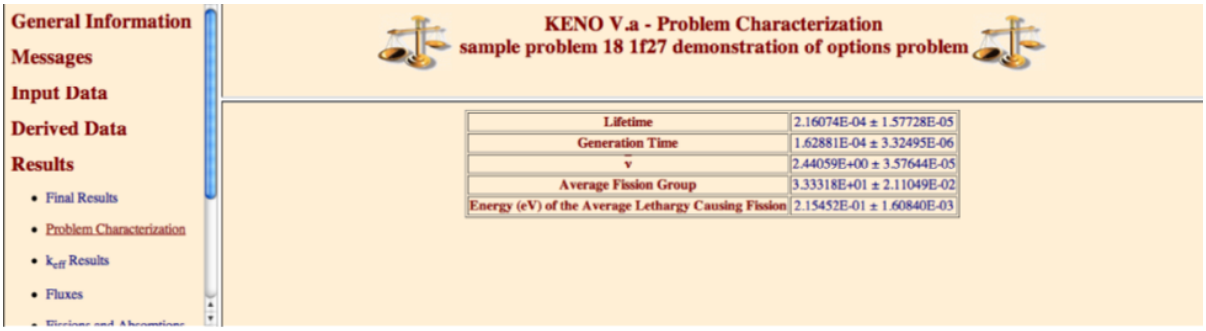

Fig. 8.1.190: Example problem characterization edit in HTML output.

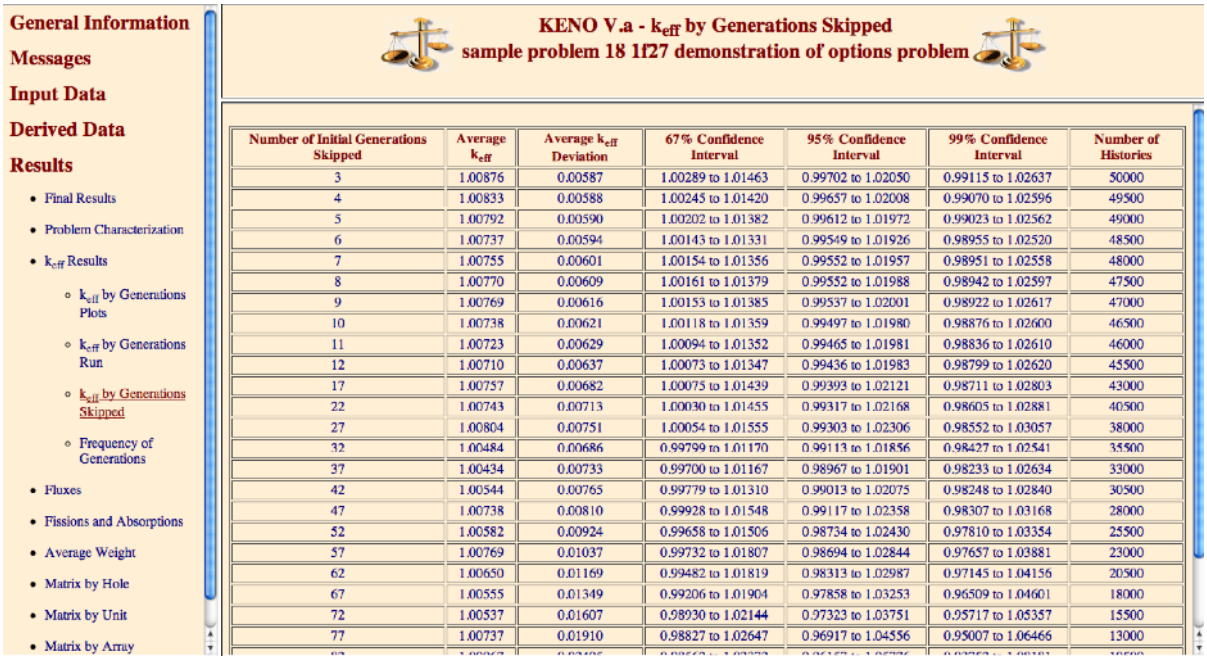
HTML output: Final k-effective edit

The final k-effective edit prints the average k-effective and its associated deviation and the limits of k-effective for the 67, 95, and 99% confidence intervals. The final k-effective edit is printed as shown in Fig. 8.1.191. This HTML output edit is available under *Results* in the section of *keff Results* in the *keff by Generations Skipped* link.



Number of Initial Generations Skipped	Average k_{eff}	Average k_{eff} Deviation	67% Confidence Interval	95% Confidence Interval	99% Confidence Interval	Number of Histories

Fig. 8.1.191: Example of the final k-effective edit in HTML output.

HTML output: Final edit of fissions, absorptions, and leakage

The final edit of fissions, absorptions, and leakage follows the final k-effective edit and includes the fission fraction for each group and the fission production, absorptions, and leakage, each with its associated percent deviation.

Tables corresponding to those available in the text output are also available in the HTML output. These data are accessed with the *Fissions and Absorptions Data* link under *Fissions and Absorptions* in the *Results* section, as illustrated in Fig. 8.1.192, where the region and group data (**FAR**=YES and **GAS**=YES) are present. To allow quicker loading of the large amounts of data in the HTML output, the data have been subdivided into several separate tables, which are accessed with the menu on the right side of the window.

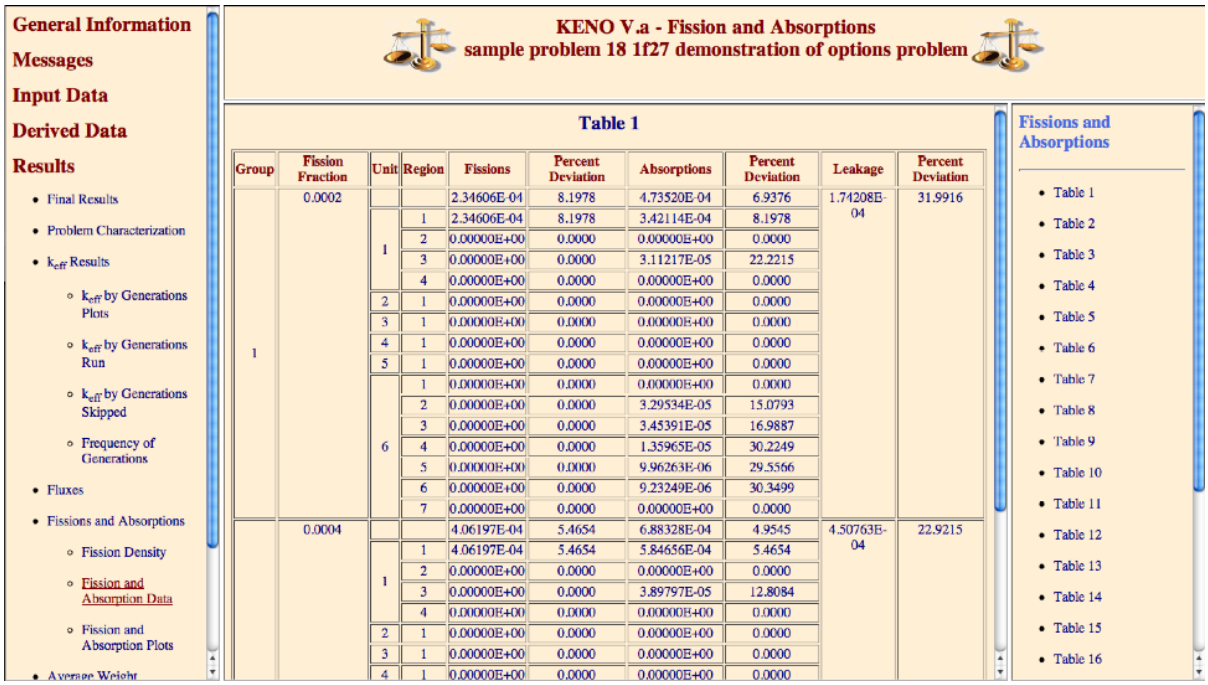

Fig. 8.1.192: Sample fissions, absorptions and leakage data in HTML output.

HTML output: Matrix k-effective by position index

The matrix k-effective by unit location (also referred to as array position or position index) is calculated if **MKP**=YES is specified in the parameter data and a global array is present in the model. An example of the matrix k-effective by position is given in Fig. 8.1.193. In the HTML output, the k-effective by position data is available in the *Matrix by Position* link in the *Results* section.

KENO V.a - Matrix by Position
sample problem 2 2c8 bare with 8 unit types matrix calculation

Array Position k_{eff}= 9.93959E-01 ± 3.35259E-03.
The array position k_{eff} is the largest eigenvalue of the fission production by array position index matrix.

Production is the number of next generation neutrons produced at the sink position by a neutron born at the source position.

Fission Production by Array Position Index Matrix

Fig. 8.1.193: Example of matrix k-effective by position index edit in HMTL output.

HTML output: Fission production by position index matrix

To obtain fission production by position information, the user must specify **MKP**=YES and **FMP**=YES in the parameter data. An example of the fission production matrix by position index for a $2 \times 2 \times 2$ array is shown in Fig. 8.1.194.

Fig. 8.1.194: Sample fission production matrix by position index edit in HMTL output.

For each position index in the array, the number of next-generation neutrons produced at position index J per neutron born at position index I is determined. The fission production matrix by position index is used to determine the matrix k-effective, cofactor k-effective and source vector by position index.

HTML output: Source vector by position index

Source vector by position index information is printed if **MKP**=YES is specified in the parameter data. An example of the source vector by position index is shown in Fig. 8.1.195. The average self-multiplication by array position is the overall average of the self-multiplication of all units used in the problem.

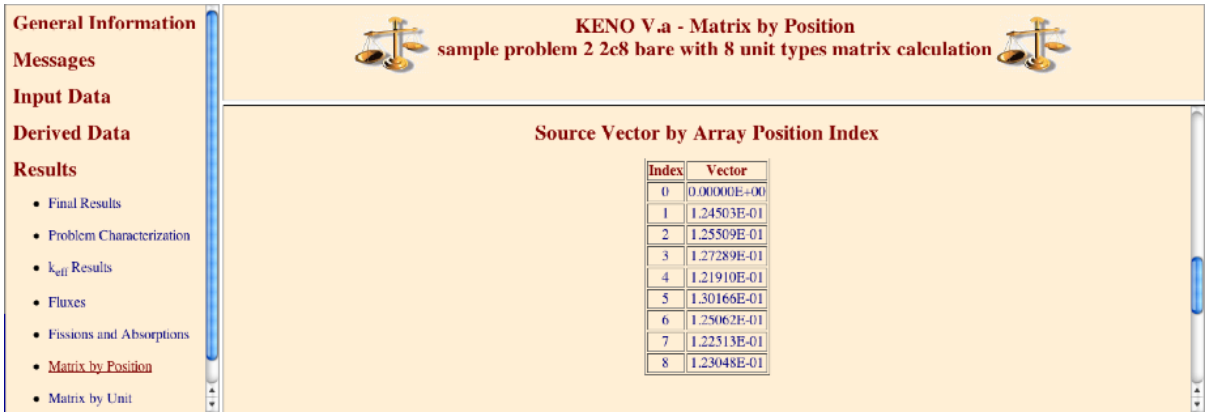

Fig. 8.1.195: Example of source vector by position index edit in HTML output.

HTML output: Cofactor k-effective by position index

The cofactor k-effective by position index edit is printed if **MKP**=YES is specified in the parameter data. An example of the cofactor k-effective by position index is shown in Fig. 8.1.196 and an example of the source vector by position index is shown in Fig. 8.1.197.

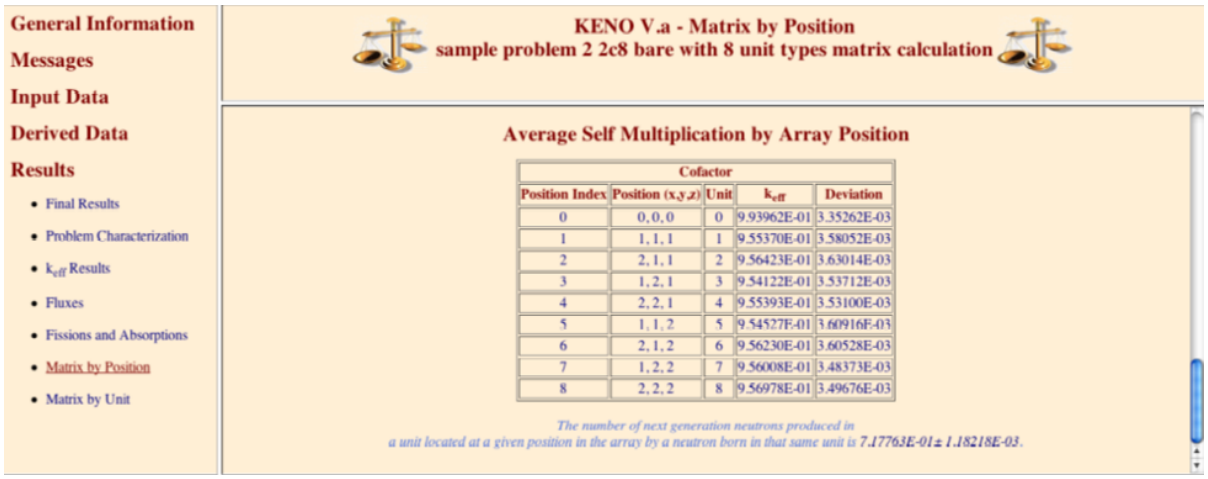

Fig. 8.1.196: Example cofactor k-effective by position index edit in HTML output.

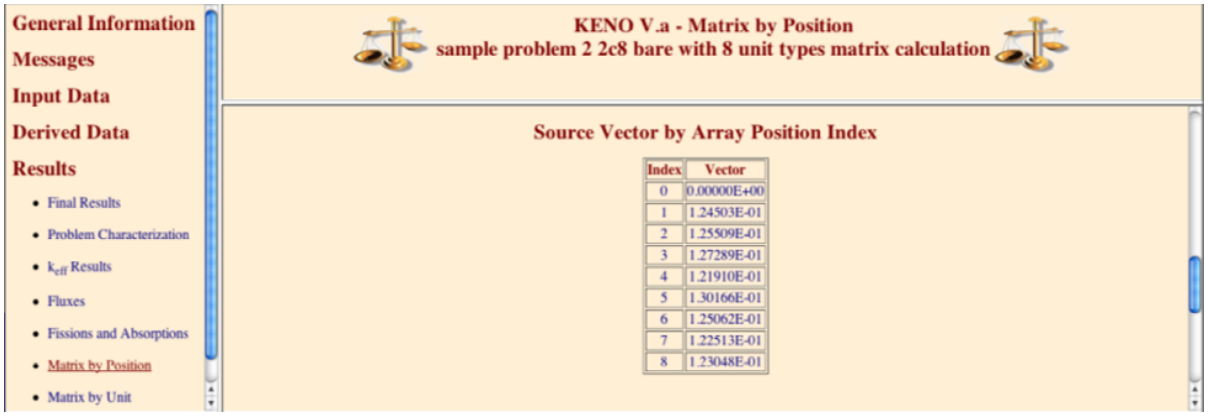

Fig. 8.1.197: Example of source vector by position index edit in HTML output.

HTML output: Matrix k-effective, fission production, source vector and cofactor k-effective by unit number

The matrix k-effective by **UNIT** number (unit k-effective) is the largest eigenvalue of the fission production by unit matrix. It is calculated only if **MKU**=YES is specified in the parameter data. An example of the matrix k-effective by **UNIT** is given in Fig. 8.1.198. Fission production, source vector and average self-multiplication by **UNIT** are all printed on the same page as the matrix k-effective by **UNIT**. The matrix k-effective HTML data by unit is available in the *Matrix by Unit* link in the *Results* section.

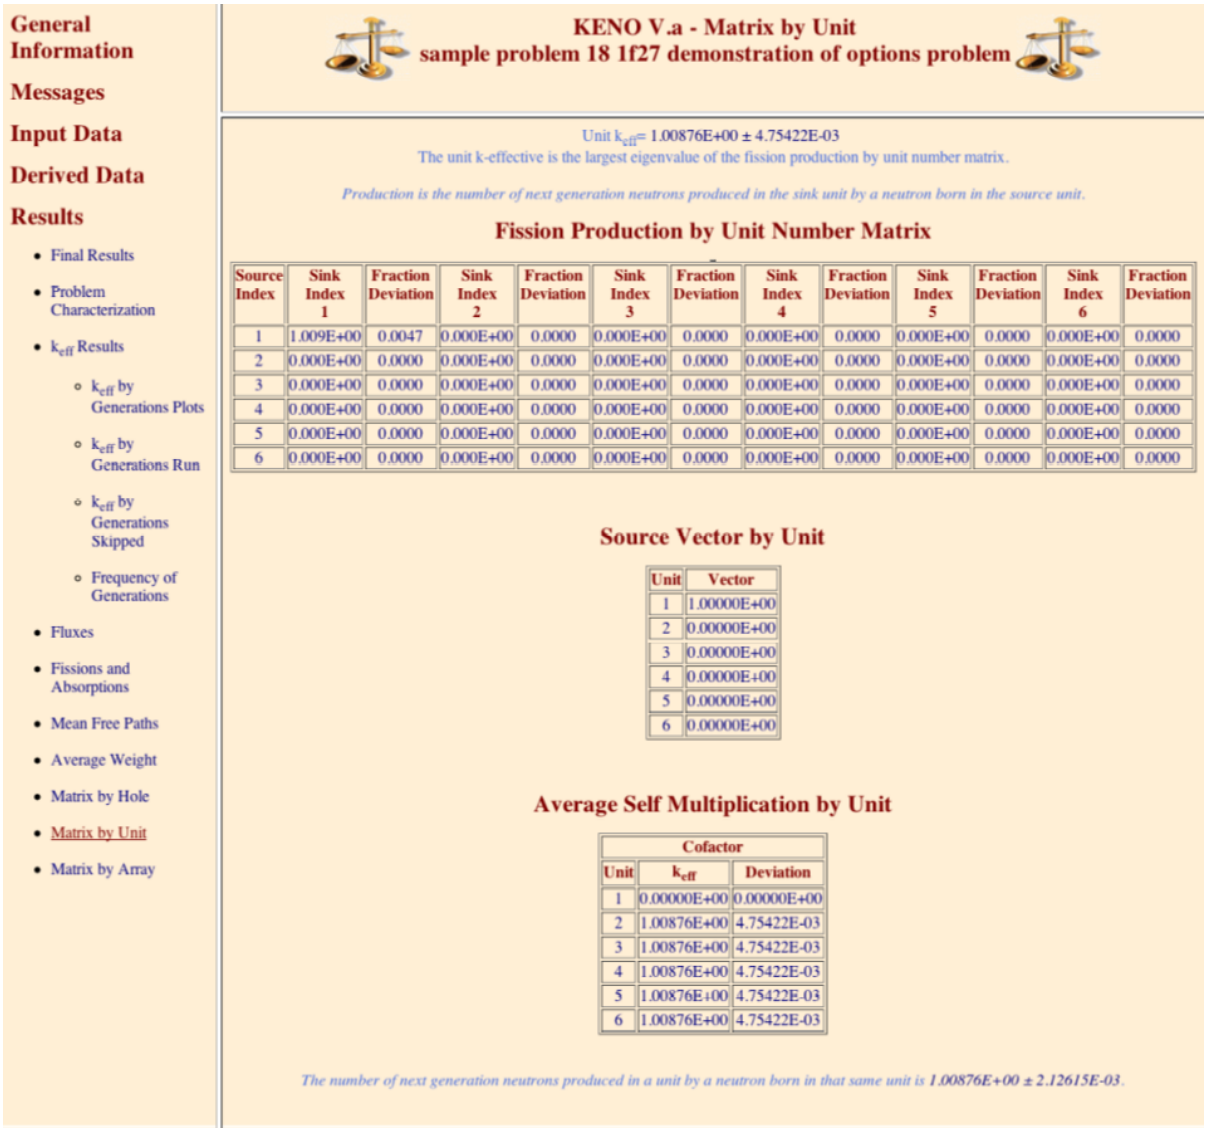

Fig. 8.1.198: Example matrix by unit edit in HTML output.

HTML output: Matrix k-effective, fission production, source vector and cofactor k-effective by hole number

The matrix k-effective by **HOLE** number is the largest eigenvalue of the fission production matrix collected by **HOLE** number and is calculated if **MKH**=YES was specified in the parameter data. An example of the matrix k-effective by **HOLE** number is given in Fig. 8.1.199. Fission production, source vector and average self-multiplication by **HOLE** are all printed on the same page as the matrix k-effective by **HOLE**. The matrix k-effective HTML data by **HOLE** is available in the *Matrix by Hole* link in the *Results* section.

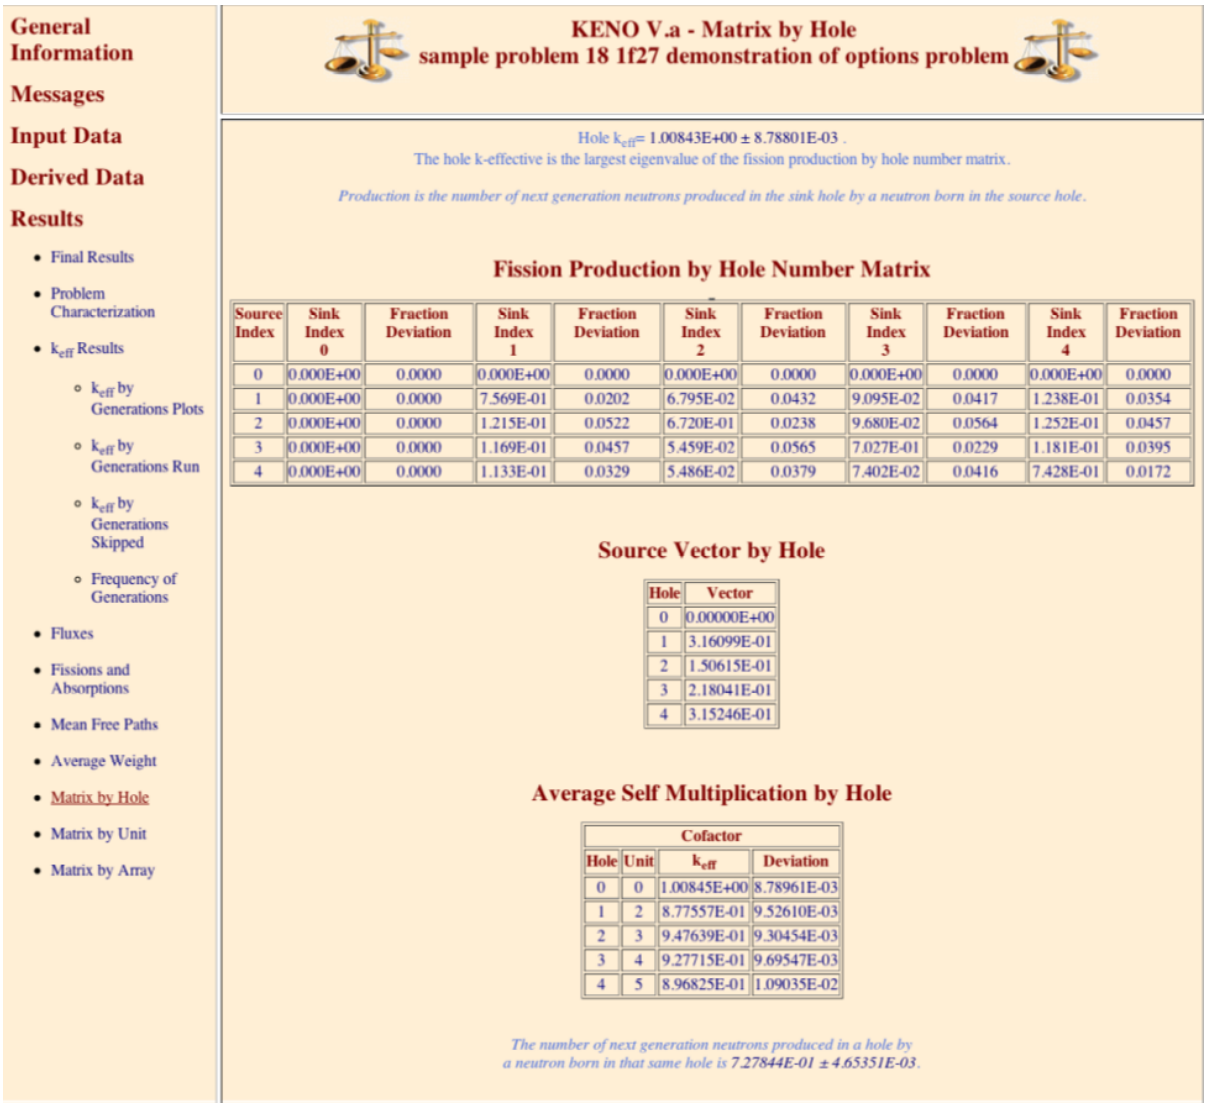

Fig. 8.1.199: Example matrix k-effective by hole edit in HTML output.

HTML output: Matrix k-effective, fission production, source vector and cofactor k-effective by array number

The matrix k-effective by array number is the largest eigenvalue of the fission production matrix collected by array number and is calculated if **MKA**=YES is entered in the parameter data. The number of next generation neutrons produced in array number J by a neutron born in array number I is given in this fission production matrix.

The matrix k-effective HTML data by array is available in the *Matrix by Array* link in the *Results* section, with an example shown in Fig. 8.1.200. Fission production, source vector and average self-multiplication by **ARRAY** number are all printed on the same page as the matrix k-effective by **ARRAY** number.

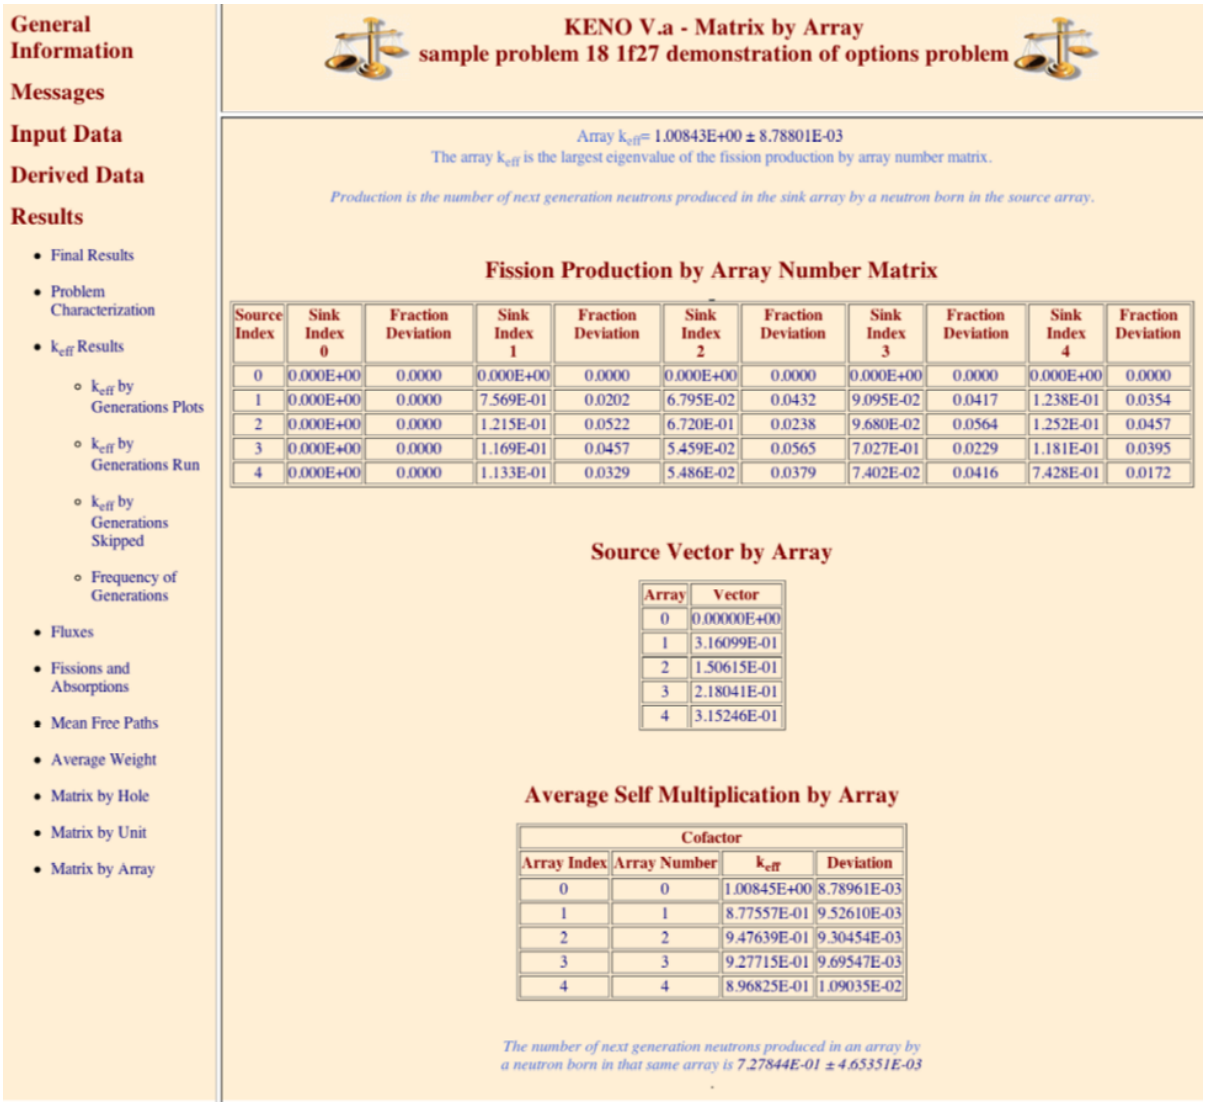

Fig. 8.1.200: Example matrix by array edit in HTML output.

HTML output: Fission density edit

The fission density edit is optional. In the HTML output, the fission density edit is available in the *Fission Density* link of *Fissions and Absorptions* under the *Results* section, as shown in Fig. 8.1.201.

Fig. 8.1.201: Example fission density edit in HTML output.

HTML output: Flux edit

Printing the fluxes is optional; they are only printed if **FLX**=YES is specified in the parameter data. The fluxes are printed for each unit and each geometry region in the unit for every energy group.

In the HTML output, a table of flux data can be accessed with the *Scalar Fluxes* under *Fluxes* in the *Results* section, as shown in Fig. 8.1.202. The fluxes for each unit in the problem are accessed from links on the right side of the page. Separate links are presented for *Angular Fluxes* and *Flux Moments* if they are requested in the problem.

Fig. 8.1.202: Example scalar flux edit in HTML output.

HTML output: Final results table

The final results table contains a summary of the most important physics parameters of the system and the number of error and warning messages generated during execution.

In the HTML output, the final results table is accessed with the *Final Results* link in the *Results* section, as shown in Fig. 8.1.203.

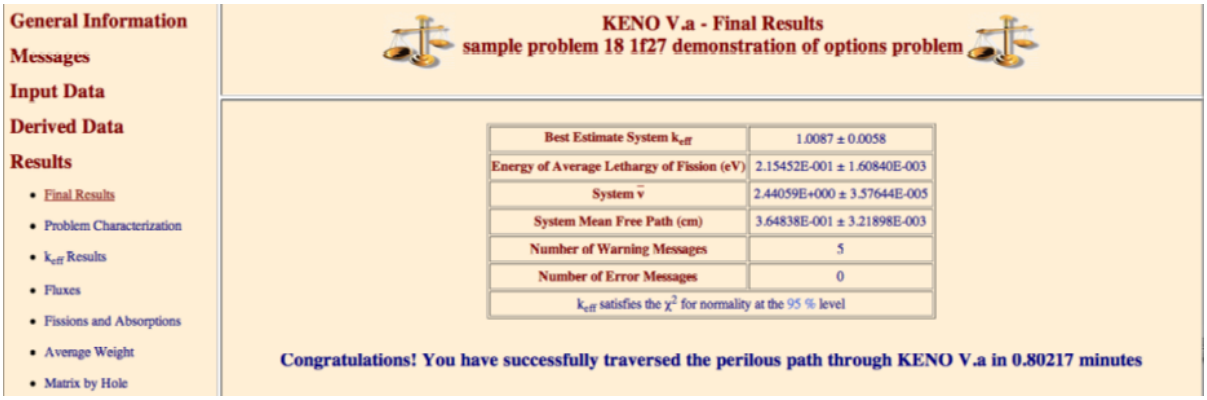

Fig. 8.1.203: An example of the final results table in HTML output.

8.1.6 WARNING MESSAGES AND ERROR MESSAGES

KENO prints warning and error messages that are identified by K5- or K6- for KENO V.a and KENO-VI, respectively, followed by a unique number (i.e., K5-001 is the identifier of the first message for KENO V.a). The generic symbol for messages originating in KENO V.a and KENO-VI is K?, where the question mark stands for 5 or 6. For additional information concerning the message, refer to the identifier number in this section.

Warning messages appear when a possible error is encountered. If the code alters data, that fact is stated in the message. It is the responsibility of the user to verify correct usage when a warning message is printed.

When an error is encountered, a global error flag (MFLAG) is set true and an error message is printed. The code immediately stops or execution is terminated with an error code if the error is too severe to continue. The warning and error messages in this section may show an underscore ____ or a numbered underscore (1) where data will be printed by the code. The explanation of the message will show an underscore or a numbered underscore to indicate the corresponding data.

8.1.6.1 Messages

KMSG001 *** WARNING *** K?-001 FOLLOWS: READ FLAG NOT FOUND. ASSUME PARAMETER DATA FOLLOWS.

> This message occurs in subroutine INITAL. It indicates that the word `READ` was not the first word of data encountered after the title card. If a parameter data block is to be entered, the code expects the words `READ PARAMETERS` to precede the parameter input data. If the word `READ` is not the first word, the code expects parameter input data immediately.

KMSG002 ** ERROR ** K?-002 FOLLOWS: THE NUMBER OF ENERGY GROUPS IS OUT OF RANGE FOR THE CROSS SECTION LIBRARY ON UNIT ___ THE INPUT MAY NOT SPECIFY A VALID DATA SET ON THIS UNIT OR THE MODULE THAT WAS TO CREATE THE CROSS SECTION LIBRARY ON THIS UNIT MAY HAVE FAILED

This message occurs in subroutine INITAL after subroutine PARAM has been executed. Unit number ____ should be checked to ensure that it was properly specified in the job control language. The data set name associated with this unit number should also be verified. This information is given in the printout in the third table. The module that generated the cross sections should be verified as having executed properly and that the data were saved or passed correctly. When this message is printed for an AMPX working format library, a STOP 108 is executed. When this message is printed for a mixed cross section format library, a STOP 109 is executed.

KMSG003 *** WARNING *** K?-003 FOLLOWS: MAT ID=___ WAS NOT FOUND IN THE WEIGHTS LIBRARY FOR THE SPECIFIED ENERGY GROUP STRUCTURE.

This message is printed in subroutine LODWTS when loading biasing factors from the direct access scratch file. It indicates that weights library did not contain biasing factors for this ID for the group structure that corresponds to the cross sections (multigroup), or to the binning structure (continuous energy). Default biasing factors will be substituted. The location of this set of biasing parameters should be checked to verify that the substitution does not cause a problem.

KMSG004 *** ERROR *** K?-004 FOLLOWS: INVALID INPUT PARAMETER NAME ___

This message comes from subroutine PARAM and indicates that the keyword for entering parameter data was misspelled or in error in some other way. A list of allowed keywords is given in Table 8.1.1 in the KENO input outline.

KMSG005 *** ERROR *** K?-005 FOLLOWS: AN ERROR WAS ENCOUNTERED IN THE ALPHANUMERIC PARAMETER DATA. THE DATA WAS ___

This message comes from subroutine PARAM and indicates that the keyword for the alphanumeric parameter data was entered correctly, but the data associated with it were not YES or NO as is required. The____ ____ in the error message could be something like `FLX`=YEX instead of `FLX`=YES.

KMSG006 ** WARNING ** K?-006 FOLLOWS: READ FLAG FOUND WHEN LOOKING FOR END FLAG. PARAMETER INPUT ASSUMED COMPLETE

This message occurs in subroutine PARAM. It indicates that the keywords `END PARAMETERS` were not found. The keywords `READ`____ were found instead. The code assumes the parameter data are complete and proceeds normally.

KMSG007 ** ERROR ** K?-007 FOLLOWS: ATTEMPT TO FIND END PARAMETER FLAG WAS UNSUCCESSFUL.

This message from subroutine PARAM occurs during the reading of the parameter data if the word `END` is found and it is not followed by the word `PARAMETERS`. A STOP 118 may be executed when this message is printed.

KMSG008 ** ERROR ** K?-008 FOLLOWS: AN END OF FILE WAS ENCOUNTERED WHILE ATTEMPTING TO READ PARAMETER DATA

This message is from subroutine PARAM. A STOP 118 may be executed when this message is printed.

KMSG009 ** WARNING ** K?-009 FOLLOWS: DUE TO INCONSISTENCIES BETWEEN INPUT AND RESTART DATA, FISSIONS AND ABSORPTIONS BY REGION WILL BE CALCULATED BUT NOT PRINTED. INPUT DATA SET FAR=NO, BUT DATA FROM THE RESTART UNIT SPECIFIED YES.

This message occurs in subroutine PARTBL and is mostly self-explanatory. The original problem (parent case) that wrote the restart data specified data inconsistent with the parameter data input to the restarted problem. The title of the parent case is given at the end of the parameter tables. The specification of the restart unit RST is given in the third table of the KENO output.

KMSG010 *** WARNING *** K?-010 FOLLOWS: DUE TO INCONSISTENCIES BETWEEN INPUT AND RESTART DATA, FLUXES WILL BE CALCULATED BUT NOT PRINTED. INPUT DATA SET FLX=NO, BUT DATA FROM THE RESTART UNIT SPECIFIED YES.

This message occurs in subroutine PARAM. The original problem (parent case) that wrote the restart data specified data did not agree with the parameter data input to the restarted problem. The title of the parent case is given at the end of the parameter tables. The specification of the restart unit RST is given in the third table of the KENO output.

KMSG011 ** ERROR ** K6-011 FOLLOWS: A BOUNDARY GEOMETRY WORD WAS NOT SPECIFIED FOR UNIT ___

This KENO-VI message is from subroutine SGGM_KENOG. A `BOUNDARY` card must be associated with each unit identifying the outermost region of the unit.

KMSG012 ** WARNING ** K?-012 FOLLOWS: INPUT PARAMETER NBK WAS ENTERED AS ___. IT WAS CHANGED TO ___. AT LEAST ___ POSITIONS ARE NECESSARY TO ACCOMMODATE THE NEUTRON BANK DATA.

This self-explanatory message is from subroutine PARTBL. `NBK` should not be entered as input data unless it is known that the default value is inadequate.

KMSG013 ** ERROR ** K6-013 FOLLOWS: MEDIA DATA MUST BE ENTERED FOR UNIT ___

This KENO-VI message is from subroutine SGGM_KENOG. Either another `UNIT` card or an `END GEOM` card was encountered prior to inputting `MEDIA` data for the current unit.

KMSG014 ** ERROR ** K?-014 FOLLOWS: ERROR - KEYWORD ___ ___ IS NOT A VALID MIXING TABLE KEYWORD.

This message is from subroutine MIXING_TABLE. It can only be encountered if a mixing table is expected (i.e., `READ MIX` or `READ MIXT` has been entered as data). At this point the only valid keywords are `MIX=`, `EPS=`, `SCT=` or `NCM=`. The keyword that was entered is printed in the message. See Sect. 8.1.3.10 for assistance in setting up the mixing table data.

KMSG015 ** ERROR ** K5-015 FOLLOWS: AN ERROR WAS FOUND IN THE HEMISPHERE DESIGNATION

This KENO V.a message was printed by subroutine K5GM_KENOG. It signifies that the geometry keyword has been destroyed after it was read. This indicates a code bug.

KMSG016 *** ERROR *** K?-016 FOLLOWS: ** ERROR ** A VALUE MUST BE ENTERED FOR LIB IN THE PARAMETER INPUT SO CROSS SECTIONS CAN BE MIXED.

This message is from subroutine DATAIN. It occurs when a mixing table has been read but the unit number for the AMPXS working library is undefined. This is corrected by entering LIB=____ in the parameter input data and making sure the desired AMPXS working library is properly defined as being on that unit in the job control language.

KMSG017 *** ERROR *** K?-017 FOLLOWS: UNRECOGNIZABLE GEOMETRY WORD ___

This message is from subroutines K5GM_KENOG, SGGM_KENOG, K5GM_CENTER or SGGM_CENTER. In the process of reading the geometry data, the word ____ was encountered when a geometry word was expected. Several of these messages may be generated. A message is generated for each word of data that is read, until a valid geometry word is found. The data are out of phase or the geometry word is misspelled. The previous geometry word should be checked to ensure that it has the correct entries. See Sect. 8.1.8.1 and Sect. 8.1.8.2 for lists of accepted geometry words.

KMSG018 ***** ERROR ***** K6-018 FOLLOWS: INVALID INDEX INTO KEYWRD ARRAY. INP=___ CHECK SUBROUTINE KENOG FOR A CODE ERROR.

This KENO-VI message is from subroutine SGGM_KENOG. This message usually means that a code error was introduced when changes were made to the program. Subroutine KENOG, function LCOMPR, and KEYWRD data block should be checked.

KMSG019 ***** ERROR ******** ERROR ******** ERROR ******** ERROR ******** ERROR ******** ERROR ******** ERROR ******** ERROR ******** ERROR ******** ERROR ******** ERROR **** K6-019 FOLLOWS: A GLOBAL UNIT HAS NOT BEEN SPECIFIED. **** ERROR ******** ERROR ******** ERROR ******** ERROR ******** ERROR ******** ERROR ******** ERROR ******** ERROR ******** ERROR ******** ERROR ******** ERROR ****

This KENO-VI message from subroutine SGGM_KENOG indicates that a GLOBAL UNIT has not been specified. The outermost unit in the problem must be specified as the GLOBAL UNIT. See Sect. 8.1.3.4 to determine the correct specification.

KMSG020 *** ERROR *** K6-020 FOLLOWS: GEOMETRY WORD INDEX OUT OF RANGE ON SCRATCH UNIT ___ FOR GEOMETRY WORD NUMBER ___ INP=___ GWRD=___

This KENO-VI message from subroutine SGGM_READGM means that INP is negative or larger than NP when the geometry data are read from the scratch unit, SKRT. This usually means that a code error was introduced when changes were made to the program. True geometry errors should be detected when the scratch unit, SKRT, is written. A STOP 125 is executed when this message is printed.

KMSG021 *** ERROR *** K?-021 FOLLOWS: ___ IS AN INVALID PARAMETER NAME FOR BIASING DATA. ID= OR WT= OR WTS= SHOULD HAVE BEEN ENTERED.

This message is from subroutine RDBIAS. See Sect. 8.1.3.7 for assistance in determining the proper procedure for entering biasing data.

KMSG022 *** ERROR *** K?-022 FOLLOWS: PROBLEM IN READGM, IGEO=___ IS AN INVALID GEOMETRY TYPE

If this message has not been preceded by other geometry error messages, it indicates a code bug.

KMSG023 *** ERROR *** K5-023 FOLLOWS: REFLECTION OR PERIODIC BOUNDARY CONDITIONS ARE ILLEGAL ON A CURVED BOUNDARY.

This self-explanatory KENO V.a message from K5GM_JOMCHK indicates that only a vacuum or a white boundary condition is allowed on a curvilinear surface.

KMSG024 K?-024 FOLLOWS: INCORRECT FLAG RETURNED FROM AREAD. IRET=___

This message from subroutine RDBIAS indicates that an error was encountered while reading the biasing data. The biasing data were not entered properly. See Sect. 8.1.3.7 for assistance.

KMSG025 *** ERROR *** K5-025 FOLLOWS: WHITE BOUNDARY CONDITION IS ALLOWED ONLY ON CUBOIDS, CYLINDERS, OR SPHERES

This self-explanatory KENO V.a message from K5GM_JOMCHK indicates that WHITE albedo boundary conditions cannot be applied to the outermost geometry if it is a hemisphere or a hemicylinder.

KMSG026 K?-026 - ARRAY DESCRIPTION ERROR MESSAGES K?-026 FOLLOWS: SET NUMBER ___ OF THE UNIT ORIENTATION DATA CONTAINS ___ ERROR(S).

This message from subroutine RDBOX is triggered when input errors are recognized in the unit orientation data. A set of unit orientation data consists of 10 numbers as shown in the companion message KMSG027. The number of errors printed in this message is a lower bound. More errors may actually exist. This message often means that a number was omitted or a blank was omitted when entering the unit orientation data.

KMSG027 K?-027 FOLLOWS: LTYPE=___ IX1=___ IX2=___ INCX=___ IY1=___ IY2=___ INCY=___ IZ1=___ IZ2=___ INCZ=___

This message is a companion to KMSG026. It indicates how the unit orientation data description for the set named in KMSG026 was entered. See Sect. 8.1.3.5.8 for information pertaining to unit orientation data.

KMSG028 K?-028 FOLLOWS: THE ABOVE UNIT ORIENTATION CARD(S) CONTAIN(S) AT LEAST ONE OF THE FOLLOWING ERRORS. 1. IX1, IY1, IZ1, INCX, INCY, OR INCZ IS LESS THAN OR EQUAL TO ZERO 2. IX2 IS LESS THAN IX1, IY2 IS LESS THAN IY1, OR IZ2 IS LESS THAN IZ1 3. IX2 IS GREATER THAN NBXMAX, IY2 IS LARGER THAN NBYMAX, OR IZ2 IS LARGER THAN NBZMAX 4. LTYPE IS LESS THAN 1 OR GREATER THAN NBOX

This self-explanatory message is from subroutine RDBOX. It pertains to the input orientation data for LOOP. See Sect. 8.1.3.5 for input instructions.

KMSG029 *** ERROR *** K?-029 FOLLOWS: THE ARRAY SIZE HAS BEEN SPECIFIED INCORRECTLY. NBXMAX=___ NBYMAX=___ NBZMAX=___ UNIT ORIENTATION DATA CANNOT BE READ UNLESS NBXMAX, NBYMAX AND NBZMAX ARE GREATER THAN ZERO.

This message from subroutine ARAYIN indicates that the array definition data were incorrectly specified. It occurs only if one or more of NBXMAX, NBYMAX, or NBZMAX is less than 1. In the array information data these are entered in the form `NUX=____ NUY=____ NUZ=____`. See Sect. 8.1.3.5. If a unit orientation data description is to be entered, NBXMAX, NBYMAX, and NBZMAX must all be greater than zero.

KMSG030 *** ERROR *** K?-030 FOLLOWS: END ___ FLAG WAS NOT FOUND. ___ ___ WAS READ INSTEAD.

This message from subroutine ARAYIN occurs if the unit orientation data description is terminated with the incorrect `END` flag.

KMSG031 *** ERROR *** K?-031 FOLLOWS: ___ IS AN INVALID PARAMETER NAME IN THE ARRAY DATA.

This message is written from subroutine ARAYIN if the array data block contains an incorrect keyword. The allowed keywords include NUX=, NUY=, NUZ=, FILL, LOOP, ARA``* =, ``TYP =. See Sect. 8.1.3.5 for additional assistance. A STOP 101 is executed when this message is printed.

KMSG032 `` ERROR `` K?-032 FOLLOWS: AN ERROR EXISTS IN UNIT ORIENTATION ARRAY NUMBER ___

This message from subroutines K5_SORTA or K6_SORTA is printed when an error is recognized in the array description. The type of error that will trigger the message is for a position in the unit orientation array to be undefined, zero, negative or greater than NBOX, the largest unit number. KMSG033 is a companion message.

KMSG033 *** ERROR *** K?-033 FOLLOWS: UNIT ___ IS INVALID AT X INDEX =___ Y INDEX =___ Z INDEX =___

This message comes from subroutines K5_SORTA or K6_SORTA. It is printed for each position in the unit orientation array that is in error. The message is printed a maximum of 10 times. Refer to Sect. 8.1.3.5 for assistance in correcting the error(s).

KMSG034 *** ERROR *** K?-034 FOLLOWS: THE NUMBER OF MIXTURES REQUESTED IN THE GEOMETRY IS ___ THE NUMBER OF MIXTURE CROSS SECTIONS IS ___

This message from subroutines K5_FLDATA, K6_FLDATA or MFLDATA occurs if the number of mixture cross sections from the restart unit, RSTRT, does not equal the number of mixtures requested in the geometry for a restarted problem.

KMSG035 *** ERROR *** K?-035 FOLLOWS: IN THE ALBEDO INPUT DATA ___ IS AN INVALID FACE CODE NAME.

This message is from subroutine RDREF. It occurs if an invalid face code name was entered in the albedo data. See Table 8.1.20 in Sect. 8.1.3.6 for a list of acceptable face code names.

KMSG036 *** ERROR *** K6-036 FOLLOWS: A BOUNDARY BODY ___ WAS SPECIFIED THAT IS NOT ONE OF THE BODIES IN THE GLOBAL UNIT BOUNDARY.

This message is from subroutines K6_RDBNDS or LOADGEOM1. It indicates that a boundary body was specified to assign boundary conditions that do not exist in the global unit. The bodies specified for boundary conditions should be carefully matched with those specified in the boundary definition vector of the global unit.

KMSG037 **** ERROR ***** K?-037 FOLLOWS: AVERAGE NU-BAR AND AVG. FISSION GROUP WAS SPECIFIED, BUT THE FISSION XSEC ID (18) WAS NOT FOUND IN THE EXTRA 1-D ARRAY (MT).

This message is from subroutine IDX1D. It indicates that the parameter data contained NUB= YES, but the corresponding necessary type of data was absent from the extra 1-D array. This can be due to a code error or an error concerning the extra 1-D data (X1D= in the parameter data).

KMSG038 **** ERROR *** K?-038 FOLLOWS: INPUT DATA INDICATED NO EXTRA 1-D XSEC IDS TO BE READ, BUT A READ FLAG WAS ENCOUNTERED.

This message from subroutine DATAIN is printed when the parameter data did not specify X1D= and the words READ X1DS were encountered later in the data. If extra 1-D data are to be used, X1D= must be entered in the parameter data and appropriate code modifications must be made to properly use the extra 1-D data.

KMSG039 *** ERROR *** K?-039 FOLLOWS: INVALID START PARAMETER NAME ___

This message is from subroutine RDSTRT. It indicates that an invalid start parameter name was encountered when the start data block was being read. A list of allowed start parameter names is contained in Sect. 8.1.3.8.

KMSG040 *** WARNING *** K?-040 FOLLOWS: LNU FOR START TYPE 6 WAS ENTERED AS ___. THE LARGEST VALUE NEEDED FOR LNU IS NPG; ENTRIES BEYOND NPG WILL BE IGNORED.

This self-explanatory message is from subroutine RDSTRT. See Sect. 8.1.3.8 and Sect. 8.1.4.8 for assistance in determining a valid value for LNU. NPG, the number of histories per generation, starting neutrons are needed to fill the initial neutron bank. KENO discards the starting points beyond NPG and notifies user with this message about this action.

KMSG041 *** ERROR *** K?-041 FOLLOWS: ALPHANUMERIC START DATA MUST BE ENTERED AS YES OR NO. THE DATA READ WAS ___ ___

This self-explanatory message is from subroutine RDSTRT. See Sect. 8.1.3.8 for assistance concerning start data.

KMSG042 *** WARNING *** K?-042 FOLLOWS: END ___ FLAG WAS NOT FOUND.___ ___ WAS READ INSTEAD

This message occurs when the READ ____ and END ____ do not match. When entering data blocks, each block must start with READ ____ and end with END ____.

KMSG043 *** ERROR *** K?-043 FOLLOWS: AN END OF FILE WAS ENCOUNTERED BEFORE AN END DATA WAS FOUND. THE PROBLEM WILL NOT RUN.

This message is from subroutine DATAIN. It occurs when an end of file is encountered while reading data.

KMSG044 *** ERROR *** K?-044 FOLLOWS: A PLOT OF ZERO HEIGHT AND/OR WIDTH HAS BEEN SPECIFIED. THE HEIGHT IS ___ AND THE WIDTH IS ___ THE DELTA X IS ___, THE DELTA Y IS ___, AND THE DELTA Z IS ___ THE DIRECTION COSINES DOWN THE PAGE ARE ___ ___ ___ THE DIRECTION COSINES ACROSS THE PAGE ARE ___ ___ ___

This message is from subroutine RDPLOT. At least one of the X, Y, or Z components that make up the upper left corner and lower right corner is inconsistent or one of the direction cosines UAX, VAX, WAX, UDN, VDN, or WDN have the wrong sign. Check the plot data for consistency.

KMSG045 *** ERROR *** K?-045 FOLLOWS: ILLEGAL DATA BLOCK IDENTIFIER, ___ ___

This message from subroutine DATAIN is printed whenever an invalid data block identifier is encountered. This can be caused by having the data out of order, by omitting data or by misspelling data. A block identifier consists of the words READ XXXX where XXXX is a keyword identifying the type of data to be read. Acceptable keywords when running KENO stand-alone are listed in Sect. 8.1.3.1.

KMSG046 *** ERROR *** K?-046 FOLLOWS: IPT=___ IS OUTSIDE THE ALLOWABLE LIMIT OF ___

This message is from subroutine DATAIN. It is indicative of a code error. IPT is the index into the LPOINT array, which contains the direct access pointers for the various types of data. LPOINT(1) is the pointer for the geometry region data. LPOINT(2) is the pointer for the array description (unit orientation) data. LPOINT(3) is the pointer for the mixing table data. LPOINT(4) is the pointer for volume data. LPOINT(5) is the pointer for the biasing or weighting data. LPOINT(6) is the pointer for the start data. LPOINT(7) is the pointer for the albedo data. LPOINT(8) is the pointer for the mixed cross section data. LPOINT(9) is the pointer for the energy and inverse velocity data. LPOINT(10) is the pointer for the plot data. LPOINT(11) is the pointer for the biasing input data. LPOINT(12) is the pointer for the grid data for fluxes. LPOINT(13) is the pointer for importance mapping data. LPOINT(14) is the pointer for reactions data. LPOINT(15) is the pointer for definitions data. LPOINT(16) is the pointer for system responses data. LPOINT(17) is the pointer for tallies data. LPOINT(18) is the pointer for the albedo-xsec energy correspondence data.

A STOP 152 is executed when this message is printed.

KMSG047 ***** ERROR ***** K6-047 FOLLOWS: SECTOR DATA WAS NOT FOUND FOR ARRAY ___

This KENO-VI message is from subroutine SGGM_ARRAY. This message usually means that sector data was left off the `ARRAY` contents record. See Sect. 8.1.3.4 for assistance in specifying an `ARRAY`.

KMSG048 *** ERROR *** K?-048 FOLLOWS: UNABLE TO ALLOCATE ___ DUE TO ERROR STATUS CODE ___ IN SUBROUTINE ___

This message is associated with allocating memory used to store problem dependent data. The message states the type of data memory was allocated for the error type returned when memory could not be allocated and the current subroutine. This message could be caused by insufficient system memory or a code problem.

KMSG050 *** ERROR *** K6-050 FOLLOWS: THE ___ POSITION OF ARRAY ___ IN UNIT ___ WAS SPECIFIED AS ___ WHICH IS LESS THAN 1 OR GREATER THAN ___, THE NUMBER OF UNITS IN THAT DIRECTION.

This self-explanatory KENO-VI message from subroutine SGGM_CORSIZ indicates that an array was not properly placed in a unit. This is usually due to the incorrect definition of one of the array indices in one dimension (X, Y, or Z) such that it was specified outside the array bounds in that dimension.

KMSG051 *** ERROR *** K?-051 FOLLOWS: SURFACE ___ OF BOUNDARY LABEL ___ REQUESTED A DIFFERENTIAL ALBEDO THAT IS NOT ON THE ALBEDO DATA SET. THE REQUESTED ALBEDO NAME IS ___

This message is from subroutine ALBRD. A list of the albedos that are on the standard albedo data set is given in Table 8.1.23 (Sect. 8.1.3.6).

KMSG052 *** ERROR *** K?-052 FOLLOWS: INTERPOLATION CODE SHOULD BE IN THE RANGE 1 TO 5 INT: ___

This message is from subroutine XSEC_INTERP. This indicates an error in the continuous energy point data. INT is the interpolation code from the data. A STOP 104 is executed in conjunction with this message, and a traceback may be printed from subroutine STOP.

KMSG053 *** ERROR *** K?-053 FOLLOWS: LOG INTERPOLATION SHOULD NOT BE USED WITH NEG OR ZERO ARGUMENT XP: ___

This message is from subroutine XSEC_INTERP and indicates that a LIN-LOG interpolation was requested with a non-positive value. A STOP 104 is executed in conjunction with this message, and a traceback may be printed from subroutine STOP.

KMSG054 *** ERROR *** K?-054 FOLLOWS: A SURFACE NUMBER ___ WAS SPECIFIED THAT IS LARGER THAN NUMBER OF SURFACES IN THE INDICATED GLOBAL BODY. THE PROBLEM WILL NOT BE RUN.

This message is from subroutines K5_RDBNDS or K6_RDBNDS. It indicates that an incorrect surface was specified to which a boundary condition was to be assigned. The surfaces of the bodies specified for boundary conditions should be carefully matched with those specified in the bounds of the global unit. Corresponding albedo surface numbers for all geometric shapes supported by KENO V.a and KENO-VI are listed in Table 8.1.21 and Table 8.1.22, respectively.

KMSG056 *** ERROR *** K?-056 FOLLOWS: MIXTURE ___ LACKS EITHER NU*FISSION OR CHI DATA

This message from subroutines NORM1D or XSEC1D indicates that a mixture that contains fissile material is missing the nu-fission cross section or the fission spectrum. A STOP 115 is executed when this message is printed.

KMSG057 *** ERROR *** K5-057 FOLLOWS: INVALID BIAS ID ___ IN REGION ___ ABOVE.

This KENO V.a message is from subroutines K5GM_PRTJOM or K5GM_READGM. It is printed if a negative or zero bias ID is entered for the specified geometry region. Review Sect. 8.1.3.4 for correct geometry data specification information.

KMSG058 *** ERROR *** K6-058 FOLLOWS: INVALID BIAS ID IN REGION ABOVE.

This KENO-VI message is from subroutine SGGM_PRTJOM. It is printed if a negative or zero bias ID is entered for the specified geometry region. Review Sect. 8.1.3.4 for correct geometry data specification information.

KMSG059 *** ERROR *** K?-059 FOLLOWS: THE CALCULATION WAS TERMINATED BECAUSE OF EXCESSIVE SPLITTING.

This message from subroutines K5_GUIDE or K6_GUIDE is printed only if message K?-128 is printed 50 or more times for a given generation. This indicates that the problem and/or the code is incapable of achieving a reasonable solution. If changes have been made in the code, they should be carefully scrutinized. If a biasing data block has been entered (Sect. 8.1.3.7), it should be checked carefully.

KMSG060 *** WARNING *** K?-060 FOLLOWS: THE ANGULAR SCATTERING DISTRIBUTION FOR MIXTURE ___ HAS BAD MOMENTS FOR THE TRANSFER FROM GROUP ___ TO GROUP ___ ___ MOMENTS WERE ACCEPTED

This message from subroutine BADMOM indicates that the moments from the cross section data are incorrect for the group transfer shown. The code replaces the incorrect moments with acceptable moments and proceeds normally. The moments printed in the last line of the message should match those printed in the eighth line. The user can suppress these messages by entering an appropriate value for the cross section message cutoff parameter, `EPS=` in the mixing table data, Sect. 8.1.3.10. See Sect. 8.1.4.4.4 for assistance in determining an appropriate value.

KMSG061 *** ERROR *** K6-061 FOLLOWS: ___ IS NOT A VALID UNIT NUMBER, A UNIT NUMBER MUST BE A POSITIVE INTEGER.

This KENO-VI message is from subroutine SGGM_KENOG. A unit number must be an integer greater than 0.

KMSG062 *** ERROR *** K6-062 FOLLOWS: INSUFFICIENT DATA FOLLOWED THE KEYWORD ARRAY.

This KENO-VI message is from subroutine SGGM_ARRAY. The data following the keyword ARRAY are misspelled or incomplete. See Sect. 8.1.3.5 for assistance in determining the correct method for inputting array data.

KMSG063 *** WARNING *** K?-063 FOLLOWS: NUCLIDE ___ ___ HAS NO GAMMA PRODUCTION DATA. *** WARNING ***

This message from subroutine MIXMIX indicates that somehow KENO has been told to run a coupled neutron-gamma problem, and the indicated nuclide has no neutron to gamma transfer data. This means this nuclide cannot produce any gammas. This message should never occur in KENO, as it should have ignored all gamma data from a coupled library.

KMSG064 *** WARNING *** K?-064 FOLLOWS: THE ANGULAR SCATTERING DISTRIBUTION FOR MIXTURE ___ HAS BAD MOMENTS FOR THE TRANSFER FROM GROUP ___ TO GROUP ___ ___ MOMENTS WERE ACCEPTED. THE P0 COEFFICIENT IS ___

This message from subroutine BADMOM is printed to inform the user that the cross sections were altered by the code because the moments from the cross section data were incorrect for the group transfer shown. The P_0 coefficient was larger than the cross section message cutoff parameter `EPS`, but the relative change in the moments was smaller than `EPS`.

KMSG065 *** WARNING *** K?-065 FOLLOWS: AN AMPX WORKING LIBRARY WAS SPECIFIED ON UNIT ___ BUT NO MIXING DATA WAS READ. MIXED CROSS SECTIONS FROM UNIT ___ WILL BE USED.

This message from subroutine ICEMIX occurs if the parameter data specified `LIB=____` but no cross section mixing data block was entered. The cross section mixing data block begins with `READ MIXT`. See Sect. 8.1.3.3 for parameter data and Sect. 8.1.3.10 for mixing table information.

KMSG066 *** WARNING *** K?-066 FOLLOWS: ___ MIXTURES WERE REQUESTED IN THE GEOMETRY, BUT ONLY ___ MIXTURES ARE ON THE MIXED CROSS SECTION LIBRARY.

This message from subroutine ICEMIX indicates that more mixtures were requested in the geometry region data than were available on the mixed cross section library. See Sect. 8.1.3.3 for the specification of the unit number of the mixed cross section library (**XSC**=), Sect. 8.1.3.10 for the specification of the mixing table, and Sect. 8.1.3.4 to determine the mixtures used in the geometry region data.

KMSG067 *** ERROR *** K?-067 FOLLOWS: THE ADJOINT INPUT PARAMETER WAS _ BUT THE ADJOINT INDICATOR FROM THE MIXTURE CROSS SECTION LIBRARY WAS _. KENO WILL NOT EXECUTE.

This message from subroutine ICEMIX occurs if the adjoint input parameter `ADJ=` specified a forward calculation and the cross sections were adjointed, or the adjoint input parameter specified an adjoint calculation and the cross sections were not adjointed. T indicates true, F indicates false.

KMSG069 ___ IS AN INVALID GEOMETRY TYPE INDEX

This KENO V.a message from K5GM_HOLEXT is a companion message to KMSG091, and will follow it.

KMSG070 *** ERROR *** K?-070 FOLLOWS: ERROR IN SUBROUTINE WRTRST. NDX=___

This message from subroutines K5_WRTRST or K6_WRTRST occurs only if the type of data to be written on the restart (`WSTRT`) unit is undefined (i.e., `NDX` is greater than 15). `NDX` is the index in the LPOINT array as described in messages KMSG046 and KMSG058. This error is usually caused by code errors that were introduced when changes were made to the code. A STOP 133 is executed when this message is printed.

KMSG071 THIS INTERSECTION MAY BE DUE TO ROUNDOFF IN CALCULATING THE ARRAY BOUNDARY DIMENSIONS. FOR ROUNDOFF ERRORS, INCREASE THE DIMENSIONS OF ALL SUBSEQUENT REGIONS SHARING THAT BOUNDARY. +X -X +Y -Y +Z -Z ARRAY ___ ___ ___ ___ ___ ___ ___

This KENO V.a message from K5GM_JOMCHK is a companion message to KMSG092 and will follow it.

KMSG072 CUBOID ___ ___ ___ ___ ___ ___

This KENO V.a message from K5GM_JOMCHK is a companion message to KMSG092 and will follow it.

KMSG073 *** ERROR *** K?-073 FOLLOWS: ___ MIXTURES WERE REQUESTED IN THE GEOMETRY DATA, BUT ONLY ___ OF THESE WERE FOUND IN THE MIXED CROSS SECTIONS.

This message from subroutines K5_MASTER or K6_MASTER indicates a mixture number used in the KENO model was not included in the cross sections defined in the READ MIXT block.

KMSG074 *** ERROR *** K6-074 FOLLOWS: INVALID GEOMETRY TYPE IN VOLCUB. IGEO =___

This KENO-VI message from subroutine SGGM_VOLCUB is probably the result of a code error.

KMSG075 *** ERROR *** THE PROBLEM WILL NOT RUN

This KENO V.a message from subroutines K5GM_HOLE or K5GM_HOLCHK is a companion message to KMSG188.

KMSG076 *** ERROR *** K5-076 FOLLOWS: POSIT ERROR — ILLEGAL GEOMETRY TYPE X =___ Y =___ Z =___ K1 =___ K2 =___ K =___ IGEO =___

This KENO V.a message from subroutine K5GM_POSIT indicates that the history at X,Y,Z in region K in the unit with regions K1 to K2 has a geometry type IGEO which is not valid geometry type. This is caused by a code error.

KMSG077 *** INFORMATION WARNING *** K5-077 FOLLOWS: POSIT WARNING — POINT NOT IN GEOMETRY X =___ Y =___ Z =___ K1 =___ K2 =___

This KENO V.a message from subroutine K5GM_POSIT indicates that point X,Y,Z is not within any region between K1 and K2. This is usually caused from specifying start data that tries to start histories outside the geometry.

KMSG078 *** ERROR *** K5-078 FOLLOWS: INVALID GEOMETRY ENCOUNTERED FOR THE LAST GEOMETRY REGION. IGEO=___

This KENO V.a message from subroutine K5GM_CORSIZ says the geometry type of the last geometry region of the global unit is invalid. This indicates a code bug.

KMSG079 *** ERROR *** K6-079 FOLLOWS: UNABLE TO DETERMINE IF QUADRATIC IS CONVEX OR CONCAVE. CHECK FUNCTION VEXCAV CALLED FROM QUAD.

This self-explanatory KENO-VI message is from function SGGM_VEXCAV. It indicates a problem with an arbitrary quadratic. KENO-VI is missing the data indicating whether a surface is convex or concave and so was unable to determine this for the current arbitrary quadratic.

KMSG080 *** ERROR *** K5-080 FOLLOWS: UNRECOGNIZED GEOMETRY TYPE. IGEOM =___ IN SUBROUTINE PRTJOM

This KENO V.a message from subroutine K5GM_PRTJOM indicates a code bug. This error should be reported to scalehelp@ornl.gov.

KMSG081 *** ERROR *** K5-081 FOLLOWS: ERROR IN HEMISPHERE DESIGNATION. ISET =___ IN SUBROUTINE PRTJOM

This KENO V.a message from subroutine K5GM_PRTJOM indicates a code bug. This error should be reported to scalehelp@ornl.gov.

KMSG082 *** ERROR *** K5-082 FOLLOWS: ERROR IN PRTJOM WITH HEMICYLINDER DESIGNATION. NHCYL =___

This KENO V.a message from subroutine K5GM_PRTJOM indicates a code bug. This error should be reported to scalehelp@ornl.gov.

KMSG083 *** ERROR *** K5-083 FOLLOWS: FOR ARRAY ___, THE _ DIMENSIONS OF UNIT ___ AT (___ ___ ___) DO NOT MATCH THOSE OF UNIT ___ AT (___ ___ ___) FOR UNIT ___ +_ =___ AND -_ =___ WHILE FOR UNIT ___ +_ =___ AND -_ =___

This KENO V.a message is from subroutine K5GM_ARASIZ. The common faces of adjacent units must be the same size and shape. This message occurs whenever this requirement is not met. One or more of the dimensions of the units specified in the message may be incorrect, or the array definition data may be incorrect. Carefully check the input data relating to the geometry region data and the array definition data as described in Sect. 8.1.3.4 and Sect. 8.1.3.5.

KMSG084 *** ERROR *** K?-084 FOLLOWS: UNIT ___, IN UNIT ORIENTATION ARRAY NUMBER ___ IS UNDEFINED IN THE INPUT DATA.

This message from subroutines K5GM_ARASIZ or SGGM_ARASIZ occurs when the array description data block specifies a unit that was not defined in the geometry region data. Verify the array definition data and the geometry region data as described in Sect. 8.1.3.4 and Sect. 8.1.3.5.

KMSG085 *** ERROR *** K?-085 FOLLOWS: UNIT ___ AT POSITION X=___ Y=___ Z=___ IN UNIT ORIENTATION ARRAY NUMBER ___ IS INVALID BECAUSE IT IS LESS THAN ZERO OR LARGER THAN THE LARGEST UNIT NUMBER IN THE INPUT DATA.

This message from subroutines K5GM_ARASIZ or SGGM_ARASIZ occurs if the unit number named in the message is less than or equal to zero or greater than NBOX (the number of different units). The position of the offending unit is also given. This error usually results from leaving some positions undefined in the unit orientation array or from erroneous data in the unit orientation data. (This includes extra data, mistyped data and omitted data.) See Sect. 8.1.3.5 for additional information.

KMSG086 *** ERROR *** K6-086 FOLLOWS: GEOMETRY WORD INDEX OUT OF RANGE. IGEOM =___ IN SUBROUTINE PRTJOM

This KENO-VI message from subroutine K6_PRTJOM is self-explanatory. The printed value of IGEOM must be greater than zero and less than 24 in KENO V.a or less than 27 in KENO-VI to be valid. If the geometry words (see Sect. 8.1.3.4) are correct, this message is due to a code error that has been introduced when changes were made to the code.

KMSG087 *** ERROR *** K6-087 FOLLOWS: INSUFFICIENT DATA FOLLOWED THE KEYWORD MEDIA.

This KENO-VI message from subroutine K6_MEDIA. Either the material, bias ID, or sector data were not included on the media card, or non-integer data were inadvertently entered. See Sect. 8.1.3.4 for additional information on the type of data required on a MEDIA card.

KMSG088 *** ERROR *** K6-088 FOLLOWS: SECTOR DATA WAS NOT FOUND FOR MEDIA ___

This KENO-VI message from subroutine K6_MEDIA. Either the material, bias ID, or sector data were not included on media card _____ or non-integer data were inadvertently entered. See Sect. 8.1.3.4 for additional information on the type of data required on a MEDIA card.

KMSG089 *** ERROR *** K6-089 FOLLOWS: VOLUME HAS BEEN MULTIPLY DEFINED. GENERATION = ___ NEUTRON = ___ UNIT =___ PARTICLE AT POSITION X=___ Y=___ Z=___ IS LOCATED INSIDE THE FOLLOWING REGIONS IN THE UNIT:

This KENO-VI message from subroutine K6_PRTPOS out of either subroutine SGGM_TRACE or K6_TRACK. It is caused by incorrectly specifying the region definition vector in the media cards of a unit. It may be caused by a volume defined as part of more than one media record or incorrectly specifying regions that share a common boundary so the boundary between regions is contained in more than one region. See Sect. 8.1.3.4 for more information concerning vector definition arrays on MEDIA records.

KMSG090 *** ERROR *** K?-090 FOLLOWS: THE PROBLEM HAS TERMINATED BECAUSE THE PARTICLE HAS ENTERED AN INFINITE LOOP. THIS IS POSSIBLY DUE TO A PROBLEM WITH THE CODE. UNIT ___ ARRAY ___ HOLE ___

This self-explanatory message indicates that a history has become totally lost, and this message prevents the code from wasting time in an infinite loop. This message should never occur. This error should be reported to scalehelp@ornl.gov.

KMSG091 *** ERROR *** K5-091 FOLLOWS: UNIT ___ CONTAINS THE FOLLOWING GEOMETRY INCONSISTENCIES:

This message from subroutines K5GM_JOMCHK, K5GM_HOLEXT or K5GM_HOLHOL indicates that one or more intersecting geometry regions were encountered in unit____. KMSG092 is the companion message from subroutine JOMCHK and specifies the regions that intersect. KMSG069 is the companion message from subroutine HOLEXT. KMSG163 and KMSG179 are the companion messages from subroutine HOLHOL. The geometry region data should be corrected and the problem resubmitted. Sect. 8.1.3.4 may provide assistance in correctly specifying the data.

KMSG092 *** ERROR *** K5-092 FOLLOWS: REGION NUMBER ___ INTERSECTS REGION NUMBER ___.

This KENO V.a message from subroutine K5GM_JOMCHK is a companion message to K5-91 and K5-94. It specifies the intersecting regions. The user must determine which region is incorrectly specified or if the data are out of order. KENO V.a REQUIRES THAT EACH SUCCESSIVE GEOMETRY REGION MUST COMPLETELY ENCLOSE THE PREVIOUS REGION. THIS DOES ALLOW COMMON FACES AND TANGENCY.

KMSG093 *** ERROR *** K5-093 FOLLOWS: INVALID GEOMETRY TYPE. IGEO=___

This KENO V.a message is from subroutine K5GM_JOMCHK. IGEO must be greater than zero and less than 20. If it does not fall in this range, a code error is the probable cause. K5GM_KENOG or K5GM_READGM are the subroutines likely to have the code error. Verify that all the geometry words (`fgeom`, Sect. 8.1.3.4) are correct.

KMSG094 *** ERROR *** K5-094 FOLLOWS: THE REFLECTOR DIMENSIONS ARE INCONSISTENT.

This KENO V.a message is from subroutine K5GM_JOMCHK. It is a companion to message K?-095 and is printed whenever one or more intersecting geometry regions are encountered in the external reflector.

KMSG095 *** ERROR *** K5-095 FOLLOWS: REGION NUMBER ___ IN UNIT NUMBER ___ CONTAINS AN ERROR IN THE DIMENSIONS.

This KENO V.a message from subroutine K5GM_VOLUME indicates an error in the geometry input data such that the negative dimension specification for a cube or cuboid is larger than the positive dimension specification (i.e., the -X dimension is greater than the +X dimension, or the -Y dimension is greater than the +Y dimension or the -Z dimension is greater than the +Z dimension). This message is also printed if the magnitude of the chord for a hemicylinder or hemisphere is larger than the radius. See Sect. 8.1.3.4 for assistance in specifying the geometry correctly.

KMSG096 *** ERROR *** K5-096 FOLLOWS: THE VOLUME DEFINED BY REGION ___ IN UNIT ___ IS NEGATIVE.

This KENO V.a message from subroutine K5GM_VOLUME is printed whenever a negative volume is calculated. This can be caused by the positive dimension being smaller than the negative dimension on a face of a geometry region. It can also be caused by having intersecting regions, or it may be the result of round-off when the volumes are calculated. Either the geometry regions are incorrectly specified, the data are out of order, or the dimensions are so tight fitting that round-off causes the net volume of the region to be

negative. If the error is caused by round-off, adjust the appropriate dimensions slightly. See Sect. 8.1.3.4.

KMSG097 *** ERROR *** K5-097 FOLLOWS: THE VOLUME FOR UNIT ___ IS NEGATIVE.

This KENO V.a message is from subroutine K5GM_VOLUME. A negative volume for a unit can be caused by having intersecting regions within the unit, or by having a unit consisting of one region and having a positive dimension smaller than the negative dimension on one or more faces. Message K5-95 or K5-96 may accompany this message. See Sect. 8.1.3.4 for assistance in specifying the geometry data correctly.

KMSG098 *** ERROR *** K6-098 FOLLOWS: PROBLEM IN UNIT ___ THE ARRAY TYPE SPECIFIED IN THIS UNIT IS UNDEFINED. SPECIFY IF THE ARRAY TYPE IS CUBOID, HEXPRISM, OR DODECAHEDRON.

This KENO-VI message is from subroutine K6_ARASIZ. The array type specified in this unit in an unknown type. See Sect. 8.1.3.5 for how to enter array definitions.

KMSG099 *** ERROR *** K?-099 FOLLOWS: PROBLEM WITH UNIT ___ THE OUTERMOST GEOMETRY REGION OF A UNIT UTILIZED IN THE UNIT ORIENTATION DESCRIPTION OF THE ARRAY DATA MUST BE A ___

This message is from subroutines K5_ARASIZ or K6_ARASIZ. It can occur when the boundary region of a unit in an array is not consistent with the array type. The unit specified should be corrected so that the outer boundary is of the type required, or it should be replaced in the unit orientation data with a unit that has the correct outer boundary.

KMSG100 *** ERROR *** K?-100 FOLLOWS: THIS PROBLEM WILL NOT BE RUN BECAUSE ERRORS WERE ENCOUNTERED IN THE INPUT DATA.

This message is from subroutines K5_MASTER or K6_MASTER, and indicates that other error messages were printed in the problem output. These messages should be located and the data corrected accordingly. Execution is terminated with error code 129.

KMSG101 *** ERROR *** K?-101 FOLLOWS: NO FISSILE MATERIAL WAS FOUND IN SUBROUTINE START

This message is from subroutine START. It indicates that none of the mixtures used in this problem has an associated fission spectrum. Either the geometry data did not specify a fissionable mixture number, the mixing table is incorrect, the wrong mixed cross section data set was mounted, or the mixed cross section data set was incorrectly or incompletely made.

KMSG102 *** ERROR *** K?-102 FOLLOWS: THE START DATA SPECIFIES THAT NEUTRONS CAN BE STARTED IN THE REFLECTOR. HOWEVER, NEUTRONS WILL NOT BE STARTED BECAUSE THE OUTER REGION OF THE REFLECTOR IS NOT A CUBE OR CUBOID. NEUTRONS CAN BE STARTED FOR THE EXISTING GEOMETRY IF XSM,XSP,YSM,YSP,ZSM AND ZSP ARE ENTERED AS START DATA. XSM,XSP,YSM,YSP,ZSM AND ZSP MUST FIT WITHIN THE OUTER REGION OF THE REFLECTOR.

This message is from subroutine START. Start type 0 allows starting points throughout noncuboidal regions. If a start type other than 0 or 6 is desired and the outermost region of the reflector is not a cube or cuboid, then data must be entered to specify an imaginary cube or cuboid within this outer region. See Sect. 8.1.3.8 for assistance in specifying this data.

KMSG103 *** ERROR *** K?-103 FOLLOWS: START TYPE ___ IS OUT OF RANGE.

This message from subroutines K5_START or K6_START indicates that the start type was less than zero or greater than 9. The start type is defined by entering the keyword NST= followed by the desired start type in the start data. The available starting options are given in Table 8.1.26, Sect. 8.1.3.8.

KMSG104 *** ERROR *** K?-104 FOLLOWS: A POSIT ERROR INDICATES THAT THE POINT X=___ Y=___ Z=___ DOES NOT OCCUR WITHIN UNIT ___ IF XSM, XSP, YSM, YSP, ZSM, ZSP WERE ENTERED IN THE START DATA, VERIFY THAT THEY FIT WITHIN THE OVERALL COORDINATES OF THE SYSTEM. THE OVERALL COORDINATES MAY NOT BE PRINTED FOR A BARE ARRAY.

If XSM, XSP, YSM, YSP, ZSM, ZSP were entered in the start data, they should fit within the overall coordinates of the system. The overall coordinates may not be printed for a bare array. This message from subroutines K5_START or K6_START may result from precision difficulties. It is allowed to occur a maximum of five times before being considered fatal. A code error may be the cause of this message if it becomes fatal.

KMSG105 K?-105 *** WARNING, ONLY ___ INDEPENDENT STARTING POSITIONS WERE GENERATED. ***

This message is from subroutines K5_START or K6_START. KENO must have *npb* (NPG=, see parameter data, Sect. 8.1.3.3) starting positions. This message is to inform the user that fewer than *npb* starting positions were generated. The remaining starting positions are randomly selected from those that were generated, thus giving duplicate starting positions. If the number of independent starting positions is nearly *npb*, the starting distribution is probably acceptable. If it is much smaller than *npb*, a different start type should be used to give a better starting distribution (see Sect. 8.1.3.8). The amount of time allowed to generate the starting positions is controlled by parameter TBA= (see Sect. 8.1.3.3). If the start data are appropriate, it may be necessary to increase the value of TBA to ensure generating *npb* starting positions.

KMSG106 *** ERROR *** K6-106 FOLLOWS: POSIT ERROR — UNIT ___ HAS MULTIPLY DEFINED SPACE AT X = ___ Y = ___ Z = ___ SECTOR INSIDE

This KENO-VI message from subroutine SGGM_POSIT is usually the result of an incorrectly specified starting point for the initial source distribution when NST=3, 4 or 6 is specified in the start data. The starting point may not be consistent with the unit's position in the global array. The message can also be caused by improperly specifying media records. MEDIA records in the specified units should be checked for multiply defined volumes. X, Y, Z is the location of the neutron, and SECTOR INSIDE is the sectors which contain that point. See Sect. 8.1.3.4 for correct geometry words.

KMSG107 *** ERROR *** K7-107 FOLLOWS: POSIT ERROR — UNIT ___ HAS AN UNDEFINED SPACE AT X = ___ Y = ___ Z = ___ SECTOR INSIDE

This KENO-VI message from subroutine SGGM_POSIT may result from not specifying all volumes in the unit using media records. It could also occur from start data if a particle is attempting to start outside the global unit or in an undefined space. Geometry should be checked for the specified unit.

KMSG108 *** ERROR *** K?-108 FOLLOWS: POSITION (___,___,___) IS NOT VALID FOR THE POSITION OF THE SPIKE FOR START TYPE 2.

This message from subroutine START2 indicates that NXS, NYS or NZS was entered as zero. See Sect. 8.1.3.8 for the correct start data specification.

KMSG109 *** ERROR *** K?-109 FOLLOWS: INVALID GEOMETRY TYPE IN START. IGEO =___

This message from subroutines K5_STRTSU or K6_STRTSU is likely the result of a code error. This error should be reported to scalehelp@ornl.gov.

KMSG110 *** ERROR *** K?-110 FOLLOWS: THE PROBLEM WILL NOT BE EXECUTED BECAUSE NO FISSILE MATERIAL WAS FOUND.

This message from subroutines K5_VOLFIS or K6_VOLFIS occurs when the volume of fissile material is found to be zero. It should be verified that the fissile material was correctly specified in the geometry data, and the volume of the fissile material in the printout should be nonzero. The mixing table should be verified as being correct or that the correct Monte Carlo mixed cross section data set has been used if a mixing table is not used. If the fissile region is small compared to the rest of the problem and the region volumes are calculated using TRACE or RANDOM types with default number of traces or particles, the fissile region volumes may be incorrect (even zero). If the volumes calculate to be zero, this message may be issued. In this case, the volume calculation (see Sect. 8.1.3.13) should be corrected. A STOP 131 is executed when this message is printed.

KMSG111 ******* WARNING ******* K?-111 FOLLOWS: RESTART DATA IS NOT AVAILABLE FOR RESTARTING WITH GENERATION ___ AS SPECIFIED IN THE INPUT DATA. **** **** HOWEVER, AVAILABLE RESTART DATA HAS ALLOWED RESTARTING WITH GENERATION ___

This message from subroutine RDCALC indicates that *nbas* (BEG= in Sect. 8.1.3.3) was not consistent with the set of restart data that was to be used. A set of restart data is written every *nrstrt* (RES= in Sect. 8.1.3.3). The value of *nbas* should be 1 greater than one of these generations.

KMSG112 ******* ERROR ******* K?-112 FOLLOWS: ERROR IN RESTART. PARAMETER DATA AND RESTART DATA DO NOT AGREE NUMBER PER GENERATION FROM RESTART, NPBT=___NUMBER PER GENERATION FROM INPUT DATA, NPB=___ NUMBER OF ENERGY GROUPS FROM RESTART, NGPT=___ NUMBER OF ENERGY GROUPS FROM INPUT DATA, NGP=___

This message is from subroutine RDCALC. A restarted problem MUST use the same number per generation and the same number of energy groups as the parent problem that wrote the restart data. It should be verified that the correct data set is mounted on unit *rstrt*. (RST= in Sect. 8.1.3.3). This message can also be caused by a code error.

KMSG113 *** ERROR *** K?-113 FOLLOWS: ERROR IN RESTART. PARAMETER DATA AND RESTART DATA DO NOT AGREE. FISSION DENSITIES, FLUXES, OR REGION DEPENDENT FISSIONS AND ABSORPTIONS WERE REQUESTED, BUT THE GEOMETRY DATA IS INCONSISTENT. NUMBER OF GEOMETRY REGIONS FROM RESTART, KMAXT=___ NUMBER OF GEOMETRY REGIONS FROM INPUT DATA, KMAX=___

This message is from subroutine RDCALC. It should be verified that the correct data set is mounted on unit *rstrt* (RST= in Sect. 8.1.3.3). A code error can also cause this message.

KMSG114 *** ERROR *** K?-114 FOLLOWS: PARAMETER DATA SPECIFIED FLUXES BUT THE RESTART DATA DID NOT INCLUDE FLUXES.

This message is from subroutine RDCALC. The restarted problem can turn off fluxes if the parent case that wrote the restart data set calculated fluxes. However, if the parent case did not calculate fluxes, the restarted problem cannot calculate fluxes either. If the correct restart data set was mounted on *rstrt* (RST= in Sect. 8.1.3.3), the parameter data FLX=YES must be removed from the input data or FLX=NO must be entered later in the parameter data of the restarted problem.

KMSG115 *** ERROR *** K?-115 FOLLOWS: PARAMETER DATA SPECIFIED REGION DEPENDENT FISSIONS AND ABSORPTIONS, BUT THEY WERE NOT INCLUDED ON RESTART

This message is from subroutine RDCALC. The restarted problem specified FAR=YES in the parameter data block but the parent case that wrote the restart data set did not calculate region-dependent fissions and absorptions. The restarted problem can turn off region-dependent data if the parent case calculated them, but cannot turn them on if they were not calculated by the parent case. It should be verified that the correct restart data set is mounted on *rstrt* (RST= in Sect. 8.1.3.3). FAR=YES should be removed from the parameter data of the restarted problem, or FAR=NO should be added later in the parameter data. Sect. 8.1.3.3 illustrates methods of changing the parameter input data.

KMSG116 *** ERROR *** K?-116 FOLLOWS: EXECUTION IS TERMINATED.

This message from subroutine RDCALC is a companion to messages K?-112 through K?-115. A STOP 121 is executed when this message is printed.

KMSG117 *** ERROR *** K?-117 FOLLOWS: THE CALCULATION WAS TERMINATED BECAUSE ERRORS WERE ENCOUNTERED IN THE START DATA.

This message is from subroutines K5_GUIDE or K6_GUIDE. It will be accompanied by one or more of messages K?-101 through K?-104 or K?-106 through K?-110. A STOP 130 is executed when this message is printed.

KMSG118 *** ERROR *** K?-118 FOLLOWS: EXECUTION TERMINATED. RAKBAR HAS BECOME ZERO OR NEGATIVE.

This message is from subroutines K5_GUIDE or K6_GUIDE. If this message appears without other error messages, a code error is the probable cause. For such a case, this error should be reported to scalehelp@ornl.gov.

KMSG119 k?-119 JOB PULLED GENERATION= ___ NEUTRON = ___

This message from subroutine REPORTIT indicates that the problem is looping, or the time allotted for each generation, *tbtch* (TBA= in Sect. 8.1.3.3) is too small. If *tbtch* (TBA=) is increased significantly and the message occurs again for the same generation and the same neutron, it is due to a code error. Without a functional system-dependent routine (PULL) to interrupt execution, the problem will loop indefinitely, and this message will not be printed.

KMSG121 *** ERROR *** K?-121 FOLLOWS: EXECUTION TERMINATED DUE TO INSUFFICIENT TIME IN THE JOB STEP. ___ SECONDS ARE NEEDED PER GENERATION, BUT ONLY ___ REMAIN IN THE JOB STEP.

This message is from subroutines K5_GUIDE or K6_GUIDE. If more histories are desired, the job control language should be changed to allow adequate time and resubmit the problem. This message is inaccessible on computers lacking job control language to specify the maximum execution time.

KMSG122 *** ERROR *** K?-122 FOLLOWS: EXECUTION TERMINATED DUE TO EXCEEDING THE TIME SPECIFIED FOR THE PROBLEM.

This message is from subroutines K5_GUIDE or K6_GUIDE. If more histories are desired, *tmax* (`TME=` in Sect. 8.1.3.3) should be increased to allow computation of the desired number of histories.

KMSG123 K?-123 EXECUTION TERMINATED DUE TO COMPLETION OF THE SPECIFIED NUMBER OF GENERATIONS.

This message from subroutines K5_GUIDE or K6_GUIDE states that the requested number of histories has been completed. If more histories are desired, the number of generations (`GEN=` in Sect. 8.1.3.3) should be increased.

KMSG124 *** ERROR *** K?-124 FOLLOWS: THE OPTION TO USE EXTRA 1-DS WAS SPECIFIED, BUT ID NO.___ WAS NOT FOUND IN THE EXTRA 1-D ARRAY.

This self-explanatory message is from function INDX. If extra 1-Ds are specified in the parameter data (`X1D=`, Sect. 8.1.3.3), extra 1-D IDs must be entered as data. See Sect. 8.1.3.9. A STOP 107 is executed when this message is printed.

KMSG126 *** ERROR *** K5-126 FOLLOWS: CROSS ERROR ___ ___ ___ ___ ___ ___ ___ ___

This KENO V.a message from subroutine K5GM_CROS indicates a code error. The printed data, left to right, are as follows: IGEO,K,X,Y,Z,X1,Y1,Z1. IGEO is the geometry type, K is the region number, X,Y,Z is the current position, and X1,Y1,Z1 is the end point of the path. A STOP 103 is executed when this message is printed.

KMSG127 *** ERROR *** K5-127 FOLLOWS: NHCYL=___

This KENO V.a message from subroutines K5GM_CROS or K5GM_KENOG indicates invalid hemicylinder information as the result of a code error. A STOP 104 is executed when this message is printed.

KMSG128 *** ERROR *** K?-128 FOLLOWS: NEUTRON BANK IS FULL. SPLITTING NOT ALLOWED

This message from subroutine TALLYONGRID indicates that the neutron bank is too small to allow additional splitting. This can occur if the bank size, *nbank* (`NBK=` in Sect. 8.1.3.3 is too small, if the biasing or weighting data are incorrect (Sect. 8.1.3.7), or if the biasing data are incorrectly utilized in the geometry description (Sect. 8.1.3.4).

KMSG129 *** ERROR *** K?-129 FOLLOWS: ** ERROR IN SUBROUTINE ALBEDO ** FACE NUMBER ___ USES ___ ALBEDO NUMBER=___ INCIDENT XSEC ENERGY GROUP=___ INCIDENT ALBEDO ENERGY GROUP=___ INCIDENT ANGLE INDEX=___ RANDOM NUMBER=___

This message from subroutines K5GM_ALBEDO or SGGM_ALBEDO indicates that a code error was encountered when determining the output energy group during the albedo treatment.

KMSG130 *** ERROR *** K?-130 FOLLOWS: PROBLEM IN SUBROUTINE ALBEDO: FACE NUMBER ___ USES ___ ALBEDO NUMBER=___ RETURNING XSEC ENERGY GROUP=___ INCIDENT ALBEDO ENERGY GROUP=___ INCIDENT ANGLE INDEX=___ RETURNING ALBEDO ENERGY GROUP=___ RANDOM NUMBER=___

This message from subroutines K5GM_ALBEDO or SGGM_ALBEDO indicates that a code error was encountered while computing the returning angle in the albedo treatment.

KMSG131 *** ERROR *** K?-131 FOLLOWS: NO FISSIONS WERE GENERATED

This message from subroutine NSTART indicates that none of the histories in the generation encountered a fissile material, so no fission points were generated.

KMSG132 K?-132 FOLLOWS: ONLY ___ INDEPENDENT FISSION POINTS WERE GENERATED FOR GENERATION ___

This message from subroutine NSTART indicates that fewer than *npb* (`NPG=` in Sect. 8.1.3.3) fission points were generated during the previous generation. Because *npb* fission points are required by the code, the remaining fission points are randomly selected from those that were generated, thus using duplicate fission points. If the k-effective of the system is significantly less than 1.0, several of these messages should be expected in the first few generations. The code attempts to set RAKBAR so the message can be expected to occur about once every 100 generations. The message may occur more frequently in a correctly modeled problem. However, if the number of fission points is considerably less than *npb* for most of the generations, the answer can be affected.

KMSG133 *** WARNING *** K?-133 FOLLOWS: THE CALCULATION CONCLUDED WITHOUT PRODUCING RESULTS BECAUSE NO ACTIVE GENERATIONS WERE RUN. THE NUMBER OF GENERATIONS RUN WAS NOT GREATER THAN THE NUMBER OF GENERATIONS SKIPPED.

This message from subroutine KEDIT occurs if the number of generations completed is less than *nskip*+1 (`NSK=`, Sect. 8.1.3.3). In this instance, the summaries for the problem cannot be printed.

KMSG136 *** ERROR *** K5-136 FOLLOWS: GEOMETRY TYPE - IGEO = ___ - OUT OF RANGE IN ___

This message from subroutines K5GM_SRMAX, K5GM_CRMIN or K5GM_CRMAX occurs if the geometry indicator is invalid as the result of a code error. A STOP 127 is executed in conjunction with this message and a traceback may be printed from subroutine STOP.

KMSG137 *** ERROR *** K?-137 FOLLOWS: THERE ARE MISSING CROSS SECTIONS. CHECK THE OUTPUT FOR OTHER ERROR MESSAGES.

This message from subroutine FILLSG says that not all the cross sections requested have been found. There should be other previous messages giving more detail on what cross sections are missing.

KMSG138 *** WARNING *** K?-138 FOLLOWS: A WEIGHT OF 0.0 INDICATES THAT WEIGHTS WERE NOT READ OR GENERATED FOR THE BIAS ID. WEIGHTS OF 0.0 WILL BE DEFAULTED TO 0.5 PRIOR TO EXECUTION.

This message is from subroutine PRTWTS. It is printed to alert the user that weights were not entered, defaulted, or generated. This message may appear as the result of a code error.

KMSG139 *** ERROR *** K?-139 FOLLOWS: NO VALID MIXTURES WERE FOUND IN THE GEOMETRY DESCRIPTION.

This message from subroutine ICEMIX indicates that the geometry data did not specify any valid mixtures. The geometry data (Sect. 8.1.3.4) should be checked and any errors that are found should be corrected. This message can also be triggered if the unit orientation data description is not properly entered for geometry having more than one unit.

KMSG140 *** WARNING *** THE UNIT THE HOLE IS IN IS NOT USED IN THE MODEL, SO THE PROBLEM WILL NOT BE TERMINATED BECAUSE OF THIS ERROR.

This KENO V.a message from subroutine K5GM_HOLCHK is companion message to KMSG188.

KMSG141 *** ERROR *** K?-141 FOLLOWS: DATA CANNOT BE CHANGED WHEN A PROBLEM IS RESTARTED AT A GENERATION GREATER THAN ONE.

This message from subroutine DATAIN is printed if data other than parameter data are entered for a problem being restarted at a generation greater than 1. If data other than certain parameter data are to be changed, the problem must be restarted with the first generation. The error flag is set so the problem will not execute.

KMSG142 *** ERROR *** K?-142 FOLLOWS: NO GEOMETRY DATA HAS BEEN SPECIFIED IN THE INPUT DATA.

This message from subroutine DATAIN indicates that a geometry data block was not entered for the problem either as input data or from the restart unit. The data needs to be corrected and the problem resubmitted.

KMSG143 *** ERROR *** K?-143 FOLLOWS: UNIT ORIENTATION DATA IS REQUIRED IF MORE THAN ONE UNIT TYPE IS SPECIFIED IN THE GEOMETRY DATA.

This self-explanatory message is from subroutine DATAIN. Enter an array i or unit orientation data block as described in Sect. 8.1.3.5 and Sect. 8.1.4.6.

KMSG144 *** WARNING *** K?-144 FOLLOWS: DUE TO INCONSISTENCIES BETWEEN INPUT AND RESTART DATA, MATRIX INFORMATION BY UNIT TYPE WILL BE CALCULATED BUT NOT PRINTED. INPUT DATA SET MKU=NO, BUT DATA FROM THE RESTART UNIT SPECIFIED YES.

This self-explanatory warning message is from subroutine PARTBL. The matrix information by unit type cannot be eliminated if it was calculated by the original problem (parent case) that wrote the restart data. However, printing it can be avoided. It should be verified that the correct problem is being used for restarting the problem (the title is printed at the bottom of the parameter tables). The specification of the restart unit, RST, in the third table of the output should also be verified.

KMSG145 *** WARNING *** K?-145 FOLLOWS: DUE TO INCONSISTENCIES BETWEEN INPUT AND RESTART DATA, MATRIX INFORMATION BY UNIT LOCATION WILL BE CALCULATED BUT NOT PRINTED. INPUT DATA SET MKP=NO, BUT DATA FROM THE RESTART UNIT SPECIFIED YES.

This self-explanatory warning message is from subroutine PARTBL. The matrix information by unit location (also called array position or position index) cannot be eliminated if it was calculated by the original problem (parent case) that wrote the restart data. However, printing it can be avoided. It should be verified that the correct problem is being used for restarting the problem (the title is printed at the bottom of the parameter tables). The specification of the restart unit, RST, in the third table of the output should also be verified.

KMSG146 *** ERROR *** K?-146 FOLLOWS: PARAMETER DATA SPECIFIED MATRIX INFORMATION BY UNIT TYPE BUT IT WAS NOT FOUND ON THE RESTART UNIT.

This message from subroutine RDCALC is printed if a restarted problem requests matrix information by unit type when it was not requested and calculated by the original problem (parent case) that wrote the restart data. It should be verified that the correct restart data are being used and that the restart unit (RST) is correctly specified. The request for matrix information by unit type (MKU=, in the parameter data) should be eliminated if it is not necessary. The problem must be restarted with the first generation (BEG=1, in the parameter data) if matrix information by unit type is required and was not calculated by the parent case. A STOP 121 is executed in conjunction with this message.

KMSG147 *** ERROR *** K?-147 FOLLOWS: PARAMETER DATA SPECIFIED MATRIX INFORMATION BY UNIT LOCATION BUT IT WAS NOT FOUND ON THE RESTART UNIT.

This message from subroutine RDCALC is printed if a restarted problem requests matrix information by unit location (also called array position or position index) when it was not requested and calculated by the original problem (parent case) that wrote the restart data. It should be verified that the correct restart data are being used and that the restart unit (RST) is correctly specified in the first table following the parameter table. The request for matrix information by unit location (MKP=, in the parameter data) should be eliminated if it is not necessary. If matrix information by unit location is required and it was not calculated by the parent case, the problem must be restarted with the first generation (BEG=1, in the parameter data). A STOP 121 is executed in conjunction with this message.

KMSG148 *** ERROR *** K?-148 FOLLOWS: AN ERROR WAS ENCOUNTERED WHILE ATTEMPTING TO READ RESTART DATA FROM UNIT ___ NDX =___ NREC =___

This message from subroutines RDRST or RDRST_ERROR is printed if a problem is encountered while reading restart data from the restart file. This may be caused by the specified section of the restart file not being present or the file section being the wrong length. The restart file is corrupted. It should be verified that the problem ran to completion and a restart file was generated. Problems in the input should be corrected, and the problem should be run again. If the problem persists, contact the SCALE helpline.

KMSG149 *** ERROR *** K?-149 FOLLOWS: A CROSS SECTION LIBRARY WAS SPECIFIED FOR A RESTARTED PROBLEM, BUT MIXING TABLE DATA WAS NOT AVAILABLE. THE PROBLEM WILL NOT EXECUTE.

This message from subroutine READ_MIXED_XSECS means that LIB= was entered in the parameter data block and a mixing table data block was not available. A flag is set to terminate execution when the data reading has been completed. If cross sections are to be used from the restart unit (RST=), the LIB= or XSC= should be eliminated from the parameter data. If new cross sections are to be mixed, LIB= must be specified in the parameter data. The IDs in the mixing table must be available on the cross section library specified by LIB= . A problem can be restarted using a new mixed cross section library by specifying XSC= in the parameter data.

KMSG150 *** ERROR *** K5-150 FOLLOWS: TOO FEW ENTRIES WERE SUPPLIED IN THE REFLECTOR GEOMETRY DESCRIPTION.

This KENO V.a message from subroutine K5GM_KENOG indicates that too few data entries were supplied for the geometry word REFLECTOR. The mixture ID, bias ID, one of

the thickness/region specifications or the number of regions to be generated was omitted or incorrectly specified. Each REFLECTOR entry requires (1) a mixture ID, (2) a bias ID, (3) N entries for the thickness/region specifications, and (4) the number of regions to be generated. The thickness/region can be obtained from the Increment Thickness column of Table 8.1.25 for the material to be used in the regions generated by the REFLECTOR specification. N is the number of thickness/region specifications required by the geometry shape: N=1 for spheres or hemispheres, N=3 for cylinders and hemicylinders, and N=6 for cubes, cuboids, and cores. A flag is set to terminate the problem when the input data reading is completed.

KMSG151 *** ERROR *** K?-151 FOLLOWS: ___ IS AN INVALID ARRAY TYPE IN THE ARRAY DEFINITION DATA.

This message from subroutine ARAYIN indicates that a parameter name was misspelled or the data were out of order. See Sect. 8.1.3.5 for a list of the array parameter names. A stop 137 is executed in conjunction with this message.

KMSG152 *** ERROR *** K?-152 FOLLOWS: IRET=___ A PREMATURE TERMINATION WAS ENCOUNTERED WHILE READING ARRAY DATA. IRET=1 INDICATES AN END WAS FOUND. IRET=2 INDICATES AN END OF FILE.

This message from subroutine ARAYIN indicates that an array number was specified without entering the corresponding UNIT ORIENTATION DESCRIPTION. See Sect. 8.1.3.5 and Sect. 8.1.4.6 for assistance.

KMSG153 *** ERROR *** IF THE UNIT THIS HOLE IS IN IS USED IN THE MODEL, THE PROBLEM WILL NOT BE RUN.

This KENO V.a message from subroutine K5GM_READGM is a companion message to KMSG188.

KMSG154 *** ERROR *** K?-154 FOLLOWS: ARRAY LEVEL ___ IS LARGER THAN ___, THE NUMBER OF ARRAYS. CHECK THE ARRAY AND GEOMETRY INPUT FOR AN ARRAY OR UNIT THAT IS RECURSIVELY NESTED.

This message from subroutines K5GM_SORTA or SGGM_SORTA indicates that the array data specified in the problem are recursively nested. An example of this follows:

array 1 contains array 3 array 2 contains array 1 array 3 contains array 2

Thus, the definition of array 1 and array 3 are intertwined in a never-ending loop. The array data (Sect. 8.1.3.5) should be corrected and the problem resubmitted. If the input data did not specify recursive nesting, a code error has occurred. A STOP 139 is executed in conjunction with this message.

KMSG155 *** ERROR *** K?-155 FOLLOWS: THE NESTING FLAG OR NUMBER OF ARRAY LEVELS HAS BEEN DESTROYED BY A CODE ERROR. THE ORIGINAL NESTING FLAG WAS SET _ IT IS NOW SET _. THE ORIGINAL NESTING LEVEL WAS ___, IT IS NOW ___

This self-explanatory message is from subroutines K5GM_LODARA or SGGM_LOADARA. A STOP 140 is executed in conjunction with this message.

KMSG156 *** ERROR *** K?-156 FOLLOWS: MIXTURE ___ CONTAINS AT LEAST ONE ZERO VALUE FOR THE TOTAL CROSS SECTION.

This message is from subroutine XSEC1D. All the total cross sections must be positive. Zero total cross sections can occur if all the components of a mixture are mixed with a zero-number density. Correct the mixing table for the specified mixture and resubmit the problem.

KMSG157 *** ERROR *** K5-157 FOLLOWS: THE FIRST HOLE IN A UNIT MUST FOLLOW A VALID GEOMETRY REGION.

A STOP 141 accompanies this KENO V.a message from subroutine K5GM_READGM. If holes are to be used in the geometry region data (Sect. 8.1.3.4), they must follow the region in which they are to be placed. This message indicates that HOLE was the first geometry description in a unit or was placed inside an ARRAY description. Correct the geometry region data and resubmit the problem.

KMSG158 *** ERROR *** K5-158 FOLLOWS: THE NUMBER OF HOLES IS INCORRECT. IHOL=___ NUMHOL=___

This KENO V.a message is from subroutine K5GM_READGM. A code error is the probable cause of this error.

KMSG159 *** ERROR *** K?-159 FOLLOWS: ARRAY NUMBER ___ SPECIFIED IN THE GEOMETRY REGION DATA WAS NOT ENTERED IN THE ARRAY DATA.

This message from subroutines K5GM_SORTA or K5GM_HOLE or subroutine SGGM_SORTA occurs if the array number specified for an ARRAY region description of the EXTENDED GEOMETRY data (Sect. 8.1.3.4) did not have the corresponding UNIT ORIENTATION DATA entered in the ARRAY DATA (Sect. 8.1.3.5). A STOP 142 is executed in conjunction with this message when it is printed from subroutine SORTA. The data should be corrected and the problem resubmitted.

KMSG160 *** ERROR *** K?-160 FOLLOWS: THE HOLES ARE RECURSIVELY NESTED.

This message from subroutines K5GM_HOLE or SGHM_HOLE indicates that the geometry region data description (Sect. 8.1.3.4) specifies holes that are recursively nested. This can occur if a unit contains a hole whose definition traces back to the same unit or are defined in terms of each other. A simple example of recursive nesting is

KENO V.a:

```
  UNIT 1      CUBE  0  1  2P10.0    HOLE  2  3*0.0
  UNIT 2      CUBE  0  1  2P10.0    HOLE  1  3*0.0

KENO-VI:
```

```
  UNIT 1 CUBOID  10 6P10.0 BOUNDARY 10 HOLE 2 1  3*0.0
  UNIT 2 CUBOID  10 6P10.0 BOUNDARY 10 HOLE 1 1  3*0.0

Thus ``UNIT`` 1 contains ``UNIT`` 2 and ``UNIT`` 2 contains ``UNIT`` 1.
The geometry region data should be checked for recursive nesting. In the
absence of recursive nesting, a code error is the probable cause of this
message. A STOP 143 is executed when this message occurs and a traceback
is printed.
```

KMSG161 *** ERROR *** K5-161 FOLLOWS: THE GLOBAL ARRAY SPECIFIED IN THE GEOMETRY REGION DATA IS ___ BUT THE GLOBAL ARRAY SPECIFIED IN THE ARRAY DATA IS ___. EXECUTION IS TERMINATED.

This KENO V.a message is from subroutine K5_FLDATA. A STOP 144 is executed in conjunction with it. The global array specified in the array data (Sect. 8.1.3.5) was entered using the keyword GBL=. It was not consistent with the implied global array from the geometry region data (Sect. 8.1.3.4). The global array number in the geometry region data is defined to be the array number in the global unit or of the last ARRAY description that does not immediately follow a UNIT definition (i.e., other geometry definitions occur between UNIT and ARRAY). The data should be corrected, and the problem resubmitted.

KMSG162 *** ERROR *** K5-162 FOLLOWS: THE GLOBAL ARRAY WAS NOT CONSISTENTLY SPECIFIED. THE ARRAY DATA SPECIFIED ARRAY NUMBER ___ AND THE GEOMETRY DATA SPECIFIED ARRAY NUMBER ___.

This KENO V.a message from subroutine K5GM_SORTA occurs if GBL= in the array data (Sect. 8.1.3.5) does not agree with the global array number implicitly set in the geometry region data (Sect. 8.1.3.4). The geometry region data define the global array number in the global unit or to be the array number of the last ARRAY description that does not immediately follow a UNIT definition (i.e., other geometry definitions occur between UNIT and ARRAY). A flag is set to terminate execution when the data reading is completed.

KMSG163 *** ERROR *** K5-163 FOLLOWS: HOLE NUMBER ___ (UNIT NUMBER ___) INTERSECTS REGION NUMBER ___

This self-explanatory KENO V.a message is from subroutine K5GM_HOLHOL.

KMSG164 *** ERROR *** K5-164 FOLLOWS: HOLE NUMBER ___ (UNIT NUMBER ___) INTERSECTS REGION NUMBER ___.

This self-explanatory KENO V.a message is from subroutine K5GM_HOLEXT.

KMSG165 *** ERROR *** K5-165 FOLLOWS: ** ERROR ** GEOMETRY TYPE OUT OF RANGE IN SUBROUTINE ADJUST. IGEOH = ___

This KENO V.a message from subroutine K5GM_ADJUST indicates that the geometry type, IGEO, falls outside the allowable range of 1 through 19. This can occur if a HOLE references an undefined unit number. If all the unit numbers referenced by the holes are valid, a code error is the probable cause.

KMSG166 *** ERROR *** K5-166 FOLLOWS: THE PLUS CUBE FACE IS NOT GREATER THAN THE MINUS CUBE FACE PLUS FACE = ___ MINUS FACE = ___

This self-explanatory KENO V.a message is from subroutine K5GM_KENOG.

KMSG167 *** ERROR *** K5-167 FOLLOWS: ONE OR MORE PLUS FACES OF A CUBOID ARE NOT GREATER THAN THE CORRESPONDING MINUS FACES +X = ___ -X = ___ +Y = ___ -Y = ___ +Z = ___ -Z = ___

This self-explanatory KENO V.a message is from subroutine K5GM_KENOG.

KMSG168 *** ERROR *** K5-168 FOLLOWS: THE CYLINDER RADIUS IS NOT GREATER THAN ZERO, OR THE + HEIGHT IS NOT GREATER THAN THE - HEIGHT RADIUS = ___ +H = ___ -H = ___

This self-explanatory KENO V.a message is from subroutine K5GM_KENOG.

KMSG169 *** ERROR *** K5-169 FOLLOWS: THE SPHERE RADIUS IS NOT GREATER THAN ZERO - RADIUS = ___

This self-explanatory KENO V.a message is from subroutine K5GM_KENOG.

KMSG170 *** ERROR *** K5-170 FOLLOWS: A REPLICATE THICKNESS IS LESS THAN ZERO SURFACE NUMBER = ___ THICKNESS = ___

This KENO V.a message from subroutine K5GM_KENOG specifies that a thickness on a replicate was specified as a negative number. This is not allowed, as it would lead to an intersection.

KMSG171 *** ERROR *** K?-171 FOLLOWS: DIRECTION COSINES DOWN THE PAGE WERE ALL INPUT AS ZERO.

This message from subroutine RDPLOT indicates that the values for UDN=, VDN- and WDN= were all zero. A zero value vector does not define a direction, so an error has occurred. See Sect. 8.1.3.11 for information concerning direction cosines down the page.

KMSG172 *** ERROR *** K?-172 FOLLOWS: DIRECTION COSINES ACROSS THE PAGE WERE ALL INPUT AS ZERO.

This message from subroutine RDPLOT indicates that the values for UAX=, VAX= and WAX= were all zero. This is an error because a zero-value vector does not define a direction. See Sect. 8.1.3.11 for assistance in defining direction cosines across the page.

KMSG173 *** ERROR *** K?-173 FOLLOWS: ERRORS WERE DETECTED IN THE INPUT DATA FOR PLOT ___. IT WILL NOT BE DRAWN

This message from subroutine RDPLOT is a companion to messages K?-171, K?-172, K?-174, and K?-180. The error that triggered the companion message should be corrected, and the problem resubmitted.

KMSG174 *** ERROR *** K?-174 FOLLOWS: ERROR IN KENO PLOT DATA- ___ ___ SHOULD BE ENTERED AS ___YES, OR ___NO

This self-explanatory message is from subroutine RDPLOT. The error should be corrected, and the problem resubmitted. See Sect. 8.1.3.11 for assistance.

KMSG175 *** WARNING *** K?-175 FOLLOWS: DUE TO INCONSISTENCIES BETWEEN INPUT AND RESTART DATA, MATRIX INFORMATION BY HOLE WILL BE CALCULATED BUT NOT PRINTED. INPUT DATA SET MKH=NO, BUT DATA FROM THE RESTART UNIT SPECIFIED YES.

This self-explanatory warning message is from subroutine PARTBL. The matrix information by hole cannot be eliminated if it was calculated by the original problem (parent case) that wrote the restart data. However, printing it can be avoided. It should be verified that the correct problem is being used for restarting the problem (the title is printed at the bottom of the parameter tables). The specification of the restart unit, RST, in the third table of the computer output should be verified.

KMSG176 *** WARNING *** K?-176 FOLLOWS: DUE TO INCONSISTENCIES BETWEEN INPUT AND RESTART DATA, MATRIX INFORMATION BY ARRAY WILL BE CALCULATED BUT NOT PRINTED. INPUT DATA SET MKA=NO BUT DATA FROM THE RESTART UNIT SPECIFIED YES.

This self-explanatory warning message is from subroutine PARTBL. The matrix information by array cannot be eliminated if it was calculated by the original problem (parent case) that wrote the restart data. However, printing it can be avoided. It should be verified that the correct problem is being used for restarting the problem (the title is printed at the bottom of the parameter tables). Specification of the restart unit, RST, in the third table in the computer output should also be verified.

KMSG177 *** ERROR *** K?-177 FOLLOWS: PARAMETER DATA SPECIFIED MATRIX INFORMATION BY HOLE BUT IT WAS NOT FOUND ON THE RESTART UNIT.
